Abstract

Background: Major depressive disorder (MDD) is a serious public health concern worldwide. A treatment approach that incorporates measurement-based care (MBC) and shared decision-making between patients with MDD and their providers may foster patient engagement and improve clinical outcomes. While digital tools such as mobile apps show promise for expanding health interventions, these apps are rarely integrated into clinical practice.

Objective: The primary objective of this ongoing study is to determine whether implementation of a digital tool—the *Pathway Platform*—in primary care improves adherence to MBC practices; here, we present the study methods.

Methods: This large-scale, real-world implementation study is based on a pilot study of an earlier iteration of a mobile app (the *Pathway app*) that confirmed the feasibility of using the app in patients with MDD and showed a positive trend in patient engagement in the app arm. In addition, a user-centered design approach that included qualitative assessments from patients and providers was used to improve understanding of the patient journey and care team workflows. User feedback highlighted the need for enhanced features, education modules, and real-time data sharing via integration with the electronic health record. The current iteration of the *Platform* includes the newest version of the *Pathway app*, education modules for both patients and providers, and real-time patient-level data sharing with the electronic health record. The study takes place in primary care sites within the Advocate Aurora Health system in Illinois and includes adult patients with MDD who were recently prescribed monotherapy antidepressant medication (defined as a new start, medication switch, or dose change in the past 3 months). Clinical performance and selected patient outcomes will be compared before and after the implementation of the *Platform*.

Results: Patient recruitment was completed in July 2022, with initial results expected in mid-2023.

Conclusions: This study will provide useful insights into real-world integration of a digital platform within a large health system. The methods presented here highlight the unique user-centric development of the *Pathway Platform*, which has resulted in an enhanced digital tool with the potential to foster MBC and shared decision-making, improve patient-provider communication, and ultimately lead to optimized treatment outcomes for patients with MDD.

Introduction

Background

Major depressive disorder (MDD) is a common recurring mental health disorder and a serious public health concern worldwide [1,2]. In 2019, an estimated 19.4 million adults in the United States had at least 1 major depressive episode, which represents 7.8% of the adult US population [3]. The economic burden of MDD for 2020 in the United States was estimated at US $326.2 billion, with approximately 73.2% of the cost attributed to impairment in role function [4,5]. Many factors complicate the treatment of MDD, including multiple antidepressant therapy options, the importance of adherence and adequate duration of therapy to optimize response, and the variation commonly seen in time to response and medication tolerability among patients. American Psychiatric Association MDD treatment guidelines recommend considering many factors during initial treatment selection, such as patient symptoms and comorbidities, medication side effect profiles, and patient preference [6]. These guidelines suggest close monitoring of therapeutic benefit and tolerability during the first 4-6 weeks and then throughout treatment, incorporating structured measures of symptom severity, side effects, treatment adherence, and functional status to help assess response to treatment [6,7]. Systematic assessments and a strong therapeutic alliance between provider and patient remain key for tailoring a treatment plan to match the unique needs of each patient, highlighting the importance of measurement-based care (MBC) and shared decision-making (SDM).

Measurement-Based Care and Shared Decision-Making

MBC includes treatment adjustment evaluation using quantitative measures of symptoms, level of functioning, and quality of life while treating patients with MDD [7]. American Psychiatric Association clinical guidelines recommend MBC during initial screening as well as for monitoring depression throughout treatment [6]. By quantifying clinical outcomes, MBC provides guidance for timely treatment reassessment and modifications tailored to the individual needs of the patient and has been shown to improve outcomes and quality of care [8]. This systematic approach to treatment may have positive effects on the patient-provider relationship and enhance SDM. MDD often requires long-term antidepressant treatment; however, this is challenging for many patients because of barriers such as short consultation times with their care teams and limited involvement in the treatment decision-making process. An increased focus on MDD-relevant patient education, including clarification of the benefits of a specific treatment plan and alignment of such a plan with the patient's values, can help overcome treatment barriers. Primary care providers can incorporate MBC and play a major role by involving patients with MDD in the SDM process. In addition, SDM can foster patient-provider engagement and increase patient satisfaction [9].

Digital Tools in MDD

Overview

Many mobile apps have recently been developed and are available for the management of depression. Patients with MDD and their treatment providers may benefit from the use of these apps to assist in disease management. However, the majority of these apps have been assessed only in the research setting and have not been integrated into the clinical workflow. Most apps do not undergo a rigorous evaluation of interventions and instead rely on evidence-based theory for design; this may result in limited evidence of efficacy, leading to potential patient misinformation. Attrition is another major challenge for many depression management apps because of poor personalization to improve user-based engagement [10]. In addition, many mobile apps are only patient-facing and have not incorporated a care team interface, and the use of tracked content including symptoms and engagement with interventions in a single app is rare [10]. Creation of user-friendly mobile apps that incorporate user-centered design with input from patients with MDD and health care providers (HCPs) [11] can improve the development process, iteration speed, and implementation success, with the potential to improve patient outcomes in MDD [12-14].

Pathway App and Pathway Platform for Patients With MDD

Takeda Pharmaceuticals U.S.A., Inc., Lundbeck LLC, and Advocate Aurora Health (AAH) have partnered to cocreate a digitally enabled care experience with users (patients and care teams) and software developers, as well as health-tech product development specialists (Ctrl Group / Fora Health) to improve patient-provider engagement in the management and treatment of MDD. A digital mobile patient interface—the *Pathway app*—was designed with a conversational texting interface to allow patients to record daily mood symptoms, function, medication adherence, and side effects [11]. The *Pathway app* captures changes in a patient's response to antidepressant pharmacotherapy and includes standard outcome measures, such as the 9-item Patient Health Questionnaire (PHQ-9) for depression [11]. Patient interaction with the *Pathway app* allows for increased patient awareness of symptoms and overall functioning [11]. Through the *Pathway app*, up-to-date information can be shared with the patient's HCP to guide clinical discussions and enhance SDM between patients and their clinicians at routine visits as well as between visits, with the aim of optimizing individualized treatment plans and improving overall outcomes [11].

XSL•FO
RenderX

Testing of Pathway App in a Pilot Feasibility Study

The *Pathway app* was tested within a real-world pilot feasibility study (ClinicalTrials.gov NCT03242213) in patients with MDD who had recently started or undergone a switch to antidepressant monotherapy [15]. Patients were randomized 1:1 to the control arm (standard of care; n=20) or the app arm (standard of care plus the *Pathway app*; n=20) [15]. The first iteration of the *Pathway app* included patient-reported outcomes (PROs) related to depression, well-being, cognitive symptom tracking, medication adherence, and side effects. The *Pathway app* enabled patients to track their symptoms, monitor their treatment progress, and manually share the data collected with their care team. Results from the pilot study confirmed the effectiveness and feasibility of using the *Pathway app* in patients with MDD and showed a trend toward improved patient engagement in the app arm, albeit in a small sample size [15].

Pathway App Follow-up Interviews (Round 1) With Patients and HCPs

After the pilot study, 2 rounds of semistructured qualitative research interviews were conducted by a study team with expertise in qualitative research and user-centered design methods; results were determined using thematic analysis based on a structural coding framework. Round 1 interviews were performed to obtain feedback from patients and HCPs to understand their experience and perceptions of current and new *Pathway app* features to help ensure creation of a more user-centered design [15]. The user-centric approach created an opportunity for continued reassessment based on user feedback, faster iterations, optimized system performance, and sustainability. It also helped enhance the usability of the system, with the ultimate goal of improving treatment outcomes by supporting an expanded understanding of MDD treatment, assisting care team workflows, and providing people living with depression additional support throughout their treatment journey [11]. New features were included in the *Pathway app* that were not part of the pilot feasibility study, such as HCP visit preparation, patient education, and goal setting.

Patients reported that the ability to prepare for HCP visits using the *Pathway app* helped reduce their anxiety, improved the ease of communication with their HCPs, and enhanced the efficiency and effectiveness of appointments. Patients also found that the goal-setting feature of the *Pathway app* helped them focus on their goals and find a constructive purpose. Among the feedback from HCPs on the patient education feature of the *Pathway app*, many commented that it reduced their burden and was visually appealing and engaging.

Development of the Pathway Platform

Data from the round 1 qualitative interviews gathered from the *Pathway app* pilot feasibility study pointed to the need for enhanced rapid communication of real-time data shared with the care team, integration of the app into the MDD care pathway within the electronic health record (EHR), and education of the care team about usage of these data [11,13]. Building on these results, the *Pathway Platform* was created, which includes a newer iteration of the *Pathway app*, real-time integration of patient data with the Epic EHR (Epic Systems Corporation), as well as an app-based education program for patients and a web-based educational training program for the care team (Figure 1).

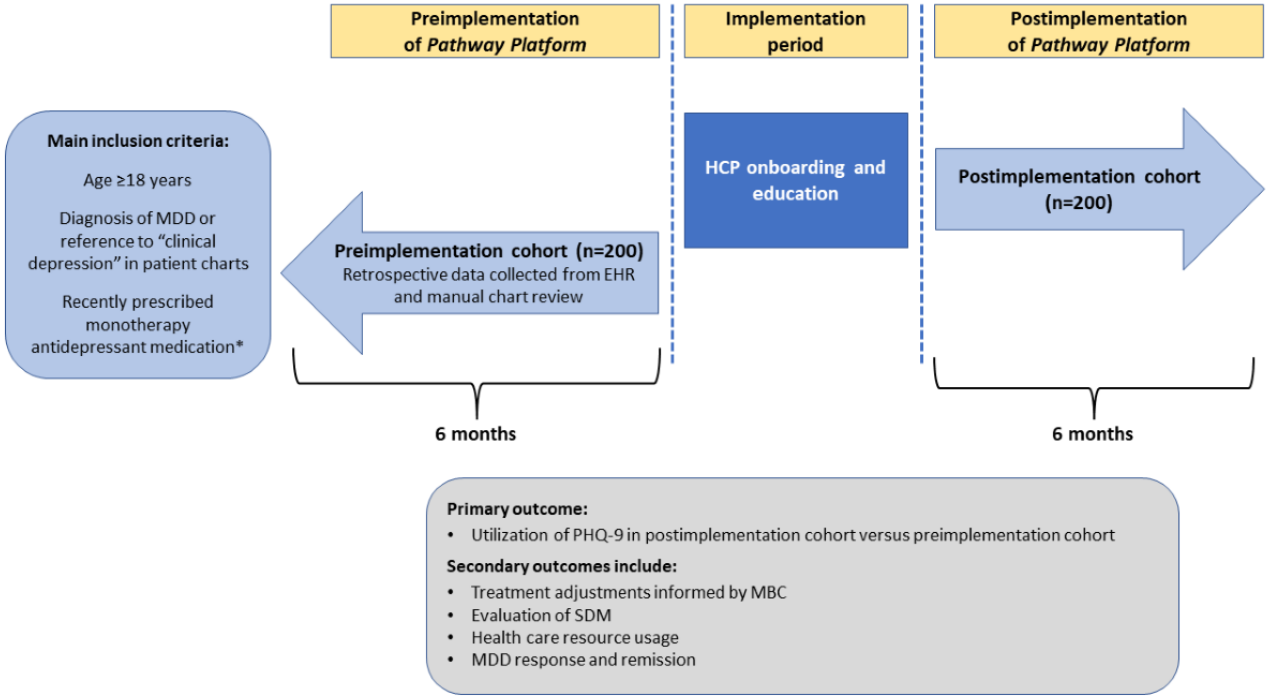
Figure 1. Design of the Pathway Platform. EHR: electronic health record.

Pathway Platform Follow-up Interviews (Round 2) With HCPs

Round 2 of qualitative research interviews was conducted with HCPs to understand workflow, usability, and clinical use of the *Pathway Platform*. An ongoing partnership with care teams provided an opportunity for continuous reassessment of the *Pathway Platform* based on user feedback. Key insights included the importance of clinical visit preparation and data visualization for SDM, collaborative goal setting and tracking for patient engagement, and optimization of the educational support tools for both patients and care teams [15]. This feedback was used to add value to the *Pathway Platform* for all users and optimize features prior to the clinical integration study presented here.

XSL•FO
RenderX

Rationale and Aim of the Study



In this ongoing, large-scale, real-world implementation study, it is our aim to test the scaling and integration of the digitally enabled *Pathway Platform* along with educational interventions at multiple primary care sites within the AAH system [11] and assess its impact on MBC and other evidence-based processes (ClinicalTrials.gov NCT04891224). The primary objective of this study is to determine whether implementing the *Pathway Platform* in the primary care setting improves adherence to MBC through PHQ-9 usage. Secondary objectives are to determine improvement in the additional clinical process measures as well as MDD remission and response outcomes in patients using the *Pathway Platform*.

Methods

Study Design

This real-world interventional study uses a pre- and poststudy design to assess the impact of implementing the *Pathway Platform* in the primary care setting (Figure 2) [11]. Regarding implementation of the *Pathway Platform*, the study design is divided into 3 periods: preimplementation, implementation, and postimplementation.

Figure 2. Schematic representation of the real-world implementation study. EHR: electronic health record; HCP: health care provider; MBC: measurement-based care; MDD: major depressive disorder; PHQ-9: 9-item Patient Health Questionnaire; SDM: shared decision-making. *New start, medication switch, or dose change in the past 3 months.

Preimplementation

The preimplementation cohort consists of patients who meet the inclusion criteria for enrollment in the study and have visited one of the participating clinics at least 6 months prior to implementation of the *Pathway Platform*. Study outcomes will be assessed using retrospective data collection, including chart reviews and electronic data pulls 6 months prior to implementation of the *Pathway Platform*.

Implementation

The implementation period will entail educating care team members before the enrollment visit and onboarding. To confirm eligibility, patient history will be evaluated for 3 months prior to enrollment. During the implementation period, the care team members involved in MDD management will receive education on evidence-based clinical practices for depression care, such as MBC and SDM. Training will be provided for patient onboarding to the *Pathway Platform* and usage of the EHR to view data collected in the platform.

Postimplementation

The postimplementation cohort consists of up to 200 patients from the same participating clinics who meet the eligibility criteria and provide written informed consent to download the *Pathway app*. In this cohort, data on patient outcomes will be collected prospectively over 6 months with the option to continue using the app at the 6-month mark until a common study end date (data collected beyond 6 months will be used for exploratory analysis). At the end of 6 months, retrospective EHR and manual chart reviews will be conducted, and performance related to MBC and SDM will be assessed. Clinical performance and selected patient outcomes will be compared before and after implementation of the *Pathway Platform*. Additional patient outcomes will be assessed after implementation among patients with MDD using the *Pathway Platform*.

Study Sites and Centers

This study is being performed within up to 20 primary care clinics in the AAH care system and will include up to 400

XSL•FO
RenderX

patients with MDD. Advocate is the largest HCP organization in Illinois, with 12 hospitals, 20 health centers, and more than 250 care sites. It is one of the largest accountable care organizations in the United States, caring for more than 2 million patients annually. General practitioners at AAH provide diagnoses, treatment, and clinical care for adults aged ≥18 years experiencing chronic diseases, with MDD often being included among those. Sites representing different geographic locations, patient populations, and care models for depression management, including behavioral health integration models, will be identified to participate in the study.

Ethical Considerations

This study will be conducted in accordance with legal and regulatory requirements, and the protocol was reviewed by the AAH institutional review board prior to patient recruitment or data collection (approval number AHC-6680-75000249). Because this is designed as a real-world evidence study, investigators and study team members will not be physically located at the sites routinely, so all patients will provide consent through an e-consent process.

Study Population

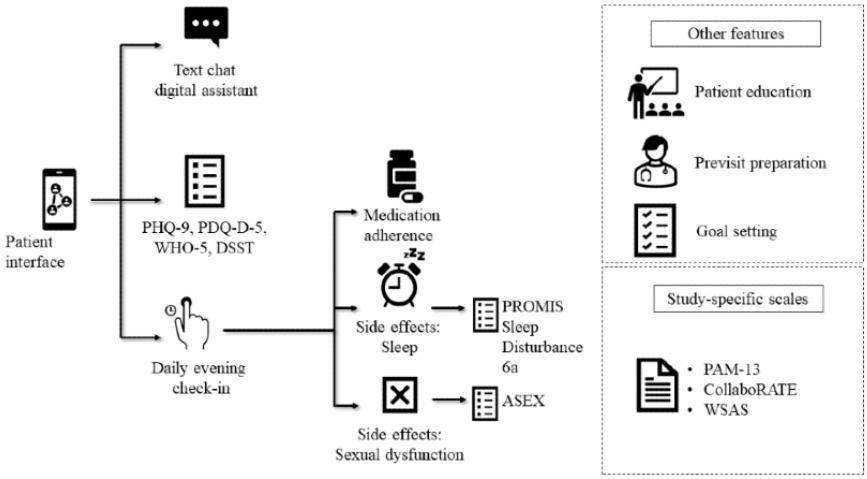
All trained care team members who manage patients with MDD within the participating AAH clinics will be invited to participate in this implementation study and will have access to a web-based educational resource center and an app-based educational program for patients.

Inclusion and Exclusion Criteria

Eligible patients aged ≥18 years, diagnosed with MDD based on *International Classification of Diseases, Tenth Revision*, codes or who have a reference to "clinical depression" in their patient charts, and have recently (past 3 months) been prescribed monotherapy antidepressant medication or had a recent switch (past 3 months) in medication or medication dose, will be included in this study. Patients should be able to use the *Pathway Platform* based on clinician's judgment (eg, own an Apple iPhone version 5 or later version or a smartphone with an Android operating system and have an active data plan or regular Wi-Fi access).

To be eligible, patients should have tolerability concerns or an inadequate response determined by a PHQ-2 (includes the first 2 questions of the PHQ-9, which cover the degree to which a patient has experienced depressed mood and anhedonia within the past 2 weeks) score ≥3, or a PHQ-2 score <3 with a PHQ-9 score of ≥5 recorded in medical records in the past 6 weeks or during screening [16]. Patients with a missing PHQ-2 score in the past 6 weeks or who are unable to perform PHQ-2 during the enrollment visit; who have been diagnosed with bipolar depression, schizophrenia, or schizoaffective disorder; or who are no longer under primary care for depression (have transitioned to a psychiatric care team) will be excluded from this study.

Study Procedures and Measurements



The *Pathway Platform* consists of 3 components: the latest iteration of the *Pathway app*, EHR integration, and educational scaffolding.

Pathway App

This study will deploy the most recent iteration of the *Pathway app*, which prompts patients to complete the following 4 scales every 2 weeks: PHQ-9 and 5-item Perceived Deficits Questionnaire–Depression (PDQ-D-5) to assess depression status, 5-item World Health Organization Well-being Index (WHO-5) to assess quality of life, and Cognition Kit Digit Symbol Substitution Test to assess cognition [17-20]. The *Pathway app* also includes a daily evening check-in to collect information on medication adherence and side effects; patients reporting side effects related to sleep will be prompted to complete the Patient-Reported Outcomes Measurement Information System (PROMIS) Sleep Disturbance item 6a, and patients reporting side effects related to sexual dysfunction will be prompted to complete the Arizona Sexual Experience Scale (ASEX). There will be an optional function to set and track goals using the goal attainment scale adapted for depression during clinical visits with an HCP [21]. Patients are also provided with a feature they can use to prepare for an upcoming visit with their care team, along with other features (Figure 3).

XSL•FO
RenderX

Figure 3. Features of the *Pathway app*. ASEX: Arizona Sexual Experience Scale; DSST: Digit Symbol Substitution Test; PAM-13: 13-item Patient Activation Measure; PDQ-D-5: 5-item Perceived Deficits Questionnaire–Depression; PHQ-9: 9-item Patient Health Questionnaire; PROMIS: Patient-Reported Outcomes Measurement Information System; WHO-5: 5-item World Health Organization Well-being Index; WSAS: Work and Social Adjustment Scale.

For purposes of evaluating this implementation study, 3 additional scales assessing patient-provider engagement and functional improvement will be deployed at baseline and at the end of the study (13-item Patient Activation Measure [PAM-13], CollaboRATE [also included as a 3-month postenrollment assessment], and Work and Social Adjustment Scale [WSAS]) [22-24]. During the study, if a patient's response to item 9 of the PHQ-9 indicates a change in their suicidal ideation, they will receive a pop-up notification to contact their HCP or emergency services immediately. A similar instruction is also given in routine clinical practice. Patients will also be informed during the consent process that the information provided to the *Pathway Platform* is not directly or continuously monitored in real time by care teams.

EHR Integration

Data collected by the *Pathway app* will be electronically transmitted and stored in the patient's EHR. The data will be accessible to the care team and provide a longitudinal summary that may assist in SDM and depression management. Providers can view the data either before or during the patient visit and use it to discuss future depression management.

Educational Scaffolding

A web-based educational training program for primary care team members was developed using evidence-based medicine, building on the concepts of MBC and SDM as they relate to depression management. This education resource center houses a series of videos where key leaders in depression treatment and management from psychiatry and primary care speak about the strategies to optimize patient outcomes and suggest practical applications of the *Pathway Platform* in primary care along with supporting evidence from the pilot study. Care team members are asked to review the videos before the first patient is enrolled, which will be tracked to evaluate the proportion of providers who completed the education. Additionally, a guide for the care team is available. The training program includes a care provider audit and feedback where provider performance related to PHQ-9 use will be presented during the study period. An app-based education program along with a training manual was developed for patients, which describes the functionality of the *Pathway Platform* and how to use and interpret the data collected.

Study Outcomes

Evaluation of the success of the *Pathway Platform* implementation will be performed by comparing study outcomes among both cohorts (pre- and postimplementation). The primary outcome will be usage of PHQ-9 in the postimplementation cohort versus the preimplementation cohort over a 6-month period. The primary end point will be the change in the proportion of patients with at least 2 PHQ-9 scores before and after implementation. Secondary outcomes will include treatment adjustments informed by MBC, evaluation of SDM, MDD remission and response, and health care resource usage, including referrals to behavioral health and primary care follow-up after hospitalizations. Results from PRO scales, such as PAM-13, CollaboRATE, and WSAS will be assessed to compare baseline and 6-month follow-up data among patients using the *Pathway Platform*.

Exploratory outcomes, including medication adherence, goal attainment, and PHQ-9, PDQ-D5, and WHO-5 scores, will be evaluated among patients who use the *Pathway Platform*. Safety assessments will include adverse events related to the *Pathway Platform*. No adverse events are expected in this minimal-risk study; however, all serious adverse events that are spontaneously reported during the study period will be collected. Causality with study procedures will be determined for all serious adverse events and deemed "related" or "not related" to the intervention.

Statistical Analysis Plan

The following hypotheses will be examined: (1) PHQ-9 use will be greater after implementation compared with before implementation of the *Pathway Platform* and (2) provider processes and patient depression-related outcomes will have greater improvements after implementation of the *Pathway Platform* compared with previous practice patterns. For primary and secondary hypothesis testing, process measures, patient clinical outcomes, and health care resource usage will be compared before and after implementation of the *Pathway*

XSL•FO
RenderX

Platform. Additional PROs will be evaluated after implementation only, which will be from patients using the *Pathway Platform* at baseline and at the end of the study.

For preimplementation, outcomes will be assessed among patients who visited one of the study clinics at least once over the preimplementation study period and were eligible to use the *Pathway Platform* if it had been available. For the postimplementation period, the *Pathway Platform* will be the data source for paired *t* test analysis, assessing change in continuous variables, including PHQ-9 scores. Categorical outcomes will be presented as proportions and compared using the Pearson chi-square test. Continuous outcomes will be assessed for normality and presented as means and SD or medians and IQRs; continuous outcomes will be compared using the Student *t* test for independent groups. Two-tailed tests using a significance threshold of P=.05 will be used for all tests.

Data Collection and Management

The schedule of evaluations is given in Table 1. Data from the EHR and manual chart reviews will be collected from two cohorts: (1) patients attending clinics after implementation (postimplementation cohort) and (2) patients attending clinics before implementation (preimplementation cohort). For each cohort, data will be collected over a 6-month period. Data on patient outcomes and *Pathway Platform* usage will be collected throughout the study starting on day 1 through month 6 for each patient using the platform. Similarly, data on report usage by the care team will be collected throughout the study. In addition, the number of times the care team educational resource material is viewed will be recorded between day 1 and month 6.

[l]AE: adverse event.

[m]SAE: serious adverse event.

[n]During the conduct of the study, adverse events or serious adverse events will be reported. As such, reports will be spontaneously notified, and causality of any AEs will be assumed unless there is evidence to the contrary.

Results

Patient recruitment was completed in July 2022, with initial results expected in mid-2023. Findings are expected to provide insights into the improvements that can be made in clinical workflows to enhance collaborative care, depression management, clinician and patient experience, adherence to medication, patient-provider engagement, and depression outcomes in the primary care setting for patients with MDD [11]. EHR integration and efficiencies with current AAH information technology platforms will also be assessed [11].

Discussion

Primary care centers are significant providers of mental health services for patients with MDD. Among US adults with MDD, 33% reported receiving mental health treatment within primary care during the previous 12 months compared with 21% who received treatment from a psychiatrist [25]. MBC in patients with MDD allows the primary care provider to accurately identify whether a patient is making enough progress toward their treatment goals. Treatment decisions based on MBC give patients a better understanding of the disease, including how adherence impacts their symptoms [8].

A common barrier to adherence is when an HCP's choice of treatment plan is not agreed upon by the patient. SDM is a systematic approach that improves patient education and helps primary care physicians provide treatment in conformity with evidence-based guidelines [26,27]. SDM can help increase adherence to drug treatment in the primary care setting and results in improved social functioning compared with usual care when used as part of a multifaceted relapse prevention program [9,28]. Involvement in SDM is associated with a higher probability of receiving quality care and improvement in symptoms [29].

Digital technology platforms, such as mobile apps, can offer low-cost interventions to monitor and improve services for certain patient populations that are difficult to retain in treatment and may also promote better health [30]. The *Pathway Platform* is a digital platform designed to improve patient outcomes by supporting an expanded understanding of MDD treatment, assisting care team workflows, and providing additional support to patients with depression throughout their treatment journey [11,15]. The patient-facing interface includes a digital assistant that allows those with MDD to interact with the *Pathway Platform* in a chat-based conversational text interface. The information collected from a patient using the *Pathway Platform* is intended to assist the care team in managing the patient's depression through improving MBC and SDM, thereby enhancing patient-provider engagement and ultimately patient outcomes.

The uniqueness and strengths of this study design are the real-world implementation of a digitally enabled care pathway with EHR integration in real time for patients with MDD and a continuous educational program for both patients and care teams in the primary care setting. In addition, the care team interface and patient-provider engagement help incorporate the use of PROs and emphasize the importance of SDM. Integrating the *Pathway Platform* to support MBC and SDM will improve the clinical workflow, depression management, adherence to medication, patient-provider engagement, as well as depression outcomes and care.

SDM and the involvement of both patients and physicians promote healthy relationships, with the benefit of helping patients with MDD feel greater support throughout their treatment, including web-based connections and care when needed, and can help ensure the safety of everyone involved in the process. By cocreating the *Pathway Platform* with users, including user-centered design methods, extensive preimplementation feedback and optimization, incorporation of the care team workflow, and patient preferences, the chances for successful implementation are greater. From a digital perspective, the *Pathway Platform* has the potential for eventual scalability and sustainability outside a research setting. Clear documentation of the study design and implementation methods will allow for replication at other health care institutions.

Limitations include a smaller sample size and geographically limited study centers, which prevent broader generalizability. Additionally, the use of a pre- and postevaluation design and lack of randomization can be seen as sources of accidental bias.

Data obtained from this real-world implementation study will allow for functional assessment of the *Pathway Platform* within the AAH care system and will determine its effects at a primary care level in patients with MDD. The *Pathway Platform* has the potential to improve patient-provider engagement for patients diagnosed with MDD and will address whether engaging these patients on an ongoing basis using digital tools can lead to better health outcomes. Overall, the study is planned to demonstrate the value of an appropriate MDD clinical care pathway by providing useful insights into a high-impact health care system.

Acknowledgments

This study was funded by Takeda Pharmaceuticals U.S.A., Inc., and Lundbeck LLC. Under direction of the authors, medical writing assistance was provided by Damanjeet Ghai, PhD, and Leandra Dang, PharmD, on behalf of Syneos Health Medical Communications, LLC. Takeda Pharmaceuticals U.S.A., Inc., and H. Lundbeck A/S provided funding to Syneos Health for support in writing this manuscript.

Abstract

Background: Asthma is a common lung condition that cannot be cured, but it can usually be effectively managed using available treatments. Despite this, it is widely acknowledged that 70% of patients do not adhere to their asthma treatment. Personalizing treatment by providing the most appropriate interventions based on the patient's psychological or behavioral needs produces successful behavior change. However, health care providers have limited available resources to deliver a patient-centered approach for their psychological or behavioral needs, resulting in a current one-size-fits-all strategy due to the nonfeasible nature of existing surveys. The solution would be to provide health care professionals with a clinically feasible questionnaire that identifies the patient's personal psychological and behavioral factors related to adherence.

Objective: We aim to apply the capability, opportunity, and motivation model of behavior change (COM-B) questionnaire to detect a patient's perceived psychological and behavioral barriers to adherence. Additionally, we aim to explore the key psychological and behavioral barriers indicated by the COM-B questionnaire and adherence to treatment in patients with confirmed asthma with heterogeneous severity. Exploratory objectives will include a focus on the associations between the COM-B questionnaire responses and asthma phenotype, including clinical, biological, psychosocial, and behavioral components.

Methods: In a single visit, participants visiting Portsmouth Hospital's asthma clinic with a diagnosis of asthma will be asked to complete a 20-minute questionnaire on an iPad about their psychological and behavioral barriers following the theoretical domains framework and capability, opportunity, and motivation model. Participants' data are routinely collected, including demographics, asthma characteristics, asthma control, asthma quality of life, and medication regime, which will be recorded on an electronic data capture form.

Results: The study is already underway, and it is anticipated that the results will be available by early 2023.

Conclusions: The COM-B asthma study will investigate an easily accessible theory-based tool (a questionnaire) for identifying psychological and behavioral barriers in patients with asthma who are not adhering to their treatment. This will provide useful information on the behavioral barriers to asthma adherence and whether or not a questionnaire can be used to identify these needs. The highlighted barriers will improve health care professionals' knowledge of this important subject, and participants will benefit from the study by removing their barriers. Overall, this will enable health care professionals to use effective individualized interventions to support improved medication adherence while also recognizing and meeting the psychological needs of patients with asthma.

Introduction

Background

Asthma is a common lung condition affecting over 5.4 million people in the United Kingdom. For some people, it can affect daily activities and lead to life-threatening consequences [1]. Asthma cannot be cured, but it can usually be effectively controlled with available treatments, provided they are taken as recommended [1]; however, it is well recognized that up to 70% of patients do not take their asthma treatments as recommended (ie, they are nonadherent) [2]. This is perhaps not unexpected in the context of a chronic condition requiring daily treatments, which must be taken even when the person feels well [3]. People may also have concerns about using long-term medicines (including steroid inhalers), or there may be other psychological or behavioral barriers to adherence [4]. Nonadherence to asthma treatments results in poor asthma control with persistent asthma symptoms, more frequent asthma attacks, and greater impairment in quality of life [5]. There are also significant economic implications associated with "wasted" medications and additional health care requirements, such as doctors' appointments and visits to the accident and emergency department, which contribute to the overall cost of asthma care in the United Kingdom, exceeding £1 billion (1£=US $1.103) per year [6].

Health care professionals play an important role in engaging and educating patients about the importance of their asthma treatments, monitoring asthma control, and identifying whether a patient is adherent or not [7]. Adherence is a complex process for the patient, who must be able to start prescribed medications, take the medications as prescribed (correct dose, inhalation technique, and frequency), and be persistent (obtaining refills to maintain adherence over time) [8]. There are limited resources available in a busy health care setting to ensure a complete understanding of each individual's psychological and behavioral barriers, with a one-size-fits-all approach obtaining limited success [9]. As such, there is a persistent unmet need for a tool that can effectively identify these barriers to adherence in a clinical setting, allowing health care professionals to provide effective personalized treatments for nonadherence in patients with asthma.

Asthma adherence research has been able to identify population-specific psychological or behavioral needs, including (1) partnership between patient and health care professional [8], (2) issues around medication, (3) education about asthma and its management, (4) health beliefs, (5) self-management interventions, (6) comorbidities, (7) mood disorders and anxiety, (8) social support, (9) nonpharmacological methods, (10) access to health care, and (11) professional factors. However, in the clinical field, such knowledge is relatively limited, with findings only showing that people with asthma are vulnerable to adherence problems and that targeted adherence interventions to facilitate population-specific barriers are not always effective. Thus, beyond identifying the vulnerability to nonadherence and targeting known barriers, a patient's personal psychological needs must be understood with in-depth and detailed insight. In addition, there is a need to establish which techniques, tools, or services are likely to successfully promote individualized ways to encourage behavioral change and adherence optimization.

In a clinical setting, health care professionals only have the resources to identify whether a patient is adherent or nonadherent to treatment; as a result, they are responsible for engaging and educating patients about the importance of their asthma treatments and monitoring asthma control. This assessment does not consider the individual barriers to each patient's adherence, and the one-size-fits-all strategy is not optimum. However, because the patient's complete picture is not presented (due to lack of feasibility, such as health care professionals' time), health care professionals lack the resources to empower the patient to address their psychological needs. Therefore, a practical resource is needed for the health care provider to receive a 360-degree picture to help personalize each patient's treatment effectively.

The Theory

It is important that the psychological needs of patients can be easily assessed to allow for the patient's personal needs to be understood, promoted, improved, and supported [10]. When focusing on adherence behavior, the currently available tools are questionnaires, but these are long and complex to complete. The capability, opportunity, and motivation model of behavior change (COM-B) model is a new questionnaire that is shorter and easier for patients to complete [11]. It involves 3 key components: capability, opportunity, and motivation [12]. This theoretical approach has not been used extensively for people with asthma. However, COM-B is meant to be comprehensive, concise, and applicable to all behaviors. The COM-B is designed to serve as a starting point for selecting interventions that are most likely to be beneficial, and particular interventions to address each component have been identified [13].

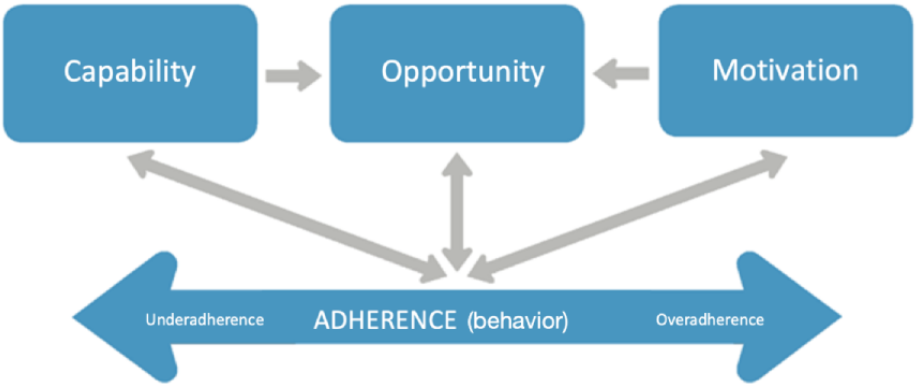
The model suggests that at any time, a particular behavior will occur when the person concerned has the capability and opportunity to engage in the behavior and is more motivated to enact the behavior over other competing behaviors. Having high COM would lead to the successful performance of behavior (see Figure 1 for a visual representation of the COM-B for adherence [14]). COM-B is designed to provide an overarching model that captures all the factors known to influence behavior change: physical capability, psychological capability, physical opportunity, social opportunity, reflective motivation, and automatic motivation [15]. Its origin can be found in the 14 domains of the theoretical domains framework (TDF: see Table 1). The TDF is an overall theoretical framework consisting of

XSL•FO
RenderX

14 domains that integrate components from numerous health behavior change theories; hence, these 14 domains are regarded as essential aspects of behavior change in health psychology. The TDF can be used to help discover the elements influencing a certain behavior without overlooking key factors. As a result, the COM-B model comprises components that are hypothesized to drive behavior. Additionally, the COM-B can be placed at the heart of the behavioral change wheel (see Figure 2); thus, this framework can be used as a mapping system [16].

Despite the COM-B model being widespread, there is only one generic self-evaluation questionnaire to assess people's perceptions of capabilities, opportunities, and motivations intended for use in multiple behaviors and a range of diverse populations [13]. Although there was evidence of this questionnaire's acceptance, validity, and reliability, this questionnaire has not been used with patients in a medical setting. As a result, this study will be able to further demonstrate the questionnaire's usefulness and reliability.

Figure 1. Application of the capability, opportunity, and motivation model of behavior change to adherence [16].



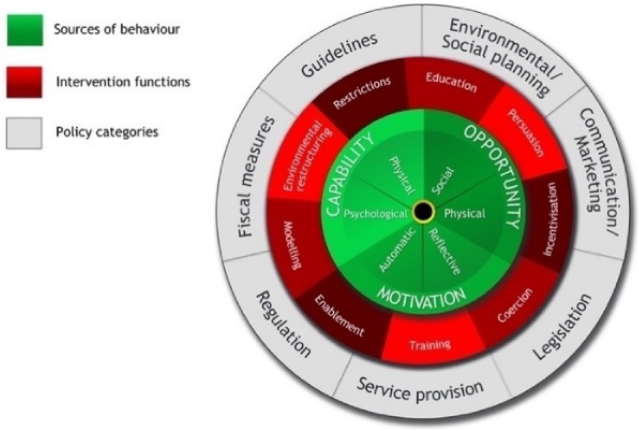


Table 1. Capability, opportunity, and motivation model of behavior change and the 11 domains of the theoretical domains framework mapped out [10].

Components of the capability, opportunity, and motivation model of behavior change	Domains in the theoretical domains framework
Capability	
Psychological	• Knowledge • Skills • Memory, attention, and decision processes • Behavioral regulation
Physical	• Skills
Opportunity	
Social	• Social influences
Physical	• Environmental context and resources
Motivation	
Reflective	• Social or professional role and identity • Beliefs about capabilities • Optimism • Beliefs about consequences • Intentions • Goals
Automatic	• Social or professional role and identity • Optimism • Reinforcement • Emotion

Figure 2. The behavioral change wheel, capability, opportunity, and motivation model of behavior change at the center [15].

Overview

This study will assess whether the brief COM-B questionnaire can identify the same psychological and behavioral barriers as the current longer questionnaires (barriers to medication adherence questionnaire) and therefore assess the COM-B questionnaire's ability to identify any important factors that may need to be addressed to support patients to take their asthma treatments as recommended.

We will also see whether there are any links between the type and severity of asthma that someone has, their other medical problems, how much treatment they have to take each day, and the COM-B questionnaire responses. This may help us better identify people who may struggle to take their medications properly and why. Again, we will use information routinely collected in the clinic, including lung function test results and medication prescription reviews, to do this.

Methods

Overview

This study will employ a cross-sectional survey design focusing on adherence to asthma treatment. It will be delivered through REDCap, a web-based platform. Participants will be recruited when attending their routine clinical review with the asthma service or while an inpatient at Queen Alexandra Hospital in Portsmouth, United Kingdom. Routinely collected patient data, including demographics, asthma characteristics, asthma control, and medication regime that is already collected as part of their clinical review, will be recorded on an electronic data capture form (e-CRF) through the REDCap platform. They will then be asked to complete the series of questionnaires, all completed on the web. Patients will also be provided with a paper copy of each questionnaire. When the questionnaire is completed, the user will be provided with debriefing information.

Participants will be asked to complete a set of questionnaires that will assess the following:

1. Psychological and behavioral barriers that may affect the participant being able to take their asthma treatments as recommended: the brief COM-B questionnaire (which is being validated as part of this study) and the 61-item Theoretical Domain Framework Questionnaire.
2. Their asthma symptoms and how well controlled their asthma is (Asthma Control Questionnaire [ACQ-6]), the impact their asthma has on their quality of life (Mini Asthma Quality of Life Questionnaire), and the level of anxiety or depression they may be experiencing (Hospital Anxiety and Depression Scale). All of these questionnaires are used routinely at clinic reviews.
3. Their use of technology at home and any challenges they face with this: Digital Readiness Questionnaire.

The COVID-19 pandemic has changed the way people with asthma access their care with a move to remote consultations and questionnaire completion. The COM-B questionnaire may well be suitable for this approach. However, it is essential to assess digital readiness in this population to understand whether this is feasible and inform the design of future studies if the COM-B questionnaire proves to be successful.

It should not take more than 20 minutes to complete. The questionnaires are all validated and approval has been granted for their use in this study.

Eligibility Criteria

Participants will be drawn from a range of adults with asthma who take regular medication for their condition. The inclusion and exclusion criteria are presented in Textbox 1.

XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria of the study participants.

Inclusion criteria

- Aged 18 years or above
- Willing and able to give informed consent for participation in the study
- Diagnosing of asthma confirmed by a health care professional and requiring maintenance asthma treatment, including an inhaled corticosteroid.

Exclusion criteria

- Unable to comprehend the study and provide informed consent, for example, insufficient command of English in the absence of someone who can adequately interpret.

Sampling and Sample Size

A power calculation was conducted to determine the sample size, using the 6 components of the COM-B model that are hypothesized to drive behavior, namely physical capability, psychological capability, physical opportunity, social opportunity, reflective motivation, and automatic motivation. Using the G-power analysis for 6 predictors, a minimum of 146 participants are needed. The G-power analysis was run using SPSS to offer a sensitivity power analysis of the effect size that this sample size was sensitive to detect.

As a result, to detect a standardized effect size of Cohen *d*=0.43 with 80% power (α =.05, 2-tailed), G*Power suggests we would need 146 participants in independent tests. A paired sample *t* test with 30 participants would be sensitive to the effects of Cohen *d*=0.53 with 80% power (α=.05, 2-tailed). This means the study would not reliably detect effects smaller than Cohen *d*=0.53. To detect a Pearson correlation coefficient of ρ=.21 with 80% power (α=.05, 2-tailed), G*Power suggests we would need 146 participants.

Recruitment

All people with asthma who are under the care of the asthma service at Portsmouth Hospitals University National Health Service (NHS) Trust will be invited to participate in this study. This will include recruitment from primary care sites. In addition, both outpatients and inpatients will be approached and invited to participate.

Study Assessment

This section describes the information that will be recorded in the participant's RedCap report, which will be anonymized using the participant's unique study number.

Participant Clinical Characteristics

The following information is routinely collected and used as part of standard care and following consent and recruitment to the study will be transcribed from a participant's clinical care records and will be recorded on the e-CRF.

Patient Details and Demographics

1. Age, gender, ethnicity, school or work status, educational level
2. Smoking status and pack-year smoking history
3. Asthma severity is defined using British Thoracic Society stages
4. New or established patients to the asthma service
5. Medical comorbidities

Asthma Characteristics

1. Age when asthma diagnosis was made
2. Spirometry—this will either be captured as part of their routine clinic visit or can be historic (within the last 12 months)
3. Type 2 (T2) biomarkers: peripheral blood eosinophil count and fractional exhaled nitric oxide (FeNO)—this will either be captured as part of their routine clinic visit or can be historic (within the last 12 months)
4. Number of exacerbations in the preceding 12 months (number of courses of steroids, number of emergency department attendances or hospital admissions)
5. Current asthma treatments

Adherence Assessment

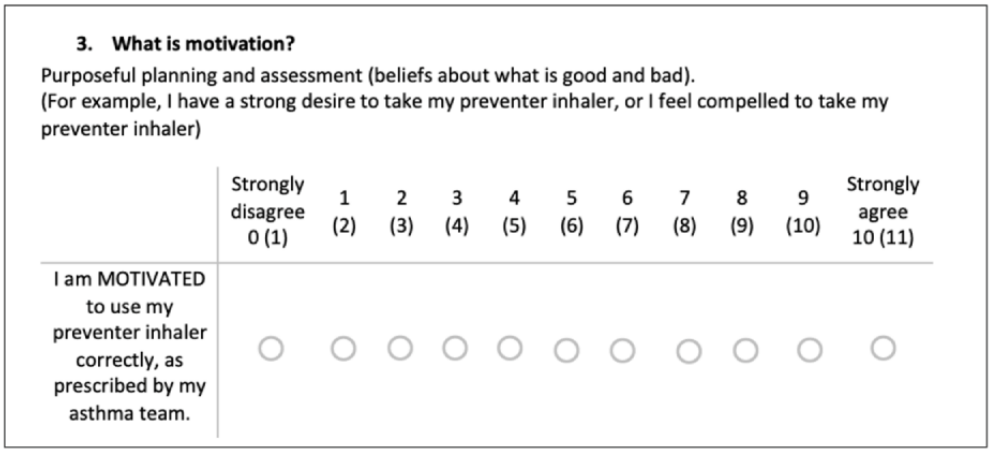
1. Medicines possession ratio (MPR)—this measurement will consider the past 12 months of the participant's adherence. Adherence will be defined as an MPR ≥80%
2. Advanced measures of adherence (such as FeNO suppression) where available

Complexity of Medication Regime

1. Total number of medications taken each day
2. Number of doses of inhaled medications per day

Questionnaires Collected

The asthma COM-B questionnaire [13] measure will be responsible for identifying one's capabilities, opportunities, and motivations regarding asthma medication adherence. In the questionnaire, these measures will be presented as individual questions, forming 6 matrix tables.



This questionnaire will be brief, with 6 items asking them to rate their understanding of their psychological and physical capacities, opportunities, and motivations for adhering to asthma treatment on a Likert scale (see Figure 3, for example items from the questionnaire adapted from Keyworth et al's [17] COM-B measure). This tool would follow the structure, formatting, and length of other questionnaires given to patients during their initial assessments. As a result, it will be easily integrated into the health care system, providing health care providers with immediate responses to patients' psychological needs and potentially getting a better understanding when meeting with the patient.

XSL•FO
RenderX

The ACQ [15,18] consists of 6 items covering day and nighttime symptoms, activity limitations, and rescue bronchodilator use. A score of ≥1.5 reflects poor asthma control.

The Mini Asthma Quality Of Life Questionnaire standardized version [16,19] measures four domains: symptoms, activity limitation, emotional function, and environmental stimuli.

Figure 3. Items 1 of 6 from the adapted capability, opportunity, and motivation model of behavior change questionnaire to target known drivers of adherence in people with asthma. This figure was adapted from Keyworth C et al [17] which is published under Creative Commons Attribution 4.0 International License [20].

Adherence Measures

The 61-item Theoretical Domain Framework Questionnaire [21,22] will determine the individual's behavior in terms of the theoretical domains framework (see Table 1).

The Test Of Adherence To Inhalers [23,24] is a 12-item questionnaire designed to assess adherence to inhalers in patients with asthma.

Digital Readiness Measure

The Digital Readiness Scale [17] was followed to investigate the effectiveness of using technology tools for medical practices in the NHS. This scale will be adapted to 6 items assessing participants' use of digital tools, interest in digital tools, and challenges faced by participants while using digital tools [25].

Statistical Analysis

Data Exclusion

Participants are free to withdraw from the study, and this will not affect their treatment. Participants will consent at the start of the survey to allow their anonymized study data to be retained and analyzed by the study team if they withdraw from the study. Withdrawn participants will not be replaced.

Data will be analyzed once 146 participants have completed the questionnaire. All data will be handled within the general data protection regulations conditions, which came into force in May 2018.

Once a survey is completed, it is locked, and time-stamped so the survey responses cannot be edited further. Required fields are specified on the survey form, and partial or incomplete responses will not limit the survey response. Once the survey response limit is reached, the public URL will redirect to a message notifying that the survey is closed.

Data Management

All data collection will be completed on the web. The research team will use the Redcap electronic cloud solution to store and manage all consent and study data. The cloud services are NHS compliant and approved for use in surveys.

Data will be stored on a secure password-protected electronic research database hosted on a secure NHS server with appropriate backup systems, antivirus software and security protocols compliant with NHS information governance standards. Data entered into the electronic database will be accessible only by a restricted number of research personnel listed in the delegation log of the survey master file.

There will be a survey master file with a delegation log of approved users in the file. Before anyone can use the database, they will have to be included in this list, with the approval of the chief investigator. The chief investigator and survey coordinator will have access to all research data collected in this study to perform the data analyses required.

A data manager will perform regular data quality control checks, and reporting and statistics will be performed using tools built into the survey distribution platform. A comprehensive audit log will be maintained throughout the study and exported and stored in the survey master file on study closer.

Overview

Patient scores for the behavioral components of physical capability, psychological capability, social and physical opportunity, and reflective and automatic motivation will be tabulated, so that adherence and asthma characteristics can be recorded for each behavioral source against predefined behavioral change techniques based on the behavioral change wheel [12].

Summary Statistics

Demographics or baseline characteristics of each participant will be produced, as well as summaries for all participants

XSL•FO
RenderX

combined. Normally distributed continuous variables will be summarized by the mean to characterize the population. Nonnormally distributed variables will be summarized by the median to characterize the population.

Primary Analysis

The primary analysis will comprise the correlation of outcomes from the brief COM-B questionnaire and the TDF questionnaire, as well as the Spearman rank correlation coefficients (ρ; strength of the relationship) and a hierarchical multiple regression analysis. For example, the capability result of the questionnaire will be compared to knowledge, skills, memory attention and decision processes, behavioral regulation, and skills. In addition, some exploratory analysis between the variables will be conducted—this will be used to derive the content validity of the brief COM-B questionnaire.

Secondary Analysis

Descriptive statistics will be used to illustrate levels of asthma control, medication adherence, and perceptions of capabilities, opportunities, and motivations. One-sample *t* tests, within participants' ANOVA and deviation contrasts will be used to explore differences between levels of capabilities, opportunities, and motivations regarding adhering to their asthma medication programs.

For each capability, opportunity, and motivation variable, separate cluster analysis models will be used to examine associations between the COM-B with levels of adherence measured by MPR and FeNO suppression to explore the key psychological and behavioral barriers indicated by the COM-B questionnaire and methods of determining adherence in a clinical setting.

Multiple regressions will be conducted to test the levels of adherence. In addition, other variables such as demographics and asthma characteristics will be taken into consideration.

Exploratory Analysis

Network analysis between variables including (but not limited to):

1. Type of asthma (T2 or non-T2 defined by the presence of a T2 inflammatory signal assessed using FeNO and peripheral blood eosinophil count)
2. Asthma severity using British Thoracic Society or Scottish Intercollegiate Guidelines Network (SIGN) stage
3. Level of asthma control assessed using the ACQ6 questionnaire (a score of ≥1.5 reflects poor asthma control)
4. Quality of life measured using the mini-asthma quality-of-life questionnaire score
5. Number of comorbidities
6. Complexity of treatment (number of inhaled doses per day, total number of medications taken each day)
7. Informative analysis of digital readiness will be performed by summarizing all participants combined responses, reported in percentages

Procedure for Missing, Unused, or Spurious Data

There are no plans for multiple imputations or other corrections for missing data.

Ethical Considerations

Statement of Compliance

All staff working on this study will hold evidence of good clinical practice training before undertaking any responsibilities, and all staff working within the research study team are also part of the respiratory clinical care team and are involved in PhD supervision. Written informed consent will be obtained from all participants after an adequate explanation of the aims, methods, and anticipated benefit of the study using the participant information sheet. A signed copy of the consent form will be given to the participant, and copies will be filed in the study master file and the participants' medical notes.

Participants' anonymity will be maintained throughout by identification on a password-protected electronic database and e-CRFs only by initials and participant ID number. All documents will be stored securely and only accessible by study staff and authorized personnel; the study will comply with the Data Protection Act.

Potential Benefits or Risks of Study Participation

This study is a low-risk questionnaire study; however, any risks to the participants have been carefully considered—any participants who were observed struggling with the psychological aspect of the questionnaire or the questionnaire raised further issues patients will have these errors highlighted and will be informed with the correct health care professional to look after their care. This is a beneficial outcome for participants' self-care and management and ensures that they obtain the correct level of care.

This study analyzes a wide variety of behavioral barriers and will help provide a clear picture of the psychological needs that are associated with asthma adherence. Understanding this information is important in the context of managing lung conditions, from treating patients in primary care through to feeding this information back to intervention designers.

Other Ethical Considerations

The study will not be initiated before the protocol, and the survey's material such as the consent forms, survey answers, and participant information sheets have received favorable opinions from the health research authority and the respective NHS research and development (R&D) departments. Should an amendment be made that requires Research Ethics Committee (REC) approval, as defined by REC as a substantial amendment, the changes will not be instituted until the amendment has been reviewed and received approval or favorable opinion from the REC and R&D departments. However, a protocol amendment intended to eliminate an apparent immediate hazard to participants may be implemented immediately, providing that the REC is notified as soon as possible, and approval is requested. Other amendments will be implemented under the direction of the REC.

All participants will have adequate time to consider participation in the study, as per good clinical practice guidelines.

XSL•FO
RenderX

Participants who are already enrolled in other research surveys will be invited and allowed to participate in the study if they so wish.

Patient Public Involvement Process

Patients having first-hand knowledge of coping with chronic respiratory disease were sought out for patient involvement in this study. We have spoken with our respiratory patient representatives in person, over the phone, and via email. These individuals have participated in earlier research projects and have lived with respiratory problems. To ensure that we address the issues that are pertinent to persons with airway disorders, they helped define the main questions and establish our study objectives. To reduce waiting times for patients who decided to participate in the study, assistance was also sought with the design of participant recruitment and the implementation of the study within a typical clinical visit. Additionally, they contributed to creating the participation information sheet and cowrote the lay summary.

Results

The study is already underway, and it is anticipated that the results will be available by early 2023.

Discussion

The COM-B asthma study will investigate an easily accessible theory-based tool (a questionnaire) for identifying psychological and behavioral barriers in patients with asthma who are not adhering to their treatment. This will provide useful information on the behavioral barriers to asthma adherence and whether or not a questionnaire can be used to identify these needs. The highlighted barriers will increase health care professionals' knowledge of this important subject, allowing for practice change and better information for interventions to remove those barriers. Overall, this will enable health care professionals to use effective individualized interventions to support improved medication adherence while also recognizing and meeting the psychological needs of patients with asthma.

Acknowledgments

We would like to thank our participants for their contribution. We also thank the following for their help in the delivery of this survey: Priyanka Abrahams, Selina Begum, Nadine Darnley, Aaron Manzano, Dipu Thomas, Jon Winter, Rachel Harvey, Bryony Reeve, Sofia Folini, Alexandra Niculescu and Ruth De Vos. This study was funded by the South Coast Economic and Social Research Council Doctoral Training Partnership (project category: training grant, for PhD thesis titled "An Adherence Support-Pathway for Asthma (ANASA): Adopting a Behavioral Change Model to Enable an Effective Adherence Pathway, Based on the Psychological and Behavioral Needs of Persons with Asthma."

Data Availability

The data sets generated or analyzed during the current study are available from the corresponding author on reasonable request.

Abstract

Background: Prenatal care, one of the most common preventive care services in the United States, endeavors to improve pregnancy outcomes through evidence-based screenings and interventions. Despite the prevalence of prenatal care and its importance to maternal and infant health, there are several debates about the best methods of prenatal care delivery, including the most appropriate schedule frequency and content of prenatal visits. Current US national guidelines recommend that low-risk individuals receive a standard schedule of 12 to 14 in-office visits, a care delivery model that has remained unchanged for almost a century.

Objective: In early 2020, to mitigate individuals' exposure to the SARS-CoV-2 virus, prenatal care providers implemented new paradigms that altered the schedule frequency, interval, and modality (eg, telemedicine) of how prenatal care services were offered. In this paper, we describe the development of a core outcome set (COS) that can be used to evaluate the effect of the frequency of prenatal care schedules on maternal and infant outcomes.

Methods: We will systematically review the literature to identify previously reported outcomes important to individuals who receive prenatal care and the people who care for them. Stakeholders with expertise in prenatal care delivery (ie, patients or family members, health care providers, and public health professionals and policy makers) will rate the importance of identified outcomes in a web-based survey using a 3-round Delphi process. A digital consensus meeting will be held for a group of stakeholder representatives to discuss and vote on the outcomes to include in the final COS.

XSL•FO
RenderX

Results: The Delphi survey was initiated in July 2022 with invited 71 stakeholders. A digital consensus conference was conducted on October 11, 2022. Data are currently under analysis with plans to submit them in a subsequent manuscript.

Conclusions: More research about the optimal schedule frequency and modality for prenatal care delivery is needed. Standardizing outcomes that are measured and reported in evaluations of the recommended prenatal care schedules will assist evidence synthesis and results reported in systematic reviews and meta-analyses. Overall, this COS will expand the consistency and patient-centeredness of reported outcomes for various prenatal care delivery schedules and modalities, hopefully improving the overall efficacy of recommended care delivery for pregnant people and their families.

Introduction

Prenatal care, one of the most common preventive care services in the United States, endeavors to improve pregnancy outcomes through evidence-based screenings and interventions [1]. Despite the prevalence of prenatal care and its importance to maternal and infant health, there are several debates about the best methods of prenatal care delivery, including the most appropriate schedule frequency and content of prenatal visits [2]. For patients, adaptable scheduling and assimilation of telemedicine into prenatal care visit schedules provide convenience, save time, and reduce resource outlays for patients. For prenatal care providers and clinics, it allows enhanced operation of facility space by permitting flexibility in scheduling and prioritizing in-person access for pregnant individuals with acute needs. With many regions facing limited access to timely obstetrical care across the United States, whether due to the clinic's capacity or geographic limitations (eg, travel time), innovative application of new approaches to prenatal care will become essential. Current US national guidelines recommend that low-risk individuals receive a standard 12 to 14 in-office visit schedule—a care delivery model that has remained unchanged for almost a century. Other guidelines from peer countries (eg, Canada, Europe, and Australia), as well as national consensus panels, have recommended a reduced visit schedule based on recommended prenatal care services for average-risk people, typically 7 to 11 visits [3-6].

In early 2020, to mitigate individuals' exposure to the SARS-CoV-2 virus, prenatal care providers implemented new paradigms that altered the schedule frequency, interval, and modality (eg, telemedicine) of how prenatal care services were offered. COVID-19 pandemic–related changes to how prenatal care was provided accelerated existing plans of the American College of Obstetricians and Gynecologists (ACOG) to redesign prenatal care for low-risk pregnant people. ACOG urgently convened a multidisciplinary panel to review how prenatal care was administered to the average-risk individual [5]. The panel provided recommendations for (1) prenatal visit schedules (care initiation, visit timing, and frequency); (2) integration of telemedicine (web-based visits and home devices); and (3) care individualization. However, it was recognized that there were significant gaps in evidence needed to guide national policy change on prenatal visit schedules, including visit frequency and modality. Meta-analyses of studies that addressed the prenatal care visit schedules and the effects on maternal or infant outcomes have noted inconsistencies in which outcomes are routinely collected and reported [7-10]. There is a need for consistent reporting of maternal and infant outcomes in future clinical trials that compare the traditional 12 to 14 in-office visit approach with new models of prenatal care schedules that incorporate different frequencies of visits and use of telemedicine.

Core outcome sets (COSs) are key tools for ensuring consistent, homogenous reporting of outcomes across studies. The use of COS can result in improved clinical practice via standardization of outcomes across studies, thereby making it easier to compare outcomes. Furthermore, the use of COS can reduce the risk of outcome-reporting preference, ensuring that all trials contribute functional information [11]. The objective of this study is to develop a COS to standardize outcome selection, collection, and reporting for future studies that compare prenatal care schedules with different frequencies of prenatal visits delivered across any modality (eg, in-office care, group prenatal care, or telemedicine).

Methods

Steering Committee

This study has been prospectively registered with the Core Outcome Measures in Effectiveness Trials initiative website (registration number 2021). We will follow reporting guidelines for developing COS, as outlined by the Core Outcome Set-Standards for Development and follow the Core Outcome Set-Standardised Protocol Items statement [12,13]. A steering group including prenatal care providers, clinical researchers, and obstetric health care policy makers has been formed to guide the development of this COS. Members of the steering group were selected to represent various disciplines, geographical areas, and expertise. Within the steering committee, a study advisory board has been established, which consists of a study coordinator (BN) and 2 members of the steering committee (MT and AP) who will conduct the day-to-day management of the study.

XSL•FO
RenderX

Definitions

The steering committee recommended that the COS should apply to clinical studies evaluating the frequency of prenatal care schedules for average-risk individuals receiving prenatal care when compared to current US national guideline recommendations of a 12 to 14 in-office visit schedule. Average risk was defined broadly using a prior consensus committee definition and includes all pregnant individuals seen by maternity care providers (eg, obstetrician gynecologists, family medicine physicians, nurse practitioners, and certified nurse-midwives), without significant comorbidities requiring exclusive care by a maternal-fetal medicine physician [5]. The potential interventions covered by the COS could include the recommended frequency of prenatal care visits in several modalities: (1) traditional 12 to 14 in-office appointments versus reduced number of in-office visits; (2) method of delivery of the frequency of various types of prenatal care visit recommendations (traditional 12 to 14 in-office visits versus a reduced number of visits provided by a hybrid of in-office combined with telemedicine modalities); and potentially (3) other innovative models of prenatal care schedule recommendations (traditional 12 to 14 in-office visits compared to a reduced number of scheduled visits using care delivery models such as group prenatal care or pregnancy medical homes that incorporate either in-office only or a hybrid of in-office and telemedicine).

Study Overview

Overview

This study will be divided into three separate phases: (1) ascertaining potential core outcomes, (2) defining core outcomes for inclusion, and (3) consensus meeting.

Phase 1: Developing a Preliminary Core Measurement Outcome Set

Two systematic reviews were recently commissioned for evaluating the effect of varying the frequency of prenatal care visit schedule recommendations on maternal and infant outcomes [5,10]. To identify any additional outcome measures published in the literature, we will supplement these systematic reviews with an electronic investigation with no date or language boundary using the databases of MEDLINE via the PubMed interface, Web of Science, Embase, and CENTRAL to identify outcome measures in systematic reviews that reported on the effect of different frequency of prenatal visit recommendations on maternal and infant outcomes. We will evaluate unpublished collected works (ie, "gray literature") by searching Google Scholar and screening the first 100 results as is commonly done, based on the assumption that the most applicable results would emerge first [14].

We will also identify potentially relevant outcome measures from the medical literature to inform the consensus process. Data sources that may be considered as systematic reviews of published studies and reviews of published qualitative work that have evaluated the effect of the recommended frequency of scheduled prenatal visits on maternal and infant outcomes. A list of outcomes from published studies will be supplemented by a review of qualitative research studies investigating patients' opinions regarding the frequency of prenatal care visits.

Steering group members will be provided with a preliminary outcome list, as well as a summary of the systematic reviews and the strength of evidence for each outcome (based on either the Cochrane Handbook for Systematic Reviews of Interventions [15] or the Grading of Recommendations Assessment, Development and Evaluation [16]). The list of core outcomes will be piloted and adjusted by the steering group, incorporating both professional expertise and public member perspectives, before finalizing. The steering group members will be asked to "From the following list choose the 'minimum standard outcomes' that you think are important when developing a COS for the frequency of prenatal care visits (FORCAST) recommended schedule." Every respondent will be given the option to include, exclude, or combine each outcome with other outcomes that have similar clinical definitions (eg, combining gestational age at birth and preterm birth into a single outcome) to limit the number of COS outcomes and increase the likelihood that the COS is applied in future research. Steering group members will also be given the opportunity to add outcomes they believe are critical for the COS. Steering group members will be encouraged to base their COS decisions on the strength of evidence reported in the medical and public health literature. Steering group member responses will be tabulated into an outcome inventory spreadsheet. Responses to the survey will be reviewed independently by the advisory board members, duplicate suggestions will be removed, and the remaining responses will be grouped into domains of maternal or infant outcomes. Additional outcomes proposed by the steering committee will be added to the COS if at least 2 members write in the outcome, per specifications of the Core Outcome Measures in Effectiveness Trials handbook [11]. The steering committee will then review the domains and finalize a comprehensive list of outcomes. Following the steering group's consensus, the list of outcomes will then be prepared for the Delphi survey [11]. All language for the COS will be developed using definitions from professional organizations and patient-facing resources tested across diverse populations where possible. Definitions will be piloted with 3 public members to confirm readability and comprehension.

Phase 2: Conducting a Delphi Survey to Gain Consensus Opinion on Items to Include in a Standardized COS

Overview

We will conduct a Delphi panel to develop the stakeholder-informed COS [11]. In a COS structure, this method is used for attaining convergence of opinion from stakeholders on the importance of different outcomes in sequential questionnaires sent electronically. We will use sequential web-based questionnaires with participant feedback between rounds to incorporate the perspectives of diverse stakeholders who contribute to and receive prenatal care, including (1) public members: persons who are currently using prenatal care, have used prenatal care in the past year, or provide nonmedical support to pregnant and postpartum people (eg, pregnant and postpartum people, family members); (2) prenatal care providers and researchers: health care providers who administer prenatal

XSL•FO
RenderX

care (eg, obstetrician or gynecologists, family medicine physicians, neonatologists, advanced practice practitioners, and nurses) with representation from both academic and community health settings and investigators involved in perinatal research (eg, clinical researchers and health services researchers); (3) public policy members: individuals involved in development of guidelines, regulation, and payment for pregnancy and postpartum care (eg, clinical guideline developers, public health representatives, and medical insurance payer representatives).

Recruitment

We aim to recruit a minimum of 20 public members, 20 providers and researchers (including a mixture of academic and community providers), and 20 public health and public policy members, with balanced representation across identities, including race and US geographic regions. Potential participants will be invited to participate in the Delphi survey with a personalized email describing the project. Public participants, including patients who have experienced prenatal care and their support people, will be recruited through patient organizations and community members affiliated with the ACOG and other national maternity care organizations. Patient advocacy groups that serve historically marginalized populations (eg, pregnant people of color) will be specifically contacted through professional networks of the steering committee and professional organizations to ensure the representation of diverse perspectives. Following these initial contacts, we plan to use snowball sampling, a research technique in which recruited individuals help to identify other potential participants, with a focus on expanding the diversity of geography and lived experiences of included perspectives. Prenatal providers and researchers will be recruited through professional maternity care organizations (eg, the ACOG, Society of Maternal Fetal Medicine, American Academy of Family Physicians, and American College of Nurse Midwives). Additional leaders in prenatal care practice and research will be identified by the steering committee and invited to participate. Public policy members will be recruited from leading organizations supporting prenatal care policy and payment such as the ACOG, Centers for Disease Control and Prevention, and medical insurance payers. Participants must be able to speak and read English fluently, but no other exclusion criteria will be applied. Baseline demographic information (age, gender, race, and ethnicity) and practice information (if a prenatal care provider) will be obtained for each participant at the beginning of the survey. Participants will be asked to complete the survey in 7 days, with a reminder email sent at the end of 14 days to prompt completion. Participation will be optional and consent to participate will be implied if a contributor responds to the survey.

Delphi Procedures

Before starting the survey, participants will be assigned a unique identifier to anonymize their responses and allow identification and linkage of individual responses in rounds of the Delphi exercise and feedback. Participants will be invited to provide their name and consent to be acknowledged as a member of the Delphi panel in the publication arising from this research. We anticipate a 3-round survey; however, the round 2 results will be reviewed by the steering committee to consider the need for a further Delphi survey round. All participants who complete the first round of the Delphi exercise will be invited to participate in the second. All participants who complete the second round will be invited to participate in the third. The first-round survey will include scoring of core outcome measurement items informed by the preliminary list from phase 1. Outcomes will be ranked on a 1-9 Likert scale, ranging from least important to critical importance (1-3 is of limited importance, 4-6 is important but not critical, and 7-9 is critical) [16]. In round 1, participants can suggest new items to be included in the second round. If 2 or more participants suggest an additional core outcome measure, it will be reviewed by the steering group and unique outcomes will be entered into round 2. All core outcome measures from round 1 will be carried forward to round 2. Participants will also be given the opportunity to share explanations for their ratings through web-based message boards.

Following round 1, the study advisory board will calculate the median and range of scores for each round 1 outcome by the stakeholder group, as well as the pooled median and range for all participants. Explanations shared through message boards will also be collated and shared with scoring summaries. For each round, the number of participants who were invited but do not participate (ie, attrition rate) will be calculated and shown in the final publication of the COS. Prior to completing round 2, each participant will receive their own score on each potential core outcome measure, as well as the scores by stakeholder group and overall. Participants will be asked to reflect on their own scores and on the scores of other participants before rescoring each individual outcome. After the round 2 survey has closed, the percentage of participants scoring each outcome will be calculated and tabulated for each individual, the stakeholder groups, and the overall pooled group. If 70% of the core outcomes have reached a consensus to be either included or excluded (as defined below) after round 2 of the Delphi survey, the third round of the Delphi will be omitted, and the group will proceed to the consensus meeting. If participants have not come to a consensus at the conclusion of round 2, similar procedures will be repeated for round 3.

Consensus for inclusion will be defined as when ≥70% of participants scored the outcome “critical” for decision-making (a score of 7-9) and <15% of participants in the stakeholder group scored the outcome of “limited importance for decision-making” (a score of 1-3). Consensus for an outcome to be excluded from the COS will be defined when ≥70% of participants in the stakeholder group scored the outcome of “limited importance for decision-making” (a score of 1-3) and <15% of participants in the stakeholder group scored the outcome as “critical for decision-making” (a score of 7-9) [11]. Although there is no consensus regarding the ideal number of outcomes to include in a COS, based on existing literature and expert opinion, the steering committee has established a preset goal of 10 outcomes for the COS to enable the implementation and use of the COS [17]. Items that reach consensus to be included (as defined above) for all 3 stakeholder groups will be automatically included in the final set of FORCAST COS recommendations, even if there are more than 10 core outcomes. Items that reach consensus to be excluded (as defined above) by all 3 stakeholder groups will be removed. If after the final

XSL•FO
RenderX

round of the Delphi survey no core outcome measures are excluded, the steering committee will determine outcomes to be brought forward to the consensus meeting using at least one of the following three criteria: (1) the mean outcome measure is scored as critical (a score of 7-9) by ≥70% of all participants included in the Delphi survey; (2) the top 10 outcome measures from the 3 different stakeholder groups (public members, prenatal care providers and researchers, and public policy members); or (3) outcome measures considered critically important by ≥70% of 1 or more of the different stakeholder groups [17].

Phase 3: Holding a Consensus Meeting to Identify the Main Items to be Included in the COS

A web-based consensus meeting will be held to review outcomes without consensus, resolve remaining discrepancies, and approve a final COS for the frequency of scheduled prenatal care visits. The consensus meeting will include at least 7 of the 9 steering committee members and 3 representatives from each of the 3 stakeholder groups (9 members), selected to maximize diversity, as voting members. Additionally, any participant who completed all 3 rounds of the Delphi survey will be invited to observe and provide their perspective in discussions. The meeting will begin with an initial briefing on the purpose and scope of the meeting, including a summary of the results from the initial rounds of the Delphi, outcomes with consensus for inclusion and exclusion, and outcomes where consensus has yet to be reached. The panel will begin with outcomes that reached consensus from all stakeholder groups for inclusion or exclusion to approve those results. The panel will next consider items that did not reach a consensus. These items will be the focus of the meeting. All consensus meeting participants will be given an opportunity to discuss each item and share their perspectives on why it should or should not be included in the final COS. Members of the steering group and the 3 representatives from each stakeholder group will receive a summary of the results and be asked to independently consider items remaining that did not reach consensus to be either automatically included or excluded. The steering committee and stakeholder representatives will then take a majority vote on whether the core outcome measure should be included in the final COS. While the preset goal of the consensus meeting is to encompass no more than 10 outcomes, if it is determined that more than 10 outcomes are necessary, these additional outcomes will be included. A summary of this process and the voting results will be published with the final report. Those outcomes excluded will be listed in the final publication. The final COS will be sent to all participants who participated in the 3 Delphi rounds in order to give them the opportunity to comment on the final results. The steering committee will draft the FORCAST COS guideline for publication and dissemination.

Ethical Considerations

The study was determined exempt by the University of Michigan institutional review board, as it was deemed nonhuman subject research (HUM00217486).

Results

The Delphi survey was initiated in July 2022 with 71 invited stakeholders. A web-based consensus conference was conducted on October 11, 2022. Data are currently under analysis with plans to submit them in a subsequent manuscript.

Discussion

Applying a COS for the frequency of recommended scheduled prenatal care visits and mode of visit interaction is needed to assist forthcoming clinical studies, systematic reviews, and evidence-based clinical guidelines to decide which prenatal care approach has the strongest efficacy and clinical usage, and for whom. Many prenatal care interventions, including laboratory tests, vaccinations, and routine screenings, are supported by robust randomized controlled trial evidence with consistent outcomes demonstrated through meta-analyses. However, schedules and methods of prenatal care delivery recommendations overall have not yet been subjected to these rigorous standards of assessment.

Maternity care stakeholders, including health care providers, health systems leaders, and payers, have numerous methods of prenatal care delivery to choose from, including the traditional visit schedule (visits every 4 weeks until 28 weeks, every 2 weeks until 36 weeks, and weekly until delivery); reduced visit schedules (8-9 visits based on necessary prenatal services); telemedicine; group prenatal care; and others. Establishing this COS may potentially generate a set of measures for assessing the relationship, effect, and magnitude of prenatal care visit schedules on maternal and infant health outcomes and help stakeholders to determine the comparative value of recommended prenatal care visit schedules. Establishing a COS is paramount to ensure pregnant individuals have access to the most effective prenatal care recommendations, delivered through the most efficient care delivery model.

Acknowledgments

We wish to thank Lamiya Ahmed and Megan McReynolds from the American College of Obstetricians and Gynecologists for the organizational support of this project and providing layperson feedback for core outcome set definitions as well as editing the manuscript as public member representatives. We also wish to thank Sarah Block for her assistance with the preparation of this manuscript.

BC was affiliated with the Department of Medical Education at the University of Tennessee College of Medicine, UT Health Sciences Center at the time of the trial and is currently affiliated with the Baptist University College of Osteopathic Medicine, Baptist Health Sciences University, Memphis, TN.

Data Availability

All data sets used and analyzed during the FORCAST study will be held by the FORCAST team at alexfrie@med.umich.edu

Authors' Contributions

MT and AFP are the chief investigators; they conceived the study and led the proposal and protocol development. All authors made substantial contributions to the conception and design of the core outcome set study. B-HN was the lead trial methodologist. MT and AFP drafted the manuscript. All authors commented on revisions to draft versions of the manuscript, read, commented on, and approved the final manuscript. All authors are members of the overall FORCAST study team.

Conflicts of Interest

AFP is a consultant for Maven. TAMS is a consultant to MCPAP for Moms as obstetric engagement liaison, which is supported via Beacon Health Options via the Massachusetts Department of Mental Health and Medical Director of Lifeline for Moms through UMass Chan Medical School; both focus on perinatal mental health. TAMS has received a speaker honorarium from Miller Medical Communications. The remaining authors declare that they have no competing interests.

Abstract

Background: Pneumonia is a leading cause of death in patients with end-stage chronic kidney disease treated with dialysis. Current vaccination schedules recommend pneumococcal vaccination. However, this schedule disregards findings of rapid titer decline in adult hemodialysis patients after 12 months.

Objective: The primary objective is to compare pneumonia rates between recently vaccinated patients and patients vaccinated more than 2 years ago. As an exploratory objective, antipneumococcal antibody titers in hemodialysis patients will be determined as a function. Factors influencing antibody kinetics will be identified.

Methods: Within this prospective multicenter study, we aim to compare 2 strata of vaccinated patients: those recently vaccinated and those vaccinated more than 2 years ago. A total of 792 patients will be enrolled. Twelve partner sites (within the German Centre for Infection Research [DZIF]) with allocated dialysis practices participate in this study. All dialysis patients who are vaccinated against pneumococcal infection in accordance with Robert Koch Institute guidelines prior to enrollment will be eligible. Data on baseline demographics, vaccination history, and underlying disease will be assessed. Pneumococcal antibody titers will be determined at baseline and every 3 months for 2 years. DZIF clinical trial units coordinate titer assessment schedules and actively follow-up on study patients for 2-5 years after enrollment, including validation of end points of hospitalization, pneumonia, and death.

XSL•FO
RenderX

Results: The study has enrolled 792 patients and the last follow-up has been completed. Currently, the statistical and laboratory analyses are ongoing.

Conclusions: Results will increase physician adherence to current recommendations. Establishing a framework for the efficient evaluation of guideline recommendations through a combination of routine and study data will inform the evidence base for future guidelines.

Introduction

Background

The global burden of disease continues to shift from acute communicable to chronic noncommunicable diseases and from years of life lost to years lived with disability [1]. Advanced chronic kidney disease (CKD; stages 3, 4, and 5 out of 5) is among the most common chronic health conditions in Germany [2]. Among CKD 5D (chronic kidney disease stage 5 with an indication for dialysis) patients, acute infections remain a leading cause of morbidity, mortality, and costs [3]. The most common infectious disease in CKD 5D patients is vaccine-preventable pneumonia. Recommendations in current vaccination guidelines acknowledge this substantial risk [4,5].

Observational studies suggest that pneumococcal vaccines lower mortality and morbidity in CKD 5D patients [6,7]. While a recent meta-analysis demonstrated the efficacy of pneumococcal vaccination in reducing pneumonia in the overall adult target population [8], randomized or well-designed prospective studies in a hemodialysis population are still lacking. Prior immunological studies in hemodialysis patients have been limited by low patient numbers and mixed populations (CKD 1-4, hemodialysis, and renal transplant recipients) [9]. While these studies suggest good immunogenicity of the vaccines, no attempts were made to verify the relevance of titers toward clinical end points in this population.

Current vaccination schedules recommend pneumococcal vaccination for patients older than 60 years or at increased risk for invasive pneumococcal disease every 6 years [4,5]. However, this schedule ignores preliminary findings of rapid titer decline in hemodialysis patients. Specifically, titers seem to decline substantially after 6 to 12 months in adult dialysis patients [10]. A limited number of studies with a longer follow-up period suggest a possible benefit of revaccination after 2 years [11,12].

Scientific Rationale

Pneumonia is a leading cause of death in patients with end-stage chronic kidney disease (stage 5) treated with dialysis (CKD 5D). Acknowledging that many infectious complications are vaccine-preventable, specific recommendations have been issued for patients at risk.

In CKD 5D patients, these recommendations are based on weak evidence, namely immunologic studies [9] demonstrating the induction of antibody production and retrospective cohorts compare vaccinated to unvaccinated patients. Until today, not a single prospective study demonstrating a clinical benefit of pneumococcal vaccination in hemodialysis patients has been published. Furthermore, the aforementioned immunological studies suggest a rapid decline of protective antibodies in such patients, calling the current Robert Koch Institute (RKI) recommendation of vaccinating every 6 years into question.

While further research into the efficacy of pneumococcal vaccinations in hemodialysis patients is required, withholding vaccines would be unethical. However, comparing vaccinated patients to patients unwilling or unable to be vaccinated is likely to be a biased approach. We will thus compare 2 strata of vaccinated patients—those recently vaccinated and those vaccinated more than 2 years ago—concerning their protective antibody titers and their rates of pneumonia. We hypothesize that patients vaccinated more than 2 years ago, while in line with the current recommendation, no longer possess sufficient antibody response (<0.35 µg/mL serotype-specific IgG as defined in the World Health Organization [WHO] recommendation [13]) and thus have a risk of pneumonia comparable to an unvaccinated patient. Simultaneously, we will analyze titers of protective antibodies over time and identify factors predicting a more rapid decline.

Objectives

Primary Objective

The primary objective is to compare pneumonia rates between newly vaccinated hemodialysis patients and those vaccinated against pneumococcal infection more than 2 years ago.

Explorative Objectives

The explorative objectives are as follows:

- To describe the pneumococcal antibody titers in hemodialysis patients as a function of time since vaccination
- To determine factors influencing antibody kinetics (eg, age, prior or ongoing immunosuppression, medication, and prior vaccination history)
- To explore the relationship between antipneumococcal antibody titers and the incidence of pneumonia in

XSL•FO
RenderX

hemodialysis patients and to extrapolate a possible cutoff for protection from pneumonia
- To evaluate the role of patients' history (eg, underlying kidney disease) and clinical course (eg, prior hospitalizations) on pneumonia and vaccine response

Methods

Study Design

This is a prospective, multicenter, noninterventional study of vaccine efficacy in hemodialysis patients. All dialysis patients who are vaccinated against pneumococcal infection in accordance with RKI guidelines before enrollment will be eligible. Eligibility depends on the agreement of signing an informed consent allowing for data entry into the study electronic case report form (eCRF) and participation in the electronic quality registry, thus enabling data transfer from the patient's Kuratorium für Dialyse und Nierentransplantation e.V. (KfH) electronic health record into the eCRF, titer assessments, and active follow-up observation. A minimum of 792 patients will be enrolled.

Participating sites will screen all hemodialysis patients at their outpatient dialysis clinic for eligibility. Eligible patients will be approached and informed by their physicians. If a patient agrees to participate in the study and signs an informed consent form (ICF), basic data regarding vaccination history, underlying disease, and so on will be entered or imported electronically into the study eCRF. Pneumococcal antibody titers will be drawn at baseline and every 3 months. For newly vaccinated patients, baseline titers will be drawn 4 weeks after vaccination. Deutsches Zentrum für Infektionsforschung (DZIF; English: German Center for Infection Research) clinical trial units (CTUs) will coordinate titer assessment schedules and inform the participating physicians of upcoming blood samplings. The samples will be taken on dialysis days from an already inserted-intravascular catheter. DZIF CTUs will actively follow up on study patients for 2-5 years after enrollment. This follow-up will include validation of all hospitalizations and deaths documented in the electronic registry to assess whether the primary end point (all-cause pneumonia) occurred. During months 25-30, only the primary end point will be recorded (ie, no blood samples will be taken). Additionally, dialysis units will be contacted every 6 months to assess if pneumonia occurred that did not require hospitalization. Blood samples will be stored frozen at DZIF CTUs, and titers will be analyzed at the end of this study. All therapies and diagnostics, including vaccinations, will be administered solely as part of the clinical routine and as recommended by appropriate guidelines (eg, RKI Ständige Impfkommission [STIKO] recommendations). Thus, Arzneimittelgesetz (AMG) does not apply to this study, and participating physicians do not require Good Clinical Practice (GCP) certification.

Data Collection

Study nurses will enter data into the eCRF either directly or by transfer of an extract from the patient's electronic registry file (Qualität in der Nephrologie [QiN]; English: Quality in Nephrology database). The registry will also alert the study nurse to events during follow-up such as hospitalization, death, and transfer out of the dialysis unit, which are reliably captured because they are needed for billing purposes.

The central data repository will be the eCRF. Source documents will be stored in each patient's study file.

Study Procedure

In principle, all KfH dialysis practices will be eligible to participate in this study. KfH practices can be considered representative of the German dialysis population since they are widely distributed throughout Germany and about 20%-25% of all hemodialysis patients are treated there. Site selection will depend on the willingness of the attending physicians to participate and key characteristics of the practice (eg, site location and number of patients). Criteria for site selection will be developed by QiN-group and DZIF-Köln. A number of suitable KfH dialysis practices will be allocated to each of the 12 DZIF CTU sites: Universitätsklinikum Bonn, Medizinische Klinik Borstel, Universitätsklinikum Eppendorf, Universitätsklinikum Gießen und Marburg, Standort Gießen, Medizinische Hochschule Hannover, Universitätsklinikum Heidelberg, Universitätsklinikum Köln (AöR), Universitätsklinikum Schleswig-Holstein/Campus Lübeck, Universitätsklinikum Gießen und Marburg, Standort Marburg, Klinikum der Universität München, Technische Universität München, and Universitätsklinikum Tübingen.

QiN-group will assist DZIF CTU personnel with site selection and internal KfH study participation formalities. DZIF CTU personnel will cooperate with the KfH physicians to assist in setting up subject prescreening and informed consent procedures. Informed consent will be obtained by treating physicians.

The sample size has been calculated to demonstrate a significantly lower all-cause community-acquired pneumonia (CAP) rate in newly vaccinated patients compared to patients vaccinated more than 2 years before enrollment.

The incidence of pneumonia in hemodialysis patients was reported as 29.0/100 patient-years (py) [14]. Data on the efficacy of pneumococcal vaccines for preventing pneumonia in hemodialysis patients is lacking. However, a recent meta-analysis demonstrated pneumococcal vaccination to result in a relative risk for pneumonia of 0.72 (95% CI 0.69-0.94) in an immunocompetent target population (ie, adults at risk or >65 years) [8].

In general, immunological studies in hemodialysis patients have been carried out with limited patient numbers and in mixed populations (CKD, hemodialysis, and renal transplant recipients) [9]. Most studies suggest good initial immunogenicity, but titers seem to significantly decline after 6 to 12 months in adult dialysis patients [10]. The limited number of studies with longer follow-up periods suggests a possible benefit of revaccination after 2 years [11,12].

For the purpose of this calculation, we assume protection from pneumonia in the first 2 years to be equal to the protection recently demonstrated in an adult immunocompetent target population (relative risk 0.72) and afterward return to baseline. Thus, expected rates of pneumonia are 29.0/100 py in patients

XSL•FO
RenderX

vaccinated >2 years ago and 20.88/100 py in patients vaccinated <2 years ago, respectively. To demonstrate the superiority of a more recent vaccination in preventing pneumonia with α=.05 and (1–β)=0.80, we would thus require 2 groups of 442 patients each (884 patients overall). Furthermore, the rate of pneumonia is also likely to be greater in an underprotected population than seen in the overall hemodialysis population, which includes a relevant number of freshly vaccinated patients. Additionally, the possibility of an unbalanced distribution of recently vaccinated patients (in a ratio of up to 1:7) was considered. A first statistical analysis will be discussed in an interim study report after 18 months.

Amendment After Interim Study Report

After an enrollment period of 18 months, which had been extended twice, 710 patients had been included in the study and had a fully documented vaccination status, 174 less than planned. 596 had been vaccinated less than 2 years ago, and 114 had been vaccinated 2 or more years before enrollment, respectively. This represents a ratio of 1:5, which was well within the range of an unbalanced patient distribution, which had been explored in the sample size calculation. Assuming that further recruitment would continue at this ratio and that risk reduction remained at 0.72, 792 patients were then considered sufficient if the observation period was extended to 2.5 years. These assumptions yielded a power (1–β) of 0.81 while keeping the type-I error at α=.05.

Eligibility Criteria

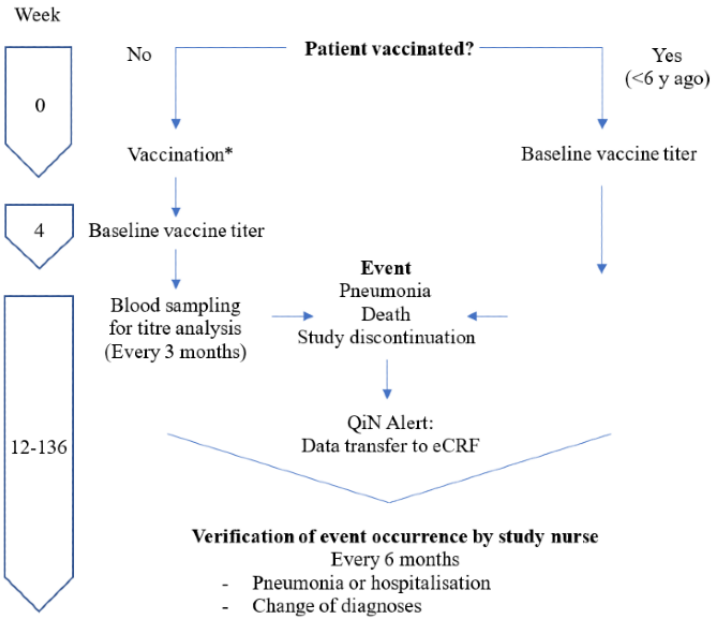
Inclusion Criteria

The inclusion criteria included:

1. Patients who signed ICF, including enrollment in the registry database (QiN-registry)
2. Patients with stage 5 CKD treated with chronic hemodialysis
3. Patients who are vaccinated against pneumococcal infection in accordance with current STIKO recommendations
4. Patients who were 18 years or older

Exclusion Criteria

The exclusion criteria included patients unwilling or ineligible for vaccination against pneumococcal infection under current STIKO recommendations.



A subject may withdraw from the clinical trial at any time for any reason without consequences. Discontinuation from the study will have no influence on the availability of vaccination for that patient. In case of premature discontinuation, the reason for discontinuation should be collected, but it is not obligatory. In the event of withdrawal, all blood samples will be destroyed according to data protection requirements. Data cannot be removed from already-completed studies or scientific analyses. A subject who discontinues the trial will not be replaced.

Enrollment of Study Subjects

Eligible study subjects will be identified by their dialysis physician. If the subject does satisfy eligibility criteria and signs the ICF, he or she will be enrolled into the Duration of Protection From Pneumonia After Pneumococcal Vaccination in Hemodialysis Patients (DOPPIO) study by entering their data into the enrollment log and registering the subject in the eCRF. Basic data regarding vaccination history, underlying disorders, and so on will be captured directly in the study eCRF or transferred into the eCRF from the QiN database. The study's conduct is illustrated in Figure 1.

Blood samples for pneumococcal antibody titer analysis will be drawn at baseline and every 3 months (with a range of 6 days). For newly vaccinated patients, baseline titers will be drawn 4 weeks after vaccination (Figure 1). A total of 6750 blood samples from 789 study subjects will be collected and analyzed.

Figure 1. Schedule of vaccine titer assessments in the course of the Duration of Protection From Pneumonia After Pneumococcal Vaccination in Hemodialysis Patients (DOPPIO) study. *Decision for or against vaccination will be based upon the advice of the treating physician previously (along STIKO [Ständige Impfkommission]–criteria) and is not related to DOPPIO. eCRF: electronic case report form; QiN: quality in nephrology.

XSL•FO
RenderX

DZIF CTU study nurses will coordinate titer assessment schedules and inform participating physicians of upcoming blood samplings. Samples will be drawn over an existing venous or arteriovenous access before dialysis and thus constitute only a minimal additional burden for both patients and physicians. All titers will be analyzed at the end of the study. An enzyme immunoassay will be performed to detect the presence of pneumococcal antibodies.

Management of Samples

For all subjects, 9 mL of blood will be collected in a 9-mL tube provided by the sponsor. Samples will be taken every 3 months after the baseline sample. For newly vaccinated patients, baseline samples will be taken 4 weeks after vaccination.

Immediately prior to the blood draw, the staff member performing the procedure will verify the subject's identity. A label will be attached to the tube. The tube will be centrifuged within 3 hours after sampling. The tube will be shipped to the allocated DZIF site and frozen within 24 hours. Subject number, date of sampling, number of aliquots, date and time of preparation, and the subject's consent are documented in a sample identification list at the KfH dialysis practices and recorded as source data. Samples will be stored at DZIF CTUs and sent frozen in 1 batch to the laboratory at the end of the study. Results will be transferred electronically to the study nurses at the end of the study for recording into the eCRF.

Data Management Plan

The data will be recorded securely and electronically. The data are the sole property of the sponsor and must not be made available in any form to third parties, except for authorized sponsor's representatives or appropriate regulatory authorities, without written permission from the sponsor. Data obtained from KfH via QiN becomes the property of the sponsor, as specified in the agreement between KfH and DZIF. Only data from enrolled patients will be transferred. The investigator will ensure that all data are entered legibly, completely, accurately, and conform to source documents.

The investigator will review and approve data, with the investigator's validation serving as attestation of the investigator's responsibility for ensuring that all data are complete, accurate, and authentic.

All information obtained during the study will be recorded digitally in conformity with the applicable laws and regulations.

Ethics Approval

Overview

The study was approved by the lead Ethics Committee of the Medical Faculty of the University of Cologne (Cologne, Germany; No. 17-274) and subsequently received secondary approval by the 11 Ethics Committees of the respective DZIF CTU sites (ref. DZIF CTU site list, section study procedure).

The study was further approved by the Paul-Ehrlich-Institut (PEI), Federal Institute for Vaccines and Biomedicines, as a noninterventional study (NIS401) and registered at ClinicalTrials.gov with the identifier NCT03350425.

The study will be performed in accordance with all applicable laws and regulations, including the International Conference on Harmonization Guideline for Good Clinical Practice (GCP), the ethical principles that have their origins in the Declaration of Helsinki (current official version: World Medical Association [15]), and applicable privacy laws such as national laws and the General Data Protection Regulation, which has been in effect since May 25, 2018. The minimum required deidentified personal data will be captured in an electronic database, and any publication of study results will be anonymized, only containing summarized statistical analyses.

Subject-Informed Consent

KfH physicians will assist in setting up subject prescreening and informed consent procedures. Informed consent will be obtained by the treating physicians. The ICF will be signed prior to any study activities by the subject and treating physician conducting the informed consent process. No compensation is foreseen for study participants.

Study Conduct and Statistical Analyses

The primary objective of this study is to compare pneumonia rates and outcomes between both groups. To achieve this, the raw number of events and raw rates of events per 100 patient years will be computed. For each group, the mean, median, SD, IQR, and minimum and maximum of demographical variables like age and sex will be computed. These observed variables will be used to build a Cox proportional hazard model. If applicable, this model will incorporate time-varying covariates and consider recurring events. To quantify the expected protective effect of a high titer level, multiple functional relationships will be explored, including but not limited to linear, quadratic, and step functions. Step functions will be created by dividing the titer levels into 10 mutually exclusive strata and estimating each risk individually. If possible, the largest difference between 2 neighboring strata will be identified as a threshold for an adequate titer level.

The secondary objectives of this study are to describe antibody titers as a function of time and factors influencing antibody kinetics. Descriptive statistics for titer levels at all intervals will be computed for absolute values as well as relative values (relative to the first observed or personal maximum). Levels for patients grouped by age, sex, and other variables of interest will be calculated. To allow a comparison, the mean, median, SD, IQR, and minimum and maximum titer levels will be calculated.

To identify which factors influence the absolute antibody titer level, multiple multivariate models will be built. In patients with available titers, risk factors for insufficient protection will be determined by multiple regression analyses of data including vaccination history and timing, medication exposure since last vaccination, history of underlying kidney disorder, dialysis, and demographic factors.

The titer levels will be assessed graphically by comparing boxplots of the titer levels at different time intervals. Concurrent titer levels will be tested for statistically significant differences by using a *t* test or a Mann-Whitney U test, whichever is applicable.

XSL•FO
RenderX

Differences in hospitalization as well as vaccination rates between KfH centers will be studied. QQ plots and tests for normal distribution will be performed on the observed hospitalization rates. Vaccination rates will be studied for outliers. For all factors used in model building, a region of common support will be established.

Results

The study has enrolled 792 patients and the last follow-up has been completed. Currently, the statistical and laboratory analyses are ongoing.

Discussion

Overview

Patients on dialysis are among the best documented for any chronic condition in outpatient medicine. This prospective study is among the first to capitalize on that and to demonstrate the integration of routine data and study data into a single data set. This framework for the efficient evaluation of guideline recommendations will form the evidence base for future guidelines and will increase physician adherence to current recommendations.

Principal Results

Data on baseline demographics, vaccination history, and underlying disease will be assessed. Pneumococcal antibody titers will be determined at baseline and every 3 months for 2 years. DZIF CTUs coordinate titer assessment schedules and actively follow up on study patients for 2 years after enrollment, including validation of hospitalization, pneumonia, and death. We will analyze antibody titers over time and identify factors influencing antibody kinetics. In addition, the relationship between antibody titers and the incidence of pneumonia in hemodialysis patients will be investigated, and a possible cutoff for protection from pneumonia will be extrapolated.

Limitations

Our study has several limitations. The study is conducted during the SARS-CoV-2 pandemic, which leads to interruptions in observation (especially serologically) and a novel cause of pneumonia. In addition, the study does not investigate the causative pathogen of pneumonia. However, *Streptococcus pneumoniae* has historically been the most common cause of pneumonia, by far [16], and remains the most common bacterial cause of CAP, leading to the hospitalization of adults today. In the United States, 5 to 15 percent of CAP cases have been attributed to *S pneumoniae* [17-19]. More recent comprehensive molecular testing of lower respiratory tract specimens indicates that this is an underestimate and suggests more than 35% of cases may be due to *S pneumoniae* [20]. This percentage has been proven to be even higher in Europe [21,22]. Finally, the study was performed in a single country with a homogeneous population of participants, which limits generalizability to other populations.

Nonetheless, we believe that the study is suited to answer the clinically important question of the duration of antipneumococcal vaccination.

Conclusions

Current vaccination schedules recommend pneumococcal vaccination for CKD-5D patients every 6 years. However, this timing disregards findings of rapid titer decline in adult hemodialysis patients after 6 to 12 months. By comparing pneumonia rates between recently vaccinated patients and those who were vaccinated more than 2 years ago, we may estimate the duration of protection by antipneumococcal vaccination. In addition, antipneumococcal antibody titers in hemodialysis patients will be determined as a function of time since vaccination and provide further conclusions.

Through its conduct, this prospective study will increase physician adherence to current recommendations. Establishing a framework for the efficient evaluation of guideline recommendations through a combination of routine and study data will inform the evidence base for future guidelines.

Data Availability

Data will be available as publication after finalization of the study.

Abstract

Background: Despite experiencing many adversities, American Indian and Alaska Native populations have demonstrated tremendous resilience during the COVID-19 pandemic, drawing upon Indigenous determinants of health (IDOH) and Indigenous Nation Building.

Objective: Our multidisciplinary team undertook this study to achieve two aims: (1) to determine the role of IDOH in tribal government policy and action that supports Indigenous mental health and well-being and, in turn, resilience during the COVID-19 crisis and (2) to document the impact of IDOH on Indigenous mental health, well-being, and resilience of 4 community groups, specifically first responders, educators, traditional knowledge holders and practitioners, and members of the substance use recovery community, working in or near 3 Native nations in Arizona.

Methods: To guide this study, we developed a conceptual framework based on IDOH, Indigenous Nation Building, and concepts of Indigenous mental well-being and resilience. The research process was guided by the Collective benefit, Authority to control, Responsibility, Ethics (CARE) principles for Indigenous Data Governance to honor tribal and data sovereignty. Data were collected through a multimethods research design, including interviews, talking circles, asset mapping, and coding of executive orders. Special attention was placed on the assets and culturally, socially, and geographically distinct features of each Native nation and the communities within them. Our study was unique in that our research team consisted predominantly of Indigenous scholars and community researchers representing at least 8 tribal communities and nations in the United States. The members of the team, regardless of whether they identified themselves as Indigenous or non-Indigenous, have many collective years of experience working with Indigenous Peoples, which ensures that the approach is culturally respectful and appropriate.

Results: The number of participants enrolled in this study was 105 adults, with 92 individuals interviewed and 13 individuals engaged in 4 talking circles. Because of time constraints, the team elected to host talking circles with only 1 nation, with participants ranging from 2 to 6 in each group. Currently, we are in the process of conducting a qualitative analysis of the transcribed narratives from interviews, talking circles, and executive orders. These processes and outcomes will be described in future studies.

Conclusions: This community-engaged study lays the groundwork for future studies addressing Indigenous mental health, well-being, and resilience. Findings from this study will be shared through presentations and publications with larger Indigenous and non-Indigenous audiences, including local recovery groups, treatment centers, and individuals in recovery; K-12 and higher education educators and administrators; directors of first responder agencies; traditional medicine practitioners; and elected community leaders. The findings will also be used to produce well-being and resilience education materials, in-service training sessions, and future recommendations for stakeholder organizations.

community-engaged research; Indigenous; Native nations; COVID-19; resilience; well-being

Introduction

Background

The widespread COVID-19 pandemic has tested the limits of medical resources and public health, moved society toward a more isolated lifestyle, and challenged the lives of many, including several heavily impacted populations [1]. At the time this project started (2020), some of the populations most affected by COVID-19 in the United States were living in the 22 sovereign Native nations in Arizona. More than 103,000 cases of COVID-19 were diagnosed in the citizens of Native nations in Arizona, accounting for 50% of the cases in some counties [2]. Compared with other races and ethnicities in the United States before the COVID-19 pandemic, American Indian and Alaska Native populations (note that we use the terms American Indian and Alaska Native, Native American, Indigenous, and Native for this paper interchangeably to refer to Indigenous Peoples of the United States) were disproportionally affected by illnesses and chronic diseases and had an overall lower life expectancy [3]. Despite experiencing many adversities, American Indian and Alaska Native populations have demonstrated tremendous resilience during the COVID-19 pandemic, drawing upon Indigenous determinants of health (IDOH) and Indigenous Nation Building [4].

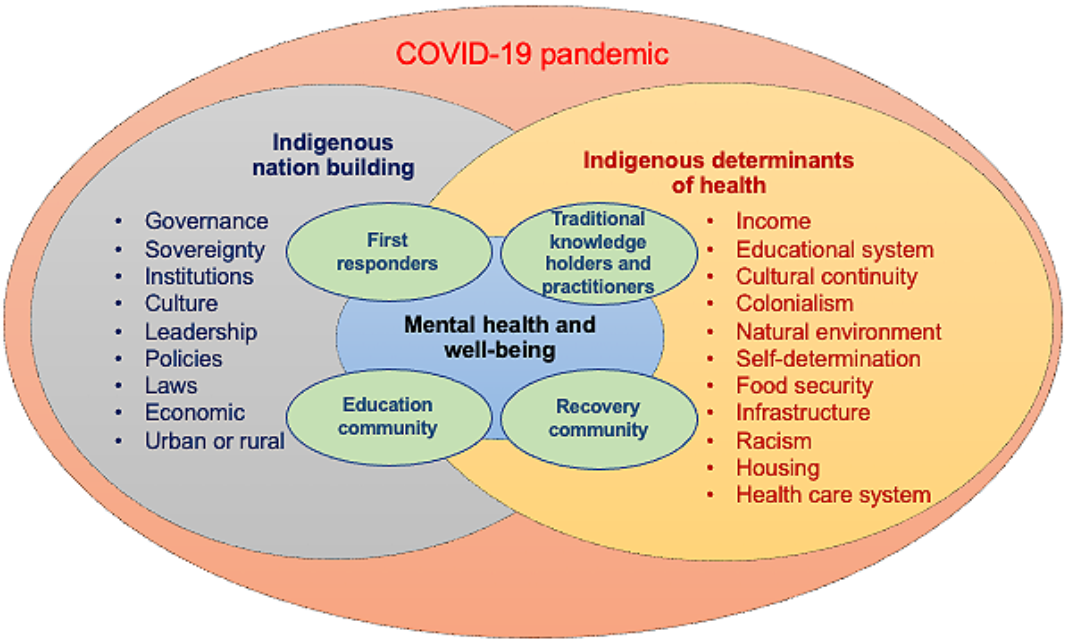
Purpose

Our multidisciplinary team of scholars sought to implement the study described in this paper to achieve two aims: (1) to determine the role of IDOH in tribal government policies and actions that support Indigenous mental health and well-being and, in turn, resilience during the COVID-19 crisis; and (2) to document the impact of IDOH on Indigenous mental health, well-being, and resilience of 4 specific community groups—first responders, educators, traditional knowledge holders and practitioners, and the substance use recovery community living or working (or both) in or near 3 Native nations in Arizona. The overarching research question for the study was as follows: What are the IDOH in Native nations and communities that shape mental health and well-being and, in turn, resilience during the COVID-19 pandemic? We posited that the use of IDOH, an Indigenous Nation-Building framework [5,6], and complementary data collection methods would be useful for understanding the mental health needs, assets, and resources of Native nations during the COVID-19 crisis to best formulate future research, practices, and policy initiatives [6]. Native nations have maintained a sense of autonomy as sovereign entities and have responded to the pandemic by leveraging community assets informed by language, land, history, and ceremony [7]. This research was designed to guide tribal programs to improve the mental health and well-being of Indigenous Peoples in Arizona, especially during tumultuous times such as a pandemic.

Conceptual Framework

To guide this study, we developed a conceptual framework (Figure 1) based on the IDOH, Indigenous Nation Building, and concepts of Indigenous mental well-being and resilience. Social determinants of health (SDOH) refer to conditions in the environments where people are born, live, learn, work, play, worship, and age that affect a wide range of health, functioning, and quality-of-life outcomes and risks [8]. Indigenous Peoples have unique historical, political, and social contexts that also affect health and differ from the traditional definitions of the SDOH. IDOH includes a wide variety of physical, social, and cultural conditions that can affect the health status of Indigenous Peoples [4,9]. Poverty, racism, geographic location, and education systems are examples of social impacts on the health and life expectancy of American Indian and Alaska Native populations that can put them at an increased risk for COVID-19 [9-12].

Indigenous Nation Building refers to “the political, legal, spiritual, educational, and economic processes through which Indigenous Peoples engage in order to build local capacity to address their educational, health, legal, economic, nutritional, relational, and spatial needs” [13-15]. These processes are an assertion of the federally recognized sovereignty of the Native nations. Sovereignty, applied to federally recognized Indigenous nations in the United States, means that such nations are distinct political entities with the right of self-government. Recognized through treaties, acts of congress, and presidential executive orders, Indigenous nations have a government-to-government relationship with the federal government [16,17]. During the pandemic, Native nations took the steps necessary to ensure the protection of their citizens from the threats of COVID-19 with the implementation of stay-at-home orders; weekend lockdowns (restricting citizens from leaving their communities); and the closure of businesses, establishing vaccination centers, mask mandates, and other preventive recommendations. The assertion of sovereignty serves as an important means of managing the risks to citizens’ health, a mechanism for maintaining adequate sociocultural strength, health, and well-being in Indigenous populations [18].



The concept of Indigenous mental health and well-being is receiving increased attention in the literature as scholars uncover the unique stressors that Indigenous Peoples face as well as the culturally distinct approaches that Indigenous nations and communities use to support resilience [19-21]. A key component of Indigenous mental health and well-being is the recognition of the impact of historical trauma. Historical trauma is a cumulative, multigenerational experience of trauma that impacts emotional and psychological well-being from one generation to the next and can disrupt the strength of the community in Native nations [22,23]. The impact of historical trauma is reflected in American Indian and Alaska Native populations

XSL•FO
RenderX

using drugs and alcohol at younger ages and at higher rates than other populations [24-27], reporting serious psychological distress at higher rates [28], and committing suicide at younger ages than non–American Indian and Alaska Native populations [29]. Historical trauma affects Indigenous populations and manifests in many ways, including by impacting Indigenous mental health and well-being outcomes. Even with historical trauma, American Indian and Alaska Native populations have maintained their resilience through the continuation of ceremonial practices, speaking heritage languages, passing on oral histories, and implementing local strategies to reinforce social support systems and cultural capital [30].

In the United States, approximately 4.2 million Americans identify as American Indian and Alaska Native [31]. The living conditions for American Indian and Alaska Native populations vary greatly, with 78% living off reservations and 22% living on reservation lands [32]. Regardless of residence, the cultures of American Indian and Alaska Native populations generally emphasize connections to others, the past, the natural world, and traditional homelands [21,33]. This worldview is demonstrated by strong family bonds, respect for the wisdom of elders, and the maintenance of cultural traditions. These practices preserve, maintain, protect, and serve as solutions against threats to mental health and well-being in Indigenous communities [21,34].

Figure 1. Conceptual framework.

Methods

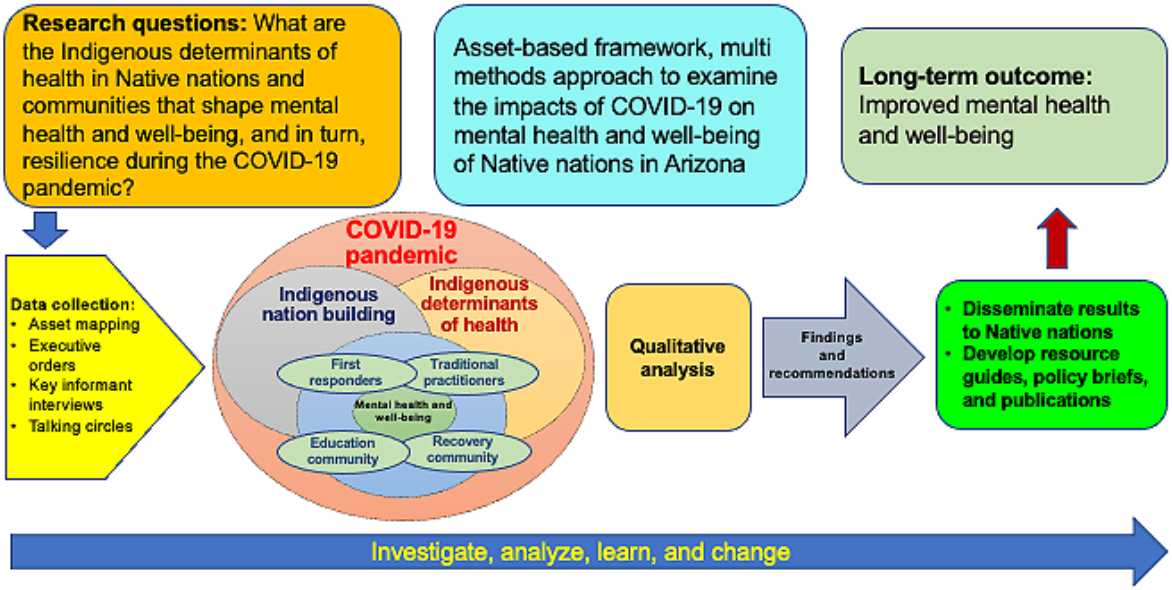
Overview

This study merged the IDOH and Indigenous Nation-Building frameworks to establish an understanding of the interrelationship of sovereignty, land jurisdiction, cultural identity, continuing effects of colonialism, and resilience that impact mental health and well-being. The research design focused on 4 groups in 3 Native nations and an urban Indigenous health center near one of these nations that have served their communities while remaining exposed to the effects of the COVID-19 pandemic or were heavily impacted by physical distancing restrictions. These groups included first responders, educators, traditional knowledge holders and practitioners, and members of the substance use recovery community.

In the analysis, mental health and well-being were not addressed from a psychological or individual clinical orientation but through a contextual and external environmental lens, otherwise understood as a systems orientation [35]. A systems orientation has been used in understanding perspectives within human service program systems and the relationship of organisms in their natural habitat, but to our knowledge, it has never been used to investigate mental health and well-being in Native communities [36].

Indigenous Guided Research

The research process was guided by the Collective benefit, Authority to control, Responsibility, Ethics (CARE) principles for Indigenous Data Governance to honor tribal and data sovereignty [37-39]. The CARE principles ensure that, when working with external research partners, Native nations receive the following: (1) collective benefit of research findings, (2) authority to control data, (3) responsible research partners who support self-determination, and (4) ethical research partners who honor the rights and well-being of sovereign nations and their community members. Individuals from 3 Native nations and an urban Indigenous health center in Arizona participated in this study with approval from their institutional review board (IRB), Tribal Council, or Cultural Preservation Office. The research approval process spanned 7 months (June 2020 to January 2021) and was preceded by multiple years of relationship building through research and service between members of the research team and each of the 3 nations. Our study was unique in that our research team consisted predominantly of Indigenous scholars representing at least 8



XSL•FO
RenderX

tribal communities and nations in the United States. The members of the team, regardless of whether they identified themselves as Indigenous or non-Indigenous, have many collective years of experience working with Indigenous Peoples and are committed to the health and well-being of tribal communities. A community researcher from each Native nation was hired as a vital member of our research team to aid in recruiting participants, scheduling interviews and talking circles, translating interviews from the Native language into English, and providing overall expertise to ensure that methodologies and approaches were culturally congruent and respectful.

Research Design

The team investigated the resilience and contextual factors that either facilitated or hindered these efforts. The goal of understanding resilience was informed by the Indigenous Nation-Building framework [14,40]. As depicted in Figure 2, data were collected through a multimethods research design that documented the contextual factors that contribute to mental health and well-being among the people of the Native nations. Contextual factors included educational systems, socioeconomic status, access to food and health care, and systemic oppression. Special attention was placed on the assets and culturally, socially, and geographically distinct features of each Native nation and the communities within them. Indigenous Peoples and nations demonstrated resilience in many ways during this difficult period. American Indian and Alaska Native populations have experienced substantial and unique challenges during the pandemic, including increased levels of anxiety, stress, and depression. The team explored these emotions and resilience strategies through interviews and talking circles. Figure 2 provides an overview of the research questions, data collection methods, and the expected outcomes. This paper presents our methodological protocol for each aim.

Figure 2. Research methodology.

Aim 1: Determine the Role of IDOH in Tribal Government Policy and Action That Support Indigenous Mental Health, Well-Being, and, In Turn, Resilience During the COVID-19 Crisis

Asset Mapping

Community asset–based mapping is a process that actively seeks the best use of community resources and creates a profile of existing buildings, programs, and services in the community [41,42]. Our team began the study by searching Google Maps, publicly available reports, and other relevant community resources. A spreadsheet of electronically available assets was compiled, including the title or name of the asset, contact information, and type or category of the asset. Categories of assets included mental health; general health; education; cultural resources including traditional knowledge holders, economic, recreation, and government and social services; and other resources including religious and spiritual resources. The team consulted with community researchers and a select group of community members from each Native nation to confirm the accuracy and completeness of the lists. Next, the team worked with colleagues at our university's Geographic Information System laboratory to create resource maps. The maps were created for each of the 3 Native nations, including separate maps according to the asset type or category for each nation. The research team then reviewed the full list and maps and coded each asset using a codebook developed from key terms in the conceptual framework. At least 2 researchers independently coded each nation's asset list; any discrepancies were discussed, and a final coding was determined by the team. Finally, the team created a community resource guide for each of the 3 nations; these guides were organized by category and included both the lists and the maps of the assets identified through this phase of the study.

Executive Orders Coding

Executive orders, executive directives, and public health emergency orders were collected for each of the 3 participating nations from March 1, 2020, to June 15, 2022. Each executive order or directive (1 nation uses the term directives rather than executive orders) was scanned for content, and a team of 6

XSL•FO
RenderX

researchers, working in pairs, developed a codebook based on the content of all the orders. The orders were coded according to the issuing authority (ie, top-ranking executive leaders or public health authority), the topics, and any requirements of the order. For example, an executive order issued by the Native nation's president or chairperson requiring employee vaccinations was coded by the nation, the issuing office or authority, and the code "vaccination requirement." Each order or directive was coded by an independent researcher and verified by a second researcher. Any discrepancies as well as the need to establish new parent or child codes were discussed by the entire coding team; final decisions were reached through consensus of the team.

Federal executive orders or directives, such as a federal mask mandate, and guidance from the Centers for Disease Control and Prevention (CDC) may have informed the executive orders, directives, or public health emergency orders of the participating Native nations. For example, the CDC issued the guidance for safety measures such as social distancing, hand washing, and mask wearing, which, in turn, was followed by governments across the country. Native nations also instituted CDC-recommended safety measures and encouraged their citizens to follow them, as evidenced in the executive orders, executive directives, and public health emergency orders examined in this study. However, as federally recognized Native nations are sovereignty entities and have a legal status higher than the states [43], the state executive orders of states adjacent to or surrounding the lands and jurisdictions of the participating Native nations are not included in the coding or analysis.

Upon the completion of the coding, the analysis will begin. Using content analysis, researchers will examine the orders to determine what actions governments took or policies were developed to support the resilience and mental well-being of their citizens.

Aim 2: Document the Impact of IDOH on Indigenous Mental Health, Well-Being, and Resilience of 4 Specific Community Groups

Recruitment

Recruitment parameters for participants were that they must be aged 18 years; identify as someone who works in or is a citizen of 1 of the 3 participating Native nations; and identify as a member of one of the four informant groups: (1) first responder—identify as a first responder (ie, they are associated with law enforcement, fire department, or emergency management training or work as emergency room doctors or nurses); (2) educator—identify as an educator or teacher; (3) traditional knowledge holder or practitioner—identify as a traditional medicine person or as being a part of a medical people association and have the knowledge and experience in maintaining, participating in, and practicing traditional Native ways of life; and (4) substance use recovery member—identify as a substance use recovery provider or an individual in substance use recovery who uses recovery services. Exclusion criteria were being incarcerated, incapacitated, or unwilling to provide informed consent to participate in the study activities or currently participating in a substance use recovery program (recovery group only). We prioritized recruiting individuals who identified as American Indian and Alaska Native. However, for some subgroups, providers and personnel included non-Indigenous individuals who worked within or for the participating communities. These individuals represented 13% (12/92) of all the interviewees. For the recovery community, the team also recruited from an urban Indigenous health center, Native Americans for Community Action, based in Flagstaff, Arizona.

Participants were recruited through email, in-person presentations to related entities and individuals within specified subgroups and communities, and face-to-face interactions. The research team used snowball sampling and social networks guided by community researchers' and investigators' community contacts.

Informed consent was obtained using multiple methods in an effort to provide flexibility as the COVID-19 situation evolved. These methods primarily included a signed informed consent form mailed to the participants, the review of an oral or web-based script via phone, and verbal consent given by the participants. If participants provided oral consent, the researchers documented the participant's name, date of consent, and specified the conditions of consent. In some cases, oral consent was provided in the participants' respective Indigenous language.

All subgroups (first responders, educators, traditional knowledge holders and practitioners, and members of the substance use recovery community) from each partnering community participated in key informant interviews. Only 1 Native nation and 3 subgroups (educators, members of substance recovery community, and traditional knowledge holders and practitioners) participated in talking circles. In an effort to follow the CDC guidelines for safety during the pandemic, interviews and talking circles were conducted via a password-secured Zoom link or by telephone. Talking circles were conducted after the interviews were completed.

Key Informant Interviews

Each participant completed an individual 1- to 2-hour interview intended to identify SDOH and the conditions that may have contributed to mental health stressors or sources of strength during the COVID-19 pandemic and IDOH contributing to stress or strength. The interviewees were given a US $25 gift card for their time. Guided by the need to obtain a representative sample, the team attempted to conduct at least 4 interviews with a goal of 10 with each subgroup from each participating nation. The protocol for the key informant interviews for all 4 subgroups was similar but had some nuances by subgroup, as described in subsequent sections for each community group. The interview questions were developed and edited by the whole team for a period of 2 to 3 months. The research team aimed to create "core" questions that could be used to analyze themes across groups and group-specific questions that allowed for the identification of group-specific challenges and solutions. Each group was asked 5 core questions, with additional questions relevant to the specific group. The 5 core questions were as follows:

XSL•FO
RenderX

1. Please talk about your tribal government's response during the COVID-19 pandemic?
2. What does the term "mental well-being" mean to you?
3. Has your (insert Indigenous community) cultural identity affected your mental well-being during the COVID-19 pandemic? If so, how?
4. What does the term "resilience" mean to you?
5. Has your (insert Indigenous community) cultural identity affected your resilience during the COVID-19 pandemic? If so, how?

The first responder research group was interested in learning how the pandemic may have changed the workload for first responders and how changes owing to the pandemic affected them on a personal level (eg, physical, emotional, spiritual, cultural, mental, and financial levels and on the basis of family or home and food security). We were also interested in learning about the resources that were available to them and what resources they needed during the pandemic to stay healthy. Examples of group-specific questions for the first responders group were as follows:

1. Have there been any effects of COVID-19 on you personally, and if so, how? (prompts: physically, emotionally, spiritually, culturally, mentally, family, finances, and food security)
2. Has COVID-19 affected your job? If yes, how?
3. Is there anything else that could be done by people at your work to help you? (prompts: check on you, talk with you, use humor, do things different, and if so, like what?)
4. What, if any, resources are available to you to help you stay healthy? (prompts: agencies, people, and places)

The education research group was interested in understanding how educators responded to the transition from face-to-face learning to web-based learning and sometimes having to switch between the 2 modalities after in-person COVID-19 exposure. Because of the circumstances experienced by the teachers, it was particularly important for the educator research group to learn about and understand their experiences of resilience and mental well-being. Specifically, it was important to give educators time to speak about the impact of COVID-19 on them individually and on their respective professional roles in education, as well as what resources and support they accessed during that time. Another area of focus was to learn more about how the range of decision-making entities (ie, school boards, tribal governments, and federal governments) impacted their role as educators. Finally, we asked questions related to personal and classroom resources that were helpful or would have been helpful during the pandemic. The questions for this group included the following:

1. What has been the impact of COVID-19 on you? (prompts: physically, emotionally, spiritually/culturally, mentally, family, finances, and food security)
2. How has COVID-19 impacted doing your work as an educator?
   - What has helped you as an educator adapt to changes caused by COVID-19?
   - How have you responded to the ways in which COVID-19 has affected your families and students?
   - How has your broader community/school responded to COVID-19?
3. What resources have you used during this pandemic to help you stay healthy?
   - What resources have you used to support students and families?
   - What resources do you wish were available to support your health and the health of students and families?
4. Tell me about the various levels of leadership that you believe impact your role as an educator.
   - How have these levels responded?
   - How has school/district leadership responded and how has it impacted you in your professional role?

In times of uncertainty, many Indigenous Peoples went to traditional knowledge holders and practitioners for assistance in resolving health issues, and the pandemic was no exception. Given that there were no Western medicines available to combat COVID-19 at the time, traditional knowledge holders and practitioners became especially important. The questions focused on how the patients of traditional knowledge holders and practitioners were affected by the pandemic and how they were coping. Furthermore, understanding how the pandemic might have impacted the tasks and duties of traditional knowledge holders and practitioners was critical to highlighting the role of cultural capital in resilience. We asked the following questions about how traditional knowledge holders and practitioners viewed the meaning of resilience and mental well-being:

1. Have the people you serve maintained resilience during the pandemic?
   - If so, how? If not, why not?
2. Has your cultural practice been impacted by COVID-19? (prompts: physically, emotionally, spiritually/culturally, mentally, financially, and adaptations)
   - If so, how? If not, why not?
3. What do you think about the changes you made?

The members of the substance use recovery research group were particularly interested in how restrictions imposed on social gatherings affected the practice of recovery for American Indian and Alaska Native populations. Although programs exist that are specifically constructed for Native American recovery (ie, The Red Road to Wellbriety and Healing of the Canoe) [44,45] and place Native American culture as central to treatment, most recovery programs that are altered to serve American Indian and Alaska Native populations use traditional practice as an added element to mainstream programs such as Alcoholics Anonymous or Narcotics Anonymous [46]. The group process, intended to remove stigma and promote social support, is an important evidence-based practice in almost every recovery program. Most American Indian and Alaska Native cultures emphasize connectedness to tribes, clans, and families. Therefore, the recovery group asked nonleading questions such as the following to understand the impact of social restrictions on recovery:

1. Please describe to me how your work has changed because of the COVID-19 pandemic.

XSL•FO
RenderX

2. Please describe to me any special qualities or circumstances that have allowed Native Americans in recovery to adapt positively to the new circumstances presented by the presence of the virus.
3. Please describe to me any special qualities or circumstances that have affected Native Americans in recovery to negatively respond to the new circumstances presented by the presence of the virus.

Talking Circles

The talking circle is a common and respectful way of sharing, listening, and learning among North American Indigenous Peoples [47,48]. Talking circles are also referred to as "sharing circles" by some Indigenous Peoples [47,49]. Facilitators of talking circles used open-ended questions designed to assess specific direct and indirect impacts of the pandemic and ways of adapting and responding to those impacts (resilience). Talking circles for this study lasted for 1 to 3 hours and included 2 to 6 individuals. The research team conducted 1 talking circle session with educators, 2 with substance use recovery community members, and 1 with traditional knowledge holders and practitioners, each of which consisted of members from a single participating nation. Talking circle participants were recruited through community partner agencies and by the community researchers. Each participant was given a gift card worth US $50 for their time. Each talking circle included variations in the key informant interview questions. The talking circle questions are presented in Textbox 1.

Textbox 1. Talking circle questions.

Educators

- To the extent you feel comfortable, share the impact of COVID-19 on you.
- How has COVID-19 impacted your work as an educator (principal, counselor, teacher, etc)?
- What resources have you used during this pandemic to help you stay "healthy"?
- Tell me about the various levels of leadership that you believe impact your role as an educator.

Substance use recovery community

- To the extent that you feel comfortable sharing, how have you been impacted by COVID-19?
- How has your recovery been impacted by COVID-19?
- How did you adapt to and respond to the impact on your recovery? Can you identify the methods, strategies, or specific programs that supported your recovery?
- What do the terms "mental well-being" and "resilience" mean to you?

Traditional knowledge holders

- To the extent that you feel comfortable sharing how has your cultural practice been impacted by COVID-19?
- How have you adapted and responded to those impacts?
- What methods or strategies have you used during this pandemic in your role as a practitioner/knowledge holder to support people?

Coding and Analysis

With participant permission, interviews and talking circles were audio recorded and transcribed verbatim for analysis. One subgroup transcribed the audio recordings from Native language to English for analysis. For Zoom sessions, participants had a choice to turn their video on or off during the interviews and talking circles. If a participant did not want their name to be displayed on the video screen, the community researcher helped the participant change their name to an alias name on the screen. If the participants chose to keep their video on, they were reminded that all video and audio sessions would be recorded. Once the audio segments from all sessions were saved, the video portions were deleted. If a participant did not wish to be audio recorded, then a researcher (not the facilitator) took thorough notes for further analysis. The research team deidentified all data, including any tribal affiliations or agency names before further analysis because participating Native nations requested that data should not be identified by the tribal communities. Participants were assigned a unique ID code to remove any connections to their personal identifying information. No identifying information was included in the descriptive or analytical result tables or reports.

Once interviews and talking circles were completed, the research team conducted quality checks of the audio recordings to ensure that the transcriptions were accurate and to eliminate any identifying information before analysis. A secondary codebook (similar to the asset mapping codebook) was created based on the conceptual framework presented in the *Introduction* section. Members of the research team, including researchers from American Indian and Alaska Native nations, regularly met to discuss the definitions and applications of the codes. After developing the initial draft of the codebook, all members of the coding team coded the same transcript to compare coding and address any issues with the codebook. The codebook was refined when new themes emerged. The codebook consisted of 30 codes and child nodes that were entered into the NVivo software (NVivo 12 Pro; Lumivero). One team member was appointed to create and manage the NVivo master project that was used to house the master codebook. The NVivo software was used

XSL•FO
RenderX

to categorize quotes with codes to perform qualitative analyses of the topics discussed in both the interviews and talking circles.

Because of the large number of transcripts, each transcript was coded by 1 coder, and interrater reliability was not calculated. Regular coder debriefing sessions, a highly structured codebook, and the purposeful discourse and integration of Indigenous and non-Indigenous interpretations of narratives ensured the reliability of the coding process [50,51]. All the coders were involved in codebook development, which included biweekly meetings for the duration of the coding process. Biweekly coding meetings allowed coders to ask for clarification on the application of the codes in the context of the interviews they were coding. This ongoing communication supported and built a consensus on the application of the codes and child nodes. In addition, as alternate interpretations of a code were discussed, analysis was guided in the codebook by the addition of inclusionary and exclusionary examples extracted from the narratives to yield agreement in the coding process [50].

This triangulation of methods (interviews, talking circles, asset mapping, and coding of executive orders) and data (eg, narratives, maps, and categories of orders) informed our understanding of the context and strategies of American Indian and Alaska Native populations and Native nations and overall research credibility. Triangulation was further strengthened through coders working in teams and through the biweekly meetings of the entire coding team.

Ethics Approval

The study was reviewed and approved by IRBs and entities that provide research oversight for the university and each of the participating Native nations (Northern Arizona University approval 1693297). Informed consent was obtained from the participants for both the interviews and talking circles that were conducted. This process has been described in the Indigenous Guided Research section. The study data were anonymized or deidentified. Individuals participating in the interviews received US $25 gift cards and those participating in the talking circles received US $50 gift cards.

Results

The number of participants enrolled in this study was 105 adults, with 92 individuals interviewed and 13 individuals engaged in 4 talking circles (Table 1). Although the goal was to interview 10 individuals from each subgroup (ie, first responders, educators, traditional knowledge holders and practitioners, and members of substance use recovery community) from each of the 3 nations, this number was not consistently achieved.

The number of interview participants in each subgroup and each community ranged from 4 to 10. Because of time constraints and challenges bringing people together during the pandemic, both via web-based platforms and in person, the team elected to host talking circles with only 1 nation, with participants ranging from 2 to 6 people. Because of the limited availability of participants, a talking circle was not conducted with the first responder subgroup.

The participant demographics are presented in Table 2. In total, 63% (58/92) of the participants identified as female and 87% (80/92) identified as Indigenous. Participant age was evenly distributed among 3 age ranges: 35 to 44 years (25/92, 27%), 45 to 54 years (25/92, 27%), and 55 to 64 years (20/92, 22%). In total, 9% (8/92) of participants were in the age range of 25 to 34 years, and 15% (14/92) of participants were aged 65 years or older.

Currently, we are in the process of conducting a qualitative analysis of the transcribed narratives from interviews, talking circles, and executive orders. These processes and outcomes will be described in future studies.

Table 1. Number of participants in interviews and talking circles.

Community	Nation A	Nation B	Nation C	Urban[a]	Total
Key informant interviews (number of participants interviewed/goal), n/N					
First responders	10/10	8/10	7/10	—[b]	25/30
Educators	10/10	9/10	7/10	—	26/30

Discussion

Principal Findings

This study embraced community-engaged research approaches to determine the role of IDOH and Indigenous Nation Building in supporting American Indian and Alaska Native mental health and well-being and, in turn, resilience during the COVID-19 crisis. The study documented the impact of COVID-19 and the resilience of 4 specific community groups of 3 Native nations and an urban Indigenous health center near one of these nations, including first responders, educators, traditional knowledge holders and practitioners, and members of the substance use recovery community. The IDOH and Indigenous Nation-Building frameworks allowed the study team to acknowledge the COVID-19 protocols implemented by sovereign nations and governing leaders to use resources and take actions needed to mitigate the impact of the pandemic. The collection and analysis of tribal policy documents, communications, actions, and available assets allowed our team to understand the communities' networks, infrastructures, and perspectives.

Engagement with members of each nation's subgroups was key to understanding the Indigenous concepts of well-being linked to collective mental health and resilience. The communication between researchers and citizens of the collaborating nations was culturally adapted to create a trusted relationship between the research team and the sovereign nations [52]. Indigenous communities have been harmed by unethical research practices in the past [52]. Developing culturally respectful research protocols renews confidence in future ethical research and aids in the protection of the sovereign nations [52]. Other practices included ensuring confidentiality of information, receiving explicit consent for participation and recording interviews, encouraging individuals to communicate their answers in their Native language, and providing mental health resource lists for each participating community. The team conducted talking circles rather than focus groups, as they were deemed more culturally congruent than focus groups in this population. For many Native communities, talking circles provide a sacred environment for mutual respect in the sharing of personal observations, often pertaining to health disparities and actions that affect them within their tribal community [47-49]. In this study, talking circles were used to observe the communication of community members in discussing the impact of COVID-19 on their mental well-being and subsequent resilience.

By working alongside our university IRB, tribal IRBs, tribal councils, Cultural Preservation Offices, and tribal leaders, the team was able to ensure cultural sensitivity throughout the multimethods design and analyses of data. As sovereign nations, all research taking place within a Native nation must be approved by a tribal research review board, a tribal council, or a cultural review board. The research guidelines include ensuring benefits to the nation and its citizens and the nation's ownership of the data gathered. Regular communication and engagement with each nation—including, but not solely, the community researcher of each nation—ensured respectful interaction with tribal members and established their values and rights as citizens of sovereign nations in our research.

Our study was unique in that our research team consisted of predominantly Indigenous scholars representing at least 8 tribal communities and nations in the United States and other non-Indigenous colleagues, collectively with many years of experience working with Indigenous Peoples. The development of this team was not happenstance but intentionally crafted because the team members understood the importance of bringing together people with the right expertise, identity, and relationship. The team included 1 community researcher from each of the 3 nations; these individuals lived and worked within the communities and had multiple relationships with the community members. Although other members of the research team also had long-established relationships with the Native nations, the inclusion of individuals who lived, worked, and

XSL•FO
RenderX

interacted with the immediate local community was a critical component of the research design. These individuals not only played important roles in the recruitment of study participants but also provided key insights into the data analysis and interpretation of findings. Overall, our team's background and experience were vital to the development of socially conscious decisions in the methods used throughout the study.

Findings from this study will be shared through presentations, papers, and publications with larger Indigenous and non-Indigenous audiences, including collaborating and stakeholder organizations; local recovery groups, treatment centers, and individuals in recovery; K-12 and higher education educators and administrators; directors of first responder agencies; traditional medicine people; and elected community leaders. Data and results will be used to produce resource maps to promote service availability; advocate for research and resource expansion in the region; and be disseminated at local, regional, and national conferences and advocacy events as well as peer-reviewed journals. The findings will be used to produce well-being and resilience education materials, such as print and digital toolkits, in-service training sessions, educational materials specific to Indigenous audiences, and future recommendations for stakeholder organizations. The pending articles will consist of data analysis and results pertaining to asset mapping analysis, executive orders, and the development of a codebook. In addition, each of the 4 subgroup interviews and talking circles will be analyzed for existing patterns to address present community needs and potentially new needs that have emerged from the COVID-19 pandemic.

Limitations of the Study

This study included a small subset of 3 nations from 570 federally recognized tribal nations. Furthermore, the study was limited to Native nations within 1 geographic region of the US Southwest. In addition, among the 4 identified subgroups of the participating tribal nations, the number of interview respondents and talking circle participants was low. Finally, not all study participants were American Indian and Alaska Native. These limitations may have implications for the results. For example, very remotely located tribal communities in other areas of the country or tribal nations with differently organized leadership may have experienced COVID-19 dissimilarly than the individuals from Native nations participating in this study; therefore, a similar study conducted in a different area of the country might yield very different results than this study.

This study examined questions through a framework of Indigenous Nation Building and IDOH, which the research team determined to be the most appropriate framework for examining the issue. Other studies using a less Indigenous-centered approach could yield somewhat different findings.

Conclusions

In conclusion, this community-engaged study lays the groundwork for future studies addressing Indigenous mental health, well-being, and resilience in other communities during global crises. Asset mapping resource guides can create more opportunities for resource expansion in each participating community. Geographic Information System mapping can be further used for spatial analysis and to understand the distribution and availability of key resources in Native lands. Future intervention-based studies can also address mental well-being to enhance community resilience. The intentionality of linking Indigenous researchers with Indigenous communities to address pressing matters related to IDOH exemplifies the value and importance of the practice to build trust and mutual respect among communities, Native nations, and the academic community; it also reflects the 4 R's (respect, relationship, reciprocity, and responsibility) approach described by Brayboy et al [14], which is crucial to Indigenous research methodologies. Furthermore, Indigenous Nation Building is centered in our multifaceted and interdisciplinary approach to learn from each stakeholder group toward informing tribal sovereignty and responding to a pandemic crisis through the lens of the Indigenous community. This commitment was clearly demonstrated in 1 meeting with Indigenous elders, where the elders explicitly communicated in the Native language their appreciation for this research that included a researcher who knows the language and knows the people.

Acknowledgments

The authors would like to thank the other team members of this project who contributed in various ways: Marianne Nielson, April Petillo, Michael Petillo, Esther Cadman, David J Tsosie, Esther Lewis Yazzie, Al Yazzie, Kylene Kochampanasken, Rachel Cruz-Shurz, Lendrick Lomayestewa, Jennifer Etcitty, Kat Evans, Allyson Calamayan, Vaneka Hoskie, Kendra David, and Amy Gelatt. The authors also want to thank the citizens of the 3 Native nations and the urban Indigenous health center who were involved as participants and advisers in this project, without whom this study would not have been possible. The authors are forever grateful for the sacrifices that they made and continue to make as frontline workers in their communities, and the authors greatly admire the resilience and perseverance that they have demonstrated during these troubling times. This research received funding from the Southwest Health Equity Research Collaborative at Northern Arizona University (U54MD012388-04S6), which is sponsored by the National Institute on Minority Health and Health Disparities, and R25GM127199. The contents of this publication are solely the responsibility of the authors and do not necessarily represent the official views of the National Institutes of Health.

Data Availability

The data sets generated and analyzed during this study are not publicly available because they include data from participants of sovereign Native nations, and these data cannot be released without explicit permission from each nation. Please feel free to contact the principal investigator, Dr Julie Baldwin, if you have questions.

Abstract

Background: The quality of warfarin anticoagulation among Sub-Saharan African patients is suboptimal. This is due to several factors, including a lack of standardized dosing algorithms, difficulty in providing timely international normalized ratio (INR) results, a lack of patient feedback on their experiences with treatment, a lack of education on adherence, and inadequate knowledge and training of health care workers. Low quality of warfarin anticoagulation, expressed as time in therapeutic range (TTR), is associated with higher adverse event rates, including bleeding and thrombosis, and ultimately, increased morbidity and mortality. Processes and interventions that improve this situation are urgently needed.

Objective: This study aims to evaluate the implementation of the "warfarin bundle," a package of interventions to improve the quality of anticoagulation and thereby clinical outcomes. The primary outcome for this study is TTR over the initial 3 months of warfarin therapy.

Methods: Patients aged 18 years or older who are newly initiated on warfarin for venous thromboembolism, atrial fibrillation, or valvular heart disease will be enrolled and followed up for 3 months at clinics in Cape Town, South Africa, and Kampala, Uganda, where the warfarin bundle is implemented. A retrospective review of the clinical records of patients on warfarin treatment before implementation (controls) will be used for comparison. This study uses a mixed methods approach of the implementation of patient- and process-centered activities to improve the quality of anticoagulation. Patient-centered activities include the use of clinical dosing algorithms, adherence support, and root cause analysis, whereas process-centered activities include point-of-care INR testing, staff training, and patient education and training. We will assess the impact of these interventions by comparing the TTR and safety outcomes across the 2 groups, as well as the cost-effectiveness and acceptability of the package.

XSL•FO
RenderX

Results: We started recruitment in June 2021 and stopped in August 2022, having recruited 167 participants. We obtained ethics approval from the University of Cape Town Faculty of Health Sciences Human Research Ethics Committee, the Provincial Health Research Committees in South Africa, the Joint Clinical Research Centre Institutional Review Board, Kampala, and the University of Liverpool Research Ethics Committee. As of February 2023, data cleaning and formal analysis are underway. We expect to publish the full results by December 2023.

Conclusions: We anticipate that the "bundle of care," which includes a clinical algorithm to guide individualized dosing of warfarin, will improve INR control and TTR of patients in Uganda and South Africa. We will use these findings to design a larger, multisite clinical trial across several Sub-Saharan African countries.

KEYWORDS

drug monitoring; international normalized ratio; Sub-Saharan Africa; warfarin bundle; warfarin; anticoagulation control

Introduction

Background

Oral anticoagulation is vital for several diseases that are prevalent and increasing in Sub-Saharan Africa (SSA). Warfarin remains one of the most frequently used oral anticoagulants, particularly in lower-resource settings, such as SSA [1], but is difficult to use because of its narrow therapeutic index, wide variability in individual daily dose requirements required to achieve the desired effect and need for frequent monitoring. Achievement of the target international normalized ratio (INR) is critical to prevent the recurrence of thrombosis and bleeding. Several studies have described low time in therapeutic range (TTR) [2]. In our previous study, our own cohorts in Uganda and South Africa demonstrated a TTR of 41% [3] compared to TTRs of up to 70% in high-income settings [4].

We identified several reasons that contributed to this low quality of anticoagulation, including a lack of standardized dosing algorithms with different practices in different clinics, difficulty in providing INR results at the time patients attend clinic, a lack of patient feedback on their experiences while on treatment and education on adherence, inadequate knowledge and training of health care workers, a lack of standardization of quality improvement procedures, and the lack of availability of different dosage strengths of warfarin tablets.

A simulation study [5] in the United States suggested that improving TTR by 5% resulted in a 7.2% reduction in all adverse events in a population of 67,070 patients anticoagulated for atrial fibrillation over a 2-year period. This included 183 ischemic strokes, 269 major hemorrhages, and 662 deaths. Increasing TTR by 5% saved US $15.9 million and gained 863 quality-adjusted life years (QALYs) during this period [5]. In our population, with a median TTR of 41% [3], an improvement in TTR would be expected to have a greater impact since the relationship between TTR and mortality is nonlinear.

We aim to introduce a package of measures using a mixed methods approach, which we have termed the "warfarin bundle," in anticoagulation clinics in 2 cities (Cape Town, South Africa, and Kampala, Uganda), to improve the quality of anticoagulation. The bundle includes patient-centered and process-centered activities, namely (1) implementing a clinical warfarin dosing algorithm, (2) providing adherence support, (3) conducting root-cause analysis of warfarin-related adverse events, (4) implementing point-of-care INR testing, and (5) providing staff training. We anticipate that this warfarin bundle will be a cost-effective approach for better INR control compared to the current standard of care.

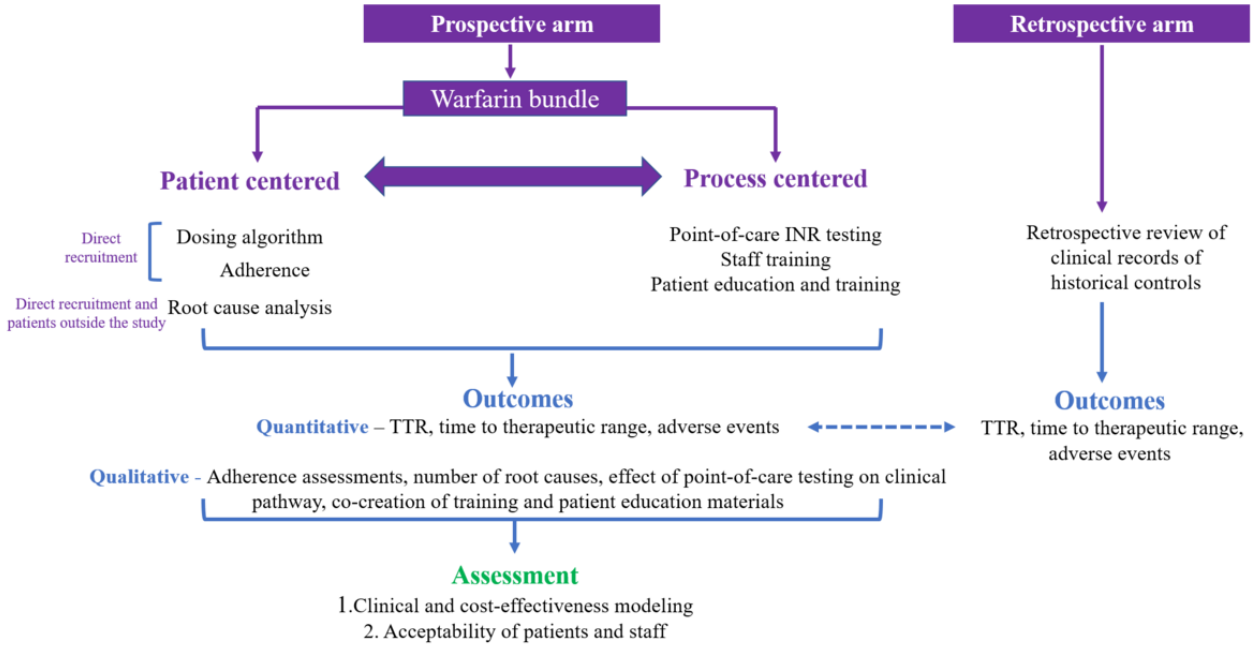
Hypothesis

Our underlying hypothesis is that implementing a bundle of measures, including a clinical algorithm to guide individualized dosing of warfarin, will improve INR control and TTR in patients in Uganda and South Africa.

Objectives

The primary objective of this study is to evaluate whether implementation of the warfarin bundle improves TTR. Secondary objectives include evaluating whether implementation of the warfarin bundle improves time to achieving a therapeutic INR or reduces the occurrence of adverse effects, assessing the acceptability of the bundle, exploring patients' experiences, and estimating cost-effectiveness.

Methods



Study Design and Setting

This is a mixed methods implementation study of patient- and process-centered activities to improve the quality of anticoagulation in Sub-Saharan African patients involving 3 hospitals in Kampala, Uganda (Mulago National Referral Hospital, Uganda Heart Institute, and Kiruddu National Referral Hospital) and 2 hospitals in Cape Town, South Africa (Groote Schuur Hospital and Tygerberg Hospital).

The general study design is described in Figure 1.

XSL•FO
RenderX

Figure 1. Study design highlighting prospective and retrospective components and outcomes. INR: international normalized ratio; TTR: time in therapeutic range.

Patient Centered Components of the Warfarin Bundle

Implementing the Use of Dosing Algorithms

Participants of Black African ancestry will be dosed according to the warfarin dose initiation algorithm developed in our preceding study in Black African patients in Uganda and South Africa, which takes account of patient age, weight, target INR, and HIV status [6] (Multimedia Appendix 1). In South Africa, patients of other ethnicities will be initiated on warfarin using warfarin dosing algorithms which have already been published [7,8] (Multimedia Appendix 2). We will collaborate with their treating clinicians and calculate a warfarin initiation dose using the relevant algorithm.

Day 0 is considered the first day that warfarin is taken. We recruited participant up to 7 days before and no more than 1 day after warfarin was initiated, meaning some individuals may have taken a single warfarin dose. We will use a paper-based dosing table, using dose formulations currently available, which has been developed for implementation (Multimedia Appendix 1).

Adherence Support

The package of adherence support offered will include data-driven counseling and interactive weekly text messaging. We will assess adherence by means of a composite of INR values above and below the therapeutic range, TTR, and self-report.

Root Cause Analysis

Root cause analysis (RCA) will be undertaken in all patients on warfarin at the INR clinic or hospital who are seen with serious thrombotic or hemorrhagic events. An RCA committee at each clinic, comprising a multidisciplinary team of 4-6 individuals, will review each case using the 9-step process of RCA described by Charles et al [9]. Root causes and corrective actions developed will be categorized on a standardized RCA data collection form to ease analysis [10]. The results of each RCA (root causes, contributing factors, and corrective actions) will be shared with staff at the clinic. Findings of RCA will be discussed at monthly study meetings to inform the overall warfarin bundle implementation (in areas such as adherence, monitoring, and education).

Process-Centered Components of Warfarin Bundle

Point-of-Care Testing

We will make point-of-care INR testing a central part of improving the clinical pathway. Currently, some patients must wait at least a day to receive their INR result and subsequent dosing guidance.

Staff Training

We will include co-design workshops discussing the rationale for the bundle and likely implementation issues with a team of clinicians involved in the provision of anticoagulation services. Training will be personalized based on local requirements, depending on the site and staff involved.

Cocreation of Patient Education and Training

Co-design workshops for the development of training material to be used in patient education will bring together patient or community representatives, health care staff, the research team, and a representative from policy makers. Different methods will be discussed and explored by the cocreation team in collaboration with representatives from the community and health care workers to ensure they are applicable to the local setting.

Participant Eligibility Criteria

Participants will be included in the study if they are adults aged 18 years or older; newly initiated on warfarin anticoagulation for the first time for venous thromboembolism, atrial fibrillation,

XSL•FO
RenderX

or valvular heart disease; provide informed consent; and are willing to comply with study procedures. We will exclude participants who are on treatment for tuberculosis, pregnant women, and patients who have had more than one dose of warfarin. For the retrospective study, we will include adults newly initiated on warfarin for more than 3 months before we implement the trial.

Sample Size and Power Calculations

To calculate our sample size, we assumed TTR in current practice to be 0.41 (based on average TTR from our audit) and the SD of TTR to be 0.25 on the basis that anticoagulation control before implementing the bundle is better than that found during the audit (0.33), due to the introduction of the clinical algorithm in a preceding pilot implementation study. We also assumed a Type I error rate of 0.05, power of 80%, and that the retrospective and prospective ratio would be 2:1. To achieve a minimum clinically important difference of 0.07 (ie, improvement from 43% to 50% TTR), we calculated that we would need at least 304 retrospective and 152 prospective participants (including a 10% contingency for losses to follow-up). This is in total across both Uganda and South Africa.

Participant Recruitment

Prospective Study

We will recruit participants for whom a decision has already been made to initiate warfarin by the managing clinician (Figure 2). Decisions regarding whether or not patients require inpatient management for the initiation of warfarin are also made by the managing clinician. Participants who meet the inclusion criteria will be consecutively screened and enrolled in the study. In cases where participants are discharged from the hospital and referred for follow-up in a clinic close to their home or in the outpatient clinic of the hospital, the clinical records used at the recruitment site and those at the referral clinic will be reviewed.

The participant's first 3 days of dosing will be driven by our new algorithm (Multimedia Appendix 1). Thereafter, dose revisions will be made according to current guidance outlined in the "Standard Treatment Guidelines and Essential Medicines List for South Africa" [11]. We will repeat the INR of participants every 2-4 days until stability is reached (2 consecutive INRs are in the target range). We will ensure close monitoring during the first 14 days of treatment. If stability is reached before the 14th day, we will continue to closely monitor the patient for the first 14 days. If the participant has not reached stability at 14 days, we will continue to monitor the participant with INRs every 2-4 days and adjust the warfarin dose until stability is reached. As we measure participants' INR every 2-4 days over this period of close follow-up, we will propose dose adjustments to the clinical team based on INR results. The clinical team will still be free to override proposed adjustments based on their clinical expertise. Once stability is reached, we will perform one more INR 1 week later, after which the participants' care will be fully handed back to the clinical team, and participants will continue to follow-up according to the local standard of care. We will continue to monitor and record all consecutive INR results for 3 months through direct contact with the participant at outpatient clinic, home visits, or electronic or paper record review.

We will collect the following data: age, sex, weight, height, indication for anticoagulation, target INR range, HIV status, recruitment center, all INR measurements during the first 3 months and the first INR after completion of the first 3 months, any dose changes, and any hospitalizations or adverse events (Table 1). We will also complete the EQ-5D-3L questionnaire and a patient-cost questionnaire to enable us to measure changes in quality of life and out-of-pocket expenditures, respectively.

We will test all patients for genetic variants that are determinants of warfarin dose and elucidate whether any patients who were poorly controlled on warfarin had a genetic profile which may have adversely affected their INR control. The genetic testing will be done at the end of the study and will also help with our future plans to validate a genetic dosing algorithm derived from our previous study's analysis of genome-wide data. (South Africa HREC: 672/2017, Uganda: JC3017). We will also obtain consent to undertake genome-wide analysis in this patient group, which will help in future meta-analyses with our previous studies' data to identify other genetic loci.

Retrospective Review of Patients' Clinical Records

The following data will be collected from clinical records: age, sex, weight, indication for anticoagulation, target INR range, HIV status, recruitment center, all INR measurements during the first 3 months, any dose changes, and any hospitalizations or adverse events. If participants in the retrospective review were initially hospitalized and then discharged, the recruitment hospital site clinical records as well as the clinical records at the referral clinic will be reviewed.

Withdrawal Criteria

A participant can withdraw from the study at any time if it is his or her wish or if it is medically necessary, as judged by the Investigator. A participant will be withdrawn if any of the following applies:

1. Voluntary discontinuation by the participant, who is at any time free to discontinue their participation in the study without prejudice to further treatment.
2. Incorrect enrollment of the participant (ie, the participant does not meet the required inclusion and exclusion criteria).
3. Participant fails to comply with the protocol requirements or fails to cooperate with the investigator.
4. Participants experiencing severe adverse events who return to standard care.

Sample Collection

Two tubes of blood (10 or 12 ml total) will be collected in ethylenediaminetetraacetic acid (EDTA) tubes and used for DNA extraction. The EDTA blood sample will be stored at either –20 C or –80 C. One tube will be shipped to the United Kingdom, and 1 kept in Cape Town or Kampala. DNA will be extracted from the EDTA sample at the Wolfson Centre for Personalised Medicine in Liverpool. We will seek ethical approval from the University of Cape Town HREC/Joint Clinical Research Centre Institutional Review Board Office, Kampala, for any future use.

Adverse Events

The decision to start warfarin will already have been made by participants' clinical teams before enrollment. We will capture warfarin-related adverse events as part of the secondary outcome measures. A blood test to obtain DNA may sometimes lead to bruising at the site of venepuncture, but all blood will be taken by trained and experienced staff. All adverse events will be recorded and appropriately reported. Investigators will assess whether adverse events were related to warfarin using the Liverpool Adverse Drug Reaction Causality Assessment Tool [12].

Cost-Effectiveness

We will perform a cost-effectiveness analysis to judge whether the warfarin bundle represents good value for money. These will be based on estimated costs associated with warfarin treatment and health outcomes expressed as QALYs and disability-adjusted life years (DALYs). Resource use will include hospital admissions, outpatient clinic visits, phlebotomy, Point-of-Care and laboratory INR tests, additional blood tests, and prescribed warfarin. External data (which may require extrapolation from other studies or countries) may be required to estimate the costs of managing rare adverse events, including strokes and major bleeds. Unit costs will be identified from a number of sources, including the Western Cape Department of Health (eg, Uniform Patient Fee Schedule), the Ugandan Joint Medical Stores catalog, and the World Health Organization "Choosing Interventions that are Cost-Effective" (WHO-CHOICE) model for estimating unit costs for hospitalizations [13]. Patients will be asked to complete the EQ-5D-3L to estimate health utilities at the initial visit and 1 follow-up visit and to complete a questionnaire to record out-of-pocket costs by telephone. The economic analysis will estimate the incremental costs per QALY gained and DALY averted and inform policy.

Study Outcomes

The primary outcome for this study is TTR over the initial 3 months of warfarin therapy, which we will measure using the Rosendaal linear interpolation method [14]. We will compare time in the therapeutic INR range between the prospectively followed participants who receive the warfarin bundle and a retrospectively reviewed patient group. This will yield an estimate of the impact of the warfarin care bundle as a whole. It will not be possible to distinguish the effect of the individual components of the warfarin bundle on TTR.

The secondary outcomes include time to achieve therapeutic INR and number of adverse events (death, bleeding, or thrombosis), which will be compared between the prospectively followed-up participants and the retrospectively reviewed patient group. We will also explore staff and patient experiences and acceptability of the warfarin bundle using in-depth interviews or focus group discussions and conduct an economic analysis of the cost-effectiveness of the warfarin bundle. In addition, we will perform a qualitative assessment of useful lessons from the RCA.

Patient and Public Involvement

Patients or the public will not be involved in the design, conduct, or reporting of this study. However, where possible, study findings will be disseminated through public and patient engagement activities.

Data Analysis Plan

For the prospective and retrospective studies, all statistical analyses will be undertaken in R. For determining percentage time in target range for each participant, all INR measurements during the first 12 weeks as well as the first INR measurement after the 12-week time point will be used, and the method of Rosendaal et al [14] will be applied. Percentage TTR will be compared between the prospective implementation group and the retrospective standard of care group using the Student *t* test. Time to achieving target INR (defined as the first of at least two INR measurements in range at the same dose) will be compared between the prospective and retrospective groups using the log-rank test (to compare the survival distributions of the 2 groups, and these will be calculated using the Kaplan-Meier estimator). Adverse events will be compared between the 2 groups using a chi-square test. A significance threshold of $P<.05$ will be applied.

XSL•FO
RenderX

The primary analysis will include all participants who remain in the project for at least 2 weeks (14 days). Our primary analysis will include only patients who have at least two weeks' follow-up, since it is unlikely that those with less than 2 weeks' follow-up will have sufficient information on INR measurements for TTR to be reliably estimated. A sensitivity analysis will be undertaken, including only participants who have completed 12 weeks (84 days) of follow-up.

We will also conduct both an intention-to-treat analysis (including all recruited patients) and a per-protocol analysis (excluding patients where health care provider decided to reject the dose recommended by the dosing algorithm). The project will follow national guidelines for best practice and be guided by local policy. Relevant data will be made openly available to other researchers in a timely way (after primary outputs are published) with as few restrictions as possible unless we are protecting intellectual property, respecting confidentiality, or honoring third-party agreements. The program management board will review access to data and will provide a governance mechanism.

We will perform a secondary analysis comparing the primary and secondary outcomes between retrospective controls from the pre–COVID-19 and COVID-19 periods to measure the impact of the pandemic on anticoagulation control.

Total direct costs will be calculated for each patient over the course of the 12 weeks. Utilities will be estimated from the administration of the EQ-5D-3L questionnaire (available in 8 languages spoken in South Africa and 2 in Uganda) and valued using the Zimbabwean value set, as none exist for these countries [15]. Regression analyses using transformed utility (or cost) as the dependent variable and controlling for clinical and demographic factors will be used to estimate the association between health utility (or cost) and TTR. These will be incorporated in a decision analytic model, also populated with data from evidence on the relationship between TTR and health outcomes (strokes, hemorrhagic events, etc), to estimate overall costs and QALYs.

In accordance with World Health Organization recommendations, the number of DALYs, expressed as the collective number of years lost due to ill health, disability, or early death, will be calculated by adding the adjusted number of years lived with disability and the number of years of life lost due to premature mortality. The years lived with disability component represents a duration that is scaled by disability severity weights that range from 0 (no adverse impact on quality of life) to 1 (burden equivalent in preference to being dead). Weightings will be applied to time with disability based on disease areas [16] and DALYs for individuals will be calculated and used as an alternative metric of cost-effectiveness (cost per DALY averted).

Ethical Considerations

The study will be conducted in accordance with the recommendations for physicians involved in research on human subjects adopted by the 18th World Medical Assembly, Helsinki, 1964, and revisions up to and including Fortaleza [17]. We obtained approval from the University of Liverpool Research Ethics Committee (reference number: 9963), the University of Cape Town Faculty of Health Sciences Human Research Ethics Committee (reference number: 710/2020), the Provincial Health Research Committees in South Africa, and the Joint Clinical Research Centre Institutional Review Board, Kampala (reference number: JC2120), before the study commenced.

Each participant in the prospective arm was required to provide written informed consent to enter the study only after a full explanation had been given and an information leaflet had been offered. Signed participant consent was obtained. For participants that were unable to read and write, an impartial witness was present during the informed consent process to witness thumbprint consent. The right of the participant to refuse to participate without giving reasons was respected. All participants were free to withdraw at any time. We did not seek patient consent for the retrospective record review; a waiver of consent was sought from the corresponding ethics committees.

All study data will be deidentified. All documents and logs containing identifiable private information about participants will be kept securely and only accessible by study staff and investigators.

Results

We started recruitment in June 2021 and stopped in August 2022, having recruited 167 participants. As of February 2023, data cleaning and formal analysis are underway. We expect to publish the full results by December 2023.

Discussion

Overview

This protocol will evaluate the implementation of the "warfarin bundle," a group of interventions aiming to improve the quality of warfarin anticoagulation in SSA. Given the complex and multifaceted challenges contributing to suboptimal anticoagulation in these populations, a mixed methods protocol, including both patient-centered and process-centered activities, was designed.

The study design has several limitations, primarily relating to the complexity of the population, the challenges of investigating anticoagulation in this particular setting, and the selection of a bundle of interventions, including patient and provider education, rather than a single intervention.

In Uganda, anticoagulation services are centralized in Kampala, and there are no control clinics that could be run concurrently in a cluster randomized trial design; within South Africa, selection of appropriate control clinics would necessitate involving another city in addition to Cape Town, thereby bringing unfeasible logistic challenges and cost. Therefore, a before-and-after design was considered most appropriate. We have shown in the preceding Audit study that we can get high-quality data from the case notes [3].

An eligibility criterion for participants in the prospective evaluation is their willingness and ability to comply with study procedures. In practical terms, this excludes individuals who travel long distances from peripheral regions of Uganda to the

XSL•FO
RenderX

tertiary facilities where anticoagulation is accessed; this may mean that the participants in the retrospective and prospective arms are not perfectly matched in terms of socioeconomic status. However, the recruitment sites are in the area of highest population density, and the majority of individuals in both the retrospective and prospective arms are anticipated to reside within Kampala and the surrounding Wakiso district.

Through the selection of a bundle of interventions, it will not be possible to attribute improvement to a single element of this. However, this is a complex patient group requiring holistic care, and several important areas have been identified for improvement. The health, economic, and qualitative aspects of the protocol are designed to evaluate the benefits of the bundle as a whole.

Conclusions

We anticipate that the "bundle of care," which includes a clinical algorithm to guide individualized dosing of warfarin, will improve INR control and TTR in patients in Uganda and South Africa. This has the potential to reduce the substantial morbidity and mortality seen among individuals requiring oral anticoagulation in these settings. We will use these findings to design a larger, multisite clinical trial in other Sub-Saharan African countries.

Acknowledgments

We would like to thank all staff at the outpatient and anticoagulation clinics of Mulago National Referral Hospital, Uganda Heart Institute, Kiruddu National Referral Hospital, Groote Schuur Hospital, and Tygerberg Hospital for their input during the planning and implementation of this study. This study is funded by the National Institute for Health Research (NIHR; project ref. 16/137/101) using UK aid from the UK Government to support global health. The views expressed are those of the authors and not necessarily those of the NIHR or the Department of Health and Social Care.

Data Availability

Relevant data will be made openly available to other researchers in a timely way (after primary outputs are published), with as few restrictions as possible unless we are protecting intellectual property, respecting confidentiality, or honoring third-party agreements. Data sharing is not applicable to this article as no data sets have yet been generated or analyzed.

Authors' Contributions

The study concept and design were conceived by ALJ, CO, CW, CHT, CSW, DAH, EA, EO, GT, JPM, KC, MB, ML, and MP. MP led the funding acquisition for this study. Analyses will be conducted by ALJ, DAH, GC, and IGA. JRS prepared the first draft of the manuscript. All authors critically revised the manuscript and approved the submitted version.

Conflicts of Interest

MP has received partnership funding for MRC Clinical Pharmacology Training Scheme (cofunded by MRC and Roche, UCB, Eli Lilly, and Novartis). MP also has unrestricted educational grant support for the UK Pharmacogenetics and Stratified Medicine Network from Bristol-Myers Squibb. He has developed an HLA (human leukocyte antigen) genotyping panel with MC Diagnostics but does not benefit financially from this. He is part of the IMI Consortium ARDAT. CW is supported by the Wellcome Clinical Research Career Development Fellowship 222075_Z_20_Z.

Abstract

Background: The medical literature has reported that recurrent bacterial vaginosis (RBV) has a relapse rate of 35% within 3 months and 60% within 12 months after antibiotic administration. Products that are able to provide a barrier effect against the biofilm produced by *Gardnerella vaginalis* could play a role in improving the results of bacterial vaginosis (BV) treatment.

Objective: This study aims to assess the performance and safety of a medical device (Polybactum) containing polycarbophil, lauryl glucoside, and glycerides (PLGG) for reducing the rate of recurrence of BV.

Methods: The study includes women who are aged above 18 years, are willing to provide signed informed consent, have a diagnosis of BV according to the Amsel criteria, and have been affected by at least 2 episodes of RBV in the last 12 months. The trial includes 2 phases. In the first phase (according to an open-label noncontrolled design), the treatment involving PLGG is administered for 3 cycles and is followed by a 1-month period of follow-up without treatment. In the second phase, a 9-month follow-up period is envisaged. Thus, for each patient, a 10-month follow-up period without treatment is planned. The study involves 5 centers (2 in Italy and 3 in Romania). We calculated a sample size of 44 pairs to achieve a power of 80% and a 1-sided significance of 5% for detecting a difference of 0.25 between marginal proportions, in comparison with the mean recurrence rate of BV reported in the medical literature. We estimated a potential dropout rate of 20%, and thus, we decided to enroll 55 patients (1-group chi-square test).

Results: The study received ethics approval in 2016 in Romania and 1 year later in Italy. Recruitment started in September 2016. An interim analysis was performed in 2019, and full study analysis results are expected in July 2023.

Conclusions: The tested medical device involving PLGG could modify the mechanisms involved in the pathogenesis of BV and could improve microbiological parameters owing to the acidifying effect on vaginal pH. We believe that the findings of our

XSL•FO
RenderX

study could be useful for other investigators who want to test different products against RBV using a standardized protocol and standardized procedures.

KEYWORDS

bacterial vaginosis; recurrent bacterial vaginosis; biofilm; polycarbophil

Introduction

Overview

The vaginal cavity is colonized in its natural state by Doderleïn bacilli, which include different species of lactobacilli. They form a biofilm over the mucous membrane and hinder the growth, adhesion, and expansion of other potentially pathogenic microorganisms.

These lactobacilli inhibit the growth of pathogens by different means involving several agents [1]. First, lactic acid, produced by the hydrolysis of glycogen contained in vaginal cells, keeps the vaginal pH at a level between 3.8 and 4.5, and thus has a bacteriostatic effect on most vaginal pathogens (excluding *Candida albicans*). Second, hydrogen peroxide, an oxidizing agent secreted by certain lactobacilli (especially *Lactobacillus crispatus* and *Lactobacillus jensenii*) present in 96% of normal vaginal microbiota, hinders the proliferation of anaerobic bacteria [2]. Third, bacteriocins, antimicrobial protein derivatives with a restricted spectrum, act by binding to a specific receptor in the target cell and destabilizing the cytoplasmic membrane through the formation of pores.

Moreover, these lactobacilli produce a barrier against the adhesion of pathogens by means of biosurfactants, which act on surface tension and inhibit the expansion of pathogens through their co-aggregation properties. Bacterial aggregation is a mechanism that leads to the formation of biofilms. Some lactobacilli not only autoaggregate, but can also co-aggregate with pathogenic microorganisms, thus creating a particular microenvironment around the pathogen with significant levels of inhibitors. *Lactobacillus acidophilus*, *Lactobacillus gasseri*, and *Lactobacillus jensenii* co-aggregate with *Candida albicans*, *Escherichia coli*, and *Gardnerella vaginalis*, preventing these pathogenic strains from expanding and adhering to the epithelium [3]. Bacterial vaginosis (BV) is a polymicrobial disease that generally occurs when the protective antibacterial activity of vaginal lactobacilli is impaired, permitting an overgrowth of anaerobes and other pathogens, such as *Gardnerella vaginalis* and *Mycoplasma hominis* [4]. BV occurs in 20% to 25% of the general female population and is the most frequent cause of vaginal discharge [5].

Because of the several risk factors associated with BV, the etiology and pathogenesis of this disease are not completely understood, and the treatment adopted is not always effective, resulting in high recurrence rates [6].

Rationale

Recurrent bacterial vaginosis (RBV) is defined by 2 to 3 episodes of BV per year [7,8]. The recurrence rates are up to 35% within 3 months [9], 43% to 61% within 6 months, and 49% to 66% within 12 months [10]. It was proven that the tendency to relapse is essentially linked to the capacity of *Gardnerella vaginalis*, and to a lesser extent of *Atopobium vaginae* (recently reclassified as *Fannyhessea vaginae*), to adhere to the mucous membrane, producing a thick biofilm that adheres strongly to the surface of the vaginal mucous membrane [11]. This biofilm is generated within 2 days after the end of standard antibiotic treatment [6]. Thus, several medical reports suggest the use (no later than 24 hours after the discontinuation of antibiotic treatment) of products able to provide a barrier effect against the production of the biofilm by *Gardnerella vaginalis*. Starting from this rationale, it was necessary to find a novel, safe, and effective product able to hinder the formation of this vaginal biofilm, without damaging the fragile equilibrium of the vaginal microbiota.

Objectives

The primary objective of the study is to evaluate the performance and safety of a 3-cycle treatment of the test product (Polybactum) for reducing the rate of recurrence of BV, considering a 10-month follow-up (ie, without treatment), and compare the obtained results to those reported by appropriately selected international literature.

The secondary objectives are to evaluate the rate of return to normality of the vaginal microflora (defined as vaginal microflora with numerous pleiomorphic lactobacilli, and no other bacteria, clue cells, or hyphae) [12] after the study therapy and to evaluate the safety of the test product.

Methods

Overview

The author FM (Milan, Italy) conceptualized the study (ClinicalTrials.gov registration: NCT02863536) and created a team involving a network of gynecologists coordinated by the University of Medicine and Pharmacy “Victor Babe ” (Timisoara, România). The team conducted a systematic review on products already on the market known to be able to provide a barrier effect against biofilm production, assuming that these products, if administered immediately after standard antibiotic therapy, could play a role in improving the results of BV treatment. The literature review established that no gold standard therapy was recommended and that the available treatments were not always effective, resulting in high recurrence rates [4].

XSL•FO
RenderX

In addition, it evidenced, on the one hand, the proven protective activity of these products, and on the other, the low number of clinical trials performed (insufficient to statistically confirm a decrease in the recurrence rate).

In the initial step, the team was involved in building the outline of the protocol and clarifying the yet pending or not identified clinical issues (ie, the product to test and the antibiotic to use). A modified Delphi method [13] was used as a reliable approach to build and create consensus among team attendees. The procedure was defined as follows:

- Polycarbophil would be tested in the planned clinical trial. The characteristic of this well-known product is the formation of a film, which acts as a mechanical barrier able to reduce specific pathogen colonization. The product is already on the market, and the related instruction for use specifies its posology.
- Metronidazole would be the antibiotic therapy to administer following the indication reported in the international guidelines [6]. This drug is the standard treatment for BV at the sites of the involved investigators.
- BV diagnosis would be performed using the Amsel criteria [14], and the Nugent test would be considered as an optional evaluation.
- Patients would be monitored during a 10-month follow-up period (ie, after the end of therapy) to verify the recurrence rate.

The concept synopsis of the planned trial was presented to Effik Italia SpA (Italfarmaco Group, Cinisello Balsamo, Italy) (Multimedia Appendix 1). The company manufactures Polybactum, a medical device containing polycarbophil, lauryl glucoside, and glycerides (PLGG), and it offered the investigator team the medical device and a partial grant to perform the trial on RBV. The agreement between the parties specified that the funder would not have any role in the design and planning of the study, or in the collection, analysis, and interpretation of the data of the future manuscript disclosing the results.

Finally, the team chose the logo (Multimedia Appendix 2), the study name POLARIS (Polybactum to Assess Recurrent Bacterial Vaginosis), and the contract research organization (Opera CRO, a Tigermed Group company, Romania) that would be in charge of the logistics and the management of the trial (protocol submission, project management, site monitoring, data management, and statistical analysis). The coordination of the scientific activity (training of investigators at satellite sites, checking the application of ethics requirements, and circulating scientific information to the study team) would be managed by the Department of Clinical Trials of the University of Medicine and Pharmacy “Victor Babe ” (Timi oara, Romania). By applying this clear division of roles [15], there would be no influence or potential persuasion by the sponsor in the study design, data collection, interpretation, or publication.

Ethics Approval

The study involved 2 centers in Italy and 3 in Romania. The National Agency for Medicines and Medical Devices of România (*Agentia Nationala a Medicamentului si a Dispozitivelor Medicale*) has approved the study, and the Italian Ministry of Health has received the notification before the start of the trial. The local ethics committees (ECs) in Romania approved the protocol on July 29, 2016 (*EC Clinica Medicală Dr Cri an*; investigator Dr Cri an), October 24, 2016 (*EC Clinica Medicală Dr Cri an*; investigator Dr Biris), and August 22, 2016 (*EC Clinica Medicală Dr Sîrbu*; investigator Dr Sîrbu), and all are located in Timisoara. The formal approvals by Italian ECs were received some months later on December 14, 2016 (#8643/2017; *EC Area 1* in Milan; investigator Dr Murina) and February 15, 2017 (#566/2017; *EC Lazio 1* in Rome; investigator Dr Inghirami) (Multimedia Appendix 3). On March 14, 2018, the study protocol was amended to extend the follow-up period, to allow the calculation (not mandatory) of the Nugent score at baseline and the final visit, and to perform an interim analysis 6 months after the inclusion of the first patient. The results of the interim analysis have been recently published [16].

Study Design

The trial includes 2 phases. In the first phase (according to an open-label noncontrolled design), the treatment involving PLGG is administered for 3 cycles, and the treatment is followed by a 1-month follow-up. In the second phase, a 9-month follow-up period is envisaged. This entails that for each patient, a 10-month follow-up is planned as follows: 1 month (from the end of the 3rd cycle of PLGG to day 78 [±6 days as the window range]) plus an additional period of 9 months (±2 months as the window range) without treatment from that date to the final visit.

Study Setting and Patient Recruitment

The 5 centers involved in the study have been selected for their previous large experience in treating BV and for their wide catchment area for patients affected by this infection. The coordinator center is located in Milano (Italy), and the remaining 4 sites are satellite centers (Table 1). In each center, a principal investigator is appointed to be responsible for identification, recruitment, data and sample collection, completion of case report forms, and checking patient adherence to the protocol during the study period.

In addition, each principal investigator is responsible for the transportation of the collected samples to the local laboratory. Indeed, a close relationship between the clinical centers and the laboratories is mandatory to assure optimal performance of the study and to maintain the planned rate of enrollment. Local laboratories analyze each patient’s vaginal smear by phase-contrast optical microscopy. The characteristics of the selected laboratories are reported in Table 2.

Any patient visiting the involved clinical centers during the study period could be enrolled. No flyers, social media, or other advertising methods are used to invite patients to participate in the study.

Dr Sîrbu	Clinica Medicală Dr Sîrbu Daniela	Timisoara, Romania	The center is required to send the samples to a unique specialized laboratory (Bioclinica SA).

Inclusion Criteria

Patients could enter the study if they fulfilled all of the following criteria: (1) presence of RBV, that is, at least 2 episodes in the last 12 months, including the episode treated before the baseline visit of this study; (2) age above 18 years; (3) BV diagnosis by the Amsel criteria in the 6 to 9 days before the study and cure with metronidazole vaginal formulation (gel for 5 days or ovules for 7 days); (4) no lactation, or lactation and no amenorrhea; and (5) willingness and ability to provide signed informed consent.

Exclusion Criteria

Patients fulfilling one or more of the following exclusion criteria would be excluded from the study: (1) menstruation at the screening or baseline visit, menopausal transition, or postmenopausal period (2001 STRAW criteria); (2) pregnancy; (3) known allergy to metronidazole or to the tested PLGG ingredients; (4) mixed vaginitis or candidiasis; (5) HIV or other immunodeficiency; (6) sex worker; (7) concomitant enrollment in other interventional clinical trials; (8) unwillingness to provide informed consent; and (9) time between the last day of the last menses and the baseline visit of >16 days or ≤5 days (this criterion was necessary to avoid bias in case of menstrual bleeding occurring during the first PLGG cycle and the consequent need to interrupt the tested product administration).

Intervention

Overview

As specifically requested by ISO 14.155 and MEDDEV 2.12/1 for postmarketing clinical follow-up (PMCF) studies, all the treatments are performed as indicated in the instruction for use for each product.

Tested Product

The tested product involving PLGG is a class IIa medical device already on the market as CE QPZ-1805-15 (issue date: March 30, 2015) presented as vaginal ovules. Its components are polycarbophil (Noveon AA1), a barrier-forming agent well known for its lack of toxicity; lauryl glucoside, a nonionic surfactant that enhances barrier properties by reducing surface tension; and Witepsol W35, an administration vehicle. It is a hard, fat suppository base delaying the sedimentation of solid components and promoting the wetting of mucous membranes.

The reasons to choose PLGG for testing in the study are as follows [17]:

- PLGG does not have any effect in terms of general tolerance, because it does not cross the epithelium. Locally, even after prolonged exposure, it does not cause any irritation to the vaginal wall, has no toxic effect on epithelial cells, and does not trigger any sensitivity reaction.

XSL•FO
RenderX

- PLGG has a specific bacteriostatic action that inhibits *Gardnerella vaginalis* growth. In fact, it has been proven that the growth of *Gardnerella vaginalis* was reduced for 48 hours on contact with PLGG (shown already at 24 hours). The inhibitory activity of PLGG has also been demonstrated against *Streptococcus agalactiae* and *Neisseria gonorrhoeae*.
- PLGG has a mucoadhesive property impairing the formation of the biofilm produced by *Gardnerella vaginalis* and allowing the product to stay on the vaginal mucosa for at least 72 hours.
- PLGG has an acidifying effect on vaginal pH, which favors the growth of lactobacillus microbiota and, at the same time, maintains a hostile environment for the recolonization of the vagina by the polymicrobial flora involved in BV.

The mass of the ovule (2.05 g each) ensures coverage of the whole vaginal cavity (about 40 cm^2).

PLGG vaginal ovule administration is started between 12 and 24 hours after the end of metronidazole vaginal treatment. Each cycle of PLGG has a duration of 1 week as follows: 1 ovule is inserted in the vagina on day 1, 1 ovule is inserted on day 4, and 1 ovule is inserted on day 7. Three cycles of treatment (minimum 72 and maximum 84 days) are required for each patient. At the baseline visit, each patient receives a total of 9 ovules for the whole study duration (3 ovules for 3 cycles). The patient is informed by the investigator to lay in the supine position for some time after ovule insertion.

The baseline visit and the first cycle of PLGG vaginal ovule administration is between 6 and 16 days after menstrual bleeding and after the end of metronidazole treatment. The following warnings are considered:

- If the baseline visit is performed in the morning (and the metronidazole treatment is terminated the previous day), the investigator would give PLGG to the patient to allow PLGG self-administration in the evening.
- If the baseline visit is performed in the evening (and the metronidazole treatment is terminated the previous day), the investigator would deliver PLGG to the patient, permitting PLGG administration directly in the medical office or self-administration at home, in the evening of the same day.
- If the baseline visit is performed in the morning of the same day when the metronidazole treatment is terminated, the investigator would give PLGG to the patient and prescribe PLGG self-administration in the evening with an interval of 12 hours from metronidazole treatment.

In the second and third cycles, PLGG vaginal ovules are administered immediately after the end of the previous menstrual bleeding. For safety reasons, the investigator could stop the administration of PLGG at any time and could prescribe different therapies necessary for the patient's health.

Antibiotic Treatment

Metronidazole (vaginal administration) is the chosen antibiotic therapy (5 g of 0.75% gel once daily for 5 days or 500 mg ovules once daily for 7 days). This drug is largely indicated by the literature as one of the best antibiotic treatments for BV, even if its extensive use and frequent patient nonadherence limit its efficacy in avoiding recurrences [18].

Interventions Not Allowed

The following concomitant medications and interventions are not allowed during the study period: oral or vaginal probiotics (eg, vaginal lactobacilli), vaginal tampons, an etonogestrel/ethinyl estradiol vaginal ring (Nuvaring) or intrauterine device, vaginal or oral antibiotic therapy or other vaginal therapies (like spermicide and douching), and other products to treat BV.

Statistical Methods

Power

Data from the medical literature evidenced that the mean recurrence rate of BV after the first episode was from 30% to 50% within 3 months after the appropriate antibiotic therapy [19]. The patients enrolled in our study, after metronidazole treatment, are not allowed to use any vaginal or oral antibiotic therapy. Thus, in this study, it would be realistic to have a mean recurrence rate of 40% after 3 months. Data collected on the recurrence rate after treatment with PLGG vaginal ovules (Effik Italia SpA, unpublished data) showed a 2% correlation between paired observations. We applied a continuity correction, and we obtained a sample size of 44 pairs to achieve a power of 80% and a 1-sided significance of 5% for detecting a difference of 0.25 between marginal proportions. We considered a potential dropout rate of 20%, and thus, we decided to include 55 patients (1-group chi-square test). At 95% CI, a P value <.05 is considered statistically significant.

Statistical Analysis

The values between visits for the primary objective are analyzed using a *t* test or chi-square test for quantitative variables. In case of binary variables and qualitative variables, a McNemar test and a symmetry test, respectively, are applied. The time to event for BV recurrence is analyzed using Kaplan-Meier curves.

The statistical tests for secondary objectives are chi-square and McNemar tests for categorical data. Moreover, a nonlinear mixed effects model analysis is applied.

All tests are 2-sided, with a nominal level of α=5%. In the primary outcome analysis, P values are not adjusted for multiplicity. Statistical analyses are carried out using SAS 9.2 (SAS Institute Inc).

Evaluation Outcomes

Primary Outcome

RBV identified by the Amsel criteria [14] is the primary outcome. The diagnosis requires that 3 of the following 4 criteria are met: (1) vaginal secretion pH greater than pH 4.5; (2) proportion of clue cells ≥20% of total epithelial cells on microscopic examination of the vaginal saline wet mount; (3) off-white and thin vaginal discharge with minimal or absent pruritus and inflammation of the vulva and vagina; and (4) fishy odor on a whiff test.

XSL•FO
RenderX

The Amsel test is considered negative (no diagnosis of BV) when no or only one criterion is met. If 2 criteria are met at baseline, the test is considered unclear, and adopting a conservative approach, the patient is not included. When 2 criteria are met in the final visit, treatment failure is declared.

The Amsel criteria are analyzed by investigators according to the following parameter characteristics:

- Color (off-white, white-grey, or milky) and type (thin and homogeneous) of the vaginal discharge: The investigator performs a direct evaluation of the vaginal secretion.
- Vaginal pH: It is evaluated by investigators using pH paper (Merck) with a range of 4.0 to 7.0. The paper is placed on the lateral vaginal wall to avoid contact with the alkaline secretion of the cervix. Alternatively, pH is evaluated by putting the paper on a swab.
- Whiff test: A sample of the vaginal discharge is placed on a glass slide or in a test tube, and a drop of 10% potassium hydroxide (10% KOH) is added to evaluate the presence of a fishy odor caused by the release of amine.
- Clue cells: Clue cells are checked in local laboratories. A vaginal smear of each patient is collected at the clinical center and sent to the local laboratory. Two drops of vaginal discharge are covered with a coverslip and examined using a phase-contrast optical microscopy technique. Clue cells are identified as vaginal epithelial cells with such a heavy coating of bacteria that the peripheral borders are obscured. The test is positive if microscopic examination of the vaginal saline wet mount shows the presence of clue cells and if the proportion is greater than 20%.

The primary outcome is measured at baseline (day 0), 30 days after discontinuation of PLGG treatment (day 78 [±6 days]), and at the end of follow-up (month 10 [±2 months]). Additional measurements for the primary outcome are performed at unscheduled visits. This is carried out whenever patients report symptoms of RBV to the investigator. The percentage (%) of RBV is calculated considering both the primary outcome results (recurrence of BV identified by means of the Amsel criteria) and the treatment failures reported in the unscheduled visits.

Secondary Outcomes

The secondary outcomes are listed and detailed in Table 3.

The secondary outcomes also include the patient global evaluation of performance using a 4-point scale as follows: 1=very good improvement; 2=good improvement; 3=moderate improvement; and 4=negligible improvement.

Safety is evaluated by collecting and analyzing the data on adverse device effects/serious adverse device effects/unanticipated serious adverse device effects and adverse events/serious adverse events during the study period and by globally assessing the safety according to the investigator, using an analogic 4-point scale as follows: 1=excellent; 2=good; 3=fair; and 4=poor.

All secondary endpoints are measured at baseline (day 0) and 30 days after discontinuation of PLGG treatment (day 78 [±6 days]). Only vaginal lactobacilli microbiota is also assessed at the end of follow-up (month 10 [±2 months]).

XSL•FO
RenderX

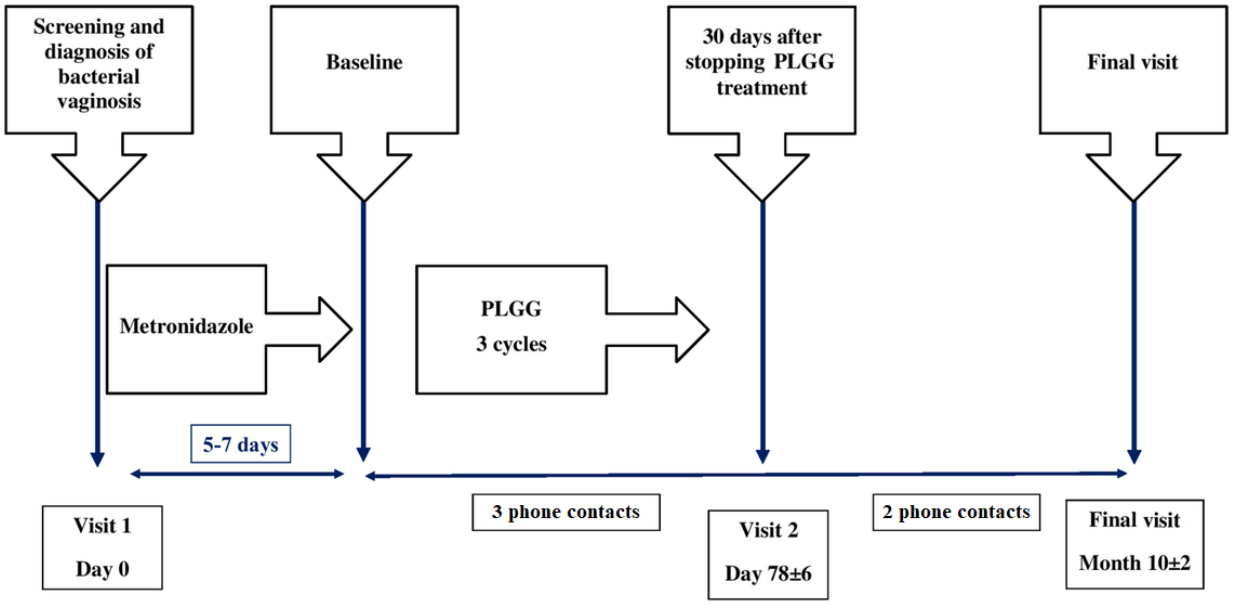
Table 3. Secondary outcome details.

Outcome and score	Evaluation
Vaginal lactobacilli microbiota	
+1 or +2 (normal)	Numerous pleomorphic lactobacilli, and no other bacteria, clue cells, or hyphae. Lactobacillary grade I or IIa.
+3 (partially impaired)	Population of lactobacilli is severely decreased. Lactobacillary grade IIb.
+4 (pathological)	Lactobacilli are severely depressed or absent because of overgrowth of other bacteria, clue cells (>20%), or hyphae. Lactobacillary grade III.
Vaginal discharge (over the last 24 hours)	
0	Not present or physiological with regard to quantity, color, and type (white, thin, and flocculent)
1	Mild abnormal (abnormal quantity with normal color and type)
2	Abnormal quantity, color, and type (white curdy, or thin, greyish, white homogeneous)
Burning (over the last 24 hours)	
0	Not present
1	Mild
2	Moderate
3	Severe
4	Unbearable
Erythema	
0	No symptoms
1	Slight
2	Moderate
3	Marked
4	Very marked
Dyspareunia	
0	Absent
1	Present

Study Procedures and Visits

Prior to any procedure of the trial, each patient is informed about the purpose and nature of the study, the potential risks, and the benefits, and is requested to provide consent by signing an informed consent form. Before starting the follow-up period, the patient is required to sign an additional informed consent form detailing the second part of the study.

The visits planned during the study period (Figure 1) are as follows: visit at day 0 (baseline), visit at day 78 (±6 days; 30 days after discontinuation of PLGG treatment), and visit at month 10 (±2 months; end of the follow-up period).



Phone calls with the patient are also planned as follows: first phone contact at 28 (±1) days after the last day of the last menses, second phone contact at 28 (±1) days after the first phone contact, third phone contact at 28 (±1) days after the second phone contact, fourth phone contact at the fourth month of follow-up, and fifth phone contact at the seventh month of follow-up.

During any phone contact, the investigator checks if the patient has BV symptoms, and if present, an unplanned visit is scheduled to confirm the diagnosis of BV based on the Amsel criteria.

The study timeline is presented in Table 4.

[a]Visit window range.

[b]BV: bacterial vaginosis.

[c]PLGG: polycarbophil, lauryl glucoside, and glycerides.

[d]Each cycle of PLGG has a duration of 1 week as follows: 1 ovule is inserted in the vagina on day 1, 1 ovule is inserted on day 4, and 1 ovule is inserted on day 7.

Results

The recruitment of patients started on September 8, 2016 (first patient and first visit). An interim analysis was conducted in 2019, which has already been published [16], and the results of the full study analysis should be available in July 2023.

Discussion

Gardnerella vaginalis is able to adhere to and displace precoated protective lactobacilli from vaginal epithelial cells, while other BV-associated anaerobes, such as *Fannyhessea vaginae* and *Prevotella*, are less active [20]. Consequently, the current paradigm is that the establishment of the biofilm of *Gardnerella vaginalis* is a required event for the initiation and progression of BV. Since the bacteria within biofilms are not effectively eliminated by the immune system or fully destroyed by antibiotics, biofilm-related infections tend to persist, and thus, not surprisingly, BV tends to have a high rate of relapse and recurrence [5]. PLGG has a specific bacteriostatic action, which inhibits *Gardnerella vaginalis* growth, and its mucoadhesive property could impair the formation of the biofilm produced by these bacteria. The PLGG constituents have important effects on the mechanism involved in the pathogenesis of BV.

In addition, the acidifying effect of PLGG on vaginal pH (favoring the growth of lactobacillus microbiota and maintaining a hostile environment for vagina recolonization by BV polymicrobial flora) could play a key role in improving the microbiological parameters over a long period.

We believe that the findings of our study could be useful for other investigators who want to test different products against RBV using a standardized protocol and standardized procedures. Regarding this, it would be interesting to collaborate with other investigators to test, using the methodology applied in this study, antibiotic therapies indicated in international guidelines [6,21] that are different from metronidazole, as well as other products to replace PLGG. Finally, it could be extremely challenging to conduct our study in geographical regions other than Europe (such as Asia or Africa) or in climatic situations radically different from the continental climate of Romania. In fact, seasonal patterns of abnormal vaginal microbiota have been recently reported in the Burkina Faso population [22], and treatment with oral metronidazole is often ineffective in African women [23].

The absence of an untreated control group represents the main limitation and weakness of the study, but we believe that it is unethical to choose patients experiencing two or more episodes of RBV as an untreated control group. In the near future, when the results of this study are analyzed, we will individuate the proper power of PLGG, and using this information, we will calculate the sample size for a comparative study involving PLGG versus a comparator (ie, a different treatment able to prevent RBV).

The Amsel criteria as originally reported [14] state the presence of clue cells on wet mount microscopy as 1 of the 4 criteria for the diagnosis of BV. The FDA guidelines [24] require not only that clue cells be present, but also that their proportion be greater than 20% of total epithelial cells. This is the clinical practice of the 5 centers involved in the study and is therefore reported in the study protocol, even though it may underestimate RBV cases.

Acknowledgments

Effik SpA (Italfarmaco group), the study sponsor, offered the tested medical device and partial grant support. The funder had no role in the design of the study; in the collection, analysis, or interpretation of data; in the writing of the manuscript; or in the decision to publish the results. We thank Adrian Bratu for support in data management and Marius Ardelean for assistance in statistical analysis.

Data Availability

The full protocol of the study has been deposited at protocols.io [25]. In addition, the data sets analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

Conceptualization, FM; methodology, FM and DFB; formal analysis, FM and SR; investigation, FM, PI, MB, DS, and CDC; writing-original draft preparation, FM, FS, SR, and DFB; writing-review and editing, FM and DFB; visualization, SR; supervision, FM; project administration, DFB, MM, LIA, and EC. All authors have read and agreed to the published version of the manuscript.

Conflicts of Interest

FM, PI, MB, DS, SR, and CDC declare no conflicts of interest. DFB and FS are employed at Opera Contract Research Organization, the Contract Research Organization that managed the study; EC is a medical consultant for Italfarmaco SpA; and LIA and MM are employed at Italfarmaco SpA.

Abstract

Background: Substance use among adolescent girls is associated with numerous risk characteristics, including engaging in sexual risk behaviors, which can lead to HIV and sexually transmitted infection (STI) diagnoses. This is an important phenomenon to target as there is a significant race-gendered paradox that occurs when Black girls use and misuse drugs. When misuse occurs among this group, they are more likely to face harsher consequences and worse health outcomes than boys and other ethnic-minority girls. Therefore, there is a need to understand the risk and protective factors of drug use and sexual risk behaviors among Black girls and develop a robust intervention that can cater for this group.

Objective: We propose the development of a strengths-based prevention education intervention for Black girls between the ages of 13 and 18 years to promote protective factors.

Methods: A sequential, mixed methods study will be conducted, and we will use the first 3 steps of the ADAPT-ITT (assessment, decision, adaptation, production, topical experts, integration, training, testing) framework to begin the development of the intervention. Three aims will be described in this protocol. First, aim 1 is to explore sociocultural risk and protective factors among Black girls between the ages 13 and 18 years in drug use and HIV/STI prevention using focus group methodology and surveys. We will conduct at least 10 focus groups to include up to 75 Black girls or until we reach saturation. Our target sample size for the quantitative portion of the study will be 200 participants. Aim 2 will focus on deciding upon an intervention based on findings from aim 1 and forming a youth advisory board to guide intervention development. Aim 3 will be to conduct a pretest of the intervention with the youth advisory board to determine if the intervention is feasible and will be accepted by Black girls.

Results: The study is part of a 2-year research pilot study award from the National Institutes of Mental Health. Data collection for this study began in October 2021. For aim 1, data collection is 95% complete. We expect to complete all data collection for aim 1 on or before May 30, 2023. Study activities for aim 2 are occurring simultaneously as data are being collected and analyzed and will be completed in the summer of 2023. Study activities for aim 3 will begin in the fall of 2023.

Conclusions: This study will be one of the few interventions that address both sexual health and drug use together and cater to Black girls. We anticipate that the intervention will be beneficial for Black girls across the nation to work on building culturally appropriate prevention education and building peer social supports, resulting in reduction or delayed substance use and improved sexual health.

Introduction

Despite substantive literature on the relationship between adolescent drug use and sexual risk behavior, gaps in prevention research may continue to place Black girls between the ages of 13 and 18 years in the United States at risk. Historically, girls of all racial and ethnic groups in the United States have had lower drug use rates than boys [1]. However, over the past decade, the prevalence of smoking cigarettes, drinking alcohol, and using illicit drugs such as marijuana has increased among adolescent girls, and specifically increased as they get older [2,3]. In the past decade, Black girls have begun to engage in substance use more frequently and at rates similar to their male counterparts [2]. This is concerning because drug use among adolescent girls is linked to a variety of risk factors, including engaging in sexual risk behaviors [4,5]. According to the 2019 Centers for Disease Control and Prevention Youth Risk Behavior Survey, while cigarette use is almost nonexistent for this group, 38.6% of Black girls admitted to using electronic vapor products, with 17% of them using within the past 30 days. Similarly, 37% of Black girls in the study used marijuana, with 24.8% using marijuana within the past 30 days [2]. The rates of marijuana among Black girls have also increased significantly from early to late adolescence [6,7]. Black girls may face a significant "gender paradox" where although they are less likely to use substances than boys and other ethnic-minority girls, they tend to face more negative health consequences from use [8].

Black girls are more at risk of being persuaded to engage in sexual risk behavior such as drinking alcohol or using drugs before having sex, having sex without a condom, and having multiple sexual partners than their White counterparts [9]. These behaviors may be the direct consequence of belonging to multiple marginalized groups (eg, race, ethnicity, class, and gender), resulting in intersecting multiple levels of oppression [10]. Such behaviors may arise from the historical and contextual factors of trauma, gendered racism, and sexual exploitation that are pervasive in the lives of Black girls [11-13]. Lack of discussion and knowledge of HIV/AIDS prevention strategies, limited or nonexistent community-based preventive resources, and gender- and racial-specific behavioral interventions in urban, underresourced communities can significantly contribute to increases in sexual risk behaviors [14,15]. Sexual health disparities and drug misuse that affect Black girls not only produce poor health outcomes but can also contribute to educational inequities [16], increases in school suspension rates [17], criminal involvement [18], income inequality [19], and sexual victimization [20].

The multiple marginalized identities of Black girls place them at increased risk of early sexual debut (ie, having sex at or before the age of 14 years), making them more susceptible to condomless sex and having partners that encourage sexual risk behaviors and making them more likely to be sexually abused, which increase their risk for HIV and sexually transmitted infections (STIs) [14,21]. In one study, the authors found that among sexually active Black girls between the ages of 14 and 19 years, 48% were diagnosed with at least 1 sexually transmitted infection [22]. Being diagnosed with an STI places individuals at an increased risk of contracting HIV [23]. In addition, adults living with HIV/AIDS are more likely to engage in risky sexual behavior during adolescence [24]. As Black women currently represent 61% of women living with HIV/AIDS [25], it is crucial to intervene with Black girls in order to provide them with prevention strategies that can be used as they transition into adulthood.

Although HIV and drug abuse prevention initiatives for adolescents exist, many are homogeneous, aim to be generalizable in nature, and do not consider unique racial and gender differences in risk and protective factors [26]. Furthermore, there are very few integrated HIV and drug abuse prevention interventions for Black girls [27]. As age can limit mobility geographically, which may then contribute to the further marginalization of Black girls due to limited power and dependency on others [28]. Multiple contextual factors that are present in the lives of Black girls are often ignored, thus leaving many strategies that are embedded in prevention interventions, such as educational components that do not center the lived experiences of Black girls, not helpful for this group [27]. Researchers have called for HIV and drug use prevention research that uses an intersectional framework to examine how multiple identities interact to have an impact on attitudes and behaviors [29,30].

This study protocol is describing the formation of a mixed methods study called "The Dreamer Girls Project," which will first understand the challenges and protective factors present in the lives of Black girls related to substance use and sexual health and then use the findings to develop a strengths-based prevention intervention. The study team will work collaboratively with a youth advisory board and use formative data collection to inform the development of the intervention. The study aims are shown in Textbox 1.

This study has the potential to provide new information about risk and protective factors for Black girls and strengths-based strategies that can be infused in HIV, STI, and drug use prevention for Black adolescents between the ages of 13 and 18 years.

RenderX

Textbox 1. Study aims.

- Aim 1: Understand sociocultural risk and protective factors among Black girls between the ages 13 and 18 years in drug use and HIV/STI prevention using focus group methodology and surveys.
  - Aim 1a: Quantify the prevalence rates of drug use and behaviors associated with HIV risk among Black girls aged 13-18 years.
- Aim 2: Decide upon an intervention based on findings from aim 1 and form a youth advisory board to guide intervention development.
- Aim 3: Assess the feasibility of the intervention through theater testing.

Methods

Conceptual Framework

The study will use intersectionality theory as a theoretical framework to guide the formative phase and overall development of the intervention [31-33]. Our usage of intersectionality theory will incorporate a culturally relevant perspective that includes the voices of Black girls, allowing them to redefine themselves, include discussions around protective factors that they themselves perceive as beneficial in their lives, and celebrate supportive structures that nurture their ability to be resilient. An intersectional perspective, therefore, provides a unified lens through which to view health disparities and develop interventions that are more responsive to race, ethnicity, gender, age, and class [28]. Intersectionality functions as a framework in this study to understand the experiences of Black girls, who possess a different social location than Black women based on their age and cognitive and psychological development. In addition, because an intersectional perspective can be strengths based, it moves the blame away from individual behaviors to systemic and contextual factors that have historically placed Black girls at risk. The framework considers the cultural and historical context of Black girls that influences their susceptibility and exposure to drug use and sexual risk behaviors, as well as highlights the significance of systemic racism, classism, and misogyny within the United States as contributing factors to their exposure. Such a framework has been useful not only in designing and guiding social programs but also in developing ethnic, racial, gender, and class-responsive research for girls. It is to be acknowledged that Black girls are not a homogenous group, which means that significant within-group differences will exist. Therefore, the use of intersectionality theory as a framework allows for our study team to account for those differences in order to make interventions more appropriate to the experiences of Black girls [31].

Study Design

We will conduct an exploratory, sequential mixed methods study. The protocol is registered on ClinicalTrials.gov (NCT05014074) and was approved by Yale University Institutional Review Board.

Eligibility

Adolescent girls who identify as (1) Black, (2) identify as female, (3) are between the ages of 13 and 18 years, (4) can speak and understand English, and (5) live in the United States will be allowed to participate in this study.

Ethics Approval

All procedures performed in studies involving human participants are in accordance with the ethical standards of the institutional and national research committee, the 1964 Helsinki Declaration and its later amendments, or comparable ethical standards. The study was funded by the National Institute of Mental Health (R25MH087217) and approved by the Yale University Institutional Review Board in 2020 (IRB-2000026660). Due to the sensitivity of the research questions, we requested that written parental consent be waived for the young participants. All youth who participate in the study (including focus groups and completing surveys) will receive a youth information sheet and parents and guardians will receive a parent information sheet. Youth must give verbal consent in order to participate in the study. We will obtain informed consent from all girls who meet the eligibility criteria and want to participate before they are enrolled in study activities.

Recruitment

Purposive sampling for focus group recruitment will be used to ensure a representation of different subgroups of Black girls. The research team has relationships with community-based organizations in New Jersey and organizations that serve Black girls across the nation. Flyers will be given to program administrators at these organizations to disseminate to interested participants. Flyers for the recruitment of focus groups will also be posted on social media sites such as Facebook, Instagram, and Twitter. All girls who are interested in being a part of the focus groups will have to complete an eligibility form on Qualtrics (Qualtrics International Inc), which will ask for demographic information and contact information. Only girls who identify as Black and female, are between the ages of 13 and 18 years, and live in the United States will be allowed to participate. Research staff will contact eligible participants and will inform them of the purpose of the study and will screen them to confirm that they are eligible to participate based on inclusion criteria. Potential participants will be told that all data will be kept anonymous and confidential and that a monetary incentive of US $30 will be provided for participants who complete the focus group. Potential participants for the qualitative component of this study will also be informed that their responses to questions will be recorded. Upon confirmation of their desire to participate, they will be given a date, time, and Zoom (Zoom Corp) link if web-based or a physical location if appearing in person. The institutional review board has approved this study and agreed to waive parental consent due to the sensitivity of the topic. Youth assent will be obtained verbally. All youth and parents and guardians will be provided an information sheet regarding their daughter's participation in the

XSL•FO
RenderX

study. All participants and parents and guardians of participants younger than 18 years will be told that they can opt out at any time during the study. Community organizations who are able to provide us with space for in-person focus groups will receive honorariums. Recruitment for survey data collection will involve sharing the survey link on various social media platforms and community organizations that serve Black girls. Only girls who identify as Black and female, are between the ages of 13 and 18 years, and live in the United States will be allowed to complete the survey. All participants who completed the survey were compensated with a US $10 gift card.

Procedures

A semistructured interview guide using intersectionality theory will be developed to explore drivers of substance use, social supports necessary to promote the prevention of substance use and supports necessary to reduce HIV risk behaviors. The study principal investigator (PI) and first author of the protocol (IO) is an expert in using intersectionality theory as a framework for studies involving Black girls. More specifically, the study PI has published studies that used intersectionality theory as a framework in analyzing quantitative and qualitative data [10,34,35] and teaching courses using an intersectionality framework [36]. After the interview guide was developed, another expert who serves as a coauthor of this protocol (KB) will review and revise the guide to ensure that questions use an intersectionality framework. KB is an expert on intersectionality theory and qualitative methodology with Black cisgender and transgender girls and women. Collectively, the study team including the study PI, who has several years of experience in designing studies for Black girls, will develop questions to ensure that girls across the development age span of 13 to 18 years would be able to understand the questions.

Data collection will involve in-depth focus groups to be conducted in a group setting at a community partner's location sites (mainly in New Jersey due to the study team's relationships with New Jersey–based community organizations) and web-based groups will be conducted on Zoom. Research in web-based settings has been increasing due to the COVID-19 pandemic and may continue to be a major platform to connect with participants. Research conducted in web-based settings has been established as effective venue for research on multiple content areas [37]. Efforts will be made to place participants into groups that are separated by demographic variables such as age or religion (ie, aged 13-15 and 16-18 years) as it is recommended to group individuals with similar life experiences for optimal focus group dynamics. Each focus group will be audio recorded, transcribed by trained research assistants, and entered into NVivo 11 (QSR International), a qualitative data analysis software package. Focus groups will aim to uncover how Black girls view substance use and sexual risk behavior in their community. Questions that will be discussed in the focus groups are (1) How do race, gender, and class impact views on drug use and sexual risk behavior among Black girls? (2) How do Black girls view their identity and expectations that they perceive from society? (3) What are the risk factors of engaging in drug use and sexual risk behavior that are specific to Black girls? (4) What are protective factors and what do they look like? and (5) What would a successful prevention intervention look like for Black girls in various communities? While 3 or 4 focus groups are recommended for saturation [38], we aim to conduct at least 10 focus groups or until no new data emerge from focus group discussions.

Training of Interviewers

Interviewers will be research staff who identify as Black women, trained by a qualitative methodology expert (KB) on how to engage and conduct focus group interviews with Black girls. The training will involve discussions around being aware of power dynamics that may emerge during the interview in order to facilitate the focus groups effectively. In addition, interviewers will be challenged on assumptions and biases that they may have of Black girls in order to assure that data collection is conducted in an objective and respectful manner that honors Black girls. All facilitators and cofacilitators must identify as Black women, as there is evidence of the importance of racial and gender matching when conducting research with vulnerable and marginalized groups such as Black girls [39].

Data Analysis

Aim 1: Understand What Environmental and Sociocultural Factors Influence Drug Use and Sexual Risk Behavior Among Black Girls

Aim 1a. Determine Prevalence Rates of Substance Use and Sexual Risk Behaviors Among a Sample of Black Girls

Within this aim, we will use a sequential exploratory study design [40] to understand risk and protective factors that are specifically mentioned by Black girls through engaging in mixed methodologies. Sequential exploratory design is used when a study team wants to follow-up or explains qualitative findings with quantitative analysis. This 2-phase approach is particularly useful for our study as we are interested in understanding the unique perspective of Black girls and want to develop an intervention catered for this population.

First, we will use focus group methodology, which will allow the study team to receive insight from Black girls themselves about what they perceive as the challenges but also strengths that may be present in their environments, families, and communities involving drug use and sexual health. Focus group methodology is useful in this phase as it not only provides a rich source of data but also allows the researcher to examine the interaction among participants [41]. We will aim to conduct at least 10 focus groups, with a goal to obtain a sample size of 75 Black girls or until data saturation is reached. We acknowledge that this is a large sample size. However, since we will be interviewing Black girls from across the nation, we believe that having a large sample size will give us richness in the data and allow us to explore differences and similarities across the groups.

After focus groups are conducted and before the analysis begins, facilitators of the focus groups will participate in debriefing meetings. These meetings will provide a space for facilitators to process each focus group and discuss possible issues of countertransference that may have occurred. This is necessary as we want to minimize any potential to influence the results of the study. In addition, the debriefing meetings provide

XSL•FO
RenderX

facilitators the space to discuss their feelings and emotions that arose during the groups. The data analysis team will include at least 3 research assistants and the study PI who has experience in analyzing qualitative analysis and leading qualitative studies. To establish confirmability the research team will code all of the transcripts. Data will be coded using NVivo version 11. Data from the interviews will be first analyzed by interviewers using open coding, whereby concepts were identified and labeled as they emerged from the data and across the focus groups. Each member of the research team will read and reread all the transcripts and develop initial codes in isolation. During weekly research meetings, the initial codes will be reviewed and discussed. Using multiple coders provides insight into finding consistency and minimizing researcher bias [42]. The team will triangulate codes, notes, and memoranda of analyses until >95% substantive agreement is achieved. Prevalent codes (based on the frequency in which a code is used by participants across and within groups) will be grouped by similarity and relevance into themes and subthemes. To increase the rigor of the study, the researchers intend to use prolonged engagement, regular team debriefings, and member checking with participants [43]. Participants of the focus groups will be asked if they are interested in being a part of the youth advisory board. The youth advisory board will be developed for the sole purpose of confirming the findings and developing the intervention. We will aim to recruit 8-10 youth upon completion of the qualitative portion of the study.

Aim 1b: Quantitative Data Collection

Based on the findings from the qualitative focus groups and the use of a sequential exploratory study design, data will be analyzed rapidly [44] and inform the development of the survey that will be administered to Black girls. In order to accurately perform rigorous statistical analysis tests such as structural equation modeling, we proposed a sample size of 200 girls as performing structural equation modeling on data requires a sample size of at least 150 [45]. We anticipate including standardized measures such as 30-day drug use and sexual risk behavior measures, adapted by the Centers for Disease Control and Prevention Youth Risk Behavior Survey [2]. In addition, we will include measures pertaining to ethnic identity, sexual orientation racial discrimination, and gender identity.

Aim 2: Decide Upon an Intervention Based on the Findings From Aim 1 and Form a Youth Advisory Board to Guide Intervention Development

Because the goal of this study is to obtain information from Black girls in order to develop an intervention for them, we will use an implementation science framework that centers the voices of participants. We will use ADAPT-ITT (assessment, decision, adaptation, production, topical experts, integration, training, testing) [46], an implementation framework that has been commonly used to adapt HIV interventions. The ADAPT-ITT model involves eight steps: (1) assessment of priorities, (2) decisions on adapting, (3) administration of intervention, (4) production of adapted version, (5) topical experts, (6) integration of feedback from topical experts, (7) training staff to implement, and (8) testing the adapted intervention. Because of the nature and funding restrictions of this pilot study, we will only complete the first 3 steps.

For aim 1, the assessment step requires researchers to obtain a comprehensive understanding of the target population. Next, for aim 2, a youth advisory board of 8-10 Black girls will be formed and will select the interventions that they will decide to adopt or adapt. The decision phase will be guided by themes that arose from the focus group and quantitative findings, in order to assure we will be choosing interventions that best meet the needs of Black girls. Our youth advisory board will first be presented with common HIV prevention interventions catered toward Black girls and women such as SiHLE (Sistering, Informing, Healing, Living, and Empowering) [47] and will be asked to vote on each of their strengths and weaknesses. We will then work with our study team, guided by the youth advisory board to either modify components of a particular intervention or create our own intervention. The study team has conducted a systematic review of the most commonly used HIV and drug use interventions that include large samples of Black girls and has expertise in the various components of interventions for this group [27].

Aim 3: Assess the Feasibility of the Intervention Through Theater Testing

Using the ADAPT-ITT framework, we will enter into step 3, which is the adaptation phase. This phase involves using an innovative pretesting methodology known as theater testing to adapt the evidence-based intervention that the study team and youth advisory board decide upon. Theater testing is a type of pretesting methodology that is commonly used to test products, such as television advertisements, videos, print advertisements, and public service announcements [48]. Using this methodology, participants, which will be the youth advisory board, will be invited to laboratory or community site to respond to a demonstration of a product (ie, of the adapted intervention). At the end of the demonstration, participants will receive a questionnaire and answer questions designed to gauge their reaction to the product. An important strength of this methodology is the opportunity to obtain reactions to messages, concepts, and visual materials in a relatively short period. Furthermore, this methodology closely resembles what is experienced by the target population; thus, an accurate assessment of their reactions to the product can be obtained.

Results

The study is part of a 2-year research pilot study award that received funding from the National Institutes of Mental Health. Data collection for this study began in October 2021. The remaining year will focus on completing data collection, analysis, and dissemination and developing the intervention components. We have published 1 manuscript based on the formative work for the development of this intervention, which was a systematic review of sexual health and drug use prevention interventions for Black girls [27]. Moreover, data collection for aim 1 is 95% complete. We expect to complete all data collection for aim 1 on or before May 30, 2023. Recruitment for aim 2 will begin in the summer of 2023.

Discussion

Anticipated Findings

The goal of this study is to understand the lived experiences of Black girls and obtain information that can be used to develop and pilot a race-specific intervention for this group. We anticipate that having Black girls co-design this intervention with the research team will have great potential to facilitate healthy behaviors and challenge negative stereotypes that impact Black girls' decision-making over the course of the study and thereafter. This study has the potential to transform the way researchers work with Black girls and cocreate in order to develop sustainable solutions toward ending the HIV epidemic and addiction. The development of racial- and gender-specific intervention specifically for Black girls is essential, and developing interventions specific to a certain demographic has proven to produce successful results in health-promoting behaviors. For instance, one HIV prevention intervention tailored to the experiences and needs of Black women in Atlanta, Georgia was assessed for efficacy at improving condom use after 1 session. The authors found that at the 6-month follow-up women who participated in the session reported more frequent condom use and recent HIV screening [49]. Gender- and racial-specific interventions often move beyond individual risk behaviors and focus on social, environmental, and political influences on the well-being of women and girls. Specific focus on racial and gender pride, healthy relationships and healthy sexuality, reproductive justice, sexual communication, and empowerment around sexual refusal are just a few key aspects of effective interventions for Black women that may be tailored to Black girls [50]. The findings of this study will assist with identifying the elements of HIV prevention interventions specific to Black girls that can be applied broadly in the area to improve sexual health and HIV and STI prevention broadly. Given the current climate, interventions that address key factors such as racism, ethnic identity, and gendered racism must be integrated with intervention efforts for adolescent girls.

Limitations

This is a formative sequential exploratory study design using mixed methods (qualitative data, cross-sectional survey data). A limitation of this study is that data will be collected via self-report and subject to response bias.

Conclusions

The Dreamer Girls Project lessons learned will aim to provide real-world contributions to implementation science regarding the uptake of a combination of evidence-based prevention interventions guided by Black girls. The evidence from this study will be used for the preparation of a feasibility trial and a more robust and larger HIV, STI, and drug use prevention clinical trial specifically for Black girls.

Abstract

Background: The introduction of self-administered injectable contraception presents an opportunity to address the unmet need for family planning. As ministries of health scale up self-administered injectable contraception, there is a scarcity of knowledge on the implementation practices and contextual conditions that help and hinder these efforts. The World Health Organization has launched the “enhancing self-administered family planning through embedded research project” (EASIER) to address this challenge.

Objective: EASIER’s objectives are to: (1) assess the coverage of self-injectable contraception, and the readiness of health systems to integrate it into the contraceptive method mix; (2) document strategies used to introduce and scale up self-injectable contraception and understand practices that have led to success and challenges; (3) identify the contextual factors that affect the adoption and implementation of self-injectable contraception throughout health systems; (4) understand whether implementation addresses users’ preferences and needs; (5) strengthen collaboration between decision makers, researchers, and implementers; support and build capacity to use evidence.

Methods: EASIER developed a global protocol that implementation research (IR) teams in Burkina Faso, Ghana, and Kenya adapted into country-level embedded IR projects. In all countries (1) at the national level, IR teams evaluate the policy environment for scaling up by conducting a desk review and in-depth interviews; (2) at the local level, IR teams implement quantitative questionnaires on structural and organizational readiness to integrate self-injection into the method mix; (3) in “case study” localities, IR teams conduct in-depth interviews and focus group discussions with implementers, method users, and community members; and (4) IR teams use participatory action research to elicit stakeholder participation and translate findings into programmatic decisions.

Results: EASIER has been launched in all 3 countries. Preliminary findings are available from Burkina Faso and Kenya. In Burkina Faso, IR teams identified the need to strengthen health worker training approaches to ensure that family planning providers at primary health care facilities are adequately oriented to depo-medroxyprogesterone acetate subcutaneous (DMPA-SC) and self-injection and capacitated to initiate women to the method. In addition, they report the need for service communication strategies that reach potential users of the method with knowledge about self-injection and how to initiate the practice. In Kenya, the findings illuminate the need for practice guidelines that county health teams can use to coordinate the rollout of self-administered DMPA-SC. In addition, Kenya’s findings underscore the importance of addressing logistical bottlenecks to help avoid stock-outs.

XSL•FO
RenderX

Conclusions: EASIER presents a strategy to embed IR in contraceptive method introduction and scale-up, address local knowledge needs, devise ways to maximize the impact of new technologies in health systems, and build capacity for using evidence in programmatic decisions. Adaptation and implementation of country-level IR studies will advance the use of IR to strengthen family planning programs.

Introduction

Overview

In recent years, self-care interventions have received attention in the global health community because of their unique potential to alleviate constraints on individuals' access to services and the pressure of increased service use on health systems [1]. Self-care encompasses manifold strategies that emphasize the needs and abilities of individuals, families, and communities to promote health, prevent and control disease, facilitate self-medication, provide care to dependent persons, rationalize the use of formal health care services, and facilitate rehabilitation [2,3]. In doing so, self-care can empower vulnerable communities to go beyond conventional health system responses and meet their needs despite health care worker shortages, humanitarian conflict, disease outbreaks, geographic barriers, and rising out-of-pocket health expenditures [4].

Unintended pregnancy, resulting from the unmet need for contraception, threatens the lives and well-being of girls and women globally. An estimated 214 million women in low- and middle-income countries (LMICs) have an unmet need for a modern method of contraception, and over half of these women live in sub-Saharan Africa and South Asia. According to the Guttmacher Institute, if all such women's demand for contraception were satisfied, there would be a 75% decline in unintended pregnancies and 76,000 fewer maternal deaths per year [5]. Since 2013, evidence on the potential of self-care approaches in family planning (FP) has emerged. It builds on the accumulation of lessons from studies that demonstrated the safety, effectiveness, and acceptability of a woman-centered intervention for increasing access to the most popular contraceptive method in sub-Saharan Africa, depo-medroxyprogesterone acetate (DMPA) [6]. DMPA subcutaneous (DMPA-SC) can be administered by trained persons, including users themselves [7]. In 2019, the World Health Organization (WHO) issued global guidelines for sexual and reproductive health self-care interventions, which encouraged member states to introduce self-injectable DMPA into the method mix and scale up access to the method throughout health systems [1].

Ministries of health (MOHs) in LMIC and FP stakeholders require knowledge on ways to harness the potential of self-care to improve the effective coverage, acceptability, and use of national FP programs and strategies to maximize the impact of self-injection for women. Guidance on scaling up access to new contraceptive methods has emphasized the need to embed research in introduction processes and support implementers to learn, adapt, and use new knowledge to improve how health systems incorporate new technologies and reach users with them as part of a broader method mix [8-10]. Facilitating these opportunities in health systems can help ensure that FP managers and practitioners have the knowledge, tools, and support necessary to promote self-care, integrate self-injection into the method mix, and assure its availability to populations consistently and in a manner that meets clients' needs. Implementation research (IR)—the systematic, scientific approach to determine how to get evidence-based interventions (EBI) to people who need it with greater speed, fidelity, efficiency, quality, sustainability, and relevant coverage—can help address this gap [11]. IR emphasizes collaboration between policy makers, decision makers, implementation teams, and local scientists who cocreate studies that are embedded in the reality of implementing organizations and address challenges to the optimal reach, delivery, and sustainment of EBI. Additional defining characteristics of IR are responsiveness to local demand for information and the positioning of research within planning and decision frameworks that use findings to improve services and systems [12].

In 2020, the WHO Department of Sexual and Reproductive Health and Research started the "enhancing self-administered family planning through embedded research" project (EASIER). EASIER is a global project which draws upon IR as a tool to help MOHs and their partners identify and evaluate programming strategies to best integrate self-injectable contraception into the method mix and support the spread of the method throughout health systems. The EASIER concept originated at the WHO based on requests from member states for support with monitoring and evaluating method introduction and scale-up. In 2021, EASIER launched an IR collaboration with partners in Burkina Faso and Kenya, and in 2022, it did so in Ghana. Although the EASIER approach emphasizes contextualization of IR studies to local conditions, across its applications, EASIER also emphasizes (1) partnerships between MOHs, local implementation teams, and local research institutions focused on identifying implementation challenges and positioning research within program processes; (2) building

XSL•FO
RenderX

capacity for data use and knowledge translation so that IR partners cocreate solutions to implementation challenges based on evidence; and (3) the dissemination of lessons learned within and across countries to help improve self-injection program implementation at scale.

To launch EASIER, the WHO developed a global protocol. The global protocol provides IR teams in different countries with common research questions, methodological guidance, and data collection instruments that they can adapt and use to facilitate systematic learning about introducing self-administered DMPA-SC and scaling up. The protocol adopts a focus on clarifying the programmatic strategies countries have used, the contextual factors that helped or hindered implementation, and the implementation challenges and outcomes that have arisen as a result. In addition, it includes guidance on how IR teams can parlay evidence generation into the design of strategies to address implementation challenges. To date, the protocol has been adapted by IR teams in Burkina Faso, Ghana, and Kenya to develop site-specific IR projects. The purpose of this paper is to describe the global protocol and, in doing so, promote opportunities for global FP stakeholders to embed IR into the rollout of new contraceptive methods, or other EBI, in health systems. In addition, the paper provides readers with access to EASIER's data collection instruments.

EASIER Global Protocol: Objectives, Theoretical Influences, and Teams

The global protocol lays out the following objectives for country-level IR teams to adapt in site-specific IR protocols:

1. Understand the coverage of self-administered DMPA-SC and the readiness of national and local health systems to integrate it into the contraceptive method mix.
2. Document strategies used to integrate self-administered DMPA-SC into the method mix, identify practices that have led to success and challenges, and obtain insight on why these did or did not work
3. Identify the contextual factors that affect the adoption and implementation of self-administered DMPA-SC throughout the health system, including service provision and user settings where the method is practiced.
4. Understand user perspectives on their demand for the method and the degree to which their preferences and needs are addressed through implementation.
5. Strengthen collaboration between decision makers, researchers, and implementers; support and build capacity to use evidence to plan and improve implementation.

To develop these objectives, the WHO synthesized elements from multiple theories and frameworks, notably Social Ecological Theory and the Consolidated Framework for Implementation Research (CFIR) [13,14]. The former, which has been applied in public health to understand health behavior change, purports that health behaviors take shape and change as the product of numerous factors that emanate from multiple levels of context and affect individuals independently and synergistically. To adapt this perspective to the study of health care systems, we blend it with the CFIR, a determinants framework that guides the study of evidence-based interventions in complex systems and why they succeed or fail. Combining these frameworks was appropriate for the EASIER global protocol, given that its goal is to understand how implementation outcomes related to introducing DMPA-SC self-administration in systems were shaped as a product of strategic implementation by actors from multiple levels of health systems (eg, community, facility, district management, and national policy) and its interaction with contextual factors which also play out at multiple levels of context. The global protocol also reflects insights from the Promoting Action on Research Implementation in Health Services framework to develop guidance on research use approaches related to objective 5 [15] (Figure 1).

The EASIER global protocol objectives reflect the need to integrate knowledge on the performance of EBI in health systems from multiple domains of program implementation, which, in the case of self-administered DMPA-SC, includes users themselves and the communities in which they are nested, as well as the need to support structures for collaborative learning, adaptation, and evidence use. Figure 2 illustrates how IR will guide efforts to integrate and support the spread of self-injectable contraception in health systems.

The research methods and procedures described in this paper are adapted into country-specific protocols in Burkina Faso, Ghana, and Kenya. To catalyze this process, staff from WHO global headquarters and country offices engage MOHs in selecting decision makers from national and local levels of health systems to serve as principal investigators (PI) of country-level IR. The role of the PI is to position the IR within policy and program implementation cycles, ensuring that research is integrated with processes used by ministries, local health management teams, and implementation partners to introduce self-injection into the method mix and scale it up. PIs have a prominent role throughout the research process, establishing partnerships with local research institutions with whom they work to identify specific implementation issues to address, select and adapt methodologies, oversee data collection, interpret results, and stimulate the use of findings in programmatic decisions. In other words, decision makers in the EASIER project are both "knowledge producers" and "knowledge consumers." In all countries, WHO country offices play a central role in helping to facilitate interactions between members of collaborative research partnerships and ensure that technical assistance is available to them when needed. See Table S1 in Multimedia Appendix 1, which describes the technical assistance that the WHO provides to in-country IR teams.

Methods

Study Environments and Design

The sections that follow describe the study design and data collection methods and procedures that are described in the EASIER global protocol. It calls for data collection to be carried out: (1) at the national level, where IR teams will evaluate the policy environment, assets, constraints, and processes for introducing and supporting the scale-up of DMPA-SC for self-administration; (2) at the local government level (eg, district, county, and provincial) in which MOHs have introduced DMPA-SC self-administration, where IR teams will assess implementation strength, service availability, and readiness to integrate the new method; and (3) in up to 6 “case study” districts (or counties and provinces) where IR teams will conduct in-depth qualitative research. The global protocol advises local IR teams on using maximum variation sampling techniques to select a geographically representative sample of districts for the qualitative case studies. Within each level of organization (national, case study county, and community), the research will sample individuals to participate in the study. The research will adopt a mixed methods design, including (1) qualitative methods at the national level and within case study countries to address objectives 1-4, that is, desk reviews of policy-related materials, in-depth interviews (IDIs) and focus group discussions (FGDs); (2) quantitative methods at the local government level in areas where governments’ have introduced self-injection to appraise implementation strength and readiness to integrate self-injection into the FP method mix (also objective 1); and (3) participatory action research (PAR) at the national level and within the case study counties to enable evidence use in programmatic decisions (objective 5).

XSL•FO
RenderX

Sampling and Procedures

Objective 1

Lessons learned from previous WHO guideline introduction activities in countries revealed that the absence of policy implementation guidance represents a chief barrier to the incorporation of WHO FP guidelines in member states' policy processes [16]. Other studies of evidence use in policy environments illuminate how this challenge plays out at the upstream stages of policy making and further downstream, where local health teams (eg, district health management teams) implement health policy [17]. To address these challenges, the EASIER global protocol describes methods IR teams can use to (1) understand the national-level policy environment for scaling up self-administered DMPA-SC at scale in countries and (2) gauge self-injection policy implementation at subnational (eg, district- and provincial-level) levels within countries. Regarding the policy environment, the study will use a policy analysis guide and IDI guide (see Instruments 1 and 2 in Multimedia Appendix 2). IR teams will use the former to review policies, guidelines, and other strategic documents relevant to the national policy and programmatic changes that were required to introduce self-injection into health systems. They will conduct IDI to understand more about the processes, arrangements, capacities, and resource considerations in relation to policy implementation generally and with respect to DMPA-SC self-administration, as well as participants understandings of the factors that have helped and hindered national-level efforts to introduce self-injection into the method mix. Researchers will first conduct the desk review and use the findings from it to customize lines of inquiry for the subsequent IDI. Purposive and snowball sampling approaches will be used to select the stakeholders for IDI. Before the interviews, stakeholders will be asked to supply IR teams with any documents relevant to the desk review that the latter were unable to obtain independently or through their professional networks. IDI participants will include MOH officials, FP experts, donor representatives, representatives from private sector nongovernmental implementing partners, private for-profit and private not-for-profit sector organizations, and health care professional organizations. For the IDIs, the sample size may vary across countries; however, the EASIER global protocol suggests that IR teams select 3 respondents from each of the 8 categories listed above (n=24). To be selected for IDIs, key informants will have to be involved with the DMPA-SC program and belong to any of the groups identified above. IR teams, in consultation with the MOH and WHO county offices, will draw a list of potential key informants from these groups. IDI informants will include those with knowledge of the reviewed documents and be available to clarify gaps in aspects of policies and pertinent issues that were not clear in the document review.

To help IR teams measure and compare across districts the degree to which local authorities have adopted and delivered self-administered DMPA-SC and the status of implementation, the EASIER global protocol has developed 2 instruments for local adaptation and use. The first is a coverage and structural readiness assessment (see Instrument 3 in Multimedia Appendix 3). In the districts (or counties) in which the government has authorized the rollout of self-administered DMPA-SC, IR teams will request leaders of local health management teams to complete this assessment, which asks for information on the availability of equipment, supplies, commodities, and infrastructure, human resources, health management information systems, supervision capacity, task shifting, community outreach, planning processes and support, financial resources, orientation to DMPA-SC guidelines, training capacity, etc. The second instrument is an organizational readiness for implementing change assessment (see Instrument 4 in Multimedia Appendix 4). For this, IR teams will enroll an additional 20 participants per implementing district (or county) to complete a questionnaire that elicits participants' perceptions of DMPA-SC self-administration, organizational culture, the existing evidence base on the EBI, the capacity of their organization to adopt self-injection as a part of the method mix and implement it, the commitment of the organization to implement it, leadership, management, and teamwork issues. Participants in this questionnaire may include district directors of health services, district reproductive health focal persons, officers responsible for supply chain, health information systems, and community health services, and private sector (ie, nongovernmental organization and private pharmacy) representatives involved in DMPA-SC.

Objectives 2 and 3

Despite their differences, all programs to introduce self-injection in primary health care settings have employed good practices and experienced challenges from which valuable learning can arise. Further, they are all subject to contextual influences that have helped or hindered programs' ability to effectively integrate and expand coverage of the new method. Understanding how these factors affect implementation effectiveness is needed to guide programmatic decisions to strengthen the scale-up of DMPA-SC self-administration in health systems. To address this information need, the EASIER global protocol provides IDI and FGD guides for IR teams to include in their qualitative case studies. These are integrated data collection tools that elicit data on the innovation characteristics and implementation strategies, whether they are effective or not, and why (objective 2), and explore how contextual factors at the district and community levels influence the DMPA-SC self-administration interventions (objective 3; see Instruments 5-8 in Multimedia Appendices 5-8). Participant selection will ensure representation of stakeholders from local health management teams, health facilities, other sectors, and communities whose insights will generate strategically relevant information on best practices, barriers and facilitators to effective implementation, and needs for adapting and enhancing interventions used to introduce and scale up the method. IR teams will purposively select district-level IDI participants, including district medical officers, reproductive health focal persons, district-level staff responsible for method procurement and supply chain logistics, health information, and community health services; representatives of nongovernmental organization involved with DMPA-SC; private sector clinicians and pharmacy workers that deliver the method; public sector health workers; and facility in-charges. At the community level, within each case study, the following groups of people will be purposively selected for the IDIs: community leaders, community health volunteers, influential men and

XSL•FO
RenderX

women from communities where self-injection has been introduced, and persons that volunteer for health activities in the community. To obtain insights on collective attitudes and beliefs about themes that emerged in IDI, IR teams will enroll groups of people from each category of participants that had participated in objective 2 and 3 IDIs at the county and community levels in FGDs. These will include public health care workers, staff from private sector venues, community leaders, and members. Among health care professionals, FGD will be segmented according to sector (public and private) and rank. At the community level, FGD will be segmented by sex. In each case study locale, IR teams are advised to conduct 20 IDIs and 3 FGDs. Each FGD should include no more than 8 participants.

Objective 4

Strategies to integrate new interventions into health systems are prone to failure if they are not optimized to address user attitudes and characteristics. Similarly, interventions that are not attuned to the realities of the wider social and cultural environment may not reach target populations effectively or change behaviors. Accordingly, the EASIER global protocol incorporates "demand-side" research. This component of the study aims at understanding the household, community, and sociocultural context of introducing self-injectable contraception, how these factors affect demand for the new method, and ways in which implementation can be optimized to address women's preferences and perceived needs. To obtain information from self-injection clients, the EASIER global protocol recommends that IR teams enroll 6 women per case study district in IDI that takes place 3 months after they initiated DMPA-SC self-administration (see Instrument 9 in Multimedia Appendix 9). The selection criteria for recruitment in these IDIs are that, upon their first interview, women were doing self-injection for the first time. IR teams should segment enrollment in these IDIs by age to ascertain a sample of an equal number of women younger than 25 years, 25-34 years, and 35 years or older, and complete interviews in private settings near participants' homes or the closest health care facility. Interviewers will ask participants to discuss their demand for contraception and the factors that condition it, the acceptability and accessibility of DMPA-SC self-administration services, their perceived needs from a FP program, whether their expectations and needs have been met, their satisfaction and experience with the method, and reasons for continuation, or discontinuation or method switching. The success of implementation also depends on the extent to which programs are attuned to the norms and realities of the communities targeted by interventions. Accordingly, the EASIER global protocol recommends IR teams to carry out FGD in case study locations with community members, such as opinion leaders, DMPA-SC users, spouses of DMPA-SC users, and religious leaders (see Instrument 10 in Multimedia Appendix 10). FGD will elicit from community members their perception regarding the compatibility between interventions used to introduce DMPA-SC self-administration and communities' shared beliefs, practices, and attitudes with respect to, for example, gender, religion, social relations, sexual and reproductive health, and the need for FP services. In addition, FGD will ask participants to reflect on the ways in which implementation can be adapted according to such factors, including influential social and communication networks that may influence the nature of demand for self-injection and FP services in general. The global protocol recommends that IR teams enroll 8 respondents per FGD in 3 FGDs per case study county.

Objective 5

The global protocol calls on IR teams to conduct PAR with study participants following the completion of Objectives 1-4 research and the analysis of preliminary findings. The purpose of PAR in EASIER is to engage participants in using evidence and translating findings into programmatic decisions toward improving the coverage, implementation, and sustainability of self-administered DMPA-SC services. The global protocol suggests that IR teams convene PAR at the national and case study levels and limit participation to individuals that were enrolled in IDI. IR teams are advised to conduct 2 PAR sessions at the national level: the first is a dissemination meeting of national stakeholders, which will involve those who participated in the national-level formative research (n=24) and up to 26 other relevant stakeholders from policy, programming, and donor circles (n=50); the second is a smaller meeting that will comprise of key national stakeholders (n=15) who will deliberate on findings and agree on implementation strategies to prioritize in the future. During PAR sessions at the national (session 1) and case study levels, IR teams will embed facilitators and rapporteurs in the large group of participants and break participants into small groups in which facilitators will guide discussions on the evidence, encouraging participants to brainstorm root causes of problems identified and understandings of why good practices were effective, rank and prioritize implementation issues that need to be addressed, discuss solutions, and recommend next steps for strengthening the introduction and scale up of DMPA-SC self-administration. Crucially, the case study-level PAR sessions will include community members and method users that participated in Objective 4 research. Their participation will be crucial to ensure that next steps reflect the perspectives of current and potential clients and the need for person-centered implementation strategies. Rapporteurs will document these discussions, recording data in a manner that does not include identifiable or personal information about PAR participants. Data collected during PAR will comprise of rapporteur reports and notes from small group activities and plenary discussions. The same data collection will be carried out in the first of the national- and case-study-level PARs. For the second national-level meeting, the research team will take notes and disseminate a meeting report.

Analytical Approaches

Objective 1

The EASIER global protocol advises IR teams on ways to triangulate qualitative analysis methodologies, including content analysis of documents analyzed from the desk review and framework analysis of IDI, to depict the policy-making and implementation characteristics, capacities, and processes in relation to the public sector rollout of DMPA-SC self-administration at the national level [18,19]. Data from the

XSL•FO
RenderX

structural and organizational readiness questionnaires will be analyzed through univariate and bivariate statistical procedures. IR teams will generate descriptive analyses to capture variation across districts in terms of levels of adoption of the new method, structural readiness, and organizational readiness to scale it up. They will draw on these data to formulate dependent variables and carry out exploratory analysis to identify factors that are associated with that outcome. This will include correlation analyses between independent variables identified from these data sets to assess potential collinearity between measures. This will inform the basis for potential multivariate analysis that brings in adjustment terms and provide a richer understanding of factors in our data that are associated with readiness for implementation and implementation strength.

Objectives 2-4

The global protocol outlines procedures for analyzing the qualitative data collected in each case study location. These data will be analyzed independently to obtain a rich picture within each case study, respectively, of the implementation process–related and contextual factors that influence the adoption and delivery of DMPA-SC self-administration and the outcomes that emerge as a product of context-process interactions. This analysis will reflect the theoretical influence of contextual analysis, a concept from "realistic evaluation" that is based on the principle of "generative causation" [20]. Contextual analysis holds that what works and for whom is contingent upon the circumstances in which initiatives are implemented. The global protocol suggests that IR teams blend framework analysis and steps adapted from grounded theory analysis to, first, identify segments of the qualitative data that reflect the context of self-injection implementation, implementation processes and characteristics, and implementation outcomes [18,21]. IR teams should then draw on methods such as "constant comparison" to compare data from alternative transcripts within each case study to generate preliminary causal pathway models (CPM) that connect implementation strategies, preconditions, implementation mechanisms, and processes with proximal and, if possible, distal outcomes [22,23]. Based on this, IR teams will generate a codebook with codes to represent each of the components of the CPM for each case study and use these to analyze the qualitative data. IR teams will formulate "context-mechanism-outcome" (CMO) configurations based on the coded data for each case study [20]. They will compare each CMO configuration against each preliminary CPM to assess the strength of the explanatory framework they have posited for each case study and the need for modifications and refinements. Depending on their conclusions, they may revert to the data analysis to carry out additional phases of coding to integrate concepts included in the initial codebooks for refined analyses (ie, axial coding), and, after this, research team members will review reports from the second rounds of coding, formulate CMO configurations, and re-examine their CPM [21]. This cycle will continue until IR teams reach consensus on their satisfaction with CPMs that are finalized based on CMO analyses. With this, IR teams will generate explanations for how contextual factors and implementation mechanisms shape the outcomes of self-injection implementation in case study locations. The research team will compare the CMO analyses and final CPM of each case study to obtain a nuanced understanding of the determinants, processes, and outcomes of DMPA-SC self-administration introduction in each country.

Objective 5

Each PAR meeting will be led by an experienced moderator and small group discussion facilitators. IR teams will present salient findings from the research and then divide the plenary group of each dissemination into small groups for discussion. Data collectors will be embedded in each discussion to take detailed notes and facilitate group discussions using flipcharts, markers, and other materials as necessary. The underlying purpose of PAR activities described above, such as reflection on root causes of problems or drivers of implementation success, is to engender among participants the capacity and impetus for "systems thinking" (ie, seeing wholes, perceiving structures that underlie dynamically complex systems, and identifying high leverage opportunities), and the elaboration of "mental models" (ie, reflection, inquiry, testing, and improving of assumptions about how things work within organizations) [24]. Using these tools, facilitators will guide small groups in discussion. During discussion, these groups will prioritize implementation issues to address in the future and suggest actions that should be taken to do so. Large group discussions will proceed, facilitated by the moderator, during which small groups will present and debate their priorities. This will continue until the large group achieves consensus on a limited set of future activities associated with the next stages of the DMPA-SC self-administration scale-up. A multistep ranking process will ensue whereby each participant ranks, individually and confidentially, each of the selected activities. The moderator and data collection team will review the activity rankings submitted by each participant and calculate for each activity the number of submissions that ranked it number 1, number 2, number 3, etc until all activities have been prioritized. The intention of this activity is to establish a shared vision for future scale-up within each case study and at the national level. This will continue until each activity is ranked in an action plan or discarded. Altogether, each PAR session should take 1 full working day.

Ethics Approval

This research protocol has been reviewed by the research project review panel (RP2), an external scientific review body that is assembled by the Department of Sexual and Reproductive Health and Research of WHO to review the department's research protocols, as well as the WHO Ethical Review Committee (protocol number WHO ERC A66003) and the adapted country protocols registered in the respective country's local institutional review boards.

Results

As of October 2020, EASIER started data collection in Kenya and Burkina Faso and started the process of protocol adaptation in Ghana. In preliminary analysis of the data from Kenya, a key emerging theme is the challenges that arise at the local management and service delivery levels owing to the absence of practice guidelines. Although policies and training curricula

XSL•FO
RenderX

are in place, implementation teams report that they lack a clear strategy on how to operationalize this policy decision. To address this, teams ask that practice guidelines provide operational detail on how county health teams should roll out the new method. Specifically, participants ask for guidance on how county health teams should adapt training, counseling, routine supervision, quality assurance, health information, and community outreach procedures to optimize the introduction of the new method and best leverage existing community-based and private sector delivery channels. A second key theme from Kenya concerns lapses in the availability of DMPA-SC commodities, which arise from bottlenecks in the procurement and distribution of the method at the national and local levels. Preliminary findings have been shared with the MOH and remedial actions are underway to address challenges.

In Burkina Faso, preliminary findings suggest that the effort to scale up self-administered DMPA-SC has achieved a relatively large scale in the country. However, health workers based at the lowest levels of care were not adequately trained to initiate women's self-injection. Although investment has been made in expanding coverage of the method, the voices of stakeholders indicate that the MOH and implementation partners should consider reforming scale-up processes to ensure that staff at primary health care facilities, which are usually closest to communities, are reached with the training they require to become able to initiate and support clients on self-injection. A second emergent theme that has arisen from preliminary analysis of the Burkina Faso IR data relates to women's awareness of the opportunity to practice self-injection. Despite efforts to make the method available, most women in the sample indicated that they had not been informed of the opportunity to self-inject DMPA-SC. The findings further imply that devising strategies to leverage community-based structures and other service communication channels to spread understanding of self-administered DMPA-SC and its availability will be crucial to strengthening the scale-up of the method. Preliminary evidence from the IR project in Ghana will become available in January 2023.

Discussion

Overview

We expect that both the quantitative and qualitative pieces of these studies will be robust. Specifically, we anticipate that the former will generate important information on the variation of coverage and implementation strength of efforts to expand the method mix through self-administration of DMPA-SC and decisions on where future interventions are required in order to address disparities and gaps. In addition, we expect that qualitative data will inform the design of implementation strategies that FP programs in the 3 countries will use to enhance method introduction and scale-up processes. By engaging stakeholders from multiple levels of the countries' health systems in PAR, we expect subsequent steps that aim at strengthening and accelerating scale-up efforts to be led by policy makers and decision makers and integrated into the implementation processes and cycles of local health care delivery teams. To facilitate this process, EASIER IR teams in each country receive support from the WHO to work with MOH counterparts and, as a group, reflect on Objectives 1-5 research findings to refine an implementation strategy that addresses priorities and challenges that were identified during PAR sessions. Based on this, IR partners in each country will develop an IR protocol to evaluate that strategy in a subsequent phase of the EASIER project. During this process, WHO will provide technical assistance to IR partners in each country, orienting them to evidence-based strategies that have been proven to address the specific issues that IR partners address in their implementation strategies, including the use of technology to enhance future implementation efforts (eg, training videos, user-clinic apps, SMS message reminder systems, etc). In addition, the WHO will support IR partners in adapting their chosen evidence-based approaches to their context and incorporating them into their plans.

Strengths and Limitations

A strength of EASIER is that it leverages a variety of implementation science frameworks and approaches to understand outcomes that have emerged from early efforts to scale up self-administered DMPA-SC in countries as well as the generative process that explains differences in these outcomes across diverse geographies within countries. The use of a global protocol will help ensure that findings across countries are comparable and that collectively they can help advance the global evidence base on the barriers, facilitators, and good practices associated with implementation success and challenges with respect to the scale-up of DMPA-SC self-administration. Further, the WHO approach to using multidisciplinary teams that place decision makers and implementers at the helm of the IR and its use of PAR integrate IR and FP program processes and create opportunities for evidence use as part of scaling up. The EASIER protocol has limitations as well. The use of a global protocol implies a rigorous adaptation process at the country level to ensure that it addresses local knowledge needs and implementation challenges and maximally benefits local actors involved in scaling up. It is primarily focused on obtaining a thorough understanding of method introduction, scale-up progress, processes, and problems in order to pinpoint challenges and prescribe solutions based on evidence. It does not evaluate specific strategies aimed at accelerating scale-up or strengthening systems, even though EASIER's findings can establish a strong foundation for doing so.

Conclusions

The emergence of DMPA-SC for self-administration has the potential to transform access to the contraceptive method considered most popular in settings where better variety and access to FP are critical for achieving global health goals. Global organizations have recognized self-administered DMPA-SC as an EBI and recommended its inclusion in countries' FP programs; however, countries lack contextually appropriate strategies for integrating it and supporting its introduction and scale-up in health systems. IR offers ways to address this gap by bringing into focus underlying implementation issues and challenges related to the introduction of new methods and explaining the implementation process–related and contextual

XSL•FO
RenderX

factors that shape whether the introductory and scale-up efforts are effective. IR also supports knowledge translation frameworks through which stakeholders use evidence to make programmatic decisions on how to address challenges. The EASIER project demonstrates ways to embed IR within the health system and employ it to help guide scaling up access to self-injectable DMPA as part of contraceptive method choice. If successful, the protocol described in these pages will propagate additional cycles of learning, adaptation, implementation, and research, with the goal of supporting the spread of this promising contraceptive method based on local evidence in Burkina Faso, Ghana, Kenya, and additional countries that join the EASIER project. Altogether, this will create new and meaningful opportunities to advance the use of IR to strengthen FP programs.

Acknowledgments

The authors would like to thank the staff members of the United Nations Development Programme, United Nations Population Fund, United Nations Childrens' Fund, WHO, and the World Bank Special Programme of Research, Development, and Research Training in Human Reproduction who dedicated time and effort to reviewing the protocol for the systematic review.

Abstract

Background: In May 2022, a case of monkeypox (currently known as “mpox”) with no history of overseas travel was reported in the United Kingdom, followed by reports of infections reported in Europe, the United States, and other countries worldwide. Due to the significant overlap in immune responses among viruses of the genus *Orthopoxvirus* (including smallpox virus, mpox virus, and vaccinia virus), it is believed that cross-immunity can be achieved by administering the smallpox virus vaccine. In Japan, a smallpox vaccine (LC16m8 strain vaccine) has been approved; however, there was no regulatory approval for the mpox vaccine during the design of this study. Although it is believed that individuals exposed to the mpox virus may receive smallpox vaccination as mpox prophylaxis, the existing evidence is not clear.

Objective: The primary objective was to evaluate the efficacy of the LC16m8 strain vaccine, approved for smallpox in Japan, for postexposure prophylaxis against mpox when administered to close contacts of individuals with mpox. The secondary objective was to investigate the safety of the vaccine for postexposure prophylaxis against mpox.

Methods: The study aimed to enroll 100 vaccinated participants who had been identified as close contacts of individuals with mpox. Consent was obtained, and the participants are inoculated with the vaccine. Daily recordings of symptoms (body temperature, headache, rash, and side effects) were made until day 21 and then again on day 28. Furthermore, additional evaluations of adverse events were performed by the investigators on days 7, 14, 21, and 28. Considering that the maximum incubation period for mpox is 21 days, the primary end point is the presence or absence of the disease 21 days after close contact. The primary analysis focused on cases within 4 days of intense contact as it has been reported that vaccination within this timeframe can reduce the incidence of the disease.

Results: The first trial participant was enrolled on July 28, 2022, and the research period concluded in March 2023. The study results will be published in a peer-reviewed scientific journal.

Conclusions: This study allowed us to investigate the efficacy and safety of the LC16m8 strain vaccine in postexposure prophylaxis against mpox.

Introduction

Monkeypox is a zoonotic pathogenic virus belonging to the genus *Orthopoxvirus* of the family Poxviridae. It was initially isolated from a cynomolgus monkey in 1958 and was named monkeypox [1]. However, in November 2022, the World Health Organization (WHO) changed the name to “mpox” as its natural host is considered to be a rodent [2]. Mpox circulates within a transmission cycle involving rodents and monkeys in tropical rainforests spanning from Central Africa to West Africa [3]. Since the first confirmed human infection in the Democratic Republic of the Congo in 1970 [4-6], human infections have been reported following bites from virus-infected monkeys and rodents, as well as, through the ingestion of undercooked meat. Human-to-human transmission via droplets and direct contact has also been documented [3,7,8]. While outbreaks have primarily occurred in central to western Africa, sporadic outbreaks have been reported in other regions as a result of travel to endemic areas in Africa. In 2003, an outbreak was reported in Texas, United States, likely caused by the importation of an infected rodent [1,9].

Mpox usually develops after a latency period of 6-13 days (maximum 5-21 days) following viral exposure [10]. After the latent period, symptoms such as fever, headache, lymphadenopathy, and myalgia persist for approximately 1 to 5 days, followed by the development of a rash. The eruptions often appear on the face and extremities and gradually elevate, forming bullae, pustules, crusting, and eventually heal 2 to 4 weeks after onset. The fatality rate is reported to be 0%-11% and tends to be higher in children; however, no deaths have been reported in the developed nations [11,12].

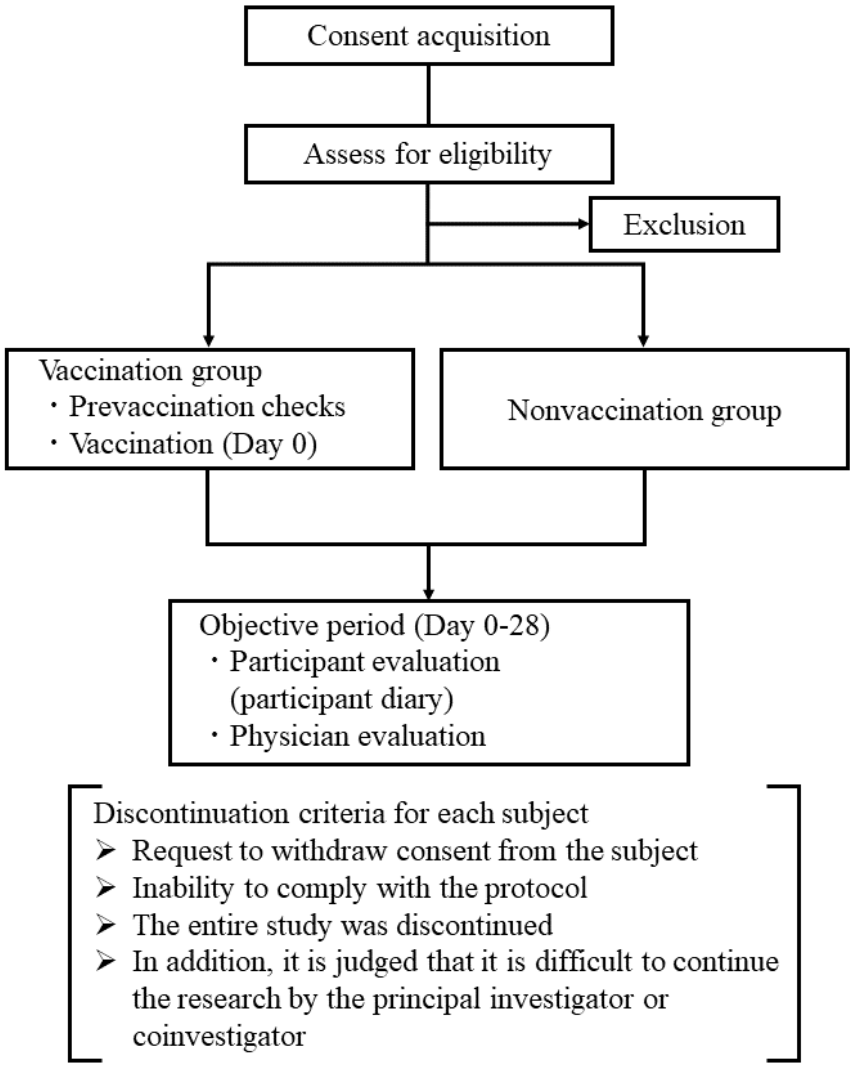
Currently, tecovirimat is approved by the Food and Drug Administration for the treatment of mpox [13,14], but there is no approved medication for mpox in Japan. As a preprophylaxis measure, vaccination using the smallpox vaccine has been reported to be beneficial due to the significant overlap in immune response among viruses of the *Orthopoxvirus* genus (including smallpox virus, mpox, and vaccinia virus). Furthermore, based on the genomic analyses of mpox strains isolated in Europe, the mpox strains circulating since May 2022 more likely originate from the West African clade and exhibit a higher homology to smallpox virus strains [15]. An analysis of epidemiological data on mpox in the Republic of Zaire during the 5-year period from 1980 to 1984 suggests that smallpox vaccination prevents approximately 85% of mpox cases [16]. For postexposure prophylaxis, the Centers for Disease Control and Prevention recommends administration of the mpox vaccine for prophylaxis, ideally within 4 days of exposure, with vaccination within 14 days also being considered; however, the efficacy may be inferior after 4 days [17].

The smallpox vaccine has been classified into 3 generations by the WHO [18]. The first generation includes the Lister strain vaccine and Wyeth's Dryvax (NYCBH strain), which were manufactured and used during the smallpox eradication program by the WHO, contributing to smallpox eradication [19]. The second-generation smallpox vaccine uses the same smallpox vaccine strain as the first-generation vaccine and clonal viral variants purified from conventional vaccine strains, including ACAM2000 [20,21]. The third-generation smallpox vaccine is an attenuated vaccine strain specifically developed as a safer vaccine at the end of the eradication phase by cell culture and animal passage with LC16m8 strain vaccine and Bavarian Nordic's MVA-BN (JYNNEOS/Imvanex/IMVAMUNE) [22-24]. Among these, the third-generation LC16 is currently approved in Japan, although it is not widely distributed and cannot be used in general practice.

In this study, the close contacts of patients with mpox were vaccinated with the LC16, which is the approved smallpox vaccine in Japan, to determine the efficacy and safety of LC16 for postexposure prophylaxis against mpox.

Methods

Overview



This is a prospective, interventional, single-arm study aimed at evaluating the efficacy and safety of the LC16 smallpox vaccine for individuals who have had close contact with patients diagnosed with mpox.

The study was conducted according to the schedule described in Figure 1 and Table 1. Informed consent was obtained from the participants within 14 days after mpox exposure, which is defined as day 0. Only participants who provided consent to be vaccinated received the vaccine. Close contacts who did not wish to be vaccinated were included in the study for reference purposes and were observed for follow-up if they had consent to participate. Participants self-recorded their body temperature, presence of headache, rash, and lymphadenopathy daily for 21 days after vaccination (or vaccine refusal), as well as on day 28. On days 7, 14, 21, and 28 after vaccination (or vaccine refusal), the investigators or clinical research coordinator contacted the participants to inquire about any reported adverse events. The investigators also evaluated the onset of mpox 21 days after close contact (day 7 to 21). The definition of mpox onset is based on the notification of the Infectious Disease Law. In the cases of nonreserved visits or cancellations, the investigators confirmed the presence or absence of onset and any side effects. The primary end point includes the presence or absence of mpox 21 days after close contact. Secondary end points include postvaccination adverse reactions, the rate of severe disease, death, presence of symptoms (fever, headache, and lymphadenopathy), and complications (secondary skin infections, bronchopneumonia, sepsis, encephalitis, and keratitis).

XSL•FO
RenderX

The investigators decided whether to administer other live vaccines within 27 days. The investigators also explained to the participants that after inoculation with a vaccine, the participant may not be inoculated with other vaccines for a stipulated time period.

[a]Not applicable.

[b]Only participant to consent for vaccination.

[c]The primary end point is assessed through participant evaluation of symptoms (body temperature, headache, rash, and lymphadenopathy), as well as physician evaluation of complications and any local reactions at the injection site.

[d]Investigators evaluate the onset of mpox 21 days after close contact.

[e]Investigators evaluate any injection-site reaction (“take”) by examination or by reviewing a picture of the inoculation site.

Study Setting

This study was conducted solely at the Center Hospital of the National Center for Global Health and Medicine (NCGM), Tokyo, Japan. NCGM is a 749-bed general hospital with close relationships to the Ministry of Health, Labour and Welfare (MHLW) and is a center for infectious disease treatment in Japan. In cases where a close contact is identified in an area far from Tokyo, a researcher from NCGM personally delivered the smallpox vaccine to the contact, obtained their consent for the study, and administered the vaccine if consent was granted. The MHLW has issued a notice on this policy and informed health centers throughout Japan. Close contacts cannot be vaccinated without participating in this study, indicating that although this is a single-center study, it encompasses the entire country of Japan.

Eligibility Criteria

The eligibility criteria for this study are shown in Textbox 1.

The primary inclusion criteria are as follows: age of 1 year or older at the time of consent, participation within 14 days of close contact with an individual diagnosed with mpox, and no clear indication of mpox.

The main exclusion criteria are as follows: evident immunopathy, use of adrenocorticosteroids or immunosuppressants, history of anaphylactic shock caused by ingredients of the smallpox vaccine, and the presence of prevalent skin disease and potential disability by vaccination.

XSL•FO
RenderX

Textbox 1. Eligibility criteria.

Inclusion criteria

- Provided written consent from the principal or proxy for participation
- Age of 1 year or older at the time of consent
- Participation within 14 days of close contact with an individual diagnosed with mpox. The definition of "close contact" refers to an individual who is determined to be a contact in an active epidemiological study conducted by the health center of the patient's address based on the criteria of an active epidemiological study issued by the Ministry of Health, Labour and Welfare
- No clear indication of mpox

Exclusion criteria

- Evident immunopathy
- Use of adrenocorticosteroids or immunosuppressants (such as cyclosporine, tacrolimus, and azathioprine)
- History of anaphylactic shock caused by ingredients of the smallpox vaccine
- Fever
- Presence of a serious acute disease
- Pregnancy
- Prevalent skin disease and potential disability by vaccination
- Not appropriate for vaccination
- Considered to be unfit to participate in this study by the principal investigators

Informed Consent

Before obtaining informed consent, the investigators ensured that the participants were given sufficient time and opportunity to gather information about the study's details and make an informed decision regarding their participation. Participation in the study was voluntary, and participants could refuse to participate or withdraw from the trial at any time without penalty or loss of benefits to which the participant is otherwise entitled. The written informed consent was signed and dated by the participant and investigators. The explanatory and consent documents were approved by the authorizing clinical study examination committee and the MHLW.

Interventions

The vaccine used in this study is a freeze-dried cell culture of smallpox vaccine LC16 (LC16m8 strain vaccine), manufactured by KM Biologics, Japan. It is a third-generation smallpox vaccine manufactured by cell culture of the attenuated virus strain [25]. The vaccine is dissolved in 0.5 mL of the attached solvent (20 vol% glycerylated water for injection) and inoculated into the skin with a bifurcated needle. The number of compressions at the site of vaccination is, as a guide, 5 for first-time inoculations and 10 for others.

Criteria for the Discontinuation of Treatment or Intervention

The investigators review the continuation of the study when the following events occur: participant requests withdrawal of consent, inability to comply with the research protocol, discontinuation of the entire study, and decision of the investigator to conclude the study due to challenges in its continuation.

Statistical Analysis

The study population (Full Analysis Set) excludes ineligible participants and those with missing data on efficacy end points among the enrolled participants. The study population for safety end point analysis is defined as the enrolled participants excluding nonvaccinated participants.

According to a systematic review on the epidemiology of mpox [26], 4 studies reported the incidence of mpox in nonvaccinated close contacts. Among individuals who were not vaccinated, 7.4% of close contacts developed mpox (92 cases out of 1238 close contacts). Therefore, for this study, we set the threshold for the incidence of mpox among nonvaccinated individuals at 7.4%. An older study also reported an incidence rate of 3 of 40 (7.5%) among family members who have been in close contact with the disease [27]. The incidence of mpox among vaccinated participants is calculated, and Bayes' theorem is used to determine the probability of the incidence being lower than 7.4% (posterior probability). Additionally, for the prior distribution of the vaccinated participants, we assume an uninformative distribution and determine that if the estimated posterior probability exceeds 90%, the vaccine has a certain effectiveness. In case no incidences of mpox occur, 33 cases within 4 days of close contact are required to obtain a 90% posterior probability.

Primary end point analysis will be performed among Full Analysis Set who had contact with an infected person within 4 days. The incidence rate and its 90% and 95% CI are calculated, as well as the posterior probability of the incidence rate less than 7.4%. For the secondary end points analysis, the severity rate, death rate, and their 95% CI for vaccinated cases are calculated. For the safety end points analysis, the number of adverse events and the incidence rate are calculated for each event using the safety population.

Ethical Approval

This study was conducted in compliance with the ethical principles stipulated in the Declaration of Helsinki, the Clinical Research Act, relevant notices, and this research protocol. Ethical approval of the research protocol and the consent document have been obtained from the Certified Review Board of the National Center for Global Health and Medicine (NCGM-C-004504-02), and the study is registered in the Japan Registry of Clinical Trials (jRCTs031220137).

Results

The first participant was enrolled on July 28, 2022. Recruitment and registration ended on December 16, 2022. Date fixation was completed in December 2022, and and the study was concluded in March 2023.

Discussion

This is a study protocol to evaluate the efficacy and safety of the smallpox vaccine, LC16m8 strain vaccine, as a postexposure prophylaxis measure in individuals who have had close contact with patients with mpox.

Owing to changes in vaccine guidelines during the study, the number of compressions at the site of vaccination is, as a guide, considered as 15 [28]. The anticipated result of this study is to demonstrate the effectiveness of postexposure vaccination as a prophylaxis measure against mpox onset and severe disease. Specifically, the absence of symptoms (fever, headache, rash, and lymphadenopathy) listed in the diary recorded by the participant during the observation period after vaccination, and the presence of antibodies at the injection site (“take”) determined by the doctor's evaluation. These findings could provide new evidence for mpox treatment with postexposure vaccination recommended by the Centers for Disease Control and Prevention.

There are some limitations to this study. First, this study had to be conducted in a short period of time owing to the rapid spread of the epidemic, and we could not afford to design a multicenter study. However, because the researchers visited participants residing in distant areas, the study can be considered to cover the whole of Japan, thus ensuring its validity. In addition, this study is open-labeled as there was insufficient time to establish a blinding system and prepare a placebo. While it is impossible to completely eliminate bias in the evaluations conducted by investigators and participants, there are objective criteria for the diagnosis of mpox; therefore, bias in the primary end point can be eliminated. Additionally, although 2 groups (vaccinated and nonvaccinated) have been formed, they were not randomized, rather participants decided whether to be vaccinated or not based on their personal preferences. Comparison between the 2 groups is challenging since this is a nonrandomized study. However, the efficacy is evaluated based on the reported incidence of mpox.

In conclusion, this is an ongoing, open-label trial, and observing the incidence of mpox in the vaccine group will provide the most definitive efficacy comparison data and other important clinical outcome data to date. If the incidence of mpox is below 7.4% in the vaccination group and the hypothesis that the LC16m8 strain vaccine is safe is valid, the LC16m8 strain vaccine would be an important treatment option for individuals in close contact with patients diagnosed with mpox. This outcome could lead to the swift integration of the LC16m8 strain vaccine into clinical practice.

Acknowledgments

The research funds used in this study and the test drug, LC16, were provided by the Ministry of Health, Labour and Welfare.

Data Availability

There are no plans to share data. As the possibility of secondary data use is explained in the consent document, secondary use of data is possible as long as a new research protocol is prepared, reviewed, and approved by the appropriate review committee.

Conflicts of Interest

None declared.

Abstract

Background: University-affiliated student-led health care services have emerged in response to the challenges faced by universities in securing quality clinical placements for health care students. Evidence of the health care benefits and challenges of student-led health care services is growing, while evidence of clinical placement performance remains variable and not generalizable. Though there have been previous attempts to develop a framework for evaluation of clinical placement performance, concerns have been raised about the applicability of these frameworks across the various placement settings. Additionally, the perspectives of all key stakeholders on the critical areas of clinical placement performance have yet to be considered.

Objective: This study's objective is to gather information on areas of measurement related to student learning outcomes, experience of placement, and costs of placement and then develop consensus on which of those areas need to be included in a framework for evaluation of clinical placement performance within the context of student-led health care services. The aim of this paper is to outline a protocol for a modified Delphi study designed to gain consensus on what is important to measure when evaluating an allied health clinical placement.

Methods: We will recruit up to 30 experts to a heterogeneous expert panel in a modified Delphi study. Experts will consist of those with firsthand experience either coordinating, supervising, or undertaking clinical placement. Purposive sampling will be used to ensure maximum variation in expert panel member characteristics. Experts' opinions will be sought on measuring student learning outcomes, student experience, and cost of clinical placement, and other areas of clinical placement performance that are considered important. Three rounds will be conducted to establish consensus on what is important to measure when evaluating clinical placement. Each round is anticipated to yield both quantitative data (eg, percentage of agreement) and qualitative data (eg, free-text responses). In each round, quantitative data will be analyzed descriptively and used to determine consensus, which will be defined as ≥70% agreement. Qualitative responses will be analyzed thematically and used to inform the subsequent round. Findings of each round will be presented, both consensus data and qualitative responses in each subsequent round, to inform expert panel members and to elicit further rankings on areas of measurement yet to achieve consensus.

Results: Data analysis is currently underway, with a planned publication in 2024.

Conclusions: The modified Delphi approach, supported by existing research and its ability to gain consensus through multiround expert engagement, provides an appropriate methodology to inform the development of a framework for the evaluation of clinical placement performance in allied health service.

Introduction

Universities face many challenges in sourcing and securing clinical placements for health students [1]. For regional universities, there is the added pressure of limited health care services from which to secure sufficient clinical placements [2]. The cost associated with paid placements is also a major concern, as paid placements can potentially create issues around placement outcomes and add to the financial burden on universities [3,4]. For example, the question for universities securing paid placements is whether the student learning outcomes or the student experiences achieved in these placements are equivalent to the amount paid. Conversely, the question may be whether an equivalent or greater outcome could be achieved through an alternate clinical placement. Placement providers also report increased costs associated with supervising students on clinical placement, including loss of productivity when working with inexperienced students, increased recruitment requirements to manage the additional workload, supervision of students on top of clinical workloads, and procuring and maintaining state-of-the-art equipment for teaching [5]. Cost of clinical placement to the clinical placement provider has been estimated to be an average of Aus $34,326 (US $22,531.3) per year for 1 student [5], influencing a health care provider's ability to offer placements without compensation [4]. As a result, university-affiliated student-led health care services have emerged to address the many challenges faced by universities in securing quality clinical placements for health care students [6].

Student-led health care services are often seen as innovative health care models providing much-needed services to disadvantaged or underserviced populations [7]. There is mounting evidence supporting the benefits of student-led health care services as both adequate providers of care and attractive educational opportunities [8]. In a recent study, allied health students co-designed and implemented a health service in a remote Aboriginal community in northern Australia, where students learned how to adapt their skills and approaches to the cultural needs of the Aboriginal community [9]. However recent reviews of the outcomes of student-led health care services more broadly, indicate the need for more rigorous reporting [10], with more specific attention to students' skill development, knowledge, and behavior required [11]. If students are not adequately prepared to operate in a fashion similar to that of qualified health care professionals, then it is possible that undertaking placement in a student-led health care service may be detrimental to their learning outcomes and overall experience of placement. Conversely, providing students with the ability to operate in authentic clinical environments where they can collaborate and regulate their own learning needs may improve overall student experience. Current findings from evaluations of student-led health care services as providers of clinical placement lack generalizability [11,12] and there is little consensus on the most critical educational outcomes that need to be measured when students are on placement within these settings [12]. Therefore, further research is needed to establish a consensus on how to evaluate student-led health care services as clinical placement providers.

Clinical placement evaluation has typically been specific to a single element of student experience, for example student confidence [13] or student satisfaction [14], or alternatively, a specific learning outcome related to a single health profession, such as clinical competency of physiotherapy students [15]. To effectively evaluate the performance of student-led health care services as providers of clinical placement, all elements of the experience that are deemed to be important must be considered together. Furthermore, an evaluation framework that can be applied to student-led health care services, which includes elements of placement performance specific to the needs and expectations of the student, the placement supervisor, the placement coordinator and to the profession is required.

Applying an evaluation framework across various health professions and health care services is not without its challenges. Previous national stakeholder consultation on use of a universal framework indicated that disciplinary and contextual differences in supervision would impact on the effectiveness of such a framework [16]. Therefore, any framework used to evaluate the quality of clinical placement needs to be consultative, collaborative, and comprehensive, so that it can accurately assess clinical placement performance across different health care settings. In addition, the framework needs to be all-encompassing and flexible so that it can be applied across different clinical placement models and different health professions [16]. A framework that can be used to effectively evaluate all clinical placement will offer the opportunity for standardization and comparability, but more importantly measure the quality of placement experience, enable quality improvement, and enhance educational opportunities [17,18].

Previous studies that have used a Delphi approach to evaluate clinical placement, or to identify factors influencing clinical placement quality, predominately exist within the medical, nursing, and allied health literature. For example, the Delphi approach has been used to engage clinical placement key stakeholders to revise clinical placement evaluation tools in physiotherapy [19], as well as to generate expert consensus between nurse clinical educators to identify important factors influencing student learning during clinical placement [20]. Additionally, a modified Delphi approach was adopted to identify key features within a quality measures framework to guide clinical placement in allied health, dentistry, medicine, and pharmacy [18]. These studies support previous notions that current tools and approaches to evaluating clinical placement quality and performance are limited in their generalizability and that key factors influencing quality in clinical placement need to be considered, that is, student learning outcomes, experience of placement, and cost of placement.

The aim of this paper, therefore, is to outline a protocol for a modified Delphi study designed to gain consensus on what is important to measure when evaluating an allied health clinical placement. This study's objective is to gather information on areas of measurement related to student learning outcomes, experience of placement and cost of placement and then reach consensus on which of those areas need to be included in a framework for evaluation of clinical placement performance within the context of student-led health care services.

Methods

The Delphi Approach

A 3-round modified Delphi study design will be conducted to establish consensus on what is important to measure when evaluating clinical placement, from the perspective of students, placement supervisors, and coordinators, as experts with firsthand experiences of clinical placement.

The Delphi is a mixed methods approach to systematically collect judgments and opinions on a topic, through sequential questionnaires to gain respondents feedback on responses from earlier rounds of questioning [21]. The primary aim of the Delphi technique is to obtain consensus among a selected panel of experts. The Delphi approach will allow for drilling down into common areas of clinical placement through multiple rounds of questioning, as well as analysis of conflicting and common viewpoints through statistical methods [22]. The Delphi technique has been used extensively in higher education, health, and social sciences to inform the development of criteria, forecasting, issue prioritization, policy formation, and framework development [23,24].

Approaches to using the Delphi technique have evolved over time, which has led to some criticism on the validity of this approach. At the heart of the Delphi technique is the ability to form consensus between experts within a particular field. However, there is currently no set level for consensus [24] with consensus previously set anywhere from 51% to 100% [25]. Additionally, previous studies indicate that panel size and the area of investigation influences consensus [26] and consideration needs to be given to achieving an expert panel of an appropriate size and make up [27].

Anonymity, iteration, controlled feedback, and statistical stability of consensus are essential components of the Delphi approach [28]. However, the time it takes to complete these types of studies is often underpredicted [24] and has been found to influence low response rates in later rounds [24,25,27]. The several adaptations of the Delphi technique have also received criticism, as many Delphi studies lack detailed methodologies, influencing their reproducibility [24,28]. Additionally, the relevance of using experts to inform research has been questioned [25-27], as expert opinion is considered inferior to more highly regarded evidence-based methods [28,29]. The term *expert* has also broadened over time and is now not only used to refer to an individual's scientific or professional expertise but can include patients or users of an intervention to create diversity within the expert panel [30]. It is not clear what the effects of a heterogeneous expert panel has on consensus building [30], however, this has become a defining feature within the Delphi technique [31].

Currently, no proven quality indicators for Delphi studies exist [30]. However, the Delphi technique does provide an opportunity to draw on the experiences and expertise of a range of key stakeholders with a diverse set of perspectives in an iterative process where complex ideas can be examined and built on to form consensus. Therefore, considering the limitations of this approach, it is crucial to plan and set standards before commencing the process to improve the robustness of the Delphi technique [28].

Expert Panel Members

Overview

A minimum of 18 and maximum of 30 experts will be recruited to the expert panel, with a minimum of 6 members (hereafter referred to as *experts*) for each identified group (ie, recent allied health graduates, placement supervisors, and placement coordinators). This panel size is viewed as manageable, where available resources can be applied to vigorously promote high response rates within rounds [32]. To achieve heterogeneity within the panel, purposive sampling to ensure maximum variation in expert characteristics will be undertaken. Experts will consist of those with firsthand experience either coordinating placement, supervising placement, or undertaking clinical placement. All experts will be aged 18 years or older, be an Australian resident, and be English speaking. Additionally, clinical placement coordinators will be required to be employed in an Australian university allied health program, with involvement in coordinating or undertaking assessment of clinical placement within the past 2 years; clinical placement supervisors will be required to be located within Australia, and have had supervised allied health students from Australia-based universities within the past 2 years; and graduates will be required to have completed their allied health program within the past 12 months from an Australian university, successfully completing a clinical placement subject of an applied or immersive nature (eg, not solely an observational placement).

Consistent with the Delphi technique, the aforementioned approach to sampling will elicit expert opinion on the topic in question, and the disciplinary areas of expertise required [33]. Suitability of panel membership has been generally based on a background or experience concerning the target issue and an ability to contribute helpful inputs to the questions being asked [33]. The heterogeneity of the expert panel, as a critical feature within the Delphi technique [33], is required to maintain quality in research design and uncover the entire spectrum of opinion on the topic [27].

Expert Panel Member Recruitment

Potential experts will be identified, and if interested, will be invited to register through an electronic short survey sent through email. In the survey, they will be asked to confirm their interest in taking part in the study or to forward it to other potential experts meeting the target group criteria. The eligibility of potential experts who have registered will be assessed and if deemed to meet the target group criteria, will be invited to participate in the study.

Placement supervisors will be identified based on their previous or current involvement in hosting allied health students on clinical placement. Placement supervisor information from across Australia will be identified through the James Cook University placement software database (InPlace) and by snowball sampling. InPlace is a web-based software application developed by QuantumIT Pty Ltd to enable universities to identify supervisors for a given site, coordinate and manage

XSL•FO
RenderX

clinical placements, and store data on placement contact information.

Placement coordinators will be identified by their previous or current involvement in coordinating clinical placement within Australian universities. Placement coordinator information will be identified through academic role descriptions on Australian university websites and membership details within discipline specific clinical placement committees.

Recent graduates will be identified by their past enrollment in a placement subject within an Australian university allied health program. This information will be identified through James Cook University alumni networks and snowball sampling whereby contact will be made with key people within clinical placement partnerships and those who hold key positions within Australian universities to identify members of the target groups who meet the inclusion criteria. Key people within clinical partnerships will include national clinical placement committed groups within professional registration bodies (eg, Exercise and Sport Science Australia, Australian Health Practitioner Regulation Agency, Occupational Therapy Australia, and Speech Pathology Australia) and existing placement arrangements with external clinical placement sites.

Panel Characteristics

Purposive sampling of experts to ensure equal representation across placement coordinators, placement supervisors, and recent graduates and to achieve maximum variation in expert characteristics, will be conducted using a matrix method to gain representation based on geographical location, experience, and exposure to clinical placement, as well as the allied health profession they represent. Textbox 1 outlines the expert panel selection criteria and the specific factors of variation intended to be achieved through purposive sampling techniques.

Textbox 1. Selection criteria and considerations for variation in expert panel members.

Placement coordinators:

- Duration in the role of placement coordinator
- Geographical locations of placements coordinated, that is, rural or remote, regional, or metropolitan areas
- Types of clinical placement coordinated, for example, student-led, role-emerging, traditional, and interdisciplinary
- Allied health discipline for which they coordinate placement

Placement supervisors:

- Level of experience supervising students on clinical placement
- Geographical locations of previous and current employment, that is, rural or remote, regional, or metropolitan areas
- Types of clinical placement supervised, for example, student-led, role-emerging, traditional, and interdisciplinary
- Allied health discipline for which they currently supervise

Recent graduates:

- Level of exposure to areas of practice while on placement
- Geographical locations of placements completed, that is, rural or remote, regional, or metropolitan areas
- Types of clinical placement completed, for example, student-led, role-emerging, traditional, and interdisciplinary
- Allied health discipline from which they graduated

Survey Design and Facilitation Within Delphi Rounds

The Delphi technique uses several rounds, whereby a series of questionnaires are provided to experts until consensus is reached [27]. Following each round, a summary of results from the previous round is provided to the experts to either gain consensus or elicit further discussion [27]. In this study, 3 or more consensus rounds will be conducted with survey questionnaires sent to each expert electronically.

Like that of a classical Delphi, the survey design will use open-ended questions, aimed at facilitating idea generation and eliciting opinion [27]. Three overarching themes, predetermined through a review of the literature, will be used to identify common areas of measurement when evaluating student-led health care services and clinical placement. These overarching themes include “learning outcomes,” “student experience,” and “cost of placement.”

A pilot questionnaire for round 1 will be tested with a small sample of people including 1 allied health placement supervisor, 1 recent graduate, and 1 allied health academic to ensure clarity of each question [34]. Textbox 2 outlines open-ended questions 1 to 5 that will be included in the round 1 questionnaire.

XSL•FO
RenderX

Textbox 2. Proposed round 1 survey questions.

Question 1: Reflecting on previous experience, what is important to measure when evaluating clinical placement?
Question 2: When evaluating learning outcomes of clinical placement, please describe what variables to measure. (Provide an example where necessary)
Question 3: When evaluating student experiences of clinical placement, please describe what variables are essential to measure. (Provide an example where necessary)
Question 4: When evaluating costs associated with clinical placement, please describe what variables are essential to measure. (Provide an example where necessary)
Question 5: Is there any additional information that you would like to provide in relation to what is important to measure when evaluating clinical placement?

Question 1 is designed to set the scene and encourage the experts to respond to the question more broadly, without leading their responses. Questions 2-4 are designed to solicit information around specific areas of clinical placement related to the predetermined themes and to direct experts to consider what specific areas of clinical placement, that is, subthemes of measurement, exist when evaluating clinical placement. The final question in the survey will allow experts to discuss other areas of clinical placement evaluation, not yet covered.

Round 2 will include a structured questionnaire that will focus on areas of measurement identified in round 1 and relate to the overarching themes of learning outcomes, student experience, and cost of placement. Experts will rank the level of importance for each area of measurement using a 4-point Likert-type scale ranging from 1=not very important to 4=very important [34]. Experts will be given the opportunity to provide suggestions on any current methods of measurement for each of the proposed areas of measurement, which then will be analyzed and presented in subsequent rounds [35].

In round 3, a list of prioritized areas of measurement from the previous round will be presented. Experts will be asked to rank their level of agreement on the areas of measurement required, using 2 options: agree or disagree. Additionally, any specific methods of measurement identified in round 2 will be ranked using a 5-point Likert-type scale ranging from 1=least effective to 5=most effective [34]. Once again, experts will be invited to provide free-text comments to further explain their position.

Data Collection

All responses will be captured using the Qualtrics web-based survey platform (version 2009; Qualtrics). For each round, each expert will be sent a unique web link to access the surveys. Expert panel members will be provided with a minimum of 4 weeks to complete all surveys within each round, with only those who participated in previous rounds being invited to participate in subsequent rounds. Weekly reminder emails will be sent to each expert until each round is completed. Once the final deadline is reached, surveys will be closed to all experts and responses will be analyzed before commencing the next round. Each survey will take no more than 40 minutes to complete and all responses will be deidentified and coded to maintain anonymity between experts.

Data Analysis

Round 1 responses will be analyzed using thematic analysis to generate themes related to “learning outcomes,” “experience of placement,” and “cost of placement,” as well as any additional themes identified through the process. The thematic analysis will follow Braun and Clark’s [36] 6-phase framework for analyzing qualitative data [36]. These steps include becoming familiar with the data, generating initial codes, searching for themes, reviewing, and defining themes, as well as the final write-up [37]. Qualitative data analysis software, NVivo (version 12; NVivo Inc), will be used to code and group data. Additionally, triangulation will occur between the main research team (LS, FB, and RB) and an independent researcher with experience in thematic analysis to ensure validity of our assumptions through the convergence of themes from different sources [38].

Round 2 and 3 quantitative data will be analyzed using percentage of agreement to confirm whether consensus had been achieved. As identified in other Delphi protocols within health and education fields, combined scores of importance and agreement must equal ≥75% to achieve consensus [39]. In accordance with round 1, qualitative data from rounds 2 and 3 will be analyzed thematically, where common themes will be identified and presented as statements in subsequent rounds.

Ethical Considerations

Informed consent will be obtained before participating in the research project through a unique electronic link, which will form the first page of the questionnaire in round 1. Expert anonymity will be maintained through coding of participant responses and any identifying information will not be linked with any research materials or questionnaires developed through the modified Delphi process or in the outputs that result from this research. Additionally, no compensation will be offered to selected experts for their participation in this study.

Ethical approval has been obtained through the James Cook Human Research Ethics Committee (H7541).

Results

Data analysis is underway, with the results of the modified Delphi study expected to be submitted for publication in 2024.

Discussion

Overview

The aim of this modified Delphi study is to obtain consensus from a panel of experts on how to measure the salient areas of student learning outcomes, student experience, and cost of clinical placement, and to gain valuable insight into the important areas of clinical placement measurement. The

XSL•FO
RenderX

outcomes of this project are intended to inform the development of a framework for evaluation of clinical placement performance.

The strength of using a modified Delphi study design for this proposed study is that it will allow for multiple perspectives from the range of stakeholders whose experiences are influenced by clinical placement performance. As a result, experts will be drawn from a variety of backgrounds to produce heterogeneity and will ensure investigation of the full scope of opinions associated with the topic [27]. The Delphi principle of anonymity also provides strength to this study's design, as it offers an equal chance for each expert to respond in a fashion that is unbiased by the identities of the other panel members [40]. By maintaining communication through electronic means and providing deidentified results in each subsequent round, this study will ensure each expert has the opportunity to react independently, eliminating subject bias and avoiding the potential of power influenced dynamics between experts [41].

Within the Delphi approach, the notion exists that members of the panel are experts in the area of interest, where the term *expert* has been defined as "an informed individual," a specialist in their field, or someone who is knowledgeable in a specific subject [27]. Within this study, the definition of *expert* is based on key stakeholders of clinical placement, which is commonly identified as students, universities, placement supervisors, and the organizations in which placement takes place [4,42], all of which, significantly influence clinical placement quality and performance. Incorporating the knowledge, views, and experiences of key stakeholders is critical to determining a best practice approach to the evaluation of clinical placement performance. Criticism of the expert opinion sought within the Delphi approach applies to the terminology used, determining who is an expert and what degree of expertise is required to offer opinion [27]. Expert opinion has also been criticized as a poor basis for making judgments on a topic and that researchers should consider whether the research question could be better answered through a systematic review [31,43]. However, current systematic reviews on clinical placement performance in student-led health care services identified limitations in the overall quality and generalizability of the research [10-12]. Therefore, this study will inform the critical appraisal of studies that intend to evaluate student-led health care services as providers of clinical placement and whether this is aligned to key stakeholder perspectives.

Consensus will be determined in this study using percentage of agreement, where scores of importance, effectiveness, and agreement must equal ≥75% to be deemed consensus. As seen in similarly designed studies [32,39], this approach favors the majority, but also allows for the anticipated variability in opinion from a heterogeneous expert panel. As a group of experts are unlikely to demonstrate 100% agreement, consensus forming is the essence of the Delphi technique, wherein an appropriate level of consensus needs to be determined to avoid bias [31,43]. Determining consensus remains a contentious issue with critics of the Delphi approach [27,32], however most Delphi researchers agree that the approach needs to be determined in advance and that resistance to consensus needs to be considered carefully, as this will yield new perspectives on the topic in question and will require further investigation [32,44].

Conclusion

This protocol paper describes a modified Delphi study design, to explore key stakeholder perspectives on important areas of clinical placement performance measurement, related to learning outcomes, student experience, and cost of placement. Despite the limitations of the Delphi approach, existing research, and its ability to gain consensus through multiround expert engagement supports this methodology as appropriate to inform the development of a framework for the evaluation of clinical placement performance. As such, the outcomes of this study are intended to form part of a framework for the evaluation of allied health student-led health care services.

Abstract

Background: This co-design research method details the iterative process developed to identify health professional recommendations for the graphical user interface (GUI) of an artificial intelligence (AI)–enabled risk prediction tool. Driving the decision to include a co-design process is the belief that choices regarding the aesthetic and functionality of an intervention are best made by its intended users and that engaging these users in its design will promote the tool's adoption and use.

Objective: The aim of this research is to identify health professional design and uptake recommendations for the GUI of an AI-enabled predictive risk tool.

Methods: We will hold 3 research phases, each consisting of 2 workshops with health professionals, between mid-2023 and mid-2024. A total of 6 health professionals will be sought per workshop, resulting in a total enrollment of 36 health professionals at the conclusion of the research. A total of 7 workshop activities have been scheduled across the 3 workshops; these include context of use, notifiers, format, AI survey–Likert, prototype, AI survey–written, and testing. The first 6 of these activities will be repeated in each workshop to enable the iterative development and refinement of GUI. The last activity (testing) will be performed in the final workshop to examine health professionals' thoughts on the final GUI iteration. Qualitative and quantitative results data will be produced from tasks in each research activity. Qualitative data will be examined through inductive thematic analysis or deductive thematic analysis in accordance with the Nonadoption, Abandonment, and Challenges to the Scale-up, Spread, and Sustainability (NASSS) framework; visual data will be examined in accordance with "framework of interactivity;" and quantitative data will be examined using descriptive statistics.

Results: Project registration with the Australia and New Zealand Clinical Trial Registry has been requested (#384098). Finalized design recommendations are expected in early to mid-2024, with a results manuscript to be submitted in mid-2024. This research method has human research ethics approval from the South Australian Department of Health and Wellbeing (#2022/HRE00131) as well as from the Human Research Ethics Committee of the University of South Australia (application ID#204143).

Conclusions: Understanding whether an intervention is needed in a particular situation is just the start; designing an intervention so that it is used within that situation is paramount. This co-design process engages end users to create a GUI that includes the aesthetic and functional details they need in a manner that aligns with their existing work practices. Indeed, interventions that fail to do this may be disliked, and at worst, they may be dangerous.

Introduction

Dashboards summarize information in a meaningful manner to ensure users can make informed decisions in accordance with organizational objectives [1]. They can take many forms, such as electronic medical records (EMRs) or electronic health records (EHRs), as well as computerized provider order entry (CPOE), to name but a few. Each is advocated as a tool that increases productivity and efficiency, improves patient health care outcomes [2], and assists health professionals to avoid errors and drive down health care costs [3]. Yet despite their advocated benefits, health professionals encounter barriers to their use and sustainability [4].

In many instances, barriers result from dashboards' imposition on the way health professionals deliver care or the way in which they are required to interact with the platform in their professional practice. A thematic analysis of physician interviews identified that using the platform not only disrupted their patient consultation but also resulted in an additional time burden due to the need to record diagnostic codes [5]. Confidence in the quality of information within these records is of concern for health professionals, with "prescriber" views reporting that patient files included "untrustworthy" information and produced "irrelevant" alerts [6]. Distrust as to the true intent of health information technology (HIT) has also been identified, with some health professionals reporting feeling that their CPOE systems are a mechanism for oversight and performance monitoring [7]. How health professionals interact with dashboards can also create issues, with research identifying pharmacist views that CPOE use can be time consuming [8] and a struggle due to functional and navigational issues [9].

Workplace practice and navigational issues, among others, can accumulate and result in a negative experience for health professionals. Of the interviewed physicians, 64.2% reported "agreeing" or "strongly agreeing" that EMRs added to the "frustration of their day." Furthermore, these physicians also had significantly higher odds of burnout [10].

The introduction of artificial intelligence (AI)–enabled technologies in health care has been reported to raise several concerns for health professionals, specifically ethicality, data management, and its influence on health care delivery [11]. Alternatively, research on AI adoption reports that as health professionals' exposure to AI increases, their positive feelings toward it also increase, as do their satisfaction and use intentions [12]. It is critical, therefore, that health professionals' engagement with AI occurs in a positive manner to encourage adoption and repeated use.

Positive interaction with AI can be achieved through end-user engagement in graphical user interface (GUI) design. Indeed, the GUI is the most prominent, and perhaps the only, element of AI-enabled software with which the user will interact. Its appropriate design is therefore paramount. Co-design as a participatory process enables meaningful engagement with relevant users [13]. It is a process where the contributions of different users are synthesized [14], and it collaboratively integrates design thinking, stakeholder knowledge, scientific evidence, and the bottom-up approach of participatory action research to produce solutions to identify and address what is important within the local context [4]. Co-design will be used by this research to develop the notifiers (eg, graphs, dials, and icons) and layouts required because it places the user at the center of the research and development process with the goal of creating the version of the GUI that best represents their design needs.

The research method detailed herein will be performed as part of a PhD project and forms part of the larger Predictive Harm Response Management (PreHaRM) Algorithmic Tool to Reduce Adverse Events in Health Care Settings project. The purpose of the larger project is to develop and test an AI-enabled predictive risk algorithm and interface for use within the hospital setting (the PreHaRM tool). The PreHaRM tool will focus on the prediction of 3 adverse events: patient falls, medication errors, and occupational violence (patient or caregiver toward staff). The larger project, including this co-design project, is supported by Digital Health Cooperative Research Centre (DHCRC) Limited. DHCRC Limited is funded under the Australian Commonwealth Government's Cooperative Research Centers Program (Project #DHCRC-0156). The co-design workshops will develop health professionals informed recommendations for the visualization of the DHCRC PreHaRM tool.

Methods

Objective

The aim of this research is to identify health professional design and uptake recommendations for the GUI of an AI-enabled predictive risk tool. The primary and secondary objectives are described in the following sections.

Primary Objective

Objective 1: Identify health professionals design preferences for GUI aesthetics and function.

Secondary Objectives

Objective 2: Identify health professional usability levels for professional practice and PreHaRM GUIs.

Objective 3: Identify health professional acceptability levels for professional practice and PreHaRM GUIs.

Objective 4: Identify health professionals' perceptions of AI in health care in relation to its implementation and adoption.

Outcome Measures

Outcome measures developed in accordance with objective 1 are as follows:

- Participant for GUI aesthetic and function preferences tabulated and narratively synthesized according to the framework of interactivity.
- Participant visual design preferences tabulated and narratively synthesized according to the elements and principles of visual design.

Outcome measures developed in accordance with objective 2 are as follows:

XSL•FO
RenderX

- Participant System Usability Scale (SUS) scores for professional and PreHaRM GUIs.

Outcome measures developed in accordance with objective 3 are as follows:

- Barriers and enablers for professional and PreHaRM GUIs tabulated and narratively synthesized according to the theoretical framework of acceptability.

Outcome measures developed in accordance with objective 4 are as follows:

- Participant "AI potential impact" scores measured by the 10-question Shinners Artificial Intelligence Perception tool.
- Participant "AI readiness" scores measured using the 10-question Shinners Artificial Intelligence Perception tool.
- Barriers and enablers to AI adoption in health care tabulated and narratively synthesized according to the Nonadoption, Abandonment, and Challenges to the Scale-up, Spread, and Sustainability (NASSS) framework.

Study Design

A total of three 2-month research phases have been scheduled from mid-2023 to mid-2024, with 2 co-design workshops scheduled per phase, one in Adelaide (University of South Australia city west campus), the other in Tonsley (Tonsley Innovation District) for Central Adelaide and Southern Adelaide Local Health Network staff, respectively. If required, participants may attend using teleconferencing software (eg, Zoom) and collaborative software (eg, Miro). Each workshop will be led by an experienced facilitator and run for approximately 2 and a half hours. A total of 2 support staff will also be in attendance: one will observe and note proceedings while a second will provide operational support to the facilitator (eg, information technology troubleshooting, handing out and collecting activity sheets).

Members of the PreHaRM clinical implementation team (CIT) will be asked to promote each workshop by circulating an invitation to colleagues within their peer network. Individuals who confirm their interest in the workshop will be emailed workshop details (ie, session date, time, and location). A total of 6 participants will be enrolled in each workshop, resulting in a total of 12 participants per research phase, for a maximum total of 36 participants (Table 1). The total number of individuals may be less than 36, as participants will be allowed to attend more than one workshop should they choose to; however, this repeat attendance is not a requirement and will be made at their discretion.

Table 1. Research phase and co-design workshop schedule.

Phase and location	Participants, n	Date[a]
Research phase 1		
CALHN[b] workshop 1	6	September
SALHN[c] workshop 1	6	September
Research phase 2		
CALHN workshop 2	6	November or December
SALHN workshop 2	6	November or December
Research phase 3		
CALHN workshop 3	6	January or February
SALHN workshop 3	6	January or February

[a]Proposed 2023 time period.

[b]CALHN: Central Adelaide Local Health Network.

[c]SALHN: Southern Adelaide Local Health Network.

Inclusion and Exclusion Criteria

Nurses have been identified as the target user of the GUI, and as such, the inclusion and exclusion criteria below reflect the need to attract a diverse range of participants from this professional group; for example, nurses of all levels (including enrolled, registered, and nursing unit managers) will be sought so the diversity of their experience can benefit the design. Criteria for enrollment are listed in Textbox 1 below.

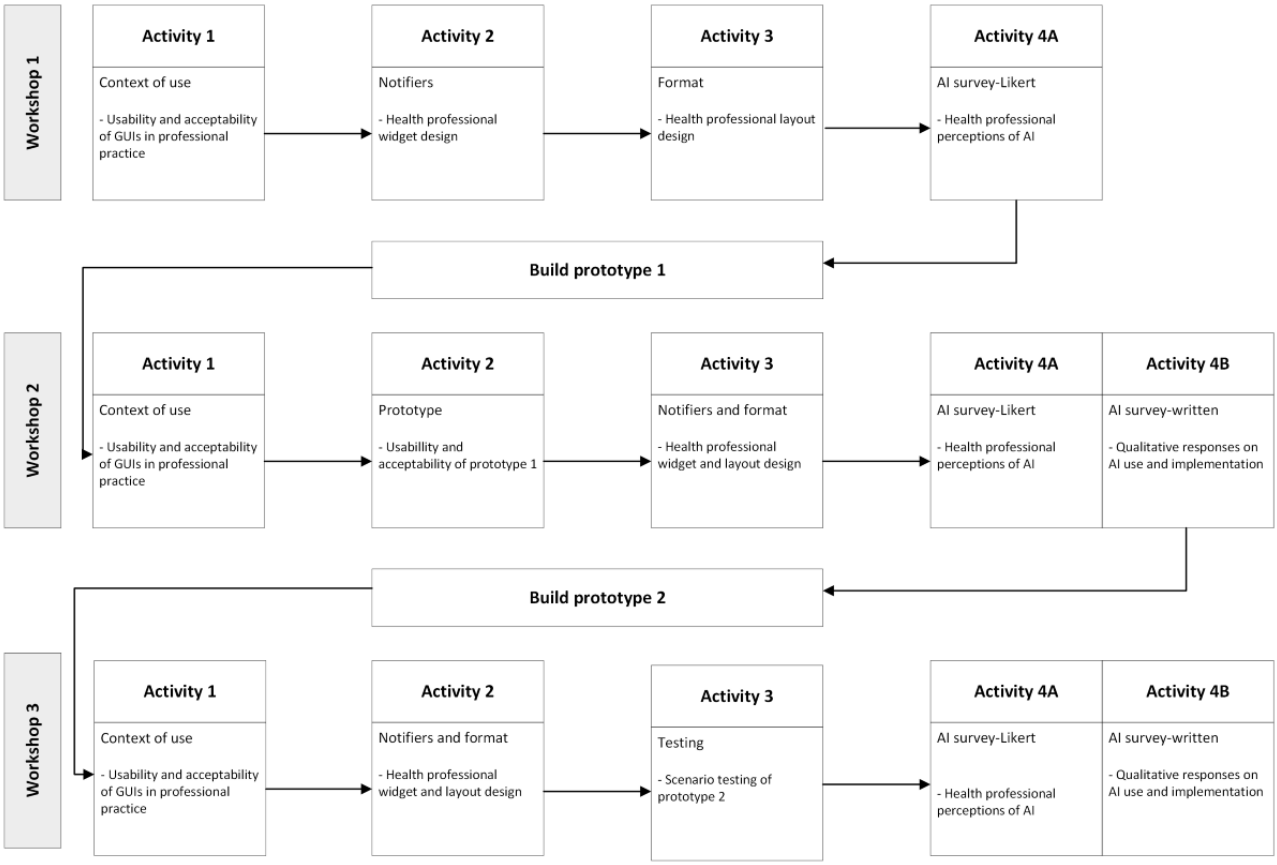
XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Enrolled nurses
- Registered nurses
- Nursing unit managers
- Nurses in noncare roles
- Use health information technology in professional role
- Able to provide informed consent

Exclusion criteria



- Not employed by SA Health
- Unable to provide informed consent

Iterative Workshops

An iterative co-design process will run across each of the workshops. Each workshop includes predesign and generative activities, noting that these activities will culminate in the testing activity held in the third workshop. Figure 1 illustrates the focus and relationship of each workshop, as well as the overall iterative co-design process.

A description of each workshop activity is provided in Table 2 below.

Figure 1. Iterative co-design process. AI: artificial intelligence; GUI: graphical user interface.

XSL•FO
RenderX

Table 2. Workshop activity matrix.

Activity	Description	Tools
Context of use	Participants will be asked about their use of GUIs[a] at work.	• Web-based survey • Moderator guide
Notifiers	Participants will be asked to design notifiers (eg, graphs, dials, or icons) that they would like to see on the PreHaRM[b] GUI.	• Generative toolkits
Format	Participants will be asked to arrange their chosen visualizations on a mock GUI.	• Generative toolkits
AI survey–Likert	Likert scale questions will investigate participant feelings toward AI[c] enabled software in health care.	• Web-based survey
Prototype	Participants will be asked to provide feedback in relation to the potential usability of the PreHaRM prototype 1.	• Web-based survey • Moderator guide
AI survey–written	Participants will be given results from previously completed surveys and asked to contextualize the results from their point of view.	• Web-based survey
Testing	Participants will be asked provide feedback on their use of prototype 2 in relation to a mock workplace scenario.	• Scenario testing • Web-based survey

[a]GUI: graphical user interface.

[b]PreHaRM: Predictive Harm Response Management.

[c]AI: artificial intelligence.

Workshop Tools

Workshop tools and the method for analyzing their respective results data are described in the follows sections.

Surveys

A background survey will be used to obtain basic participant demographic information (workshops 1-3). The SUS will be used to examine participants views on the usability and acceptability of GUIs currently used in their professional practice (“context” activity, workshops 1-3) [15]; a sample survey has been included for reference (Multimedia Appendix 1). The SUS activity survey will also be used to understand participant views on the PreHaRM prototypes 1 and 2 (“prototype” activity, workshop 2, and “testing” activity, workshop 3). The Shinners Artificial Intelligence Perception (SHAIP) framework will be used to identify health professionals’ perceptions of AI in health [11] (AI survey–Likert, workshops 1-3). The third survey will present results from the AI survey–Likert alongside written questions asking participants to interpret and report what these results mean (AI survey–written, workshops 2-3). All surveys will be delivered using a web-based platform (eg, Microsoft Forms). All data will be downloaded from the web-based survey platform for analysis. Quantitative data collected from the background, SUS, and SHAIP surveys will be examined using descriptive statistics calculated in R (version 4.2.0; R Core Team). Qualitative data collected from the AI Survey–written will be coded against the 22 themes within the NASSS framework in NVivo (version 14; QSR International) [16]. Coding will be performed by NM with checking by a second researcher; any disagreements will be reviewed by KCC.

Moderator Guide

Health professionals’ acceptance of professional practice GUIs as well as the PreHaRM prototype GUI will be examined through questions contained in a semistructured moderator guide. Their responses will be audio recorded and transcribed, and the coding of responses will then be performed against the 8 domains of the theoretical framework of analysis (TFA) [17]. Coding will be performed by NM and checked by a second researcher, with any disagreements reviewed by KCC.

Generative Toolkits

For notifier development, participants will be given example cut-outs and asked to amend them to represent how they’d prefer it to look. Blank paper, colored markers, and other materials will be provided for participants should they prefer to draw their own notifiers. For layout development, participants will be given GUI screen templates (and blank pieces of paper) onto which they can arrange their chosen notifiers to design their preferred GUI (“notifiers” and “format” activities, workshops 1-3).

Notifiers and layouts will be produced using generative toolkits. Both artifact types will be assessed to identify their aesthetic and functional characteristics. Aesthetic characteristics will be examined in relation to the visual elements that comprise each artifact (ie, line, shape, color palette, texture, typography, and form) as well as the use of visual design principles (ie, unity, gestalt, space, hierarchy, balance, contrast, scale, dominance, and similarity) [18]. Functional (or interactive) characteristics will be examined using the framework of interactivity [19]; this will be used to categorize each artifact in regard to its ideational, interpersonal, and textual intent. All artifacts will be examined by NM, with results recorded on an Excel spreadsheet developed a priori. These will be checked by a second researcher, with KCC adjudicating any disagreements. Review of the content

XSL•FO
RenderX

and frequency of these results will inform the PreHaRM design recommendations.

Scenario Testing

A mock scenario to test PreHaRM prototype 2 will be developed using CIT, the technical advisory group (TAG), and research staff input. Participants in workshop 3 will be offered 1 opportunity to attempt the tasks within the scenario ("testing" activity, workshop 3). All attempts will be video recorded, either through screen capture software or a separate video camera. Participant attempts will be examined using "navigation testing," where participants' time taken as well as navigation hits and misses will be recorded. Exploration results will be examined using descriptive statistics calculated in R. Following their completion of the scenario, they will be asked to complete the SUS questionnaire, and the resultant data will be examined as per the process described above.

Unstructured Interviews

Following the completion of each workshop, attendees will be offered the opportunity to participate in voluntary, one-on-one, unstructured interviews with NM. The purpose of the interview is to enable participants to provide further information about their workshop feedback or to provide new feedback if they feel uncomfortable raising it in a group context. Interviews will be offered through teleconferences only (Zoom; version 5.12.8; Zoom Video Communications Inc). These interviews will be offered as an opt-in opportunity, and it will be explained that participation in any workshop is not contingent on their participation in the interviews.

In unstructured interviews, it is unclear what participants may choose to discuss; consequently, inductive thematic analysis will be used to examine participant interview transcripts. This will be performed using NVivo. Participant perspectives will be coded by NM and examined by KCC.

Data Management

All workshops and follow-up interviews will be audio recorded using a digital recording device; scenario testing activities will be recorded using video cameras; hardcopy artifacts (ie, visualizations and dashboards) will be collected by PreHaRM researchers; and participant surveys will be collated using web-based software. Audio recordings will be transcribed using voice recognition Rev (Rev.com, Inc); video recordings will be reviewed using Adobe Premiere Pro (version 23.0.0; Adobe Inc); Microsoft Forms will host each survey and automatically collate responses. Once the survey period has ended, collated responses will be downloaded. All electronic data will be stored in password-protected folders at the University of South Australia, Australia. All artifacts will be stored in facilities at the University of South Australia, Australia. All data will be retained for a minimum of five years after project completion in accordance with Australian State and Commonwealth guidelines.

Peer-reviewed manuscripts, posters, and oral presentations detailing the co-design process and results will be produced; information used in these research outputs will be deidentified. If video recordings are used, then participant likenesses (audio and visual) will be obscured. Data sets generated and analyzed during this research are not publicly available due to dissemination restrictions resulting from the ethics approval process.

Ethical Considerations

A participant information sheet and consent form will be emailed to all participants before each workshop. Hardcopies will be available at the start of each session, and all individuals must read the information sheet and sign the consent form before participating. This research method has human research ethics approval from the South Australian Department of Health and Wellbeing (#2022/HRE00131) as well as from the Human Research Ethics Committee of the University of South Australia (application ID#204143). No research activity will commence until approvals from both committees have been received. All research data will be deidentified by researchers. Participants will be offered an AU $50 (US $32.82) gift card for their attendance.

Results

Recruitment for this project will commence in mid-2023, with data collection scheduled to commence in mid- to late 2023 and end in mid-2024. Co-design and review will occur throughout the data collection period.

Discussion

Strengths

The key strength of this research and the broader PreHaRM project is the purposeful engagement of end users in each research activity; this is research with health professionals for health professionals. Preliminary engagement with the state government and local health networks has been achieved through engagement with the CIT. Comprised of senior hospital staff and government health care data professionals (managers and stewards), this group provides strategic information on data collection and use within the local health care system. This insight provides PreHaRM researchers with a deeper understanding of the administrative and technical context in which health professionals work. Similarly, the PreHaRM TAG includes leaders in AI software development and interface design. This group guides researchers' thinking on the capacity of the PreHaRM algorithm. Both the CIT and the TAG have already been central to the predesign phase [20] and will continue to remain involved in the upcoming stages of the design process. Health professionals drive the generative phase of the PreHaRM tool primarily through their efforts in the "notifiers" and "format" activities, but also through their descriptions of software use and their feelings toward AI within health care. The evaluative activities of researchers and the presentation of these results back to health professionals further involve them in the iterative and generative process at the crux of this research. The broad contextualization of the health care system and guidance of AI development from the CIT and TAG, respectively, are operationalized through the generative activities of health professionals at the "coal face."

XSL•FO
RenderX

Limitations

As primary end users, nurses are the target cohort for each workshop, and their input in these sessions will inform the PreHaRM GUI. Within the hospital context, however, it is possible that other health professionals may also use the PreHaRM GUI. Callen et al [21] identified that differences in organizational culture along professional lines represent differences in attitudes toward HITs. Therefore, the focused recruitment of one health professional group is a potential limitation; future research should broaden recruitment to capture the design requirements of additional health professional cultures. Additional in situ research should be conducted with health professionals to confirm the issues they noted in the sessions are as consequential as they are real and to seek further refinements that improve the adoption of the PreHaRM tool.

Practical Significance

This project will engage health professionals in an iterative co-design process across 3 workshops. This process of repeat engagement will enable researchers to refine recommendations for the aesthetics and functionalities of the PreHaRM GUI. It is anticipated that by adopting their recommendations, health professionals will be more likely to accept and use this tool and to prevent forecast events from occurring. The target audience of this protocol is other health researchers, health professionals interested in research, and user interface and user experience design researchers.

Conclusions

The PreHaRM tool will combine an AI-enabled predictive risk algorithm with a co-designed GUI. The purpose of this algorithm is to identify the potential occurrence of adverse events, whereas the purpose of the GUI is to convey these potential events to health professionals in a meaningful manner. Indeed, the presentation of the algorithm results is paramount if the warning it displays is to be acknowledged and actioned. Co-design will be used in this research to identify end user aesthetic and functionality design recommendations to help ensure the appropriateness of the final product and its incorporation with existing work practices. This research takes as a basic assumption that the PreHaRM GUI, designed with input from health professionals, will be used by professionals to the benefit of patients and their families.

Abstract

Background: Commonly used noninvasive serological indicators serve as a step before endoscope diagnosis and help identify the high-risk gastric cancer (GC) population. However, they are associated with high false positives and high false negatives. Alternative noninvasive approaches, such as cancer-related features in cell-free DNA (cfDNA) fragments, have been gradually identified and play essential roles in early cancer detection. The integrated analysis of multiple cfDNA features has enhanced detection sensitivity compared to individual features.

Objective: This study aimed to develop and validate an assay based on assessing genomic-scale methylation and fragmentation profiles of plasma cfDNA for early cancer detection, thereby facilitating the early diagnosis of GC. The primary objective is to evaluate the overall specificity and sensitivity of the assay in predicting GC within the entire cohort, and subsequently within each clinical stage of GC. The secondary objective involved investigating the specificity and sensitivity of the assay in combination with possible serological indicators.

Methods: This is an observational case-control study. Blood samples will be prospectively collected before gastroscopy from 180 patients with GC and 180 nonmalignant control subjects (healthy or with benign gastric diseases). Cases and controls will be randomly divided into a training and a testing data set at a ratio of 2:1. Plasma cfDNA will be isolated and extracted, followed by bisulfite-free low-depth whole methylome sequencing. A multidimensional model named Thorough Epigenetic Marker Integration Solution (THEMIS) will be constructed in the training data set. The model includes features such as the methylated fragment ratio, chromosomal aneuploidy of featured fragments, fragment size index, and fragment end motif. The performance of the model in distinguishing between patients with cancer and noncancer controls will then be evaluated in the testing data set. Furthermore, GC-related biomarkers, such as pepsinogen, gastrin-17, and *Helicobacter pylori*, will be measured for each patient, and their predictive accuracy will be assessed both independently and in combination with the THEMIS model

Results: Recruitment began in November 2022 and will be ended in April 2024. As of August 2022,250 patients have been enrolled. The final data analysis is anticipated to be completed by September 2024.

Conclusions: This is the first registered case-control study designed to investigate a stacked ensemble model integrating several cfDNA features generated from a bisulfite-free whole methylome sequencing assay. These features include methylation patterns, fragmentation profiles, and chromosomal copy number changes, with the aim of identifying the GC population. This study will determine whether multidimensional analysis of cfDNA will prove to be an effective strategy for distinguishing patients with

XSL•FO
RenderX

GC from nonmalignant individuals within the Chinese population. We anticipate the THEMIS model will complement the standard-of-care screening and aid in identifying high-risk patients for further diagnosis.

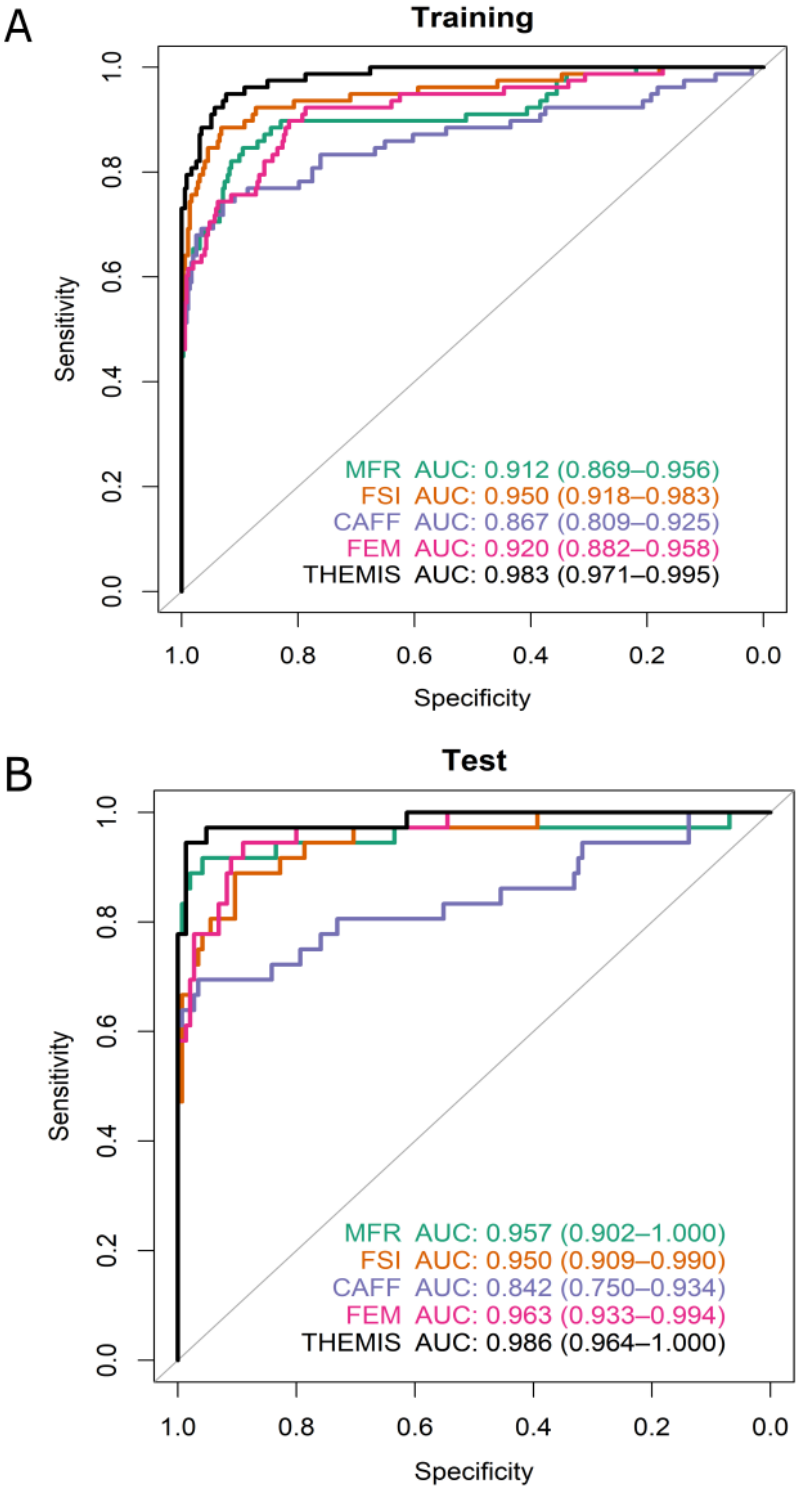
Introduction

Gastric cancer (GC) is one of the most commonly diagnosed digestive tract tumors, accounting for approximately 1.08 million new cases and an estimated 769,000 deaths in 2020 worldwide (7.7% of total cancer-related deaths), ranking fifth for age-standardized incidence and fourth for cancer-related mortality worldwide [1]. China is among the countries with the highest incidence rate of GC, although a gradual decline has been observed in recent years [2,3]. Early GC detection and its prompt treatment are strongly associated with improved prognoses for patients with GC. In Japan and South Korea, population-wide screening has been extensively implemented, resulting in effective diagnosis of tumors at early stages and improved survival rates [4]. Unfortunately, in China, most patients are diagnosed with advanced GC, probably owing to the large population and lack of standardized screening programs. While gastroscopy (upper gastrointestinal endoscope) and biopsy procedures conducted during gastroscopy remain the gold standard methods for GC diagnosis, gastroscopy is an invasive operation often met with poor compliance. Moreover, insufficient endoscopy physicians and endoscopic equipment, as well as the lack of a standardized endoscopic examination in China, present challenges for endoscopy to be used as a population-wide screening method [5].

Currently available noninvasive blood biomarker–based approaches could serve as a step before endoscope diagnosis and aid in identifying the high-risk GC population. However, these methods are associated with high false positives and high false negatives, which can potentially lead to overdiagnosis or underdiagnosis. Serological indicators such as *Helicobacter pylori* antibodies lack specificity for GC detection due to their strong association with atrophic gastritis and gastric ulcers [5]. Other indicators, including serum pepsinogen (PG), serum gastrin-17 (G-17), and MG7-Ag, are not recommended for standalone use due to their poor sensitivity and specificity [6]. A new GC score system based on age, sex, PG, G-17, and *H pylori* antibodies was introduced in China's early GC screening process expert consensus [5]. While this new GC score system might exhibit improved prediction performance [7], the cost-benefit of its clinical application needs to be analyzed. Plasma tumor markers, such as carcinoembryonic antigen, cancer antigen (CA) 19-9, CA 72-4, CA 125, and CA 242, are linked to patient prognosis but are not suitable for early cancer detection [8]. Furthermore, circulating molecules such as miRNAs have garnered attention; however, their sensitivity and specificity are limited [9,10].

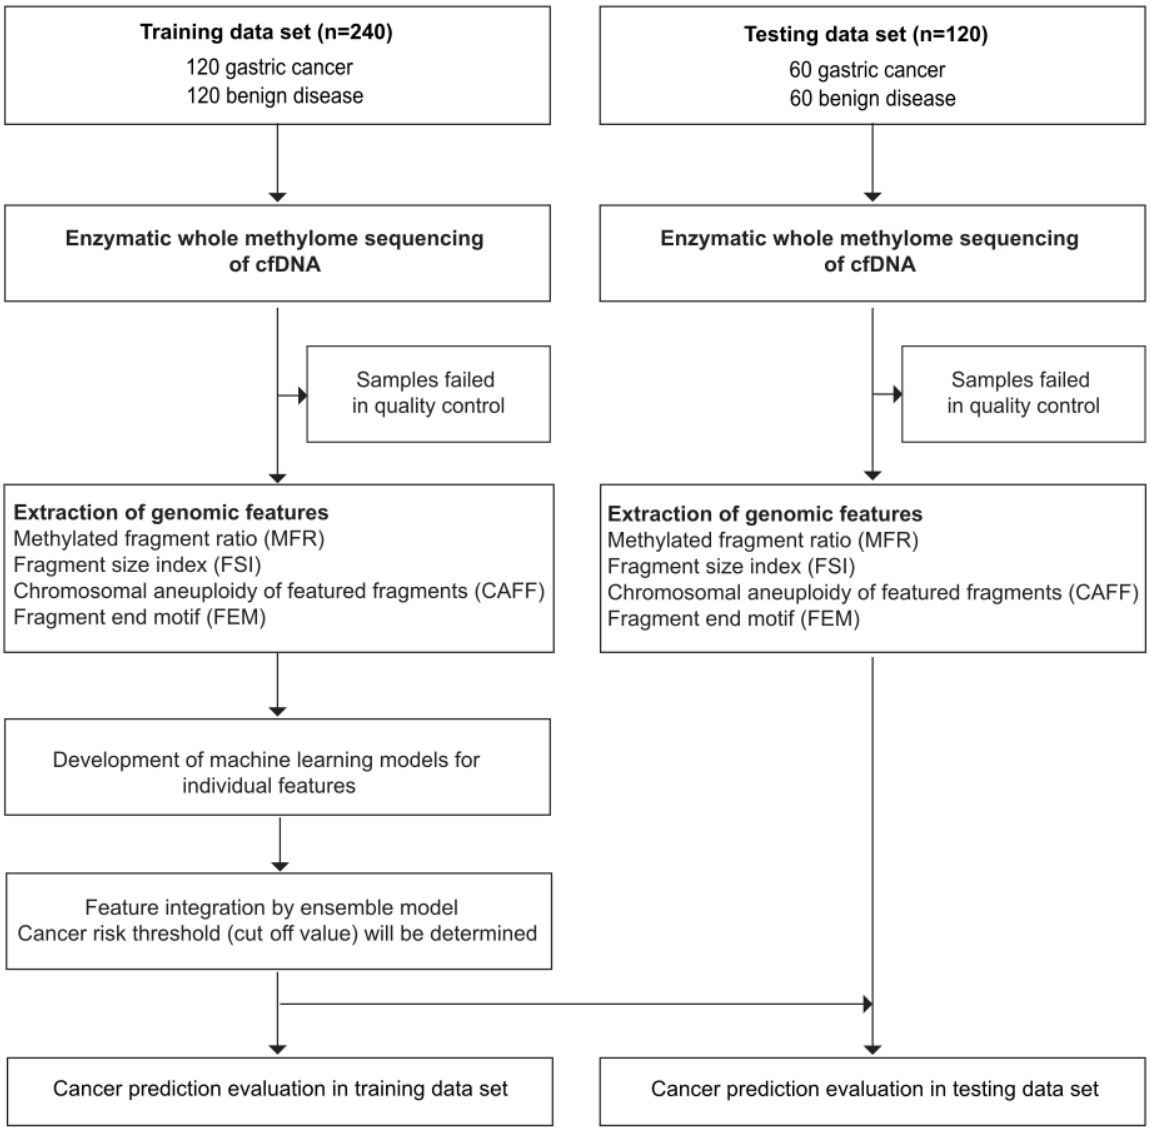
Rapid advancements in technology and analysis have identified cell-free DNA (cfDNA) as a new, simple, and noninvasive method for early cancer detection, offering enhanced specificity and sensitivity. The cancer-related features of cfDNA have been exploited in several aspects to distinguish cancer samples from healthy cases: (1) genetic alterations [11-13], (2) microsatellite instability [14], (3) hypermethylation or hypomethylation of certain genes [15,16] or across the genome [17-19], (4) chromosomal alterations [20], and (5) unique fragmentation patterns [21,22]. Among these aspects, identifying cfDNA genetic alterations poses a challenge due to the low fraction of mutation-bearing circulating tumor DNA (ctDNA) fragments in early-stage diseases or certain tumor types [23,24]. The combination of multiple features has enhanced detection sensitivity in comparison to relying on a single feature, as studied in kidney cancer [25], hepatocellular cancer, and pancreatic ductal cancer [26].



We have also previously developed a multidimensional ensemble model named Thorough Epigenetic Marker Integration Solution (THEMIS). This model integrates various cfDNA features, including methylated fragment ratio (MFR), chromosomal aneuploidy of featured fragments (CAFF), fragment size index (FSI), and fragment end motif (FEM), enabling highly sensitive early detection across a pan-cancer cohort [27]. In a subgroup comprising 114 patients with GC and 497 healthy controls, the THEMIS model showed an estimated area under the curve of 0.983 for the training data set (Figure 1A) and 0.986 for the test data set (Figure 1B). However, the fact that the model was trained on a pan-cancer cohort and the control group did not contain individuals with benign gastric diseases limits its predictive reliability for GC.

This study aimed to develop a highly sensitive GC-specific THEMIS model for the early detection of GC. This study's design is illustrated in Figure 2. Patients with GC will be enrolled in the malignant group, while the control group will comprise not only healthy individuals but also participants with benign gastric diseases, such as gastritis, gastric ulcers, and gastric polyps. Consequently, a novel model will be developed to differentiate malignant cancer from nonmalignant gastric status. A nonbisulfite enzymatic whole methylome sequencing (WMS) assay [28] will be applied to ensure the preservation of methylation signals from the cfDNA alongside the molecular fragmentation profile. The sequencing data generated from cfDNA will then be analyzed across the abovementioned multiple dimensions, encompassing methylation patterns, chromosomal copy number alterations, and fragmentation profiles. In addition, GC-related biomarkers, such as PG, G-17,

XSL•FO
RenderX



and *H pylori*, will be evaluated either independently or in combination with cfDNA features during model training to enhance the detection sensitivity. The overall clinical performance of the model, as well as its performance in each clinical stage, will be evaluated.

Figure 1. Receiver operating characteristic curve analysis showing the cancer prediction performance of the THEMIS model in the GC subgroup: (A) training data set; (B) test data set. The AUC together with the 95% CI is shown. AUC: area under the curve; CAFF: chromosomal aneuploidy of featured fragments; FEM: fragment end motif; FSI: fragment size index; MFR: methylated fragment ratio; THEMIS: Thorough Epigenetic Marker Integration Solution.

Methods

Study Objectives

This study aims to develop and validate a novel blood-based WMS method followed by the development of a multidimensional model for the analysis of various features of cfDNA specifically for early GC detection. We expect that this noninvasive liquid biopsy assay will be instrumental in distinguishing individuals with a high probability of GC. Individuals who receive a positive test result will subsequently obtain a confirmed diagnosis by gastroscopy. Conversely, individuals who receive a negative test result will considered as having a low probability of GC. For this group of patients, they would be recommended to undergo a deferred gastroscope, and possibly a repeated test annually.

The primary objective is to validate the overall diagnostic specificity and sensitivity of the model and additionally assess its performance in each clinical stage of GC. The secondary objective is to investigate the specificity and sensitivity of the model when combined with potential biomarkers such as PG, G-17, or *H pylori* levels, aimed at enhancing early GC detection.

Study Population

This study will enroll individuals who receive gastroscopy at Xijing Hospital of Air Force Military Medical University, Xi'an, China. Further, 2 groups will be formed based on the outcomes of gastroscopy: a malignant group and a nonmalignant group. The malignant group will include patients diagnosed with high-grade intraepithelial neoplasia or GC (more than 90 patients corresponding to >50% of patients in stages I and II), while the nonmalignant group will include both healthy individuals and patients with gastritis, gastric ulcers, gastric polyps, or other benign gastric diseases.

Clinical parameters, such as personal history, family history of digestive tract cancer, gastroscopic findings, and GC staging, will be systematically collected for each subject. Blood samples will be collected for WMS analysis, the results of which will be used to establish a GC diagnostic model.

XSL•FO

Inclusion Criteria

Subjects will be enrolled after understanding and signing the informed consent form, ensuring their eligibility based on the provided inclusion or exclusion criteria.

Inclusion criteria must be fulfilled: (1) age 18 years or older, male or female; (2) availability of complete clinical information; and (3) agreement of the patient to join this study with signed consent and good compliance.

An additional specific inclusion criterion for subjects to be included in the malignant group must be fulfilled: confirmation of gastric adenocarcinoma through histopathology in accordance with the American Joint Committee on Cancer's 8th Edition Cancer Staging Manual, with a pathological stage ranging from stage I to IV. This includes patients with esophageal gastric junction adenocarcinoma, regardless of histology types.

Exclusion Criteria

Subjects will be considered ineligible if any of the following exclusion criteria are met: (1) they have previously been diagnosed with any kind of malignant tumor, (2) they have received total or partial gastrectomy, (3) they have received bone marrow or organ or stem cell transplantation, (4) they have received blood transfusion within the past 6 months, (5) they have previously received any form of local or systematic antitumor treatment, (6) they had ongoing fever or received anti-inflammation therapy within 14 days prior to blood draw for this study, (7) if female, they were pregnant or lactating, and (8) clinical information was incomplete or the subject was unqualified to participate in this study.

Discontinuing Study Interventions and Patient Withdrawal

If the ongoing study is later considered to be infeasible, the principal investigator shall submit a termination application to the institutional review committee (IRC). The decision for the termination will be made by the IRC. Following the decision, the principal investigator shall provide a clinical trial termination report to the IRC.

Subjects may be withdrawn from this study for the following reasons: (1) subjects request to exit the trial and withdraw informed consent, (2) subjects refuse to have blood samples collected, even after providing informed consent, (3) sufficient blood sample collection is difficult for the subjects, and (4) subjects enrolled by mistake and are later assessed to be unsuitable for this study.

Sample Collection

In total, 20 ml of peripheral blood will be collected from each subject and stored in a Cell-Free DNA Storage Tube (Cwbiotech). Each subject's information, such as index, name, sample type, and collection time, will be marked clearly. Blood samples shall be delivered to the laboratory within 72 hours at 15 °C-35 °C to proceed with plasma extraction. In situations where timely delivery to the laboratory is not feasible, the blood samples shall be centrifuged at 4000 × g for 15 min at 4 °C and the upper layer containing plasma will be transferred to a new tube. Approximately 4 ml of plasma will be obtained and stored at −80 °C until use. Alternatively, for a period of no more than 1 month before transportation, the plasma can be stored at –20 °C.

cfDNA Extraction

The plasma samples that were prepared in the previous step will be processed for cfDNA extraction by using the MagMAX Cell-Free DNA Isolation Kit (Thermo Fisher Scientific) per the manufacturer's instructions. The quantity and quality of extracted cfDNA will be assessed with a Bioanalyzer 2100 (Agilent).

WMS Library Construction

The entire amount of extracted plasma cfDNA (capped at 15 ng if exceeding what is needed) for each sample will be used to generate WMS libraries with the NEBNext Enzymatic Methyl-seq Kit (New England Biolabs) according to manufacturer instructions, with 1 modification: 100 ng of carrier RNA (TIANGEN) will be added before denaturation by sodium hydroxide. The generated libraries will be amplified with 9 polymerase chain reaction cycles, followed by quantification using the Qubit dsDNA HS Assay Kit (Thermo Fisher Scientific). After that, the constructed libraries will be subjected to sequencing on a NovaSeq 6000 system (Illumina) with a paired-end read length of 100 bp.

Model Establishment

The estimation data set will be used to establish a machine learning model aimed at predicting cancer probability. Various features associated with plasma cfDNA fragments, such as their methylation status, will be subjected to data preprocessing, feature filtering, and model selection. This will lead to creation of respective classifier models. In a prior context, we defined these features as MFR, CAFF, FSI, and FEM.

MFR Feature

Genomic methylation status undergoes substantial alterations even in the early cancer development stage. The release of ctDNA by cancer cells can lead to changes in the methylation levels of cfDNA present in the plasma. To quantify these changes, the whole genome will be tiled into nonoverlapping 1 Mb windows. The methylation levels within each window will be quantified by the fraction of fragments featuring fully methylated CpGs, thereby resulting in the computation of MFR.

CAFF Feature

Cancer cells often exhibit chromosomal instability, with instances of partial or complete amplification or loss of chromosomal arms [29,30]. To account for this, a previously described plasma aneuploidy score will be calculated for each sample. This calculation will rely on the levels of copy number alterations in 5 specific chromosome arms, which exhibited the most significant copy number alterations when compared to baseline samples [20].

FSI Feature

The size frequency of ctDNA fragments released from cancer cells differs from that of cfDNA [31]. By tiling the whole genome into nonoverlapping 1 Mb windows, the read ratio between short fragments (100-166 bp) to long fragments (169-240 bp) will be computed, resulting in the determination

XSL•FO
RenderX

of the FSI. Subsequently, the FSI of each sample will be contrasted with the healthy population baseline, and the cancer risk for each subject will be estimated.

FEM Feature

The preferred FEMs of ctDNA differ from those of cfDNA due to DNA nuclease downregulation in the cfDNA fragmentation process [31]. The frequency of a total of 256 4-nucleotide (ie, 4-mer) fragment 5' end motifs will be analyzed, with the following modifications: (1) only fragments shorter than 171 bp will be selected for analysis, and (2) only reads mapped to the Crick strand will be used for calculation.

An ensemble classifier named THEMIS has been developed based on a generalized linear model incorporating elastic-net penalization. THEMIS is established by integration of the 4 abovementioned features, which includes the predicted cancer probability scores by MFR, FSI, and FEM along with the plasma aneuploidy scores of CAFF. R packages such as *CARET* under 20-fold cross validation will be used.

Sample Size Estimate and Statistical Analysis

The sample size was estimated using the strategy mentioned by Negida et al [32]. Based on the abovementioned pilot study, the ensemble THEMIS model reached a sensitivity of 0.94 with 0.95 specificity (Figure 1). We expect that the new model integrating similar features as THEMIS will attain a sensitivity of at least 0.9. If we consider the 95% CI width of 0.08 (2-sided test α=.05), then at least 54 cancer cases will be required. If we also expect a certain amount of dropout, such as 10%, a minimum of 60 cases will be needed. The same number of patients will be enrolled in the nonmalignant control group for this case-control study. The plan is to allocate both groups of subjects by the same 2:1 ratio into training and testing data sets. Ensuring at least 60 cases and 60 controls within the testing data set, a total of 360 subjects (180 cancer cases and 180 controls) will be enrolled. This ensures that each group is composed of no fewer than 180 subjects. The malignant group and the control group will be matched by age and sex to minimize possible confounding factors (Figure 2).

The area under the curve, constructed with a receiver operator characteristic analysis calculated by the *pROC* package, will be used to evaluate individual classifier models as well as the ensemble model's performance in distinguishing between cancer and noncancer conditions. Clinical diagnosis results, including but not limited to gastroscopy or pathological determinations, are considered the "gold standard." The cancer risk threshold (cutoff value) will be determined based on the training data set. After that, the prediction performance of the established model will be evaluated in the testing data set in several aspects, including sensitivity, specificity, positive prediction value, and negative prediction value. These variables, as well as 95% CI, will be calculated using the *epiR* package. The Cohen κ score will be calculated with the *vcd* R package to demonstrate the concordance of the predicted results versus the pathological diagnostic results. A single-blind analysis will be applied, which means that the bioinformatics analysts will be blinded to whether the subjects have GC or not. The results are considered significant if the *P* value is <.05. All statistical analyses will be performed in R (version 3.6.3; R Core Team).

Patient and Public Involvement Statement

Patients, healthy subjects, and the public will not be involved in our studies for reporting, designing, or implementation. We have no intention of sharing this study's results with the participants, unless they proactively request to receive this information.

Ethics Approval

The design and implementation of this study strictly followed the Declaration of Helsinki and Chinese medical research norms and regulations. This protocol was approved by the Medical Ethics Committee of the First Affiliated Hospital of the Air Force Medical University (Xi'an, China; approval No. KY20222222-F-1). This study was also registered at ClinicalTrial.gov (NCT05668910).

All enrolled subjects signed informed consent forms for blood sample retention, and they were fully informed that their blood samples would be used for scientific experimental research. A primary principle of this study is to protect the rights and interests of the subjects while ensuring the scientific nature of this study and the authenticity of the data. The subjects shall be volunteering to participate in this study, and their privacy will be fully respected. Throughout this study, all the data will be anonymized and maintained with confidentiality.

Results

Recruitment began in November 2022 and as of August 2023, we enrolled 250 patients. The last recruitment is expected to finish by April 2024. As for data analysis, it is anticipated to be finalized by September 2024.

Discussion

The primary aim of this study was to evaluate the effectiveness of using combined cfDNA features, determined through WMS analysis, for early cancer detection. If our model is incorporated into current clinical practices, an individual with a positive result would subsequently undergo either a gastroscopy, a biopsy, or both to ascertain the presence of GC. Conversely, a negative result would indicate a low likelihood of GC and prompt recommendations for a deferred gastroscopy, along with the possibility of an annual repeated test.

The major strength of this study is that this is the first registered observational study, to our knowledge, designed to evaluate the integrated analysis of methylation patterns, fragmentation profiles, and chromosomal copy number changes in cfDNA for early GC detection. Additionally, cfDNA studies designed for the Chinese GC population are limited. Our study will reveal whether multidimensional analysis of cfDNA is an effective strategy for differentiating patients with GC from nonmalignant individuals in the Chinese population.

This study has several potential limitations. Foremost among these is the fact that it is a case-controlled study with a relatively modest cohort size. We acknowledge that case-control studies,

XSL•FO
RenderX

especially those performed at a single site, are susceptible to selection bias. Individuals enrolled from a single hospital may not be fully representative of the diversity of a general screening population. Given these limitations, a comprehensive and sizable prospective validation within a screening population will be pursued prior to considering clinical implementation. Another limitation would be that it is impossible to include all the possible benign gastric disease types in the control group; therefore, the constructed model might have limited ability to differentiate GC from other types of benign diseases beyond this study. In addition, although the individuals will be prospectively enrolled in this study, the analysis will be carried out retrospectively. However, it is notable that the bioinformatics analysts will remain blinded to the true pathological outcomes during the validation of the model in the testing cohort, thereby mitigating the potential analysis bias.

Should the results of this research align with our expectations, they will furnish support for the use of ctDNA in early detection of patients with GC. The THEMIS model could significantly contribute by complementing the standard-of-care screening and aiding in the differentiation of high-risk patients warranting further diagnostic evaluation. The findings of this study, looking ahead, could substantially enhance early screening and early diagnosis practices, potentially resulting in a shift toward earlier-stage diagnoses and consequently elevating the 5-year survival rate for patients with GC.

Acknowledgments

This study is supported by the National Key R&D Program of China (2021YFC2500400). It is sponsored by Genecast Biotechnology, which will participate in the detection of the samples and has reviewed this paper and approved it for publication.

Abstract

Background: The US overdose epidemic is an escalating public health emergency, accounting for over 100,000 deaths annually. Despite the availability of medications for opioid use disorders, provider-level barriers, such as negative attitudes, exacerbate the treatment gap in clinical care settings. Assessing the prevalence and intensity of provider stigma, defined as the negative perceptions and behaviors that providers embody and enact toward patients with substance use disorders, across providers with different specialties, is critical to expanding the delivery of substance use treatment.

Objective: To thoroughly understand provider stigma toward patients with substance use disorders, we conducted a nationwide survey of emergency medicine and primary care physicians and dentists using a questionnaire designed to reveal how widely and intensely provider attitudes and stigma can impact these providers' clinical practices in caring for their patients. The survey also queried providers' stigma and clinical practices toward other chronic conditions, which can then be compared with their stigma and practices related to substance use disorders.

Methods: Our cross-sectional survey was mailed to a nationally representative sample of primary care physicians, emergency medicine physicians, and dentists (N=3011), obtained by American Medical Association and American Dental Association licensees based on specified selection criteria. We oversampled nonmetropolitan practice areas, given the potential differences in provider stigma and available resources in these regions compared with metropolitan areas. Data collection followed a recommended series of contacts with participants per the Dillman Total Design Method, with mixed-modality options offered (email, mail, fax, and phone). A gradually increasing compensation scale (maximum US$250) was implemented to recruit chronic nonresponders and assess the association between requiring higher incentives to participate and providers stigma. The primary outcome, provider stigma, was measured using the Medical Condition Regard Scale, which inquired about participants' views

XSL•FO
RenderX

on substance use and other chronic conditions. Additional survey measures included familiarity and social engagement with people with substance use disorders; clinical practices (screening, treating, and referring for a range of chronic conditions); subjective norms and social desirability; knowledge and prior education; and descriptions of their patient populations.

Results: Data collection was facilitated through collaboration with the National Opinion Research Center between October 2020 and October 2022. The overall Council of American Survey Research Organizations completion rate was 53.62% (1240/2312.7; physicians overall: 855/1681.9, 50.83% [primary care physicians: 506/1081.3, 46.79%; emergency medicine physicians: 349/599.8, 58.2%]; dentists: 385/627.1, 61.4%). The ineligibility rate among those screened is applied to those not screened, causing denominators to include fractional numbers.

Conclusions: Using systematically quantified data on the prevalence and intensity of provider stigma toward substance use disorders in health care, we can provide evidence-based improvement strategies and policies to inform the development and implementation of stigma-reduction interventions for providers to address their perceptions and treatment of substance use.

Introduction

Background

The US overdose epidemic is a public health emergency that continues to escalate, accounting for over 100,000 deaths annually [1]. Fueled largely by the use of prescription opioids, heroin, and synthetic opioids other than methadone (primarily fentanyl) [2-4], which contributed to 75% of overdose deaths in 2021, the epidemic has been further intensified by rises in stimulant-related overdose deaths, particularly those linked with cocaine and psychostimulants [5]. Rising cocaine and psychostimulant-related overdose deaths also often involve opioid use [6-8], and polysubstance use involving both stimulants and opioids is a growing pattern that warrants focused interventions [9]. In addition, the accidental overdose epidemic has been attributed to "multiple distinctive sub-epidemics of different drugs" that have treatments that are different, such as the availability of medications for opioid use disorder (MOUD) versus the range of behavioral health services to treat stimulant use [7,10].

National attention to this overdose epidemic highlights the need for resources for health care providers to enhance the prevention and treatment efforts toward substance use disorders [7], including provider training and integration of substance use treatment within current health care systems. Barriers may arise from providers' negative attitudes toward persons with substance use disorders [9,10], including provider stigma, defined as the negative attitudes, perceptions, and behaviors that providers embody and enact toward their patients either subtly or involuntarily [11,12]. Provider stigma is increasingly recognized as an important and understudied barrier to the effective treatment and prevention of substance use [13-15], as well as one that is notably complex. Given that it encompasses stigma professionally and personally (eg, applying labeling, stereotypes, discrimination, and social marginalization) [16], provider stigma is one of the more substantive forms of stigma that people with substance use disorders may experience, even compared with friends, family, and coworkers, and often manifests as facing scrutiny and skepticism, treatment refusal, and delayed or substandard treatment [17-19]. There are also many causes of provider stigma, including negative perceptions and attitudes (eg, viewing the "illness ahead of the person"), compassion fatigue and professional burnout, biases (both conscious and unconscious), therapeutic pessimism and helplessness (eg, negative outlook on the likely benefits of treatment), and inadequate training and skills [20-26]. As such, research efforts that focus on quantifying and addressing the scope of provider stigma toward persons who use drugs is a critical first step in enhancing the health care response to expanding the delivery of substance use treatment [27-29].

Key Scientific Objectives of Clinical Trials Network 0104

Providers are increasingly called upon to identify patients with substance use disorders and refer patients to MOUD and other treatment resources [16,30]. Thus, understanding provider stigma and attitudes toward patient substance use is especially important in developing interventions to expand access to substance use treatment. The specific aims of this study are as follows:

1. Define the scope of provider stigma toward substance use by substance type and compare this stigma to provider stigmas directed at other medical conditions.
2. Compare providers' screening, treatment, and referral practices for substance use with their screening, treatment, and referral practices for other medical conditions.
3. Identify factors related to the delivery of substance use treatment in US-based primary care and emergency medicine settings to inform educational and intervention strategies addressing provider stigma.

Methods

Study Overview and Design

This study examines provider stigma by conducting a cross-sectional national provider survey of general practice, emergency medicine, and the dental workforces (October 2020 to October 2022). A representative sample of physicians and dentists was surveyed to better understand their attitudes and

XSL•FO
RenderX

stigma toward patients with substance use disorders, and the role that these attitudes and stigma play in shaping providers' screening, treatment, and referral practices concerning the provision of substance use treatment.

Ethics Approval

The study was reviewed and approved by the single Institutional Review Board (IRB) at the University of Miami (UM; IRB# IRB00010711) that provided regulatory oversight over all the participating sites. Consent forms were not used because of the nature of the study, which involved minimal participant risks. Instead, we received a waiver of informed consent from the UM IRB, whereby the cover letter provided the required consent information needed to help inform the participant's decision to participate. Consent was, therefore, not documented in writing, but rather implied through survey completion. Opt-out, passive consent methods have been shown to be more cost-efficient and feasible, without violating participants' autonomy or essential interests [31-33]. Confidentiality was maintained using unique participant ID numbers. The master list linking participant ID numbers to participant contact information was maintained at a secure location by the designated staff for recruitment purposes. At the end of data collection, only deidentified study data were made available to the study investigators. Compensation for participation was issued, as described in further detail in the section on incentives.

Participants

Overview

The study population consisted of primary care physicians, emergency medicine physicians, and dentists. Given their regular contact with patients with substance use disorders, these providers are well positioned to either refer for or deliver substance use treatment within their routine clinical care practices [34]. We now detail the rationale for including each provider group.

Primary Care Physicians

Efforts to expand substance use treatment have largely turned to primary care settings, especially to reach patient populations that heavily rely on public health care systems (eg, those who are homeless and have low income) and that present with multiple comorbidities (eg, those with substance use and HIV) [35-37]. Recent stigma studies among primary care physicians have largely focused on opioids, particularly their attitudes toward patient opioid use and their clinical practices related to prescribing MOUD. These studies have documented negative attitudes toward persons with opioid use disorders (OUD) as well as associations between higher provider stigma and minimal offering of OUD treatment practices and referrals for the treatment of OUD in these settings [13,38-40].

Although the practice of primary care is described as the services provided from a patient's first point of "entry" on through their continued comprehensive care, primary care also routinely involves collaborating with other health care providers, including consultations and referrals [41]. Therefore, we sought to survey all primary care specialties as defined by the American Medical Association (AMA), including family medicine, general practice, internal medicine, obstetrics/gynecology (OB/GYN), and pediatrics [42]. With regard to the field of OB/GYN medicine, preventive gynecologic appointments (eg, Papanicolaou smears) often represent women's only contact with a medical care provider and thus are the only opportunity for these women to be screened and treated for other medical conditions [43-45]. A 2017 study found that around half of women either identify their OB/GYN as their primary care provider or do not have a primary care provider [46]. In addition, in the field of pediatrics, substance use is increasingly prevalent among youth and young adults; opioid misuse is being initiated at a young age, increasing the risks for future substance use disorders [47-52], whereas stimulant use (eg, methamphetamine and inhalants) is also increasing at striking rates, with about half of graduating high school students reporting the use of a stimulant at least once [53,54]. In response, the American Academy of Pediatrics has advocated the expanded use of substance use treatment for youth and adolescents and called upon pediatricians to intervene early and help prevent potential substance use among their patients [55].

Finally, as specialists in internal medicine, infectious disease physicians were specifically included in our sample, as they also often provide primary care treatment for patients with HIV, especially as HIV treatment has evolved from a fatal disease to a manageable chronic condition that warrants screening for other major medical comorbidities [56-58]. A 2018 study showed that three-fourths of infectious disease physicians also act as the primary care physicians for patients with HIV [59]. Studies suggest that the increasing rates of infectious diseases such as HIV/AIDS are driven by the opioid crisis and that integrated substance use disorder and infectious disease treatment can reduce substance misuse and infectious disease transmission, respectively [60]. The National Institute of Allergy and Infectious Diseases and the Institute of Human Virology have underscored the significant role of infectious disease providers in addressing substance use among patients in their practices [61].

Emergency Medicine Physicians

Emergency medicine physicians were included in the study population, given that they frequently encounter patients with substance use disorders, especially those at high risk for overdose, trauma, or suicide [62-64]. These patients often do not regularly seek primary care and instead use and rely on emergency departments for medical treatment [65,66]. Prior studies assessing emergency medicine physicians' regard for patients with substance use disorders have featured small sample sizes, and their findings were often limited in generalizability [17,62]. Overall, these studies documented low regard for patients with substance use disorders by emergency medicine physicians compared with patients with other medical conditions [17]. Studies have suggested that such negative attitudes can be mitigated by providing physicians with evidence-based trainings [62].

Dentists

The professional role of dentists has evolved into one that is more medically focused and encompasses limited preventive primary care, including medical chairside screenings [67]. As

XSL•FO
RenderX

health care providers who regularly manage and treat patients with dental pain, dentists encounter challenges analogous to those of other health care practitioners who encounter and treat patients who live with substance use disorders [68-70]. Dentists have reported concerns that patients are using substances, yet they often do not routinely query patients about it [71-74]. Dentists are responsible to treat many oral implications of substance use, such as rampant caries, xerostomia, tooth loss, and the pathognomonic and overt dental disease known as "meth mouth" [75,76]. However, dentists across the United States have reported minimal, if any, prior training and knowledge in the area of patient substance use [73]. As such, the American Dental Association (ADA) has called for dentists to obtain continuing education in opioid-related practices and use brief interventions to encourage and refer patients for opioid use treatment [77]. However, there are limited data regarding dentists' stigma and attitudes toward addressing substance use in their clinical practices.

Eligibility Criteria

Study participants were required to (1) currently be in clinical practice (and planning to remain so for the next year) as a primary care or emergency medicine physician (Doctor of Medicine or Doctor of Osteopathic Medicine) or a dentist (Doctor of Dental Medicine or Doctor of Dental Surgery), (2) have a current US medical or dental license (ie, not revoked or expired), and (3) agree to complete and return the survey after reading the elements of informed consent in the cover letter.

Recruitment

We purchased our sample from a licensee of the AMA and ADA who provided a systematic random sample of providers based on our selection criteria. The national sampling frame of practicing primary care and emergency medicine physicians provided by the licensee was obtained from the AMA Masterfile, the most commonly used and comprehensive sampling source for surveys of physicians in the United States [78-81]. Similarly, the sampling frame of dentists provided by the licensee came from the ADA, which maintains a list of active dentists in the United States. Our purchased sample frame from the licensee included provider name; type of degree; and any available contact information (postal address, telephone number, and email address).

We defined 6 different strata for our sample: AMA primary care physicians, AMA emergency medicine physicians, and dentists, with the members of each category identified by metropolitan and nonmetropolitan practice locations. Metropolitan and nonmetropolitan areas were defined using Metropolitan Statistical Areas, as defined by the Office of Management and Budget and used by the census. We specifically oversampled nonmetropolitan practice areas, given that there may be differences in provider stigma and attitudes, along with available treatment and referral resources, in nonmetropolitan regions compared with metropolitan ones [82] (see the section *Data Analysis Sample Size*). Systematic random samples were drawn from each stratum; every nth record was included in the sample based on the quantity requested versus the quantity available according to our specified criteria of provider characteristics. To assist our efforts to create sample weights for data analysis, the licensee provided the current population numbers for each stratum that we planned to sample.

To ensure that we only captured physicians and dentists currently in practice, we added a survey question on the cover page to assess whether the respondent was currently engaged in direct patient care. Although the AMA and ADA do track this information, we wanted to ensure that we omitted recent retirees or nonpractitioners. Within this survey question, we also asked whether the respondent planned to be in clinical practice for the next year. We chose to exclude those who planned to retire within the year, as their willingness to perform certain behaviors in the future (eg, receive future training programs and offer screening or treatment practices) may not be reflective of the current practicing workforce.

Incentives

Providers were compensated for their time dedicated to completing the survey. In line with the Dillman [83] Total Design Method (TDM), each survey included an initial payment (US $10), regardless of survey participation, with the prenotification letter. Respondents who completed the survey then received additional compensation upon completion, which was gradually increased throughout the study. This methodology of a gradually increasing compensation was used in our prior national survey of dentists and helped substantially increase our response rate [73,84-86]. Furthermore, the amount of incentive that prompted a dentist to respond proved to be a significant covariate in that study's primary outcome paper: dentists requiring enhanced incentives were significantly less likely to view expanded HIV screening (and other preventive health screenings) favorably as part of their professional role [86].

Participants were given options when selecting their method of compensation: an electronic gift card to 3 predetermined companies (Target, Walmart, and Amazon), a Visa debit card, or a mailed check. The participants also had the option of not receiving the compensation. The compensation scale upon completion of the survey (separate from the US $10 incentive in the first mailing) started with an initial payment of US $50. When the follow-up telephone prompting was initiated to recruit chronic nonresponders (ie, participants who had not responded to the initial recruitment attempts), we implemented an experimental design whereby the sample eligible for telephone prompting was randomized to receive an offer of either US $100 or US $150 upon completion (Table 1). After the US $100 and US $150 incentives were offered through the experimental design, we then offered chronic nonresponders an incentive of US $250 to complete the survey. This became necessary due to COVID-19–related challenges to the health care community, which caused staff shortages, large patient demand, and overburdened offices and hospitals; as such, increasing the incentive to US $250 helped compensate overly taxed providers who were experiencing significant clinical work burdens and time constraints during the pandemic. Notably, the availability of gradually increasing compensation time points (US $50, US $100, US $150, and US $250) will serve as important covariates in future study analyses.

[a]NORC: National Opinion Research Center.

Study Procedures

Study procedures were implemented as a collaborative effort between the study investigators and the National Opinion Research Center (NORC). The NORC has administered leading social science surveys and has extensive experience in sampling design, survey data collection, recruitment of nonresponders, nonresponse bias analysis, and weight creation.

The overall methodology behind our study procedures was guided by the TDM, which implements strategies to help achieve a high response rate for survey studies (Figure 1) [83]. We followed the TDM-recommended series of contacts with participants in the following order: prenotification inquiry, initial questionnaire mailing (which included a link to a secure internet survey site), thank-you or reminder contact, replacement questionnaire, and follow-up telephone calls. Follow-up telephone calls to nonresponding providers were made with the goal of establishing personal contact, verifying the receipt of study materials, answering questions, and prompting for questionnaire return. In addition to the alternative options, respondents were given the option to complete the survey via telephone. These telephone calls were a collaborative effort between NORC staff (telephone interviewers) and the study investigators. Prior studies have shown some significant increases in response rates when physicians conduct follow-up prompting to other physicians [87-89]. Therefore, the telephone prompting phase was designed so that the sample eligible for telephone prompting was randomized to receive an initial follow-up prompting phone call from either an experienced NORC telephone interviewer or a study investigator (one with Doctor of Philosophy credentials and the other with Doctor of Dental Medicine and Doctor of Philosophy credentials). Similar to the case of our gradually increasing compensation, our future study analyses will have the option to include telephone prompting personnel (experienced NORC telephone interviewer vs study investigator) as a covariate (Table 1).

Figure 1. Study schema.

The initial study procedure protocols included offering the option of in-person completion, whereby NORC field managers would perform in-person visits to provider offices to prompt providers to complete and return the survey and offer providers the option to complete the survey in person with the field manager. However, due to the COVID-19 pandemic, we were not able to implement in-person study visits, given the restrictions implemented at hospitals and health care offices limiting visitors and guests, in addition to the travel-related transmission concerns that NORC staff would have encountered.

XSL•FO
RenderX

Participants were given multiple options to complete the survey. Internet- and mail-delivered surveys are strategies that have proven to be more cost-effective than traditional telephone surveys and are more compatible with health care providers' constrained schedules [90]. Because the evidence comparing the effectiveness of mail- versus internet-based surveys is not conclusive, mixed-mode approaches that offer both methods of completion are generally common [91,92]. Mixed-mode approaches allow health care professionals to choose their preferred mode of response, which may be influenced by factors such as provider age, comfort with technology, personal contact, and security or privacy concerns [92,93]. As a result, the NORC continues to conduct many of their national survey studies using mixed-mode methods [94-99]. In addition, the task force of the American Association for Public Opinion Research recommends using a mail modality if using a single mode or a mixed-mode design that first uses mail contact and subsequently includes an internet-based response option [100].

We used other strategies endorsed by the TDM and supported by other studies to increase response rates, including prepaid incentives, personalized cover letters, and prepaid postage [101-103]. The survey's self-completion methodology, use of a participant identification number, and specification (in the cover letter) that survey completion implies informed consent (in lieu of a signed consent) were additional methods used to minimize time constraints and maximize completion flexibility [104].

Description of Study Assessments

Overview

The study assessment consisted of a 1-time cross-sectional survey instrument that, based on pilot-testing, required approximately 20 to 30 minutes to complete. Because research has shown that lengthier surveys result in lower response rates, especially among busy health care providers, brevity and reduced respondent burdens were both priorities in developing the survey instrument [101,105]. To ensure succinctness and respondent acceptability of our proposed survey instrument, we conducted informal practice testing among the key study team members and affiliates. The goal of this informal practice testing was to identify (1) the time required to complete the survey; (2) any questions that were confusing, difficult to interpret, inadequately written, or nonapplicable (logistical issues); and (3) any questions that were perceived as not important or too invasive (personal concerns). The feedback provided through this informal testing provided valuable input, suggestions, and edits that were reviewed by the study team for application to the final survey instrument.

The survey instrument administered to physicians differed slightly from that administered to dentists, reflecting the different scopes of practice for physicians versus dentists, along with differences in their expected training and backgrounds [106,107]. For example, survey questions querying about offering certain medical treatment practices (eg, prescribing MOUD and initiating antiretroviral therapy) were not included in the instrument disseminated to dentists. Notably, however, most measures were identical, including those assessing provider stigma.

The survey instrument included items related to providers' attitudes and stigma. The Medical Condition Regard Scale (MCRS) [108] queried participants about their views on 3 categories of substance use (opioids, stimulants, and alcohol) as well as other medical conditions (type II diabetes, depressive disorder, and HIV) selected by the study team to assess the primary outcome. Specifically, these questions asked whether a provider views a given condition as enjoyable, treatable, and worthy of resources by asking them to report their agreement with a series of statements concerning a specified medical condition (eg, "Insurance plans should cover patients like this to the same degree that they cover patients with other conditions," "Patients like this irritate me," "I wouldn't mind getting up on call nights to care for patients like this," and "Patients like this are particularly difficult for me to work with").

In addition to our primary assessment of stigma using the MCRS, we included additional measures of stigma in the attitude-assessing section, such as the Drug and Drug Problems Perception Questionnaire [109], which focuses on provider stigma in the form of provider "motivation" to treat patients with substance use disorders. We adapted other prior scales for appropriateness, such as the Link [110] study that assessed stigma in the form of general social distance and perceived dangerousness toward people with mental health disorders; in our survey, we instead assessed perceived dangerousness and social distance or isolation toward people with substance use disorders [110]. Other provider stigma measures related to persons with substance use disorders included general attitudes, attitudes toward providing medical or dental care, stereotypes, and familiarity. We also queried the providers' personal history of substance use and treatment [109-120].

The instrument included many questions assessing providers' clinical practices. To understand provider practices related to substance use treatment within the context of their overall practices, we asked participants how, if it all, they are addressing a myriad of different health care conditions that generally fall under the scope of primary care (and, in the case of dentists, general dental care): (1) type II diabetes, (2) depressive disorder, (3) HIV, (4) substance use, (5) alcohol use, and (6) tobacco or nicotine use. Of note, 5 of these conditions were queried in the MCRS section to assess providers' attitudes toward these medical conditions. However, we collapsed opioid and stimulant use into 1 condition ("drug use") and added tobacco or nicotine use to this section, as it is imperative to understand participants' clinical practices related to forms of legal substance use (tobacco or nicotine), which can then be compared with their practices related to substance use. For each health condition, physicians were asked about their screening, treatment, and referral practices related to this condition; dentists were asked a similar set of questions but were not asked about providing treatment, given their differing scope of practice under their professional license.

Additional measures included social determinants of health (ie, whether providers are addressing patients' social needs, such as homelessness, transportation, and interpersonal violence [121]); risk behaviors (in their personal lives and professional roles) [122]; subjective norms and social desirability (ie, their colleagues' and patients' perceptions of their professional role

XSL•FO
RenderX

in substance use treatment); clinical knowledge (ie, prior education or training and future training needs in addressing substance use); clinical practice (ie, year of graduation, type of clinical setting, clinical discipline or specialty, patient insurance information, and patient population); and sociodemographics (ie, age, race, ethnicity, and gender).

Data Analysis Sample Size

The data analysis plan was developed to identify significant differences among the 3 subgroups of clinicians (primary care physicians, emergency medicine physicians, and dentists). In addition, we wanted to ensure that there was significant power to find clinically meaningful relationships in our planned secondary analyses. Primary care physicians were the largest planned subgroup within our study sample due to their diverse training backgrounds (n=1411), while emergency medicine physicians (n=800) and dentists (n=800) were also included as subsets of the population of health care providers in the general care workforce. The final target population was 3011, which was the target sample from which invitations to participate were sent. Allowing for a 70% response rate would provide an expected sample of 2108. The sample size needed to be further refined to account for the planned oversampling of nonmetropolitan clinicians. Oversampling resulted in slightly different design effects (Deff) within each of the other strata (primary care physicians: Deff=1.076, effective n=918; dentists: Deff=1.067, effective n=525; emergency department physicians: Deff=1.062, effective n=527). Applying the design effect induced by the oversampling of nonmetropolitan clinicians provides an expected effective sample of 1970 (primary care physicians: n=918, 46.6%; emergency medicine physicians: n=527, 26.8%; dentists: n=525, 26.6%). Power was calculated using PASS 2020 [123] with the expected effective sample sizes and a type II error rate of 20% (for 80% statistical power). We also report the power for a 50% response rate.

With our expected effective sample size, there is 80% power to construct CIs of the mean score on the MCRS with width of 0.088 SD of the MCRS. The CI width is 0.172 SD for dentists or emergency medicine physicians and 0.13 SD for primary care physicians. The intervals widen with a 50% response rate, ranging from 0.104 SD to 0.202 SD. When comparing MCRS scores between 2 different medical conditions, there is 80% power to uncover a difference when that difference is truly at least 0.06 of the SD for the full sample. This required true difference is 0.12 SD for dentists and emergency medicine physicians and 0.08 SD for primary care physicians. For a lower response rate of 50%, the required true differences to achieve 80% power move to 0.07 SD, 0.11 SD, and 0.14 SD for the full sample, primary care physicians, and emergency medicine physicians or dentists, respectively. When comparing MCRS scores between the different clinician types, there is 80% power to uncover a true difference that is 0.20 SD between dentists and emergency medicine physicians and when the true difference is 0.18 SD between either dentists or emergency medicine physicians and primary care physicians. The corresponding required effect sizes increase to 0.24 SD and 0.20 SD if the response rate is 50% rather than the targeted 70%. These effects are all considered small effect sizes.

Furthermore, the survey was designed to have sufficient power for secondary outcomes. To illustrate this, we used a binary secondary outcome (yes or no): “addressing substance use treatment (including providing substance use treatment/prescribing medications for OUD by physicians and screening and referral by dentists) = yes” versus “not addressing substance use treatment (not providing substance use treatment/not prescribing medications for OUD by physicians and screening and referral by dentists)= no.” Calculations were again made using PASS 2020 [123] with a 2-tailed test, α=.05, β=.2 (80% power). We assumed moderately conservative values of baseline probability (P_0=.10 to .20) and R^2 of 0.2 to 0.3 for other variables in the model and examined the impact of a 1 SD change in a continuous variable (such as the MCRS score) in predicting the binary outcome. With a 70% response rate, we have >80% power to uncover a significant effect if the true associated odds ratio is in the range of 1.19 to 1.29 for the full sample (1.23-1.35 if there is a 50% response rate). This range is 1.32 to 1.45 (1.36-1.55 for a 50% response rate) for primary care physicians and 1.41 to 1.63 (1.50-1.78 for a 50% response rate) for dentists or emergency medicine physicians. These effect sizes are in the small to moderate range.

Outcomes

Our primary outcome is providers’ “regard” for patients with substance use disorders, as measured by the MCRS [108], which will be assessed by 3 separate classes of substance use: (1) opioid use (including heroin, fentanyl, and nonmedical pain medication use); (2) stimulant use (including methamphetamine, cocaine, and crack use); and (3) alcohol use. These classes of substance use will be compared with providers’ “regard” toward the other assessed medical conditions. This MCRS measure is based on an 11-item scale that is scored as a continuous indicator, ranging from 11 to 66. Lower scores indicate “low regard” (ie, high stigma), while higher scores indicate “high regard” (ie, low stigma) for the given medical condition. This measure will be assessed for both physicians and dentists.

The secondary outcomes are specific to the provider type. For physicians, the secondary outcome will assess whether US primary care providers are currently offering on-site treatment for substance use (collapsed into 1 condition, “drug use”) in their clinical practice. For dentists, the secondary outcome will assess whether US dentists are referring patients for substance use treatment in their clinical practice. We are particularly interested in exploring the relationship between provider stigma toward persons with substance use disorders and practices related to addressing substance use in their clinical settings. The analyses of the outcomes related to physicians and dentists will be addressed separately.

Statistical Analysis

Overview

In general, statistical tests are determined by the distributional properties of dependent or outcome variables. The binary secondary outcomes will be tested using chi-square tests of independence for comparisons between groups and logistic regression for the multivariable case. For binary outcomes that are not rare, we will use Poisson regression with robust SEs to

XSL•FO
RenderX

directly estimate the risk ratio (rather than the odds ratio, which diverges from the risk ratio when an outcome is not rare). According to the literature [62,108,124-126], we anticipate that "regard" will behave as a normally distributed continuous variable though the exact method of analysis will depend on the realized distribution of "regard" in the final survey data.

Our statistical approach will include descriptive statistics (mean, SD, and 95% CI) as well as mixed models and ANOVA to compare the regard for different medical conditions and across different practice settings, respectively. We will also model all outcomes as a function of a set of covariates and develop parsimonious models to identify provider characteristics associated with each outcome using the appropriate modeling procedure based on the outcome's distribution (logistic regression for binary outcomes and linear regression for "regard"). All statistical analyses will use an α level of .05.

Item and Survey Nonresponse

Our first set of analyses will explore the potential biases that might arise if nonresponders differ significantly from responders along such dimensions as urbanicity. We may then explore the patterns of missing data. We would first derive binary measures that indicate whether the value of each variable for a respondent is missing. We would then relate these new measures to "key attributes" and consider statistically significant relationships as an indication of possible bias. Key attributes would be selected on the basis of (1) likely limited degrees of missing data and (2) substantive imports. If we find nonrandom patterns of item nonresponses, we will use multiple imputation methods [127] to minimize potential resulting biases. In addition, we will examine variables such as race, gender, and region in our nonresponse analysis to assess representativeness. If necessary, we would consider using nonresponse weighting to ensure that the results reflect the population.

Data Management

Data collection activities were overseen by the NORC. All the invited providers were assigned a unique study ID number in their personalized cover letters; to ensure confidentiality, the cover letter emphasized the confidentiality of their survey participation, and their responses would not be linked to their identification. Any documentation linking provider information with the assigned unique ID was stored securely, with the access limited to specified NORC study personnel.

The NORC information technology team oversaw the data entry technology involved in electronic submissions, while production clerks were responsible for questionnaire receipt and library filing for those participants who completed the survey using paper (ie, self-administered paper questionnaire or fax. Once a completed self-administered paper questionnaire was returned to the NORC, it was sent to NORC's Computer-Assisted Data Entry vendor for data entry and subsequent posting on a secure File Transfer Protocol site.

Study Leadership and Investigator Procedures

This study was a collaborative effort among the lead Clinical Trials Network (CTN) study team, NORC, and National Institute on Drug Abuse (NIDA). The lead study team is a varied group of investigators with depth and breadth of experience in substance use disorders or treatment, internal medicine, infectious diseases, dentistry, epidemiology, public policy, social sciences, study training and supervision, provider surveys, and quality assurance monitoring. The NORC, founded in 1941, is one of the nation's well-respected survey organizations. Their widespread staff members have extensive experience in achieving a high response rate in surveys, especially those of health care professionals, as well as in sampling design, recruitment of hard-to-reach participants, nonresponse bias analysis, and weight creation, which helped ensure that the best data were obtained for our national survey. Regular biweekly conference calls were conducted via videoconferencing between the study teams and the NIDA Scientific Officer throughout the study period to discuss survey activities, recruitment, and progress.

Results

The study protocol was approved by the CTN Protocol Review Board in April 2020 and the UM IRB in August 2020. The survey instrument was officially mailed to the study sample in October 2020. Although we originally anticipated a 1-year follow-up period for data collection, our timeline was ultimately extended to 2 years due to unexpected disruptions caused by the COVID-19 pandemic. As such, data collection officially ended in October 2022, with an overall Council of American Survey Research Organizations rate of 53.62% (1240/2312.7; physicians overall: 855/1681.9, 50.83% [primary care physicians: 506/1081.3, 46.79%; emergency medicine physicians: 349/599.8, 58.2%]; dentists: 385/627.1, 61.4%). Note that the ineligibility rate among those screened is applied to those not screened, causing denominators to include fractional numbers. These rates resulted in a sample of 506 primary care physicians, 349 emergency medicine physicians, and 385 dentists.

Data analysis for the primary outcome paper, along with multiple planned secondary analyses, is currently underway, with plans to disseminate study findings in subsequent manuscripts in peer-reviewed journals. Findings from the analyses will be disseminated to CTN investigators, community partners, and representatives of the National Institutes of Health/NIDA. The planning, preparation, and submission of publications will follow the policies of the CTN Publications Committee. In addition, we plan to share our findings with a broad scientific audience through presentations at local and national conferences.

Discussion

Summary

Health care providers who practice primary care, emergency medicine, and dentistry are increasingly being called upon to help meet the growing demand for substance use treatment that surpass the availability of services [16,30]. Given their regular contact with patients with substance use disorders, these providers are well positioned to deliver and expand substance use treatment within their clinical settings [34]. However, before we can bridge this gap, we must first systematically and comprehensively understand the role of stigma in US health

XSL•FO
RenderX

care providers' treatment and clinical management of patients with substance use disorders.

Within this context, our survey findings assessed a wide range of attitudes, practices, and backgrounds of providers practicing throughout the nation. Our sampling methodology and high response rate have produced a particularly robust data set that will allow us to identify the factors, such as clinical setting and description of patient populations, related to provider stigma and the current state of substance use treatment delivery, as stated in our specific aims. In addition, our use of the MCRS will allow us to understand the magnitude and extent of provider stigma by the type of substance (opioids, stimulants, and alcohol). These 3 classes were specifically selected for not only being the most frequent types of substance use but also for being detrimental to individual and population health through overdoses, substance-related violence, and substance-related motor vehicle crashes [128-130]. Moreover, the availability of treatment modalities for these 3 classes differs; there are treatments for both OUD and alcohol use disorders [131], but recent research findings offer promise for stimulant use disorder treatment [132]. Assessing these 3 types of substance use will significantly contribute to the body of literature that assess provider stigma against substance use by substance class and how substance-specific stigma is associated with their respective screening and treatment clinical practices.

Furthermore, our study findings allow us to define provider stigma toward substance use in the context of other commonly stigmatized health conditions. The range of other conditions that we queried included different somatic, mental, and behavioral conditions (type II diabetes, depressive disorder, and HIV). Different chronic conditions can solicit different stigmas based on their visibility and perceived individual responsibility in causing the condition [133,134]; thus, it is important to select a range of chronic conditions that represent these differing manifestations and associations. In the case of HIV, provider stigma not only encompasses attributes such as prejudicial attitudes and discriminatory actions but also mortality-related judgment (due to values related to sexual practices and risk behaviors associated with HIV transmission) and fear of physical contagion from occupational exposure [135,136]. By contrast, provider stigma studies focusing on obesity and type II diabetes have shown provider stigma to be related to negative perceptions of patient behavioral factors (eg, laziness, lack of self-control, and dishonesty) [137,138]. In the context of mental health disorders, other constructs related to provider stigma include social distance (ie, self-reported willingness to engage and socialize with someone who has a mental health disorder) and perceived dangerousness (ie, the perception that people with mental health disorders are violent and should be feared) [25,139-141]. In the case of both HIV and mental health disorders, providers who elect to treat patients with these conditions have been shown to be particularly susceptible to "courtesy stigma" (ie, the subjective norms of other professionals), as colleagues and social relations question their willingness to treat patients perceived as socially or morally objectionable, which can impact providers' social and professional reputation and also contribute to provider stigma [135,142-146]. Allowing for comparisons to be made between these chronic conditions, alone and in comparison with the substance use classes, is especially critical for comprehensively capturing the lens through which health care providers view and relate to the very patients they are being called upon to treat.

The limitations of our study include the cross-sectional nature of our methodology, which limits our ability to make causal inferences or assess temporal relationships. In addition, as the survey queried provider attitudes toward conditions that are commonly stigmatized as well as potentially sensitive topics (eg, prior substance use history of family, friends, colleagues, and self), there is potential for information bias in our study findings in the form of social desirability. However, our use of a participant ID and our security of a waiver eliminating the need for a signed informed consent form was specifically implemented for confidentiality purposes, which may have mitigated any reluctance to respond to the survey truthfully.

Conclusions

Our survey was designed to identify barriers to addressing the overdose epidemic as faced by primary care physicians, emergency medicine physicians, and dentists who workforces called upon to change the way substance use treatments are delivered nationally and across patient populations. Our results can be used to inform future public health campaigns and provider-based interventions that provide new models of care, demonstrating the efficacy of initiating medication-assisted treatment in these settings [147,148]. By understanding providers' subjective norms, the ways in which they view and address substance use, and their attitudes toward patients with substance use disorders, we plan to inform the development and implementation of stigma-reduction interventions that address providers' perceptions and treatment of substance use. Although some effective interventions reduce stigma overall [149], the development of interventions specific to primary care and emergency medicine physicians and dentists requires a more granular understanding of substance-related stigma across the primary health care spectrum, particularly in settings that frequently encounter patients with substance use disorders.

Abstract

Background: Rare cancers account for approximately 24% of all new cancers. The category of rare tumor diseases includes almost 200 different entities. In particular, the treatment of patients with extensive care needs requires cooperation between service providers, both between sectors (outpatient and inpatient) and within sectors (eg, between different medical disciplines). The treatment pathway is associated with a high need for coordination and information sharing between providers. When crossing sectoral boundaries in the German health care system, interface problems between the outpatient and inpatient sectors can lead to gaps in care delivery. The multicomponent program *Trans-sectoral Personalised Care Concept for Patients with Rare Cancers* aims to optimize transsectoral cooperation and coordination of care to enhance patient involvement and the medical care coordination of patients with rare cancers.

Objective: This process evaluation will contribute to answering questions about intervention fidelity and the implementation of transsectoral communication, identifying and describing the intended and nonintended effects of the intervention, and exploring the barriers to and facilitators of the implementation.

Methods: We will include patients who participate in the intervention phase; all persons and staff involved in the development and implementation of the intervention (Onco Coach, psychologists, physicians on the contact platform, IT staff, and staff of the Bavarian Association of Statutory Health Insurance Physicians); physicians from the Ludwig-Maximilians-University Hospital Munich and the hospital of the Technical University Munich who are involved in the treatment of patients during the course of the project; and participating office–based hematologists and oncologists. Data collection will be conducted at the beginning, during, and at the end of the intervention using mixed methods. Data will be collected from questionnaires, document analyses, semistructured interviews, and structured observations and will cover different aspects of process evaluation. These include examining the context to explore existing patterns, changes in patterns, attitudes, and interactions; analyzing the implementation of intervention elements; and exploring the complex causal pathways and mediators of the intervention. Qualitative data will be analyzed using thematic analysis. The data will then be combined using between-methods triangulation.

XSL•FO
RenderX

Results: This project received funding on March 1, 2022. The intervention phase and recruitment for the process evaluation began on March 1, 2023, and the recruitment is expected to end on September 30, 2025. At the time of protocol submission in June 2023, a total of 8 doctors from hematology and oncology practices were enrolled. Data collection began on March 14, 2023.

Conclusions: The *Trans-sectoral Personalised Care Concept for Patients with Rare Cancers* project is a complex intervention that is to be implemented in an equally complex health care context. The process evaluation will help understand the influence of contextual factors and assess the mechanisms of change.

Introduction

Background

Approximately 24% of all emerging cancers are rare cancers, making them cancers with an incidence of <6 in 100,000 people per year. The *rare tumor diseases* category includes almost 200 different entities. Compared with patients with common tumor diseases, patients with rare tumor diseases develop the disease at a younger age, and the overall survival is significantly poorer [1].

Patients in the German health care system can be treated as both inpatients and outpatients in office-based settings. In particular, patients with rare, chronic, or complex diseases often cross the sector boundaries because of their complex treatment plans and the various professions involved. In the German health care system, interface problems between the office-based and inpatient sectors may cause gaps in the delivery of care [2]. Therefore, it is important to improve the design of interfaces and, thus, the coordination and integration of inpatient and office-based health care. It is the physicians' task to ensure continuous medical treatment during the transition from the inpatient sector to the continuing care sector. In particular, the treatment of patients with extensive care needs requires cooperation between service providers, both in the intersectoral area (office-based and inpatient) and intrasectoral area (eg, between different medical disciplines). The treatment path is associated with a high level of coordination and information needs between colleagues providing cotreatment or further treatment [3] (eg, information about supportive treatment, potential side effects, or complications during hospitalization). Digitalization is essential for the development of transsectoral and cross-disciplinary supply structures. Digital technologies can help improve documentation, communication, and networking in medical care [4].

Patients with cancer have to face complex considerations when making decisions about their own treatment [5] in a challenging life situation. They show a strong preference for shared decision-making (47.1%). Slightly more than one-third (36.3%) of German patients with cancer want to decide alone, and 15.9% want the physician to decide [6]. Despite the benefits of shared decision-making (eg, greater satisfaction with the treatment decision and improvement in adherence to cancer treatment), its implementation in clinical practice has hardly improved over the years [5]. Therefore, it is important to address this issue.

Trans-Sectoral Personalised Care Concept for Patients With Rare Cancers

The Trans-sectoral Personalised Care Concept for Patients with Rare Cancers (TARGET) project includes targeted digital interventions to optimize transsectoral cooperation and coordination of care to improve patient involvement (including shared decision-making) and the medical care of patients with rare cancers. The intervention will be implemented in the model region of Southern Bavaria (Swabia, Upper Bavaria, and Lower Bavaria), Germany, with a maximum of 45 hematologic and oncologic participating practices and the Comprehensive Cancer Center (CCC) Munich. For the evaluation and implementation of TARGET, the Bavarian Association of Statutory Health Insurance Physicians (KVB) and the Professional Association of Resident Haematologists and Oncologists in Bavaria will invite all office-based oncology and hematology specialists to take part. Only patients who are legally insured by AOK Bavaria, the largest statutory health insurance provider in Bavaria, will be recruited.

Deviating from the registration of the main trial [7], the summative evaluation of TARGET will adopt a prospective parallel group design with patients clustered in practices, comparing the control group (practices in Northern Bavaria) with the intervention group (practices in Southern Bavaria). The protocol of the summative evaluation will be published separately. The primary end point is the coordination of care from the patient's perspective, which will be measured using the validated German version of the Care Coordination Instrument [8]. The secondary end points include progression-free survival, overall survival, course of therapy, time up to diagnosis, and patient-reported outcomes (health-related quality of life, condition, symptoms, and health literacy). An economic evaluation using retrospective data provided by AOK Bavaria will also be conducted. This protocol describes the process evaluation that will occur alongside the main trial.

Objective

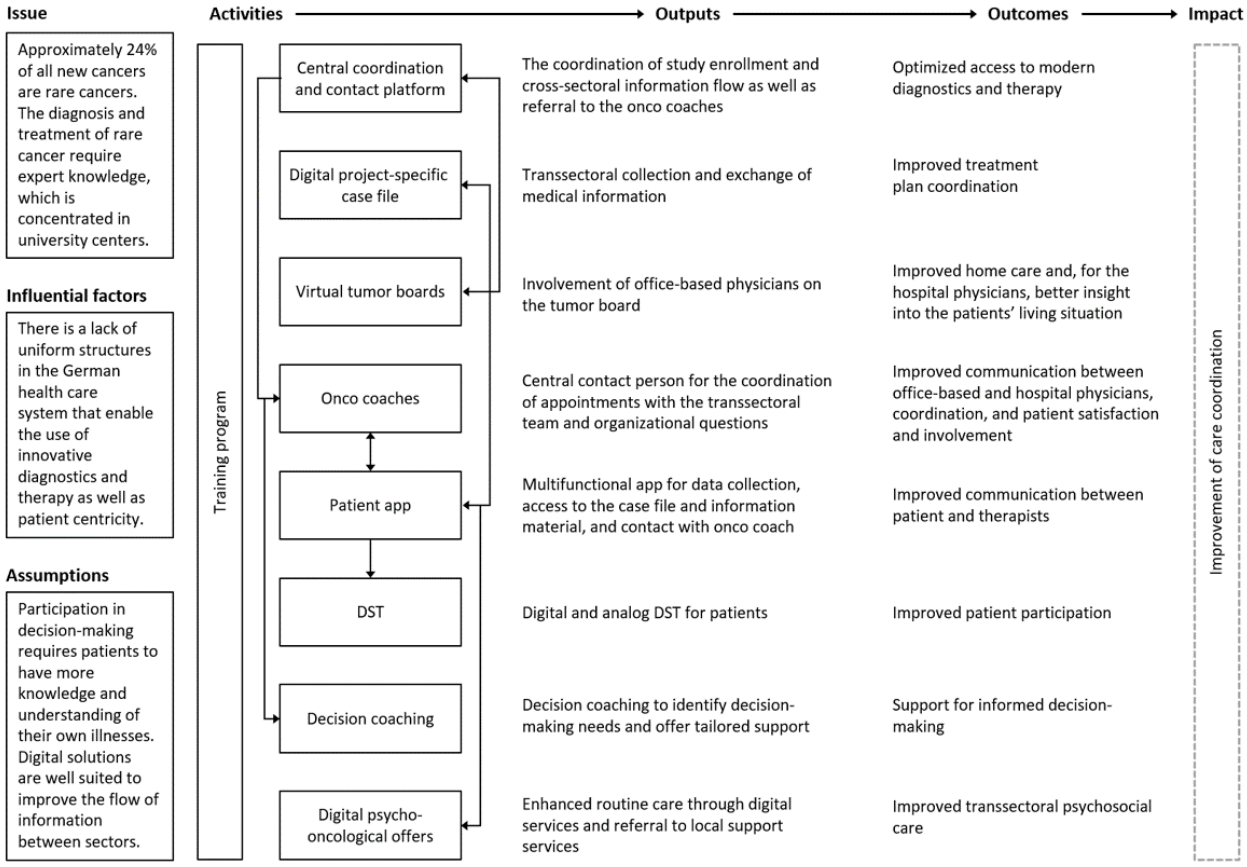
TARGET consists of a variety of components that aim at different target groups, are offered by different groups of professionals, and concern different aspects of patient care.

XSL•FO
RenderX

Therefore, a comprehensive process evaluation following the Medical Research Council guidance for process evaluation of complex interventions [9] is planned (1) to analyze contextual factors and their interactions with the intervention components; (2) to describe the intervention, its causal assumptions, and the implementation process; and (3) to assess the mechanisms of change such as participant responses and mediators. The aims are to assess intervention fidelity and the implementation of transsectoral communication, identify and describe the intended and nonintended effects of the intervention, and explore the barriers to and facilitators of implementation [9].

Methods

The reporting of this protocol follows the criteria of the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) [10] (Multimedia Appendix 1) and the UK *MRC framework for the development and evaluation of complex interventions* [11]. Mixed methods will be applied to assess processes and mechanisms at different levels.



Ethical Considerations

Ethics approval was obtained from the ethics committee of the Martin Luther University Halle-Wittenberg (MLU; 2023-032). The ethics committee will be informed of any changes in the procedure. All the participants will provide written informed consent. They will be informed of their possibility to terminate their participation at any time. The personal data collected are subject to the obligation of confidentiality and provisions of the General Data Protection Regulation. Participating practices will be reimbursed via the selective contract with AOK Bavaria for the time and effort required to participate in the training sessions, interviews, and virtual tumor boards as well as for patient inclusion and data documentation. The total compensation amount is based on the services actually provided. Patients will not receive any compensation.

Logic Model

A logic model was developed for TARGET, along with those responsible for developing the intervention components. This will guide data collection and analysis and is intended to help clarify causal assumptions. The logic model describes the intervention, its components, and its implementation. It also identifies the target group of an intervention component and how it interacts with other components and describes the current context (Figure 1).

Figure 1. Logic model of the Trans-sectoral Personalised Care Concept for Patients with Rare Cancers (TARGET) intervention. DST: digital support tool.

TARGET Intervention and Implementation

TARGET is a complex intervention comprising different components designed to promote cross-sectoral exchange and patient-centered care. The components of the intervention are as follows.

XSL•FO
RenderX

Central Coordination and Contact Platform

The participating hematologic and oncologic practices have the opportunity to quickly contact the team at the CCC Munich through phone or email via the central coordination and contact platform. The contact details can be found on the CCC Munich website. The platform will be staffed by a physician throughout the duration of the TARGET project to coordinate the enrollment of patients into the study and guarantee an optimal exchange of information between the different sectors to optimize joint patient care. The data of the patients enrolled in the study will be sent to Onco Coach for appointment scheduling to enable rapid referral to the respective expert team at the CCC Munich. The overall goal of the central coordination and contact platform is to bring the patient to the right expert as quickly as possible (eg, to optimize access to modern [molecular] diagnostics and therapy). It also serves as an interface for office-based hematologists and oncologists.

Onco Coach

All enrolled patients are assigned an Onco Coach as a central contact person for health care coordination issues. The Onco Coach play an important role in coordinating appointments with patients within the transsectoral team and mediate participation in training and supportive measures. In addition, the Onco Coach has limited access to the patient app and will reach out to all the patients via the chat function to establish contact with the treatment team. Patients can chat with the Onco Coach regarding organizational questions and problems. As a result, there is a continuous exchange between the Onco Coach and the treatment team.

Decision Coaching

Patients experiencing a decisional conflict will be offered decision coaching delivered by a trained Onco Coach or a physician in the hospital. According to the Ottawa Decision Support Framework [12], the decision coach will identify decisional needs, such as inadequate knowledge, unrealistic expectations, or unclear values, and offer tailored support to address these needs (eg, providing information, verifying understanding, or clarifying personal values).

Digital Project-Specific Case File

The digital project-specific case file is used for the transsectoral collection and exchange of medical information by establishing a link between the participating hematologic and oncologic practices and the CCC Munich and thus connects all relevant actors. The aim is to enhance coordination regarding the treatment plan. Interoperability is an essential aspect of the case file. The IT project was registered in vesta, the interoperability directory of the German health care system [13]. Availability is ensured using a platform-independent web application. The case file is a CentraXX-associated module from Kairos GmbH, which was expanded to include an oncological module for TARGET. CentraXX is a research portal focusing on the structured recording of content using biobanking and study management modules. An electronic patient record is the central storage unit in CentraXX [14]. It is technically operated by the Ludwig-Maximilians-University (LMU) Hospital Munich and professionally supervised by the CCC Munich. Plausibility checks ensure improved data quality. The web application will be set up in the hematologic and oncologic practices by the IT department of the CCC Munich. In addition, the practices will receive an on-site briefing and a manual on how to use the case file.

Patient App

The patient app is a smartphone app that is used for data collection as well as part of the intervention. It is compatible with and based on the project-specific case file with the following three basic functionalities: (1) documentation and use of various integrated forms, (2) customizable view of the coordinated case file, and (3) provision of information and training materials (eg, information on nutrition and exercise for cancer and fatigue, a decision support tool [DST], and other sources of information and support).

The assessment questionnaires can be accessed and completed via the app interface. Patients can also access a summary of the quality of life, functional, and symptom questionnaires, which can be used as personal documentation and for medical consultations. These documents are also made available to the transsectoral treatment team through the project-specific case file. The results of the questionnaires assessing care coordination and health literacy are not visible to the treatment team. This will be communicated to the patients in the study documents and within the questionnaires to avoid social desirability bias. In addition to data collection, the National Comprehensive Cancer Network (NCCN) distress thermometer [15] serves as a screening tool for the provision of psycho-oncology services (see the *Digital Psycho-Oncological Offers* section).

The patient app also allows the Onco Coach to contact the patient. All data are transmitted to the CentraXX department of the LMU Hospital. This integration makes it possible to combine all the recorded parameters and scientifically evaluate the collected data. The app is available for iOS (Apple Inc) and Android (Google LLC) and can be downloaded by patients via a QR code. Patients will receive instructions from their attending physician when they are enrolled in the study.

DST for Informed Decision-Making

To prepare for medical consultations, patients will have access to a generic DST [16] that aims at supporting informed decision-making. It is based on the Ottawa Personal Decision Guide and has been complemented with decision-related questions from question prompt lists for patients in oncology [17]. The DST will enable patients to ask for important information about their options regarding treatment or diagnostic procedures and to weigh their preferences for these options. It also includes guidance on how to deal with decisional needs, such as missing information, decisional uncertainty, and a lack of support. The tool will be available as a PDF version and in a web-based format via LimeSurvey (LimeSurvey GmbH). The links to the PDF version and LimeSurvey will be made available via the patient app and a flyer.

Virtual Tumor Boards

TARGET involves the establishment of internet-based transsectoral tumor boards, which enable joint decision-making and transsectoral information flow. Internet-based tumor boards

XSL•FO
RenderX

have already been established at the CCC Munich and will be made available to office-based hematologists and oncologists as a component of TARGET. Within the tumor boards, office-based hematologists and oncologists and the physicians of the CCC Munich discuss and jointly determine therapeutic paths. Especially in the field of precision oncology, the participating office–based hematologists and oncologists will benefit from the expertise at the CCC Munich, as a molecular tumor board has already been established there. The transsectoral tumor board allows for the sharing of this knowledge across sectors. Thus, close-to-home care can be improved, and the CCC Munich physicians can gain deeper insights into the patient's living situation. Furthermore, central tumor boards provide optimized access to clinical studies.

Digital Psycho-Oncological Offers

Psycho-oncology is standard care in certified centers such as the CCC Munich but not nationwide in outpatient settings. The aim of this intervention component is to improve cross-sectoral psychosocial care delivery and thus overcome urban-rural and outpatient-inpatient differences by ensuring the availability of timely psycho-oncological support.

For patients participating in this study, intensive multiprofessional collaboration, the rapid availability of services, and specific expertise and background knowledge in the psycho-oncological counseling context are required. To initiate psycho-oncological counseling, the NCCN distress thermometer [15] will be provided at the initial visit and every 4 weeks via the patient app. If the score is ≥5 or if the patient requests psycho-oncological support, the patient will be contacted by a psycho-oncologist within the first 24 to 48 hours after distress screening. The patient will also receive contact details. The consultation can take place via telephone, in person at the CCC Munich, or digitally via RED Connect (RED Digital Cinema, LLC) [18] and will last approximately 50 minutes. All existing psycho-oncological support opportunities will be offered to the patients (one-on-one counseling, couple or family consultations, open consultation hours, and group offers for patients and their relatives or caregivers). In addition, patients will receive information about different support offers as well as patient events, and patient chats via the patient app.

Provision of information about and potential referral to local support services will be facilitated through an intensive exchange with the existing networks called Network Psychosocial Oncology Munich, the KVB, the Bavarian Chamber of Psychotherapists, and the Bavarian Cancer Society.

Training Program

For the successful implementation of the new care concept, a modular training concept was developed, which will be implemented via the KVB's e-learning platform, CuraCampus. The training concept includes (1) training on the overall project, (2) training in shared decision-making, and (3) web-based learning after 1 year of the project.

First, the training on the overall project is mandatory for physicians from hematologic and oncologic practices. The asynchronous web-based course will last a maximum of 45 minutes.

Second, the 45-minute asynchronous web-based training on shared decision-making aims to introduce the concept of informed shared decision-making and the use of the DST in consultations. For physicians from hematologic and oncologic practices, this course is also offered on CuraCampus and advertised in mandatory training. Physicians at the hospital will also have the opportunity to take part in the course via a cloud-based platform of the University of Bremen. The offer is advertised via flyers. Teaching methods include a screencast lecture and a best practice video of a simulated physician-patient consultation in which a decision is made about palliative treatment options for pancreatic cancer. In addition, barriers and facilitators for implementing the concept of informed shared decision-making will be discussed. A voluntary multiple-choice knowledge test at the end of the course allows participants to earn continuing medical education credits. Physicians are also invited to participate in a voluntary 2-hour web-based communication training to achieve shared decision-making skills through simulated patient discussions.

Third, after 1 year of the project, another training will be offered as a refresher and update to discuss previous barriers and process adjustments and changes.

In addition, office-based hematologists and oncologists will be trained on how to use the digital case file by the IT team.

The Onco Coach will have the opportunity to participate in a 1-day decision coaching training in a blended learning format. A preexisting training program for decision coaches in oncology [19] was adapted to the special needs of the target group and to decision-making in the field of rare cancer diseases. It focuses on skills in decision coaching, shared decision-making, evidence-based health information, and (risk) communication. Decision coaching skills are trained through simulated conversations based on case vignettes.

Participants and Recruitment

We will include the following people in this evaluation.

1. We will include patients who participate in the intervention phase. Using theoretical sampling, we will take into account factors such as gender, age, diagnosis, time up to diagnosis, and course of therapy. These patient characteristics and clinical data will be extracted from medical records. The willingness to participate in an interview is requested via the central coordination and contact platform. Over the entire intervention period, a total of approximately 40 interviews are planned. Theoretical data saturation will be the decisive criterion for the number of interviews.
2. We will include all persons and staff involved in the development and implementation of the intervention (Onco Coach, psychologists, physicians on the contact platform, IT staff, and KVB staff)
3. We will include physicians from the LMU Hospital and the hospital of the Technical University Munich (TUM) who are involved in the treatment of patients during the course of the project. Owing to the number of departments in the clinics, we will use a theoretical sample based on the extent of patient contact or contact with the intervention components. At the physician level, a snowball sampling

XSL•FO
RenderX

will be used. Recruitment will be done by approaching supervisors via either email or telephone. We estimate the number of interviews over the course of the project to be 10 to 15, taking theoretical data saturation into consideration.

4. We will include participating physicians from the hematologic and oncologic practices. In the preliminary phase, the first interview is conducted with physicians from all the partaking practices. The second interview will take place at different times during the intervention phase. The sampling will be based on the characteristics of the practices and physicians (eg, the size of the practices or experience of the physicians), recruitment rate, and contact with the intervention components (eg, participation in the virtual tumor board). The aim is to map as many different contextual conditions and factors of the intervention as possible. Recruitment will be done via telephone or email.

Data Collection

Overview

Data will be collected using a mixed methods approach at the beginning, during, and at the end of the intervention. Data will be collected through questionnaires, document analyses, semistructured interviews, and structured observations and will cover different aspects of process evaluation.

The personal data collected are subject to the obligation of confidentiality and the provisions of data protection law. The data will be used exclusively for the purpose specified in the consent form. Initially, the data will be pseudonymized, and then they will be anonymized during the later course of the study. After completion of the study, the transcribed audio files will be deleted.

If available, the pseudonyms assigned in the main trial will be used. Patients will be referred for the process evaluation through the established central coordination and contact platform. The key list remains at the LMU. By agreeing to participate in an interview as part of the process evaluation, the patients explicitly consent to being contacted by the staff of the MLU.

All data collected are processed on access-protected computers and then stored safely and securely for 10 years at the Institute of Health and Nursing Science at the MLU. The pseudonymized data will not be passed on to third parties. The publication of the data takes place exclusively in an anonymized form.

All participants will receive information about the study, and informed consent will be obtained (Multimedia Appendix 2). Informed consent will be obtained by a member of the MLU evaluation team, except for patients whose consent will be obtained through the central coordination and contact platform. Interested persons will receive written information about the study project, with the opportunity to ask questions via a conversation. They will then be provided with a consent form to sign. Before data collection begins, there will be another opportunity to ask questions and confirm consent.

After the inclusion of the physicians from the hematologic and oncologic practices, the baseline characteristics are recorded using the web-based survey application LimeSurvey. The link to the survey and an individual access code will be sent to the practices via email. If necessary, an email reminder will also be sent.

Several interviews will be conducted in person, through video conference via Cisco Webex [20], or through telephone. Interview guides were developed for each target group and topic of interest, which will be piloted in the first 3 to 5 interviews and adapted, if necessary. The audio-recorded interviews will be transcribed. There is no plan to send the interview transcripts to the participants. Structured observations will be conducted using a protocol with guiding themes. The protocols will also be piloted during the first structured observations. The objectives of the data collection are described in subsequent sections and summarized in Tables 1 to 3.

Context of the Intervention

To better understand the mechanisms of change and identify barriers and facilitating factors for implementation, contextual factors will be examined. For this purpose, we will conduct semistructured interviews with responsible persons of the CCC Munich at different points during the intervention phase to explore existing structures, changes in structures, attitudes, and mutual influences. In addition, we will conduct semistructured interviews with the responsible persons, staff, and stakeholders of the intervention components and collect descriptive data on the existing resources. To better understand and describe the context in which hematologic and oncologic practices are embedded, we will also conduct semistructured interviews during the intervention phase. Baseline characteristics such as the location of the practice, practice structures, connections or cooperation with a clinic or center, and IT equipment will be assessed.

Implementation Process

We will document the implementation process of the intervention, success and failure of recruitment, and participation rates. To answer the question of how the intervention components were implemented, we will conduct semistructured interviews with all persons involved in the intervention (patients, physicians in hematologic and oncologic practices, and staff of the CCC Munich). Furthermore, we will address the question of whether individual intervention components were implemented as intended. This includes the fidelity of the intervention, the degree of implementation, conscious and unconscious adjustments, and the extent to which the respective components reached the target group. For this purpose, we will conduct quantitative and qualitative document analyses on different issues (eg, the number of participants in the training courses, the frequency of psycho-oncological consultations, the completeness of documentation, the use of the DST, and IT support). We will also use structured observations for individual intervention components (eg, the tumor board).

Mechanisms of Impact

To understand the impact of the intervention components on care coordination, we will conduct semistructured interviews with patients in the intervention group, physicians in hematology and oncology practices, persons and staff responsible for the

XSL•FO
RenderX

intervention components, and physicians in the LMU and TUM. The aim is to understand the complex causal pathways and mediators of the intervention. The theoretical concept of care coordination will be the basis for the exploration. In particular, the focus is on the domains of communication and information (including all processes, communication, and information within the attending practice) and needs-based navigation (need-assessment and needs-based navigation outside the caregiver's institution, including all stakeholders in the health care process). Furthermore, spontaneously reported unintended effects of both the intervention components and the process evaluation itself will be collected. Significant influences will be discussed with the project team.

Data Analysis

Analyses of the baseline characteristics will be descriptive. The quantitative data will be evaluated through descriptive analysis. Qualitative data will be collected and analyzed in an iterative process until data saturation is reached through thematic analysis, according to Braun and Clarke [21]. Data analysis will be carried out by 2 people independently. In case of disagreement, consensus will be reached through discussion with a third person. Finally, the data will be combined using between-methods triangulation [22], the individual components of the process evaluation will be brought together, and configurations that have led to a high degree of cross-sectoral coordinated care will be identified at the practice level. The results of the triangulation will be analyzed in reflection talks after the completion of the study. The reflection talks serve to ensure sustainability, exchange experiences, and jointly evaluate the results. The processes of data collection and analysis are iterative until data saturation is assumed. The results of the interviews will be sent to all the participants via email.

Results

The project received funding on March 1, 2022. The intervention phase and recruitment for the process evaluation began on March 1, 2023, and the recruitment is expected to end on September 30, 2025. At the time of protocol submission in June 2023, a total of 8 doctors from hematology and oncology practices were enrolled. Data collection began on March 14, 2023.

Discussion

Overview

The TARGET project is a complex intervention that is to be implemented in an equally complex health care context. Whether the implementation is successful and the intervention achieves its desired effect depends on various factors and their interactions, for example, the contextual factors in the outpatient and clinical settings, the behavior and attitudes of the different stakeholders involved, and the intervention components in relation to routine care. A comprehensive analysis of processes and an assessment of diverse perspectives have been planned alongside a logic model. The logic model will guide data collection and analyses and is intended to help clarify causal assumptions. The findings of the primary outcome *coordination of care* from the patient's perspective, measured using the validated German version of the Care Coordination Instrument [8], will be accompanied by in-depth interviews with patients and perspectives of physicians. The results will finally be reported according to the Template for Intervention Description and Replication (TIDieR) checklist [23].

The summative evaluation study will follow a parallel group design, and eligible patients will be a heterogeneous group in terms of diagnosis, stage of disease, and course of treatment. Therefore, a comprehensive process evaluation is all the more important to understand the influence of contextual factors, assess the mechanisms of change, identify intended and nonintended effects, and explore the barriers to and facilitators of implementation.

As the evaluators who conduct the process evaluation are an external team from the MLU, it is important to establish a good working relationship with all the stakeholders involved in the intervention development and implementation to ensure a close observation of the intervention. Maintaining sufficient independence while observing the work of the different stakeholders is crucial. Another challenging question is whether the emerging findings should be communicated to the stakeholders. The evaluators can either act as passive observers reporting the results at the end of the project or help correct implementation problems while they occur [9]. We will not engage in continuous quality improvement activities because this might compromise the external validity of the evaluation [9], although serious observations will be discussed with the project team.

Limitations

This process evaluation also has limitations. Even after intensive exchange with the developers of the intervention, some ambiguity over the content of the intervention, its components, and how it is intended to work remains. Owing to the high complexity, it is hardly possible to record all processes and data, so some uncertainties will remain. For example, no observation or analysis of consultations is planned. Furthermore, it will be difficult to find out the reasons for nonparticipation, both for physicians and patients, because there will be no direct access to the group. However, it is better to answer the most important core questions well than to try to answer too many questions [9]. Therefore, we started to list causal assumptions within a logic model. Moreover, additional questions may arise during the course of the process evaluation [9]. Overall, it should be considered that access to the participants and data depends on the readiness and feasibility for it in an overburdened health care system.

Conclusions

The results and detailed descriptions of the process evaluation will help interpret the results of the TARGET intervention and put them into the correct context. In addition, the results may inform future projects that adapt TARGET or its individual components to different fields of cancer care or beyond. The results may also raise needs regarding the enhancement of the skills of the involved professions.

Abstract

Background: Patients with cancer receiving neoadjuvant treatment prior to surgery are in a very stressful situation. Chemotherapy and radiation therapy put a strain on the quality of life and the pending surgery poses a relevant burden for many patients. Preparation of these patients for the intervention in terms of prehabilitation has great potential to reduce the burden of postoperative complications and may improve the clinical outcome. A prehabilitation approach also yields the possibility to address unmet patients' needs and to help them modify their lifestyle in a maintainable way. Therefore, a multimodal approach is mandatory during this critical period.

Objective: The aim of this study is to assess the feasibility of prehabilitation in an integrative medicine day clinic (PRIME-DC) prior to cancer surgery at a major university clinic. PRIME-DC is considered feasible if 80% of enrolled patients are willing and able to complete at least 6 out of the 8 weekly meetings, each lasting 6.5 hours, at such a clinic. Secondary end points aim to evaluate this multimodal program.

Methods: The PRIME-DC intervention combines mind-body medicine, exercise therapy, nutrition therapy, naturopathic counseling, and the application of a yarrow liver compress. Adult patients with cancer, with a primary tumor in the abdomen (including intraperitoneal cancer, stomach cancer, and extraperitoneal cancers such as pancreatic, bladder, rectal, esophageal, endometrial, ovarian, and cervical cancer) or the breast requiring a neoadjuvant oncological treatment setting are eligible to participate. The addressed cancer entities imply either an extensive surgical intervention with an expected need for prehabilitation (eg, abdominal surgery) or a neoadjuvant treatment of several months with a high burden of treatment-associated side effects (breast cancer). Adherence to the day clinic program is the primary end point being defined as presence during the day clinic session. Secondary end points are physical assessment and quality of life, together with a structured assessment of neoadjuvant treatment-associated side effects. Furthermore, to collect qualitative data voluntary participants of the day clinic will be interviewed in a semistructured way after completion of the day clinic program on each component of the study (mind-body intervention, exercise, nutrition, naturopathic counseling, and a yarrow liver compress).

Results: The procedures used in this study adhere to the tenets of the Declaration of Helsinki. As of February 2023, we enrolled 23 patients; the dominant cancer entity is breast cancer (18 enrolled patients).

Conclusions: The presented protocol combines prehabilitation, lifestyle modification, naturopathic counseling, dietary assistance, and naturopathic treatment in an innovative and integrative way.

Introduction

Surgical interventions are burdensome for patients with cancer. Especially the period between diagnosis and surgery is a major challenge for the patient in many ways. Besides the psychological strain of the upcoming intervention, the physiological burden of an extensive surgery, for example, an abdominal operation can be compared with running a marathon [1]. The more extensive the surgery, the higher the rate of relevant postoperative complications, particularly in patients who are frail and those with an extensive medical history.

Conventional treatment plans include rehabilitation after medical or surgical treatment. Innovative concepts developed in the mid-1990s use the preoperative phase for various measures to improve patients' postoperative results with fewer and less severe complications. Analysis of these concepts of "prehabilitation" indicated efficacy [2,3]. The initial results were positive even in rather short (2-4 weeks) interventions comprising several sessions.

However, there is growing evidence that these early prehabilitation concepts lacked fundamental aspects of preparation [4]. First, they did not address anxiety, patients' empowerment, or strengthening of self-efficacy, which is well known to have a beneficial effect on cancer care [5]. Moreover, the idea arose that preparation for extended surgery represents a "teachable moment," a point in the life of a patient where long-lasting lifestyle modification is possible [6].

To date, no such program has been installed at the University Hospital Ulm. Nonetheless, the period of neoadjuvant chemotherapy, extending over a number of months provides time for a concise, integrative prehabilitation program addressing more than just the physical aspect of prehabilitation.

A promising integrative therapy for lifestyle modification, stress relief, and reduction of anxiety is mind-body medicine (MBM). The National Cancer Institute defines mind-body practice as "a health practice that combines mental focus, controlled breathing, and body movements to help relax the body and mind. It may be useful to control pain, stress, anxiety, and depression, and for overall health" [7]. The combination of mind-body practice, which includes a variety of mindfulness-based interventions, with aspects of cognitive behavioral therapy to enhance stress-coping mechanisms, is called MBM. This integrative treatment modality was established and adapted for a day clinic setting by Paul et al [8] and Dobos and Paul [9]. The concept of MBM within a day-hospital setting is traditionally applied to groups of 8-12 patients and is believed to be most effective in this group size with respect to lifestyle modification and stress management.

MBM shows positive effects in the treatment of fatigue [10] in patients with cancer while reducing anxiety about cancer recurrence [11]. Assuming the existence of a rationale for applying MBM in advance of surgery, it is noteworthy that postoperative pain and use of opioids are reduced even with a short MBM intervention, as shown by Pester et al [12] and Hanley et al [13]. The group setting is a hallmark of MBM therapy and enables the patients to learn from one another.

Another approach to enhance patients' self-efficacy and address an unmet need in the treatment of patients with cancer may be the integration of naturopathic therapy in an evidence-based manner. There is evidence that naturopathic counseling enhances quality of Life (QoL) of patients with cancer [14]. Many patients use naturopathic methods as an additional complementary therapy, commonly without informing their oncologists [15] and without being aware of the risks of interactions between naturopathic medication and their chemotherapy. In order to save patients from falling for false claims or risking adverse effects, the Association of the Scientific Medical Societies in Germany has issued a medical guideline for the complementary treatment of patients with cancer [16]. The evidence-based foundation of this guideline enables empowering counseling of patients with cancer about how to deal with cancer- or treatment-related side effects. Work on the establishment of a structured counseling program based on this guideline is in progress [17].

The yarrow liver compress is included in the day clinic setting as it has been shown to be effective against treatment-associated fatigue [18] and to increase sympathetic modulation assessed by heart-rate variability [19]. The main topic of this session is to give the patients an experience of a specific naturopathic treatment that is recommendable for fatigue and yields a very low risk of adverse effects.

The combination of harmonizing supportive therapies might meet the needs of highly vulnerable patients during neoadjuvant treatment facing surgery. None of the named interventions has been used to support prehabilitation at University Hospital Ulm so far.

Preoperative multimodal interventions such as exercise, nutrition, and mindfulness-based treatments are thought to improve patients' physical, nutritional, and mental status. Furthermore, cancer prehabilitation may improve patients' participation in rehabilitation after cancer treatment and maintain their ability to engage in salutogenic activities. Such an

XSL•FO
RenderX

integrative approach should include exercise for physical prehabilitation, mindfulness-based interventions to improve patients' ability to cope with stress and anxiety prior to surgery, cognitive behavioral aspects to change high-risk lifestyles for the better, and last but not least, empowerment of patients to apply naturopathic therapies independently in an evidence-based manner. This combination of measures represents a promising portfolio and may show strong synergistic effects.

Methods

Overview

This study is a single-center, single-arm interventional study evaluating the feasibility of an 8-week prehabilitation program before, during, or after neoadjuvant treatment before surgery at University Hospital Ulm.

Recruitment

During the recruitment period, all patients who are being treated for abdominal or breast cancer at the University Hospital Ulm on the Comprehensive Cancer Center Ulm and for whom neoadjuvant treatment is planned or performed with curative intent are screened for eligibility. Ineligible patients are listed, and in the case of refusal to participate, the reason, if communicated, is documented. Up to 15 patients who have given informed consent are enrolled in each cycle of the study (see sample size calculation). The addressed cancer entities imply either an extensive surgical intervention with an expected need for prehabilitation (eg, abdominal surgery) or a neoadjuvant treatment of several months with a high burden of treatment-associated side effects (breast cancer).

Patients may participate in the pilot study if they meet all of the following criteria: (1) diagnosis with intracavity cancer (including stomach cancer and extraperitoneal tumors such as prostate, bladder, rectal, esophageal, endometrial, and cervical cancer) or breast cancer; (2) planned or ongoing neoadjuvant treatment prior to planned curative resection; (3) aged 18 years or older; and (4) ability to understand the nature and individual consequences of the clinical trial. Patients are excluded from participation if their American Society of Anesthesiologists physical status classification system grade is >3, if they are immobile or unable to walk unassisted, or if they are already enrolled in a study that would interfere with the intervention and outcome of this trial.

Intervention

Overview

The intervention consists of a standardized MBM program (a group-based semi-individual approach to address lifestyle medicine and to enhance mindfulness) and naturopathic counseling, which is both led by a trained doctor and mind-body therapist, application of a yarrow liver compress which is applied by specially trained nurses, physical training therapy which is led by a sports therapist, a 1-day intervention in a teaching kitchen, and an organic lunch provided by a local caterer comprising a salad, a vegetarian protein-rich meal, and a dessert. The day clinic is scheduled once weekly, each session lasting 6.5 hours. This duration is common among other day clinics in the same setting [8]. The approach is group-based to enhance social support during the process. A detailed plan of the sessions and the scheduled topics is presented in Table 1.

Apart from allergic reactions to yarrow, no specific adverse effects are expected. A casualty insurance is contracted.

The study protocol has been presented to and discussed with patient representatives, the heads of the department of gynecology, urology, gastro-oncology, and radiation therapy, and the director of Comprehensive Cancer Center Ulm. This steering committee is informed intermittently about the status of the study.

Mind-Body Intervention

We use a modified version of the standardized MBM approach established by Dobos and Paul [9]. The mind-body intervention combines aspects of the MBSR program developed by Kabat-Zinn and elements of the MBM cancer program established by Henry Benson at Harvard Medical School [20]. It combines relaxation techniques and group-based cognitive therapy to address lifestyle modification. Patients have access to digital copies of verbal instructions (script and audio files) and are encouraged to practice mindfulness techniques at home. The therapist in charge of the mind-body intervention is a board-certified internist and attended an advanced training as a mind-body-medicine therapist described in Mind-Body Medicine in Integrative and Complementary Medicine [9].

Naturopathic Counseling

Naturopathic counseling is known to enhance the QoL of patients with cancer [14] and a high percentage of patients use naturopathic methods sometimes without informing their oncologists [15]. Therefore, everyday clinic session includes naturopathic counseling based on the current guideline for complementary medicine in oncology. The counseling aims to enhance patients' self-efficacy and enables them to address neoadjuvant treatment-associated side effects at home. The counseling embraces topics such as teas, compresses, the importance of sleep and sleep-enhancing rituals, as well as aspects of aromatherapy. Patients are free to utter their personal complaints during the last days or questions about possible side effects of the neoadjuvant treatment and are given advice based on the current guidelines for complementary medicine in oncology.

Exercise Therapy Interventions

Prehabilitation exercise therapy includes a combination of strength, cardiovascular or aerobic training, yoga, qigong, and stretching exercises. The program focuses on the educational aspect, giving advice on additional home-based exercises. The duration of the supervised intervention is 1 hour a week and the intended intensity is moderate.

Liver Compress

A yarrow liver compress is applied after the patient has eaten lunch at the day clinic. The liver compresses are prepared and applied by trained nurses. We infuse 1 tablespoon of yarrow tea with cut blossoms, stems, and leaves of common yarrow (*Achillea millefolium*) with 250 mL boiling water, letting it infuse until the tea takes on a yellow color (approximately 7 min) for each patient. We soak a cotton cloth in the infusion and then wring it out. The cloth is then fanned and gently draped over the patient's right upper abdomen. A towel is wrapped around the patient's abdomen and a hot-water bottle is placed over the compress. We cover the patient with a blanket followed by a rest for 30 minutes. The cotton cloth is then removed and the patient rests for another 30 minutes.

Nutrition and Teaching Kitchen

Nutrition is addressed during each day's clinic session. It may be a topic during naturopathic counseling depending on the individual needs of the participants. Each day clinic session includes an organic lunch provided by a local caterer. The participants eat together, which enhances group cohesion. One visit to the day clinic is dedicated to a session in a teaching kitchen. Participants prepare a meal under the guidance of a trained nutritionist. Apart from the group-forming aspect of preparing and eating a meal together, this session includes counseling about nutrition during cancer and cancer therapy focusing on the individual needs of the participants. In order to support the muscle status of the participants, they are counseled to adhere to a protein-rich (1-1.5 g/kg/day) diet without specific restrictions concentrating on maintaining the pretreatment weight with respect to the individual needs of each participant.

Outcomes

Each patient's adherence to the day clinic program is the primary end point measured via the noted presence during the day clinic sessions. The secondary end points are patient-reported outcomes assessed by means of the European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire C30 (EORTC QLQ-C30) [21], the Common Terminology Criteria for Adverse Events (PRO-CTCAE) [22], the Quality of Recovery-15 score (QoR-15) [23], the 4-item patient health questionnaire for anxiety and depression (PHQ-4) [24], the Pittsburgh Sleep Quality Index (PSQI) [25], the Five-Facet Mindfulness Questionnaire (FFMQ-D) [26], and fatigue (using a numeric rating scale) and clinician-reported outcome measures such as postoperative complications ≥3 according to Dindo and Clavien [27] within 30 days after the index operation, duration of postoperative hospital stay, readmission after initial discharge from the index operation within 30 days, 6-minute walking distance (6-MWD), hand grip strength (HGS), the result of the 1-minute sit-to-stand test (1-MSTS), the intensity of analgesic treatment according to the WHO pain ladder, and adherence to neoadjuvant treatment during the day clinic program. The physical assessment is conducted by study personal. The times of assessment of the end points are shown in Table 2.

Statistical Analysis

Sample Size Calculation

Prehabilitation in an integrative medicine day clinic (PRIME-DC) is a pilot study with an explorative approach and will be held in 3 cycles. Thus, no formal sample size calculation is needed. A group size of 6-12 patients per cycle was considered reasonable for evaluation of feasibility and acceptance of the prehabilitation day clinic setting. Patients who withdraw are not replaced, which is inherent for a closed group. Therefore, a sample of 18-45 patients is to be recruited. As the patients follow a group-based MBM program, the sample size has to fit the range appropriate for an MBM therapy group, that is, 6-15 patients.

Data Analysis Plan

The data analysis will give a comprehensive picture of the data through descriptive statistics and assess the precision and certainty of estimates using different CI widths.

First, descriptive statistics are used to summarize and describe the main features of the data set. This includes measures such as mean, median, SD, minimum, maximum, and percentiles. These statistics provide a clear and concise summary of the data's central tendencies and dispersion.

Further, the impact of different CI widths on the results and conclusions is of interest. CIs with 3 different widths, namely 75%, 85%, and 95%, are planned to be calculated and compared. The estimate becomes more precise as the CI narrows, albeit with reduced certainty regarding the capture of the true parameter [28].

Once the CIs are calculated, they will be interpreted in the context of the minimal clinically meaningful difference. This refers to the smallest change in the observed variable that is considered clinically relevant or significant. If the CI includes values within the range of minimal clinically meaningful difference, it may suggest that the observed effect is practically significant.

It is a robust approach to draw meaningful insights from the collected data while considering the practical implications of the findings [28].

Ethical Considerations

The study has been approved by the University Ethic Committee of Ulm University (77/22). Before study entry, all potential participants are comprehensively informed about the project and a written declaration of consent for participation is obtained. Access to the trial is open to all patients, regardless of their statutory health insurance provider. There are no additional costs or disadvantages for the participating patients. Patients' participation is voluntary. Participants will be informed verbally and in writing about the nature and scope of the planned procedure before the start of the study. Patients can withdraw their informed consent, including the processing of their data, at any time and without giving reasons. Disclosure takes place in pseudonymized form for the analysis. The names of the participating patients and all other confidential information are subject to medical confidentiality and the provisions of the European General Data Protection Regulation of May 25, 2018. After completion of the analyses, the data are made available on reasonable request in anonymized form in accordance with the institutional regulations and the General Data Protection Regulation. The study results are presented to academic audiences through publication in peer-reviewed journals and presentations at national and international conferences. The results are disseminated in the wider community. If shown to be feasible, the concept will be assessed with regard to its efficacy in reducing postoperative complications.

Results

This trial started on June 13, 2022, and the first 2 groups of patients have already completed their day clinic sessions. The current day clinic cycle takes place from January to March 2023. Data collection is to be completed by June 2023. As of February 2023, we enrolled 23 participants, 18 of whom were diagnosed with breast cancer, 2 with rectum carcinoma, 1 with esophageal cancer, 1 with stomach cancer, and 1 with pancreatic cancer. We expect the final results to be published by December 2023.

Discussion

Overview

This study is meant to prepare patients for surgery taking into consideration physical, nutritional, and psychological aspects. Neoadjuvant treatment is a very sensitive phase in cancer treatment and many patients search for assistance. Up to now this demand often remains unheard. We want to support patients with this comprehensive program, empower them to take control of some of the treatment-associated side effects, and help them prepare for the surgery. Establishing the feasibility of such program is the first step to show the efficacy of comprehensive integrative prehabilitation.

Principal Results

The main outcome is the adherence to the day clinic program measured via physical attendance at the weekly meetings.

Limitations

It will not be possible to establish significant data about the efficacy of such an approach as this study is meant to be a feasibility trial. The protocol does not include randomization; hence this is a feasibility study. The importance of the group-based setting may impede recruitment. The restricted cancer types included in the study might hamper the possibility of generalizing the results.

Conclusions

A PRIME-DC is a promising concept to address many unmet needs of patients undergoing neoadjuvant treatment combining aspects of movement therapy, naturopathic treatment, naturopathic counseling, dietary advice, and other lifestyle modifications like stress management.

Abstract

Background: Hepatitis A outbreaks in the United Kingdom are uncommon. Most people develop mild to moderate symptoms that resolve, without sequelae, within months. However, in high-risk groups, including those with underlying chronic liver disease (CLD), hepatitis A infection can be severe, with a higher risk of mortality and morbidity. The Health Security Agency and the National Institute of Health and Care Excellence recommend preexposure hepatitis A vaccination given in 2 doses to people with CLD, regardless of its cause. There are currently no published reports of vaccination coverage for people with CLD in England or internationally.

Objective: This study aims to describe hepatitis A vaccination coverage in adults with CLD in a UK primary care setting and compare liver disease etiology, sociodemographic characteristics, and comorbidities in people who are and are not exposed to the hepatitis A vaccine.

Methods: We will conduct a retrospective cohort study with data from the Primary Care Sentinel Cohort of the Oxford-Royal College of General Practitioners Clinical Informatics Digital Hub database, which is nationally representative of the English population. We will include people aged 18 years and older who have been registered in general practices in the Research and Surveillance Centre network and have a record of CLD between January 1, 2012, and December 31, 2022, including those with alcohol-related liver disease, chronic hepatitis B, chronic hepatitis C, nonalcohol fatty liver disease, Wilson disease, hemochromatosis, and autoimmune hepatitis. We will carefully curate variables using the Systematized Nomenclature of Medicine Clinical Terms. We will report the sociodemographic characteristics of those who are vaccinated. These include age, gender, ethnicity, population density, region, socioeconomic status (measured using the index of multiple deprivation), obesity, alcohol consumption, and smoking. Hepatitis A vaccination coverage for 1 and 2 doses will be calculated using an estimate of the CLD population as the denominator. We will analyze the baseline characteristics using descriptive statistics, including measures of dispersion. Pairwise comparisons of case-mix characteristics, comorbidities, and complications will be reported according to vaccination status. A multistate survival model will be fitted to estimate the transition probabilities among four states: (1) diagnosed with CLD, (2) first dose of hepatitis A vaccination, (3) second dose of hepatitis A vaccination, and (4) death. This will identify any potential disparities in how people with CLD get vaccinated.

Results: The Research and Surveillance Centre population comprises over 8 million people. The reported incidence of CLD is 20.7 cases per 100,000. International estimates of hepatitis A vaccine coverage vary between 10% and 50% in this group.

XSL•FO
RenderX

Conclusions: This study will describe the uptake of the hepatitis A vaccine in people with CLD and report any disparities or differences in the characteristics of the vaccinated population.

Introduction

Overview

Hepatitis A (Hep A) is a viral infection of the liver caused by the hepatitis A virus (HAV). HAV is transmitted through the fecal-oral route, mainly by exposure to contaminated water sources. Hep A outbreaks are uncommon in the United Kingdom, and most people manifest mild to moderate symptoms that tend to resolve, without sequelae, within several months. In high-risk groups, however, such as people with an underlying chronic liver disease (CLD), a superimposed acute infection with HAV can be severe, potentially requiring hospitalization and carrying a higher risk of death. According to the World Health Organization, approximately 100 million Hep A infections occur globally per year, resulting in 15,000 to 30,000 deaths per year [1]. Of these, the number of people with a preexisting CLD diagnosis remains unclear.

CLD largely results from the progressive destruction and regeneration of hepatocytes, leading to fibrosis and cirrhosis, and has a range of etiologies. The most common causes of CLD include alcohol-related liver disease (ALD), chronic hepatitis B (CH-B) infection, chronic hepatitis C (CH-C) infection, and nonalcoholic fatty liver disease (NAFLD), the latter being associated with metabolic syndrome and obesity [2,3]. Deaths in the United Kingdom from CLD have increased annually for the past decade, peaking at 20.6 per 100,000 population in 2020 [4,5], and are expected to surpass the numbers of premature deaths from coronary heart disease [3], CLD-related hospitalizations in the United Kingdom have increased by half, contributing to the £2.1 (US $2.62) billion per year currently spent on treating liver disease [4,6].

The UK's public health body, the Health Security Agency, and the national guideline body, the National Institute for Health and Care Excellence, recommend preexposure Hep A vaccination to all people with CLD, regardless of the cause [7,8]. The Hep A vaccine series consists of 2 doses, with the second dose at least 6 months after the first.

The data from the United States have shown that less than one-third of at-risk adults receive any vaccination for Hep A, and only one-fifth receive both doses [2,9-12]. Adherence to the vaccination schedule was worse at the extremes of adult age, in ethnic minorities, and in those of low socioeconomic status [10]. The same is true in the United Kingdom; under 35% of eligible people receive the complete Hep A vaccination course, though these data are presented for all eligible patients, regardless of CLD status [13].

Hence, there are no published reports of Hep A vaccination coverage in people with CLD. The purpose of this study is to report Hep A vaccine coverage in people with CLD in UK primary care, with a focus on whether there are disparities as to which people with CLD receive Hep A vaccination.

Aims

The aim of this study is to report Hep A vaccination coverage in people with CLD in English primary care and the predictors of receiving a single dose or full vaccination course.

Objectives

The objectives of this study are as follows:

1. To report yearly Hep A vaccination coverage in people with CLD by:
   - sociodemographic characteristics (eg, age, sex, ethnicity, deprivation, BMI category, smoking status, and alcohol consumption)
   - etiology of CLD (eg, ALD, CH-B, CH-C, and NAFLD).
   - CLD complications (eg, renal disease, ascites, liver failure and transplant, and other cardiometabolic diseases, including diabetes and heart disease)
   - comorbidities and exposures (eg, Cambridge Multimorbidity Score [CMMS], bile duct and colon cancers, at least three doses of COVID-19 vaccine, and flu vaccination).
2. To report the predictors of 1 and 2 doses of Hep A vaccination in people with CLD.

Methods

Study Design

This is a retrospective cohort study using data from the nationally representative Primary Care Sentinel Cohort (PCSC) of the Oxford-Royal College of General Practitioners (RCGP) Research and Surveillance Centre (RSC) [14]. The RSC is one of Europe's oldest sentinel systems, and hepatitis is one of its 32 monitored conditions [15]. The database has previously been used for liver disease and hepatitis research [3,16].

We will use electronic health record data for the period between January 1, 2012, and December 31, 2022. Data will be extracted retrospectively at the time of the beginning of the study.

XSL•FO
RenderX

Setting

Data Source

Data will be extracted from the PCSC of the RSC. The PCSC consists of a nationally representative sample of 7.4 million patients registered in primary care practices in England [17,18]. Pseudonymized data will be extracted from the secure environment of the Oxford-RCGP Clinical Informatics Digital Hub (ORCHID) [19].

CLD Ontology and Curated Variables

Key population characteristics, index conditions, and outcomes will be identified using the Systematized Nomenclature of Medicine Clinical Terms (SNOMED CT), in accordance with NHS Digital [20]. To identify these, we will curate data to ensure its use in future studies, supporting the findable, accessible, interoperable, and reusable open science principles [21].

The preliminary SNOMED CT codes to be used to identify CLD as an index condition are summarized in Multimedia Appendix 1. A conceptual model and suitable ontology are developed before carrying out the data extraction [22,23]. The identification of CLD-related concepts will be based on the clinical diagnoses as recorded in primary care; the researchers will not develop ad hoc diagnostic criteria. Clinical codes for CLD will be grouped by their main etiology; a hierarchical ontological approach using the conceptual model will be followed if overlapping concepts are encountered.

Data Quality

The RSC has over 55 years of experience in infectious disease surveillance, including vaccination coverage and effectiveness studies [18,24,25]. Viral hepatitis is one of the RSC's monitored conditions.

Study Population

We will include adults registered in general practices within the RSC network with a diagnosis of CLD, as defined by our ontology, within the period between January 1, 2012, and December 31, 2022. The following inclusion criteria will be applied: (1) people registered in the RSC general practices, aged 18 years and older, with a diagnosis of CLD; and (2) the ontology for CLD includes ALD, CH-B, CH-C, NAFLD, Wilson Disease, hemochromatosis, autoimmune hepatitis, primary sclerosing cholangitis, and primary biliary cholangitis [2-4].

The following exclusion criteria are applied: (1) patients with recorded contraindications to the Hep A vaccine (confirmed anaphylactic reaction to a previous dose of Hep A containing vaccine or to any of its components); and (2) records of administration of postinfection or risk-of-infection immunoglobulins.

Variables

Overview

The study population is those with CLD as an index condition, as defined in the inclusion criteria. The variables will be curated for the identification of CLD-related codes in the computerized medical records of adults registered in the RSC network (Multimedia Appendix 1).

Comparisons will be conducted between population subgroups with different CLD etiologies, sociodemographic characteristics, complications, and comorbidity profiles.

The outcome of the first objective will be the coverage rates of Hep A vaccination among those with CLD.

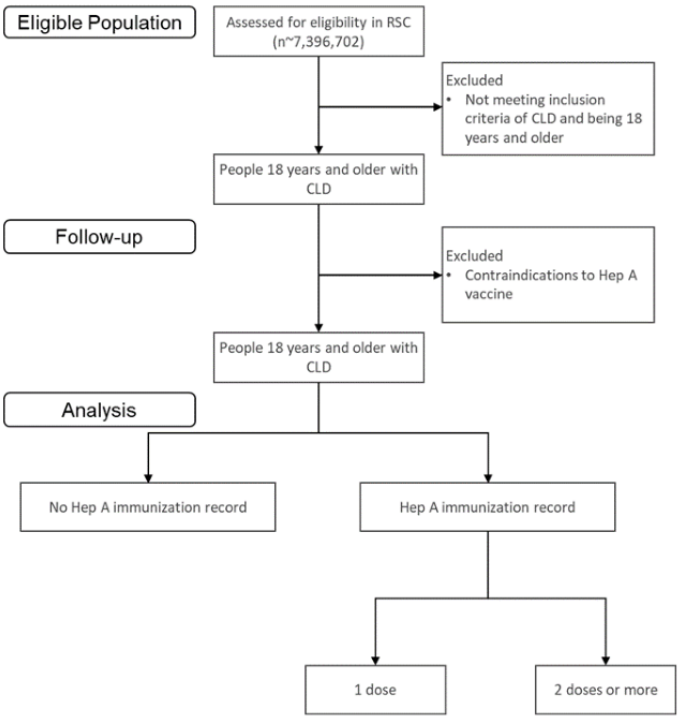
For the second objective, we will explore significant independent predictors of the following outcomes among those with CLD: (1) one dose of Hep A vaccination and (2) two doses of Hep A vaccination.

Hep A vaccination, as defined by the UK vaccination scheme, includes an initial 0.5 mL for 1 dose, followed by a booster dose of 0.5 mL after 6-12 months. The booster dose may be delayed by up to 3 years if not given after the recommended interval following the primary dose [8]. For this study, we will report boosters administered within 12 months of the first dose for the base case analysis and 3 years from the first dose for a sensitivity analysis. Hep A vaccination in the United Kingdom is available as a monovalent vaccine, as a combined Hep A and hepatitis B vaccine, and as a Hep A and typhoid vaccine [7]. We will consider any Hep A vaccination type as an outcome.

Covariates

Sociodemographic characteristics will be reported closest to the earliest date of CLD diagnosis as baseline, within a 10-year range for time-sensitive variables. These include age, gender, ethnicity (categorized into White, Black, Asian, multiracial, and other), rurality (measure of population density), region, socioeconomic status (measured using the index of multiple deprivation), obesity, alcohol consumption, and smoking. A history of comorbid conditions and complications will be extracted from 10 years of computerized medical records, including osteoporosis, bile duct and colon cancers, renal disease (including calculi), ascites, liver failure and transplant, and cardiometabolic disease. The CMMS will be used to report on comorbidity profiles [26,27].

Study Size



Age-standardized incidence rates for CLD worldwide are reported as 20.7/100,000 [28]. The RSC network comprises a nationally representative sample of 7.4 million registered patients. This brings an estimate of up to 1656 potential patients with CLD per year of study to be included in our final study population. This is consistent with previous reports on the CLD population in the RSC network [29].

In the United States, Hep A vaccination coverage is reported to range between 10% and 50% [2,9]. Therefore, we expect between 165 and 828 individuals to be found to have both the index condition and outcome of interest per year for a 10-year study period.

The study population will be categorized and stratified for analysis following the CONSORT (Consolidated Standards of Reporting Trials) diagram (Figure 1).

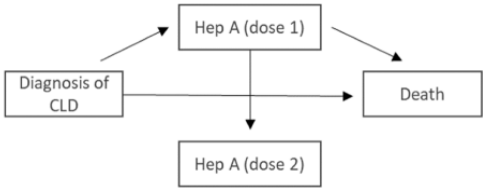
XSL•FO
RenderX

Figure 1. Consolidated Standards of Reporting Trials diagram for eligible individuals in the Research and Surveillance Centre (RSC) network for a retrospective cohort analysis of adults with chronic liver disease (CLD) in England between January 1, 2012, and December 31, 2022, evaluating hepatitis A vaccination with 1 and 2 doses as outcomes.

Statistical Analysis

Reporting Hep A Vaccination Coverage in People With CLD

Hep A vaccination rates will be calculated using the number of vaccinated people with CLD as the numerator and estimates of the CLD population in the ORCHID data set as the denominator. Baseline characteristics of each study group (eg, age and gender) will be summarized using descriptive statistics, including measures of dispersion (eg, SDs and IQRs).



To compare individual characteristics by vaccination status (eg, CLD disease type, sociodemographic characteristics, complications, and comorbidities), we will use descriptive statistics, with pairwise comparisons using the chi-square or Fisher exact tests for categorical variables and the *t* test or Wilcoxon test for continuous variables. If stratification involves more than 2 groups, differences across groups will be tested using the Kruskal-Wallis test for continuous variables and the Pearson chi-square test for categorical variables, followed by pairwise comparisons as above described. All statistical tests will be 2-sided with $P<.05$ considered statistically significant.

Reporting Predictors of 1 and 2 Doses of Hep A Vaccination in People With CLD

Overview

A multistate model will be used on a retrospective cohort of individuals identified in the ORCHID diagnosed with CLD. People enter the study on the first diagnosis of CLD, and we will model the transition probabilities between the identified states: diagnosed with CLD, first dose of Hep A vaccination, second dose of Hep A vaccination, and death (Figure 2).

Figure 2. State transition diagram for competing risks multistate model for a retrospective cohort of adults with chronic liver disease (CLD) in England between January 1, 2012, and December 31, 2022, evaluating hepatitis A (Hep A) vaccination with 1 and 2 doses as outcomes and death as a competing risk represented as an absorbing state.

A multistate survival model will be fitted to estimate the transition probabilities between the 4 identified study states (Figure 2). The states are (1) diagnosis of CLD, (2) first dose of Hep A vaccination, (3) death, and (4) second dose of Hep A vaccination. The outcome of interest is the Hep A vaccination. Therefore, the state of a second dose of Hep A vaccination is a censored state, with no further transitions to death; the moment a patient receives 2 doses of Hep A vaccination, the follow-up ends. Death is an absorbing state, with no further transitions allowed. Death is included as a competing risk for vaccination, not as an outcome. This means that when calculating the transition probabilities to vaccination, we adjust for when a person is not vaccinated because of death before vaccination rather than for any other predictors of nonvaccination.

XSL•FO
RenderX

Patients lost to follow-up will be right censored and evaluated accordingly as per the likelihood function of the "msm" R package [30].

Multistate probabilities are based on the same assumptions as a Markov process:

1. The health states considered in the model are thorough and mutually exclusive.
2. The probability to move from one health state to following states only depends on (is conditioned on) the health state of the individual at transition time (memoryless process).
3. Transition probabilities are steady over time.

The state transition probabilities will be estimated conditional on the study risk factors. Study risk factors include (1) etiology of CLD (eg, ALD, CH-B, CH-C, and NAFLD); (2) sociodemographic characteristics (eg, age, sex, ethnicity, deprivation, obesity, smoking, and alcohol consumption); (3) CLD complications (eg, bile duct and colon cancers, renal disease, ascites, liver failure and transplant, and cardiometabolic disease); and (4) comorbidities (eg, CMMS, bile duct and colon cancers, at least 3 doses of COVID-19 vaccine, and flu vaccination).

The multistate model will be estimated using the "msm" (version 1.6.9) package in R [31].

Missing Data

Descriptive analyses will be conducted on the overall study population and applicable subgroups. Data that are not documented in our database will be reported as missing.

Missing data will be presented as a separate category in univariate statistics and compared to the reference category through univariate odds ratios. Missing data categories will be imputed to the reference category if no significant differences are found in the reference category. Missing data categories will be otherwise included in the analysis as an independent category if evidence suggests they are not missing at random; for example, significant differences to the reference category exist.

Sensitivity Analysis

We will estimate 2 multistate models by varying the definition of Hep A dose 2. In the first model, the second dose must be administered within 1 year of the first dose; in the second model, dose 2 may occur within 3 years of the first administered dose. A 3-year time window between vaccinations is likely to exclude those who have been recently vaccinated. Hence the need for such a sensitivity analysis. A complete-case analysis to assess any differences due to missing data can be conducted after assessing the missingness of the descriptive data.

Spurious Data

Data quality (eg, consistency and accuracy) will be assessed at the point of data extraction through an outlier analysis comparing the covariate's values to plausible biological measures. Spurious values will be categorized as missing values and handled according to the methodology layout.

Ethical Considerations

Anonymized electronic health record data were accessible for research purposes following ethical approval from the Central University Research Ethics Committee at the University of Oxford (under reference R80951/RE001) for human participant research. Anonymized patient data were retrieved from electronic health record providers from those users who had consented for their data to be used for secondary research purposes. No form of compensation was provided to participants. Generative artificial intelligence was not used in any portion of the manuscript.

Results

The primary care cohort comprised 1704 practices and 7,396,702 registered patients between the January 1, 2012, and December 31, 2022 (Figure 1). We have created an initial clinical code ontology using existing SNOMED CT–curated variables for our sociodemographic variables, hepatitis, and CLD by etiology (Multimedia Appendix 1). The ontology will be expanded to include paraclinical indicators of CLD to identify cases where an explicit diagnosis or specific etiology has not been recorded. Other relevant covariates will be created as required for the study.

The phases of this study will include curating the required variables, conducting our data extraction, statistical analysis, and reporting of the findings through scientific publications.

Discussion

Overview

This study will inform on the state of preventive Hep A vaccination for people with CLD in a representative primary care sentinel network in England. From a total of 7.4 million patients in the RSC network, we will report on the sociodemographic and clinical characteristics of people with CLD with and without Hep A vaccination, for 1 and 2 doses.

The multistate model, adjusted for study risk factors, will identify those associated with having the vaccination. This will inform on the individual characteristics that are associated with an immunization, informing on the subgroups that could benefit from higher engagement with preventive primary care. Any disparities identified could be used to target clinical and public health interventions to improve vaccination coverage in this at-risk group.

Comparisons With Previous Work

The results will be compared to previous reports on preexposure Hep A vaccination coverage rates of 10%-50% in the United States [2,9,10,12]. For the United Kingdom, there are no published reports on vaccination coverage in this subpopulation, to the best of our knowledge.

Limitations

Selection and misclassification biases can be associated with the retrospective study design. However, this can be mitigated by the availability of reliable records in the database. Similarly, the retrospective study design has a limitation to establishing

XSL•FO
RenderX

causal relationships due to the temporality and lack of randomization. However, retrospective associations can be a timely source of epidemiological data to guide further research.

There exists potential confounding due to case-mix characteristics, which will be mitigated through multivariate time-to-event modeling in the multistate model.

Large general practice databases are susceptible to coding errors or inaccuracies that may be associated with ascertainment and misclassification biases. This is mitigated by the large representative sample of UK practices within the RSC network, which controls for random error and variation on these parameters [18].

Conclusions

This descriptive epidemiological study will fill an important gap in our knowledge about Hep A vaccination in people with CLD in the United Kingdom by describing the uptake of Hep A vaccine in people with CLD and reporting any disparities or differences in characteristics of the vaccinated population.

Data Handling and Record Keeping

Data are held on dedicated, secure servers at the RCGP data and analytics hub in the Clinical Informatics and Health Outcomes Research Group, based at the Nuffield Department of Primary Care Health Sciences, University of Oxford. The research group's secure network is sited behind a firewall within the university's network; all inbound connections are blocked, but outbound connections are allowed. Only staff members or associated members of the research group approved by the head of department can access the data from a virtual desktop (on the ORCHID secure server) using a University of Oxford computer and their unique access credentials. The use of personal equipment is not permitted and cannot be connected to a secure network. Pseudonymized study data will be archived for at least 5 years.

Acknowledgments

The study is funded by GlaxoSmithKlein's Investigator Sponsored Studies Program (GSK ISS: 14309). Dr Gayathri Delanerolle contributed to the discussion during study conception and funding acquisition.

Data Availability

Apart from necessary access by the research team, direct access may be granted to authorized representatives from the sponsor or host institutions for monitoring or audit of the study to ensure compliance with regulations.

Researchers will maintain a log of data gathering using study IDs rather than personal identifying information.

Conflicts of Interest

None declared.

Abstract

Background: Infection by human papillomavirus (HPV) induces various cancers, mainly cervical cancer but also anal and pharyngeal cancers. Reunion Island is a French department in the Indian Ocean. Due to the history of its settlement, the island's population has a wide variety of origins, and the population's sociodemographic characteristics differ from those of the French mainland. These characteristics make the island's population an original French population in its own right, particularly in terms of health. Cervical cancer incidence and mortality in Reunion Island are 10.4 per 100,000 and 4.4 per 100,000, respectively, both of which are much higher than those in mainland France. There is also a disparity in the prevalence of different HPV types, with types 33 and 52 being overrepresented and type 18 being underrepresented. However, vaccination and screening coverage in Reunion Island is low. It is important to understand the burden of infection and its risk factors in members of the young Reunionese population at risk of HPV infection to promote and evaluate the implementation of future vaccination and screening programs on a larger scale.

Objective: The RUN-SurV-HPV study will have the following four objectives: (1) to describe the prevalence of HPV genotypes in a population at risk of sexually transmitted infections in Reunion Island; (2) to describe the prevalence of HPV genotypes by anatomical site, gender, and sexuality; (3) to describe the correlates and risk factors for HPV detection; and (4) to examine HPV genotypes between different anatomical sites.

Methods: Cross-sectional analyses of 1200 routine vaginal, anal, pharyngeal, and urinary samples collected between October 2020 to December 2022 from female and male patients aged 16 to 30 years undergoing *Chlamydia trachomatis* testing at a sexually transmitted infection (STI) testing center at Reunion Island will be performed. The population included 333 women who all had vaginal and pharyngeal swabs, with 80 of them also having had an anal swab. There are 167 men who have sex with men who have had anal and pharyngeal swabs, and 120 men who have sex with women who have had a urine swab only. Results will be correlated with sociodemographic and clinical data collected routinely during the consultations. HPV detection and genotyping will be performed using the Anyplex II HPV28 detection assay (Seegene).

XSL•FO
RenderX

Results: The first polymerase chain reactions should begin in November 2023. The first results should be submitted for publication in 2024.

Conclusions: The study will determine HPV prevalence by age, sex, male sexual preference, human immunodeficiency virus status, and STI co-infection. Collecting data from young patients not usually routinely screened for HPV infection will be a simple and reproducible way of better understanding local specificities, encouraging vaccination campaigns in the short-term, and evaluating their effectiveness in the future.

Introduction

Human papillomavirus (HPV) is the most common sexually transmitted infection (STI) in the world. There are more than 100 types of HPV, with 13 classified as oncogenic. Of these, HPV types 16 and 18 are the cause of 70%-80% of invasive cervical cancers [1-3], which comprise the fourth most common cancer worldwide [4]. HPV infections also cause cancers of the vulva, vagina, penis, anal canal, and oropharynx; therefore, they affect both women and men.

Reunion Island is a French overseas department located in the Indian Ocean that is populated by more than 850,000 inhabitants. Due to the history of its settlement, the population of the island has very varied origins (ie, East Africa, the Comoros Islands, Madagascar, India, China, and Europe) that differ from mainland France. The geographical distance and its sociodemographic characteristics make it an original French population in its own right. In Reunion Island, cervical cancer is the fourth most common type of cancer in women. From 2013 to 2015, cervical cancer incidence and mortality were 10.4 per 100,000 and 4.4 per 100,000, respectively, making it the eighth deadliest cancer, 2 times higher than in mainland France [5]. These disparities can be explained partly by a low cervical cancer screening rate in the 1990s and 2000s [6] compared to the French national average, but the trend now seems to be reversing. Cervical cancer screening is a secondary prevention approach that is universally considered to be effective in reducing the incidence and mortality of this cancer in the general population. It is recommended in most developed countries. Furthermore, several studies have shown that risk factors for infection (eg, early sexual activity, high parity, precariousness) by the various STIs do not totally overlap with those in mainland France, and are, in fact, overrepresented in Reunion Island [7,8]. However, the only study to examine the link between this overrepresentation of risk factors and the incidence of cervical cancer in Reunion Island did not explain this difference in cancer incidence rates [9].

The first HPV vaccine was marketed worldwide in 2006. Initially, the first 2 vaccines protected against 2 genotypes (16 and 18) or 4 genotypes (6, 11, 16, and 18). Currently, the latest vaccine protects against 9 genotypes (6, 11, 16, 18, 31, 33, 45, 52, and 58). In 2007, the French High Authority for Health (HAS: Haute Autorite de la Sante) first implemented a community-based vaccination program that recommended HPV vaccination for girls aged 11 to 14 years with the possibility of catching up until 19 years of age. In 2019, the program was extended to include boys in the same age groups [10]. This officially came into effect in January 2021 [11]. In 2021, vaccination coverage was only 37.4% in mainland France [12]; it thus remains one of the lowest in Europe [13]. In Reunion Island, coverage was only 12.2% in 2021 based on the results of one available local research study [12]. Coverage is far short of the 90% elimination target [4]. This low vaccination rate in Reunion Island has in large part been driven by a lack of information and mistrust of vaccination from parents and caregivers [14].

The peculiarity of this population regarding its low vaccination coverage, high cancer rate compared to the national average, diverse ethnic origins, and risk factors encourages local exploration and monitoring of HPV genotype specificity. Furthermore, a previous study in women with atypical squamous cells of undetermined significance (ASCUS) Papanicolaou test results (age: mean 35.4, SD 12.3 years) and cervical biopsies of high-grade histological lesions or cancer (age: mean 48.6, SD 17.1 years) identified that the distributions of different types of HPV in Reunion Island were not similar to those observed in mainland France (eg, underrepresentation of HPV 18, overrepresentation of HPV 52, high proportion of co-infections) [15]. Moreover, there are no data on the prevalence of oncogenic HPV in Reunion Island in women younger than 30 years (for the cervical, pharyngeal, and anal areas), men who have sex with women (MSW), or men who have sex with men (MSM).

In the RUN-SurV-HPV study, we want to analyze the distribution of different oncogenic HPV types (16, 18, 26, 31, 33, 35, 39, 45, 51, 52, 53, 56, 58, 59, 66, 68, 69, 73, and 82) in a population of women and men at risk of STIs attending an STI testing center for *Chlamydia trachomatis* (CT). The inclusion of young patients at risk of STIs, and therefore at risk of HPV infection, including both women and men, will enable us to study a population in which the incidence of HPV infection will likely be high. The inclusion of men, whether MSM or MSW, is in line with the recent extension of vaccination to French men and women, regardless of their sexuality [10]. Indeed, MSM have a higher risk of anal cancer [16], and MSW, even if in a smaller proportion, are still affected by HPV-induced cancers and can be vectors of infection for women. By including men, this study will improve our understanding of HPV infection

XSL•FO
RenderX

in men and provide arguments to encourage them to be vaccinated. This type of study will allow us to obtain a more precise mapping of different oncogenic HPV genotypes in this population and evaluate an early surveillance system for changes in HPV distribution following vaccination campaigns.

The main objective is to describe the prevalence of infection by at least 1 of the 7 high-risk oncogenic HPV genotypes contained in the GARDASIL 9 HPV vaccine (16, 18, 31, 33, 45, 52 and 58) in women younger than 30 years who have had a vaginal swab and MSM who have had an anal swab for CT infection in the Reunion Island population.

The secondary objectives are as follows:

1. To describe the prevalence of infections by different high-risk (16, 18, 26, 31, 33, 35, 39, 45, 51, 52, 53, 56, 58, 59, 66, 68, 69, 73, and 82) and low-risk (6, 11, 40, 42, 43, 44, 54, 61, and 70) HPV genotypes in samples from routine vaginal, anal, or pharyngeal CT testing from women younger than 30 years; urine samples from MSW younger than 30 years; and anal samples associated with pharyngeal CT testing from MSM.
2. To investigate HPV distribution in the same patient (women and MSM) according to the swabbed location.
3. To describe the correlates and risk factors for HPV infection, including age, CT status, status of other STI infections, socioeconomic status, sexuality, reasons for consultation, HPV vaccination status, and human immunodeficiency virus (HIV) status, by patient and type of specimen.

Methods

Study Design

This protocol is for a single-center, descriptive, cross-sectional study of all samples collected from male and female patients undergoing routine CT testing at the STI testing center of University Hospital (UH) in south Reunion Island between October 2020 and December 2022.

Setting

The national recommendation for CT screening in France suggests screening all woman from 15 to 25 years of age (pregnant women included) as well as those older than 25 years with risk factors and all men (all ages). In this study, samples were obtained from patients who went to an STI testing center mainly because of a recent sexual risk or symptomatic genital affection or to be able to remove the condom in a stable relationship.

Study Population

Inclusion Criteria

The following patients were included in the study:

1. Those who consulted the STI testing center of the UH site in south Reunion Island between October 1, 2020, and December 31, 2022;
2. Female patients younger than 30 years because the national recommendation for HPV screening is from 30 years of age and following a younger population would provide insight about the first impact of the national vaccination program;
3. MSM (all ages) because they have a higher risk of anal cancer;
4. MSW younger than 30 years because they are also affected by HPV-induced cancers, are included in the new French vaccination recommendations, and comprise a specific population that is able to infect women;
5. Those who were tested for CT infection on at least 2 different anatomical sites (vaginal, pharyngeal, and anal) for women, first pass urine for MSW, and at least 2 different sites (anal and pharyngeal) for MSM;
6. Those whose residual samples were available at the microbiology laboratory of the UH of Reunion Island.

Exclusion Criteria

The following patients were excluded from the study:

1. Those who were outside the study age range,
2. Those who did not consent to the use of their data for research,
3. MSW with no sites collected and women and MSM with less than 2 sites collected,
4. Those for whom there was insufficient biological material.

Data Collection

Social and demographic data were extracted from routine clinical records. These data were collected for each person presenting for screening via a self-administered questionnaire that was routinely administered and completed during the consultation (Multimedia Appendix 1). This questionnaire met the annual variables requested by France Public Health (Sante Publique France) from STI testing centers. It included age, gender, sample type, CT test result, HPV vaccination status (self-reported), male sexual preference, and social and demographic data. The collected information was anonymous in this testing center, but patients had a choice to link their clinical data with an anonymity number or their name for each sample. For this research, data will be entered into a secure anonymous database according to current national guidelines.

Data Extraction

Data Processing by the Laboratory

Sample collection at the laboratory, the supply of sampling equipment, and the transport of the samples was carried out in compliance with the NF EN ISO 15189 standard, thus guaranteeing the integrity of the samples and their traceability.

Samples were transported to the laboratory at 4 °C in eSwab transport media (COPAN Diagnostics) for swabs (vaginal, oral, and anal) and in sterile preservative-free flasks for urine. After the CT polymerase chain reactions (PCRs) were performed, residual samples were frozen at –80 °C to perform this study.

Enclosures equipped with range temperature sensors (SpyRF) are metrologically monitored using a monitoring web platform software (JRI-MySirius), allowing the exploitation of alarms and data. An Ethernet modem is installed in each lab, thus ensuring radio frequency communication with the SpyRF.

XSL•FO
RenderX

HPV Detection and Genotyping

Samples will be tested with the Anyplex TM II HP28 Detection kit (Seegene), a semi-qualitative test for the detection of DNA and genotyping of HPV types. DNA extraction will be performed using the STARMag Universal extraction kit (Eurobio Scientific) on the STARlet (Seegene) automated system. After extraction, genotyping will be done by amplification on a CFX96 TM thermocycler (BioRad). This kit uses the human housekeeping gene, beta globin, as an endogenous internal control to verify the DNA extraction, PCR reaction, and presence of cells in each sample. This real-time multiplex assay allows simultaneous amplification, detection, and differentiation of target nucleic acids of 28 HPV types (6, 11, 16, 18, 26, 31, 33, 35, 39, 40, 42, 43, 44, 45, 51, 52, 53, 54, 56, 58, 59, 61, 66, 68, 69, 70, 73, and 82).

Processing of Medical Records, Questionnaires, and Patients' Results

Using standard software extraction tools, throughout the study, researchers will generate a list of all the information included in patients' records and self-administered questionnaires issued and completed on the day of collection. This anonymous information will then be extracted into a secure Excel spreadsheet (Microsoft Corp). HPV genotyping results will also be extracted into a secure Excel spreadsheet.

Statistical Considerations

Sample Size

Sample collection started in October 2020 and ended in December 2022. For women, 1436 swabs were collected from 665 women. A vaginal and pharyngeal swab was collected on the same day from 333 women younger than 30 years, 80 of whom also had an anal swab. For MSM, 738 samples were collected from 258 MSM. An anal and pharyngeal swab was collected on the same day from 167 MSM. Finally, 661 MSW provided a urine sample and 324 were younger than 30 years. Between 120-180 urine samples from MSW will be randomly selected for inclusion in the study, depending on the availability of stored samples from women and MSM. A total of 1200 samples will be tested (Table 1). Due to the absence of data with this type of methodology in Reunion Island, an estimated 95% CI for different prevalence levels was calculated using STATA 17.0 software (StataCorp) from vaginal swabs from women and anal swabs from MSM to address our primary objective (Table 2). This ranking was from 1% to 50% prevalence of HPV infection corresponding to 1 of the 7 potential oncogenic HPV genotypes contained in GARDASIL 9 in our previous study on ASCUS Papanicolaou tests and cervical biopsies (conservative assumption) [15].

Table 1. Description of the number of samples by gender, sexuality, and anatomical site of collection obtained between October 2020 and December 2022 from patients of all ages undergoing *Chlamydia trachomatis* testing at a sexually transmitted infection testing center in Reunion Island as part of the RUN-SurV-HPV study.

Anatomical site (n=1200)	Women (n=333), n	MSM[a] (n=167), n	MSW[b] (n=120), n
Pharyngeal	333	167	N/A[c]
Vaginal	333	N/A	N/A
Anal	80	167	N/A
Urine	N/A	N/A	120

[a]MSM: men who have sex with men.

[b]MSW: men who have sex with women.

[c]N/A: not applicable.

Table 2. Estimation of the 95% CI for human papillomavirus prevalence among women and men who have sex with men (MSM) who visited a sexually transmitted infection testing center from October 2020 to December 2022 in Reunion Island as part of the RUN-SurV-HPV study.

Prevalence (%)	Women (n=333), 95% CI	MSM (n=167), 95% CI
1	0.30-3.30	0.10-4.25
5	3.00-8.00	2.09-9.22
10	6.90-13.60	6.04-15.79
20	15.90-24.80	14.00-26.61
30	25.15-35.26	23.10-37.49
40	34.63-45.42	32.62-47.97
50	44.35-55.35	41.88-57.52

Analysis Plan

Patient characteristics will be described in terms of numbers and percentages for qualitative variables and in terms of mean and SD, median and IQR, and range for quantitative variables. The prevalence of HPV infections will be expressed as percentages. The exact binomial method will be used to calculate 95% CIs. Analysis of primary assessment criteria will be performed per patient considering only vaginal samples for women and anal samples for MSM. For analysis of factors

XSL•FO
RenderX

associated with HPV infections, associations with factors of interest will be carried out for qualitative variables by chi-square test or Fisher exact test (depending on the conditions of validity); comparisons concerning continuous variables will be carried out by Student *t* test or Wilcoxon test depending on the conditions of validity. To account for confounding effects and to identify factors independently associated with HPV infections, a multivariate analysis by logistic regression will be performed. The dependent variable will be HPV infection (yes or no). The independent variables will come from the self-administered questionnaire and laboratory results and will include sex, age, CT status, status of other STIs, socioeconomic status, sexuality, reasons for consultation, HPV vaccination status, and HIV status. The independent variables entered in the model will be variables for which the significance level will be $P<.2$ in the bivariate analysis; variables will be selected using backward stepwise regression with a significance level for removal from the model of $P\geq.1$. To investigate whether factors associated with HPV infection differ according to sex and type of specimen, subgroup analyses will be performed by swab site and sex. McNemar tests will be used to assess differences between matched samples. Cohen κ will be calculated to check the concordance of HPV infections between matched samples from the same patient. To assess this concordance for women and MSM, individuals with samples from 3 sites will be preferred over those with samples from only 2 sites. A random selection will be made to select individuals with only 2 samples in order to meet the allowable sample size.

The significance threshold for the tests will be 5% ($P<.05$). CIs will be calculated at 95%. The statistics will be calculated with the STATA 17.0 software.

Ethical Considerations

The expected benefits outweigh the potential risks to patients.

National cervical cancer screening with HPV PCR is recommended by the HAS for individuals 30 years and older. In our study population, and in accordance with national recommendations, there is no obligation to follow up or to carry out additional examinations in the event of a positive result for HPV at the cervix-vaginal level, particularly if it is one of the oncogenic or probably oncogenic HPV types. The natural history of HPV infections is specific to the population younger than 30 years. The incidence and prevalence of HPV infections are at their highest levels due to the presence of major risk factors, such as number and frequency of new sexual partners. These infections are responsible for minor cytological lesions that evolve spontaneously and favorably in the majority of cases. Indeed, in this population, viral clearance is earlier and more marked than in older women, with 50% clearance of the infection within the first 6 months and 90% clearance within 2 years. In France, to date, there is no recommendation for HPV screening, nor is there a recommendation for treatment in the event of the discovery of an oncogenic HPV infection, whether it be anal, pharyngeal, or urinary, in women, MSM, or MSW.

An information note will be given at the time of the consultation setting out the objectives of the research organized based on data collected during care.

In compliance with national legislation, ethics approval has been obtained from the ethics evaluation committee of INSERM (French National Institute of Health and Medical Research; Opinion number 22-953) and all procedures were performed in accordance with the ethical standards of the responsible committee on human experimentation and with the Helsinki Declaration of 1975.

Results

Patient recruitment began in October 2022 and ended in December 2022. Approximately 1200 samples were collected from 333 women, 167 MSM, and 120 MSW. Funding was obtained thanks to the support of the University Hospital of La Reunion. The first PCRs are scheduled for November 2023. We expect to submit the first results in 2024.

Discussion

Expected Outcomes

The results of this study, carried out in a largely unvaccinated population, will enable us to give more details on the distribution of HPV infections in the Reunion Island population before vaccination. Currently, in France, but also locally in Reunion Island, there is a desire to promote a community-based vaccination program with GARDASIL 9 to achieve a national coverage target of 80% among those aged 11 to 19 by 2030 [17,18]. The identification of the transmission of genotypes that are mostly covered by the 9-valence vaccination of patients in Reunion Island will help to reassure the general population and the doctors about the necessity of this vaccination. For MSM, it will be the first study to assess the prevalence of HPV in anal samples.

Vaccination has already been shown in several studies to be effective in reducing HPV infections [19] and precancerous lesions [20]. The Swedish study by Lei et al [21] followed a cohort of more than 1.6 million patients aged 10 to 30 years between 2006 and 2017 before, during, and after large-scale vaccination was introduced in Sweden. It showed a significant reduction in cervical cancer in vaccinated populations, with a favorable incidence rate ratio of 0.37 (95% CI 0.21-0.57) after covariate adjustment.

The Swedish team of Söderlund-Strand et al [22] has already used residual CT screening samples to carry out a prevalence study of HPV infections in a defined Swedish region and population of women and men in 2008. From 2012 to 2013, the team carried out the same study on the same population and in the same region of Sweden to identify changes in the prevalence of HPV infections. It is interesting to note that the first state-funded subsidies for HPV vaccination in Sweden were introduced in 2006 and the state vaccination campaigns began in 2012. In both cases, these vaccination recommendations were aimed solely at girls. Vaccination coverage was measured using various national registers. In 2008, when the first study was carried out, vaccination coverage among women in the population studied was 1.2%. Between 2012 and 2013, vaccination coverage among women was between 6.6%-7.5%. Coverage was highest among women and girls younger than

XSL•FO
RenderX

23 years, with a maximum of 77.8% coverage among 14-year-olds. In this study, the majority of samples were genital and came from women aged 18 to 23 years. This study identified a significant drop in the prevalence of HPV genotypes 6, 11, 16, 18, 52, and 56 in women of all ages between 2008 and 2012-2013. These results are difficult to interpret given that detection of HPV by PCR in urine is known to be low. There was variability in the prevalence of HPV genotypes not covered by the vaccine, with an increase in HPV genotypes 52 and 56 but a decrease in genotype 31. The fact that the prevalence of HPV genotypes covered by the vaccine decreased mainly in the age groups of the most highly vaccinated populations is a strong argument for vaccine efficacy and is consistent with studies carried out in other countries. On the other hand, the decrease in the prevalence of HPV infections by covered genotypes in the population studied and the fact that certain noncovered genotypes tended to increase is not consistent with the data on cross-protection by the vaccine. It would therefore be interesting to monitor locally for the possible emergence of these HPV genotypes [22]. Other teams have carried out repeated cross-sectional surveys to measure vaccine pressure on HPV infections; for example, Markowitz et al [19] carried out 2 studies in the prevaccination era (2003-2006) and vaccination era (2007-2010) among more than 4000 patients recruited through national public health surveys, which included cervico-vaginal HPV tests in women aged 14 to 59 years. This study showed a significant drop in the prevalence of HPV 6, 11, 16, and 18 vaccines in women aged 14 to 19.

These different studies, each with their own specific design, demonstrate the value of carrying out this type of cross-sectional study repeatedly over time. With regard to Reunion Island and the prospect of repeating the RUN-SurV-HPV study in several years' time, it will be important to monitor changes in vaccination coverage locally. The next study should be carried out sufficiently far in advance of the current one so that vaccination has had time to become more widespread in Reunion's population. We can then hope to demonstrate the effect of vaccination with GARDASIL 9 by identifying a significant reduction in HPV infections and monitor the appearance of other genotypes in our population of women and MSM younger than 30 years.

Comparison With Previous Work

In this study, we expect to have different results from the studies already conducted in Reunion Island. The last genotyping study of HPV infections in Reunion Island was conducted from 401 ASCUS Papanicolaou tests and 94 cervical biopsies with histopathological diagnosis of high-grade lesions or cancer performed between 2008 and 2012 [15]. After analysis, 162 (40.4%) Papanicolaou tests and 63 (67%) biopsies were HPV DNA positive. Of the 162 Papanicolaou tests, HPV genotyping was possible for 100 samples. Co-infection was found in 60% of the Papanicolaou tests. The most common HPV genotypes in the Papanicolaou tests were 51 (12.3%), 31 (10.3%), and 16 (8.4%). Of the 63 HPV DNA positive biopsies, the most frequent HPV genotypes detected were 16HR (41.3%), 52HR (16.3%), and 33HR (11.5%). Co-infections were detected in 50.7% of these biopsies [15]. It will therefore be interesting to compare our results with those of this study, which is already more than 10 years old, taking into account that the type of sampling and the characteristics of the patients will not be superposable. In addition, in our work, the number of samples taken will be twice as high and will likely have different HPV positivity rates because the samples will be taken in a population largely free of any induced HPV lesions but at risk of STIs. The samples will be more recent in healthy participants for whom social and demographic data will be available. Moreover, the evolution of HPV infection from asymptomatic to precancerous or even cancerous is slow and takes several years, reinforcing the idea that the previous study may no longer reflect the seroprevalence of HPV types in the Reunion Island population. Because of the size of our sample, our data will be more robust than the previous study, but also more up to date. Our results will not be representative of the general population of Reunion but will represent the populations most concerned by vaccination and the prevention of induced HPV lesions.

Identifying the prevalence of HPV genotypes by analyzing samples collected for CT testing has been done in several countries to map HPV infections and assess the impact of their vaccination programs [23,24]. In a pilot Australian study by Shilling et al [23], 362 residual genital CT samples were matched to vaccination status and analyzed for HPV using the Anyplex II HPV 28 detection assay. All samples were from young women aged 16 to 24 years, the majority of which were of cervical origin. In the samples analyzed, 7.8% were positive for CT. HPV genotypes 16 or 18 were detected in 3% of the women, while HPV genotypes 31, 33, 45, 52, or 58 were detected in 19% [23]. The Swedish study by Söderlund-Strand et al [24] analyzed more than 44,000 residual CT specimens, mostly from women. In women, HPV test positivity was 37.8%, of which 10% were positive for HPV 16 and 6% for HPV 51. In men, 11.2% of the samples collected were positive for HPV, primarily HPV 16 (2.1%) and HPV 6 or 51 (1.7%) [24]. In these two studies, the high prevalence of HPV infection in populations consulting for CT testing provides a suitable sample for surveillance surveys of HPV vaccination programs. These previous studies from different countries reinforce the feasibility and relevance of our study.

The concordance of HPV genotypes in the same individual at different anatomical sites remains controversial in the literature. Müller et al [25] identified a much higher prevalence of anal HPV than pharyngeal and urinary HPV in 200 MSM but found concordance for HPV 16. The work of Nugent et al [26] identified good concordance between HPV-specific anal swabbing and residual swab analysis but the latter was a combination of pharyngeal, urinary, and anal swab residue. Nakashima et al [27], on the other hand, identified good concordance between HPV in the pharyngeal and urinary tracts. The British study by King et al [28] did not identify a concordance between HPV detected at the anal and pharyngeal levels in HIV-negative MSM. Finally, the Vietnamese team of Le et al [29] identified a weak concordance of HPV infections detected at the pharyngeal and genital levels in men co-infected with other STIs. Indeed, out of 198 patients analyzed, HPV was detected at both sites with only 1 genotype match in 1 patient. All these very discordant data from the literature lead us to explore the specificities of the Reunion Island territory locally

XSL•FO
RenderX

to better understand the modalities of HPV infection of different anatomical sites in the same person.

Strengths of the Study

The strengths of this study lie in the originality of its design, with a data collection method (anonymous and tube-based analyses) that is not restrictive for the participants and investigators. This method makes it possible to include a large number of participants for more representative results. It is also easily reproducible over time, which will make it possible to repeat this type of study to monitor the evolution of HPV infections in the Reunion Island population.

The characteristics of the study population are also interesting. First, it is composed of both women and men, which coincides with the recent extension of French vaccination recommendations against HPV to adolescents of both sexes [10]. To our knowledge, there has been no previous study carried out in Reunion Island on the prevalence of HPV in men and in the pharyngeal or anal region in women. The young age of the participants matches the period of life when the prevalence and incidence of HPV infection is highest. Patients consulting STI testing centers are often in a precarious situation with risk behaviors that favor co-infections with another sexually transmitted disease, such as risk factors for HPV infections. These characteristics will therefore give us a better idea of the current mapping of HPV infections in Reunion Island. All these social and demographic data will be easily accessible to us thanks to the self-administered questionnaires systematically filled in during each consultation. These data will allow us, through subgroup analyses, to identify in our population the patients most at risk of being infected by an oncogenic HPV genotype, and thus to better target them for future preventative actions. Finally, comparison of the results from different sites in the same patient correlated with sociodemographic data will provide us with additional information on the modes of transmission and infection of HPV and will also allow us to better delimit the complementarity or similarity of screening for this infection to continue or stop it. These results will also provide information on potential targets for HPV vaccination depending on the infected site.

Limitations of the Study

This study has several limitations. The main limitation is the selection bias of our population. The population consulting STI testing centers is a specific population that cannot be extrapolated to the general population of Reunion Island. This population has an increased risk of HPV infection, and our results may be affected by this. The fact that the patients were recruited via a free screening center where they could consult spontaneously and anonymously reduced the risk of selection bias in our population. In our study, the proportion of under-age patients is likely to be low, even though this population is the main target for vaccination. Unfortunately, despite our efforts, it is difficult to have them consulted spontaneously and to include them while respecting both the anonymity of the consultation and the legislative framework for protecting the data of minors. Finally, this study was only carried out in one screening center, which could affect the results. The results may also be affected by the way the test is performed and its performance, even though it has already been validated in several studies [30,31]. The Anyplex II HPV28 detection assay is also one of the tests that will be evaluated by the VALGENT4 study with the aim of obtaining international clinical validation for uterine cervix cancer screening [32]. Although we have taken all possible precautions to avoid technical errors, results may also be influenced by the quantity and quality of viral material available in the samples collected, which is dependent on how the samples are collected, transported, and stored.

Conclusion

This original epidemiological study, which has already proved its worth in other countries, will have rapid implications by promoting vaccination campaigns and identifying the populations most at risk of being infected by an oncogenic HPV genotype. By comparing the prevalence of HPV infection in the same person and at different anatomical sites, this study will also provide a better understanding of its pathogenicity and mode of transmission and better delineate the complementarity of certain screenings. In the long term, these studies will allow for monitoring of the evolution of HPV infections and the impact of HPV vaccination campaigns in the Reunion Island population.

Acknowledgments

The authors would like to thank Lucie Chong Si Tsaon and Samir Medjane of the medical research unit of the Centre Hospitalier Universitaire de La Réunion, France, for their support and cooperation.

We would like to thank our copy editor Thomas Rospars.

This protocol was written during the fellowship of Antoine Bertolotti, which was supported by the French Society of Dermatology and College of Teachers of Dermatology of France.

Data Availability

The data sets generated and analyzed during the current study are not publicly available due to privacy issues of the participants. Data are available from the corresponding author request.

Conflicts of Interest

None declared.

Abstract

Background: A large proportion of Australians are affected by mental illness each year, and treatment gaps are well known. To meet current and future demands and enable access to treatment that is safe, effective, and acceptable, a robust and sustainable mental health workforce is required. Factors reported to attract people to work within the mental health sector include aspiring to help others, having an interest in mental health and human behavior, the desire to make a difference and do something worthwhile, personal lived experience, recognition, and value of discipline-specific roles. However, despite the various reasons people enter the public mental health workforce, recruitment and retention continue to be ongoing challenges. To date, there has been limited investigation into understanding which factors are most relevant to the current Victorian workforce. Furthermore, a comparison to health care workers outside of mental health is also needed to better understand the specific needs of staff within the mental health sector.

Objective: This study aims to explore factors related to attraction, recruitment, and retention of the public mental health workforce in Victoria, Australia.

Methods: The study is a multisite, mixed methods cross-sectional study to be conducted at 4 public hospital services within Victoria, Australia: 2 in metropolitan and 2 in regional or rural locations. Current, previous, and nonmental health workers will be asked to complete a 20-25–minute web-based survey, which is developed based on previous research and offered participation

XSL•FO
RenderX

in an optional 30-60–minute semistructured interview to examine personal experiences and perceptions. Both aspects of the project will examine factors related to attraction, recruitment, and retention in the public mental health workforce. Differences between groups (ie, current, past, and nonmental health workers), as well as location, discipline, and health setting will be examined. Regression analyses will be performed to determine the factors most strongly associated with retention (ie, job satisfaction) and turnover intention. Qualitative data will be transcribed verbatim and thematically analyzed to identify common themes.

Results: As of May 2023, we enrolled 539 participants in the web-based survey and 27 participants in the qualitative interview.

Conclusions: This project seeks to build on current knowledge from within Australia and internationally to understand role and service/system-related issues of attraction, recruitment, and retention specifically within Victoria, Australia. Seeking up-to-date information from across the health workforce may provide factors specific to mental health by illuminating any differences between mental health workers and health care workers outside of mental health. Furthermore, exploring motivators across health care disciplines and locations to enter, stay in, or leave a role in public mental health settings will provide valuable information to support how the sector plans and develops strategies that are fit for purpose.

Introduction

Background

One-fifth of Australians experience mental illness each year, and treatment gaps both in type and quality are well known [1,2]. Within Australia, there was a reported treatment gap of 45% for people with major depression, while the average duration of untreated psychosis was reported to be 6 months [3]. Moreover, among adolescents who perceived the need for mental health (MH) treatment, only 53% received it [4]. To enable access to treatment and care that is safe, effective, and acceptable to patients and their families, a robust and sustainable MH workforce is required. The Royal Commission into Victoria's Mental Health System described historical underinvestment and increasing demand, alongside updated models of care driven by the promotion of well-being rather than an illness focus, resulting in an outdated and crisis-driven service that is ill-equipped to respond adequately to people living with mental illness, their families, and caregivers [5]. A critical issue is attracting and retaining staff in the MH workforce [6]. Evidence suggests that compared to other departments (eg, general medical and surgical), the MH workforce experiences higher rates of staff turnover and lower retention, although there is a paucity of exact statistics [7]. In order to understand the factors related to the recruitment and retention of MH workers, it is important to appreciate what attracts individuals to the MH workforce, what factors impact retention, and why people leave their role in public MH.

Past research has identified barriers to people choosing to enter the public MH workforce, including the stigma of working in MH, lack of opportunity for advancement, and disparity of remuneration between the public and private sector [8,9]. However, there are also several factors that attract people to work within the MH sector including aspiring to help others, having an interest in MH or behavior, the desire to make a difference and do something worthwhile, personal lived experience, recognition and value of discipline-specific roles, and being able to use skills and knowledge within their professional framework [5,10-14]. Despite the unique reasons that motivate people to work in MH, recruitment and retention of an adequate number of trained and experienced MH staff is an ongoing concern.

In Australia, as in other jurisdictions, the demand for public health services is growing, and there is a critical shortage of experienced MH professionals, particularly within the public MH sector [5]. This problem is further exacerbated in rural and remote areas, whereby there is significant maldistribution of the MH workforce [15]. During the COVID-19 pandemic, this problem became more pronounced as staff members were seconded to help with the response to COVID-19 (eg, to work in vaccination clinics), with not all returning to their previous role as vaccination clinics wound down. Compounding this issue, international border closures prevented overseas professionals from being granted entry into Australia, which has long been a pipeline for recruitment into the MH workforce.

In summary, there are significant factors that may contribute to low recruitment and retention within the public MH workforce; yet, there has been limited investigation into understanding which of these factors are most relevant in Victoria, Australia, and where differences may be in comparison to health care workers outside of MH. This lack of data and broad consultation across the workforce may result in initiatives being misplaced or failing to address problematic areas despite best efforts. Understanding the differences between MH workers and health care workers outside of MH will reveal the most pertinent factors that may be specific to MH. Furthermore, exploring what motivates people across health care disciplines to work or not work in public MH settings or decide to leave a job in public MH across both metropolitan and regional or rural workplaces

XSL•FO
RenderX

can inform how the sector plans and develops strategies that are fit for purpose.

Study Aims

This study aims to explore factors related to the attraction, recruitment, and retention of the public MH workforce in Victoria, Australia. Specifically, the study aims to identify (1) the reasons for entering the MH workforce, (2) the reasons for staying in the MH workforce, (3) the reasons for leaving the MH workforce, and (4) reasons for not entering the MH workforce.

This information will then be used to generate and provide specific strategies that will address the challenges identified in the evaluation.

Methods

Study Design and Setting

The study is a multisite, mixed methods cross-sectional study to be conducted at 4 public hospital sites in Victoria, Australia (2 in metropolitan and 2 in rural locations). A steering committee consisting of all investigators across the 4 sites will meet regularly to oversee all operational, procedural, and policy aspects of the project's conduct.

All employees working within the MH department at each of the participating sites will be asked by email to complete a web-based survey. Staff from the wider hospital (ie, past MH workers or non-MH workers) at each site will also be invited to participate via a service-wide broadcast email. Past MH workers from each participating site who are no longer employed within the service will also be invited to participate by current employees forwarding information. Employees across all sites will also be invited to participate in a qualitative interview. Table 1 outlines the research framework.

Table 1. Research framework.

Dimensions	Attractiveness and recruitment	Retention	Method
Indicators	Reasons for joining or not entering the MH workforce	Reasons for staying in or leaving the MH workforce	N/A[a]
Phase 1	Current methods of assessment of reasons for joining or not entering the MH workforce	Current methods of assessment of reasons for remaining in or leaving the MH workforce	Preliminary interviews with managers of MH workforce
Phase 2a	Quantitative survey collection of reasons for joining or not entering the MH workforce	Quantitative survey collection of reasons for remaining in or leaving the MH workforce	Anonymous survey distribution across four sites
Phase 2b	Qualitative interview collection of reasons for joining or not entering the MH workforce	Qualitative interview collection of reasons for remaining in or leaving the MH workforce	Interviews with staff working in MH and in other departments across four sites
Phase 3	Compile a strategy for improving the attractiveness of working in public MH services	Compile a strategy for improving retention of staff working in public MH services	Propose methods to improve the attractiveness and retention of staff in MH services through data collected in Phase 2.

[a]N/A: not applicable.

Participants

Inclusion Criteria

Participants who satisfy the criteria for any of the following groups will be eligible to participate in the quantitative survey and the qualitative interview or focus group: (1) staff who are currently employed within the MH department at each of the 4 study sites, (2) staff who were previously employed within the MH department at each of the 4 study sites, and (3) staff who are currently employed outside the MH department at each of the 4 study sites and have never worked within the MH department.

Exclusion Criteria

Other than sufficient English language ability to respond to the questionnaires and interview questions in a meaningful manner, there will be no specific exclusion criteria for this study to ensure representativeness and generalizability.

Sample Size Estimation and Justification

Based on the current employment records, this study aims to collect questionnaire feedback from all employees working within the MH department of each health service; however, previous such studies have shown an approximate 30% response rate, with calculations as follows: (1) metropolitan site 1 (n=135 people), (2) metropolitan site 2 (n=150 people); (3) rural site 1 (n=111 people), and (4) rural site 2 (n=65 people).

Across the 4 sites, the aim is to collect information from 461 current MH workers. In addition, the study aims to collect feedback from 461 past MH workers and 461 non-MH workers. The overall projected sample size is 1383 participants.

Study Procedures

Consent and Recruitment

Informed consent will be obtained from all participants prior to the completion of the survey or interview. Advertising of the project will be conducted with authorization by the principal

XSL•FO
RenderX

investigator and Human Research Ethics Committee at each of the 4 sites for a period of 4 months. The study will be advertised through the distribution of emails to staff and posting information through staff intranet portals as well as by strategically placed physical posters. An email will be circulated via a broadcast that will include a link to the questionnaire, at which point they will be asked to provide informed consent to take part in the study. Current MH workers at each site will also be asked to forward the invitation to past MH colleagues who have left the public MH workforce. Participation in a qualitative interview will be offered through an indication of willingness to participate as indicated at the end of the web-based survey (see Multimedia Appendix 1) through expressions of interest in response to the flyers and through emails circulated via hospital broadcasts. There will be no costs associated with participating in this research project nor will participants be paid.

Survey Data Collection

The anonymous web-based survey was developed in conjunction with the steering committee and based on themes identified in the literature and preliminary interviews with senior hospital staff. In instances where there were no available validated measures, the research team created questionnaires for the purpose of this study based on the information available in the current literature and preliminary interviews. The survey will assess reasons for entering, staying in, or leaving public MH services, or reasons for having chosen not to work in the public MH sector. The survey will take approximately 20-25 minutes to complete. Participants will be asked to indicate their age, gender, ethnicity, highest level of education, current position, previous position (for past MH workers), discipline, hospital site, health service setting, current employment status, working hours preference, whether they are employed on a contract or an ongoing basis, duration in current position and duration working in MH (current and previous MH workers). The measures included in the web-based survey are detailed in Table 2. See Multimedia Appendix 2 for the full data collection instrument.

XSL•FO
RenderX

Table 2. Quantitative assessments in the survey.

Variable	Measure	Participants
Reasons for entering the public MH[a] workforce	Eight key factors were identified in the literature plus an option to specify others. Participants will be asked to select all the responses that apply to their circumstances.	Current and previous MH workers
Attraction to the current organization	Sixteen key factors were identified in the literature plus an option to specify others. Participants will be asked to select all that apply to their circumstances.	All
Expectations and reality of working in public MH	The reality of working in public MH compared to expectations based on prior understanding of what a career in public MH looked like will be measured on a scale from 1 to 5, where a higher score is indicative of greater consistency between reality and expectations. This was developed for this study a review of the literature and themes identified in preliminary interviews with senior hospital staff. An additional open-ended question will assess reasons why expectations were or were not met.	Current and previous MH workers
Importance of MH care	Perceptions of the importance of MH care in comparison to other health care disciplines will be assessed by 2 statements that participants will be asked to respond to on a 5-point Likert scale (1=strongly disagree to 5=strongly agree). The statements were developed for this study based on a review of the literature and themes identified in preliminary interviews with senior hospital staff. These statements assess personal opinions and general health care worker beliefs.	All
Job readiness and career development	Job readiness (ie, sufficient training) and level of career development opportunities will be assessed by 6 statements that participants will be asked to respond to on a 5-point Likert scale (1=strongly disagree to 5=strongly agree). The statements were developed for this study based on a review of the literature and themes identified in preliminary interviews with senior hospital staff.	All
Workplace flexibility	Participants will be asked to rate the perceived level of their organization's workplace flexibility on a 10-point Likert scale, with 1 being not flexible at all and 10 being very flexible.	All
Resilience	The 9-item Employee Resilience Scale [16]. Responses will be measured on a 5-point Likert scale (1=strongly disagree to 5=strongly agree). Scores will be summed to produce a total score (range=9-45), whereby higher scores are indicative of greater levels of resilience in the workplace.	All
Burnout	Measured using the Oldenburg Burnout Inventory [17] which measures 2 dimensions of burnout: disengagement and exhaustion. Disengagement refers to distancing oneself from one’s work and having negative feelings towards one’s work or service recipients, while exhaustion refers to the depletion of physical and emotional energy.	All
Turnover intention	Measured by 3 statements: “I am actively looking for another job,” “As soon as I find another job, I will quit,” and “I often think about quitting my job” [18]. Each statement has three response options: (1) no, (2) unsure, and (3) yes. Overall turnover intention will be the average of the 3 responses, with higher scores indicating higher levels of turnover intention.	All
Current employment intention	Six statements developed through a review of the literature and anecdotal evidence will assess current employment intention. Participants will be asked to select all that apply to their circumstances.	All
Team leadership	Staff perceptions of team leadership and management qualities will be assessed by 5 statements measured on a 5-point Likert scale (1=strongly disagree to 5=strongly agree). These statements were developed for this study based on a review of the literature and themes identified in preliminary interviews with senior hospital staff. A total score was produced by summing all items (range=5-25), whereby higher scores were indicative of greater perceived leadership.	All that reported being in a nonleadership role
Understaffing	A 6-item measure of understaffing [19]. Participants are asked to respond to statements on a 5-point Likert scale (1=strongly disagree to 5=strongly agree). The measure provides subscale scores for manpower understaffing and expertise understaffing (range=3-15), whereby higher scores are indicative of greater understaffing. An additional question was developed for this study specifically related to staff shortages as a result of the COVID-19 pandemic, “COVID-19 has created additional staff shortages within our department/team.”	All
Job satisfaction	The 15-item Job Satisfaction Scale [20] with slight variations in wording to suit health care workers. Participants will be asked to respond on a 5-point Likert scale (1=very dissatisfied to 5=very satisfied). This measure provides 2 subscales of job satisfaction (extrinsic and intrinsic), as well as an overall score of job satisfaction (range=15-75), whereby higher scores are indicative of greater overall job satisfaction.	All

XSL•FO
RenderX

Variable	Measure	Participants
Workplace or occupational violence	A modified 9-item version of the World Health Organization Joint Program on Workplace Violence in the Health Sector questionnaire [21] will be used to assess workplace violence.	All
Moral injury	A modified 8-item version of the validated 10-item Moral Injury Symptom Scale-Health Professionals [22]. Each item is scored on a 5-point scale (1=strongly disagree to 5=strongly agree). Items are summed to create a total score (range=8-40), whereby higher scores are indicative of higher severity of moral injury. An additional item will also be used to assess the level of distress or impairment the moral injury has caused on their lives rated on a 5-point Likert scale (1=not at all to 5=extremely).	All
Reasons for leaving public MH workforce	Seven key factors were identified in the literature and preliminary interviews with senior hospital staff, plus an option to specify others. Participants will be asked to select all that apply to their circumstances.	Past MH workers
Reasons for not entering the MH workforce	Seven key factors were identified in the literature and preliminary interviews with senior hospital staff, plus an option to specify others. Participants will be asked to select all that apply to their circumstances.	Non-MH workers

[a]MH: mental health.

Qualitative Data Collection

A semistructured interview will be offered to those interested in providing more detailed information and recommendations for change within the field. This will enable a nuanced exploration of the most pertinent, empirically relevant themes associated with attraction, retention, and reasons for leaving or not entering the MH workforce. Interviews will be approximately 30-60 minutes in duration and conducted one-on-one with the research clinician either face-to-face or via a video call (ie, Teams, Microsoft Corp or Zoom, Zoom Technologies, Inc), depending on the participants' preference. The qualitative component will cover the four areas: (1) participant demographics including age and gender; (2) questions regarding current employment information (eg, discipline and location, ie, rural or metro); (3) questions regarding the positive and negative aspects of working in the MH field, specifically related to attraction, recruitment, retention, or not entering the MH field (see Multimedia Appendix 2). Additionally, the themes identified in the literature (eg, burnout, understaffing, and moral injury) will be targeted through questioning to explore their relevance; and (4) any other factors perceived by the participant as relevant or important to attraction, recruitment, or retention.

Participant Withdrawal

Participants will be free to withdraw from the study without reason or explanation. Data collected will be retained unless otherwise specified by the participant. However, as the web-based survey is anonymous, it will not be possible for participants to withdraw their survey data.

Statistical Analysis

Quantitative Data Analysis

Quantitative data analyses will be performed using SPSS (version 27; IBM Corp). Descriptive data will be presented using means, IQR, and percentages. Descriptive statistics that will be reported include discipline, employment status, hospital site location (ie, rural and metropolitan), health care setting (ie, inpatient and outpatient), duration of current position, and duration of working in health care. Groups will be categorized according to the variables listed as follows: (1) current MH worker, previous MH worker, and non-MH worker; (2) discipline (ie, nursing, medicine, allied health, and lived experience); (3) hospital site location (ie, regional or rural, metropolitan, using pooled rural and metropolitan data); and (4) health setting (ie, inpatient, community, and nonpatient facing).

Differences between groups on outcome measures will be compared using appropriate inferential tests. Regression analyses will also be conducted to determine predictors of retention (ie, job satisfaction) and turnover intention among the metropolitan workforce, and the regional or rural workforce.

Qualitative Data Analysis

Interviews will be recorded (with informed consent), transcribed verbatim, coded, and thematically analyzed to identify common emerging themes [23-25]. Transcripts will be continuously revisited, and the accuracy verified by listening to recordings and comparing them with the transcripts. Coding of data will be conducted using Excel (Microsoft Corp).

Data Management

All electronic data will be stored securely via password protection within the primary hospital IT system in accordance with appropriate data management policies, with access available only to the research team. This includes electronic consent forms, interview transcripts, interview recordings, and survey data. All other investigators will be given access to the deidentified and pooled group data if required. Physical forms (ie, participant information and consent forms) collected during the interview or focus group process (if conducted face-to-face) will be stored in a secure, locked, cabinet at the primary hospital site and handling of the forms will be in accordance with hospital data management policies. Upon receiving informed consent to participate in the interview, the research clinician will assign participant IDs. All collected data will be stored in a deidentified manner using participant codes. The data will be reidentifiable using the code key, which will be stored separately from the data files. Only researchers employed on the project at the primary hospital site will have access to the code key.

XSL•FO
RenderX

Information that is collected for this project will be stored for 7 years and then securely disposed of.

Ethical Considerations

This study has been approved by the primary hospital Human Research Ethics Committee (HREC #008/22), and subsequently, governance approval was provided by the human research ethics committees at the other 3 sites. The findings from this project will be published and presented in a variety of forums, including peer-reviewed scientific journals and academic conferences. In all instances, information will be presented in a way that individuals and services cannot be identified achieved through presenting pooled group data only.

Results

The project received funding in May 2021, and data collection commenced in July 2022. As of May 2023, we enrolled 539 participants in the web-based survey and 27 participants in the qualitative interview. Data analysis has commenced, with results expected to be published by December 2023.

Discussion

Summary

This project seeks to evaluate factors that influence attraction, recruitment, and retention within the public MH workforce in Victoria, Australia. The design of the project, based on previous research that illustrated both role and service/system-related difficulties, sought to build on current knowledge from within the Australian context and abroad. For instance, in its investigation of Victoria's Mental Health System, the Royal Commission discovered numerous obstacles that MH workers face, which may contribute to issues of retention. These included occupational burnout, violence and aggressive behavior from patients, frequent staff turnover, insufficient staffing levels, and, in some cases, a lack of management support [5]. Similarly, MH workers in Ghana cited job-related challenges such as lack of resources and workplace violence (eg, patient aggression and physical violence), as well as service- or system-based problems including rigid hierarchical organizational structure, limited opportunity for advancement, unclear pathways for progression, and lack of feedback or recognition regarding work performance, as significant issues related to retention [11]. These challenges and barriers in retention are potentially compounded by difficulties in attracting people to specific roles, and the MH sector more broadly. This may be reflected in the reported shortage of supply in appropriately qualified people applying for advertised positions and an inability to backfill roles where someone has been promoted [19,26].

Beyond aspects of the role that may contribute to problems with retention, previous studies have also demonstrated that due to the environment (ie, design not conducive to promoting safe practices for staff and patients and burdensome procedures), MH workers are at an increased risk of experiencing job-related stressors [27,28]. These stressors warrant further attention as they have been reported to contribute to decreased staff well-being and increased rates of attrition. For example, occupational burnout and workplace violence (both physical and psychological) have been reported among MH workers and are associated with reduced job satisfaction [27,28]. Job satisfaction has been reported to be lower in health care workers compared with workers in other professions [29]. Given the high-risk environment of MH, job satisfaction may be especially low in MH settings, although to date, this has not been investigated. Furthermore, job satisfaction has been linked to higher turnover intention (ie, the desire to leave one's job) [27], which in turn may exacerbate staff shortages [29]. By exploring the relationships between these factors using both quantitative and qualitative methods, our study seeks to provide greater clarity relating to environmental aspects.

Although this study is somewhat limited by the participation of only a portion of the full workforce, one particular strength is the inclusion of both metropolitan and regional or rural services. This will allow investigation of similarities and differences and exploration of some of the unique challenges that may need to be considered in each setting. Furthermore, our study will build on others that have been conducted in regional and rural areas of Australia. Among these previous studies, factors specifically affecting attraction and retention have been explored in regional and rural areas of Queensland and New South Wales. Results indicate there are some unique differences when compared to metropolitan areas. For example, the distance and long travel times between towns that may not be adequately factored into workload expectations, limited transport options, reduced availability of services and amenities for workers and their families, less anonymity, perceptions of reduced opportunities for career advancement due to working in much smaller teams, and increased workload due to the expectation of having to educate other staff have all been reported as factors that influence staff turnover in regional and rural areas [30-32]. On the other hand, there may be particular strengths, and investigating the experiences of staff across both metropolitan and regional or rural settings will allow an examination of specific needs, and also how strengths may be leveraged.

To plan for the future and ensure that strategic initiatives are fit for purpose and aligned across employment settings, it is essential that a comprehensive evaluation of the life cycle of employment in MH settings be undertaken. Two factors should be considered. First, understanding what motivates people to work in public MH and second, how people subsequently perceive and experience their jobs, specifically what motivates them to stay or leave. Overall, this information will provide support for critical workforce planning to target the most pertinent factors identified by the current workforce, which will assist in ensuring the alignment of job supply with the demand required by the MH system, in order to create a sustainable MH workforce.

Limitations

A limiting factor of this study is the potential for participant responses to inaccurately depict those of the population, a common issue within opt-in survey designs [33]. Moreover, the location may be considered a limitation given participants were only recruited from 4 health care services within Victoria, Australia. To address this, services were selected by the Victorian Department of Health, with the goal of capturing the

XSL•FO
RenderX

most variety across the locations as possible. This study aimed to elucidate the challenges experienced by multidisciplinary teams specifically within Victorian public MH services. This means that generalizability beyond MH and Victoria may be hindered, and a potential future direction could be to replicate and extend this research more broadly for comparison and to increase the breadth of knowledge. The use of self-report measures is another limitation worth noting; and in an attempt to address this, this study selected to primarily use validated measures.

Conclusions

With this study, we aim to broaden current knowledge regarding the recruitment and retention of multidisciplinary public MH care teams, specifically within Victoria, Australia. The findings of the study will be analyzed and used to inform necessary workforce planning, which supports the alignment of job supply with the demand required by the MH system into the future.

Abstract

Background: Spinal muscular atrophy (SMA) is a progressive neuromuscular disorder that causes muscle weakness and is the leading genetic cause of infant mortality worldwide. While no definitive cure exists, the approval of 3 genetic-based therapies in Canada since 2018 has led to significant improvements in muscle function for children with SMA. With that, there are no evidence-based rehabilitation interventions and minimal evidence on the combined effects of genetic-based therapies and rehabilitation.

Objective: This protocol describes the methodology to assess the feasibility of a twice-weekly outpatient rehabilitation intervention focusing on gross and fine motor function to inform the methodology and sample size of a definitive clinical trial.

Methods: We will conduct a single-center nonrandomized pilot and feasibility trial to explore an outpatient rehabilitation intervention for children aged 6 months to 3 years with SMA treated with genetic-based therapies. Participation in the study will occur over a 25-week period, with a baseline assessment visit followed by a 12-week intervention period and a 12-week nonintervention period. The rehabilitation intervention comprises weekly physical and occupational therapy for 11 weeks. Assessments will occur at baseline (week 0), end of intervention or early withdrawal (week 12), and follow-up (week 24). Predetermined feasibility indicators will evaluate study feasibility across process (recruitment rates, eligibility criteria, adherence rates, retention rates, questionnaire suitability, and acceptability), resource (time, implementation, and execution), management (materials and data), and scientific (safety, tolerability, and preliminary efficacy) domains.

Results: This project was funded in March 2022, and data will be collected between March 2023 and December 2023. Data analysis will occur between January 2024 and March 2024, with publication expected in the fall of 2024. The protocol for the feasibility trial will be considered successful if it meets the success criteria set out for the feasibility indicators. Indicators of specific interest include all process indicators, as well as time. Exploratory indicators will be reported. Pragmatically, the results of the feasibility trial will inform changes to the protocol and the start-up of a definitive multisite trial.

Conclusions: This novel twice-weekly outpatient rehabilitation intervention will be the first step toward filling the need for an evidence-based rehabilitation intervention for children with SMA treated with genetic-based therapies. It is expected that consistent and intensive rehabilitation therapy will augment functional gains being observed in this population. In the future, a definitive trial will measure the efficacy of the intervention.

Introduction

Spinal muscular atrophy (SMA) is a progressive neuromuscular disorder in which there is a gradual degeneration of motor neurons due to a loss-of-function mutation in the survival of motor neuron 1 (SMN1) gene, which enables proper functioning of motor neurons and therefore muscle function [1-3]. There are 3 pediatric subtypes (types I, II, and III) of SMA based on the age of onset of muscle weakness and motor milestones achieved [3]. All SMA subtypes demonstrate a decline in function over time. SMA type I presents the most rapid onset and severe decline [1,4,5]. SMA types II and III have a later onset and more gradual decline [5,6]. SMA affects 1 in 6000 to 10,000 births worldwide [7-10]. As of 2020 in Canada, there are an estimated 700 to 2140 cases of SMA [11,12] with approximately 35 new cases per year [10]. SMA is one of the most common genetic causes of mortality in infants [3,13]; however, there is optimism that this will change due to the availability of new treatments.

Health Canada has approved 3 genetic-based therapies for individuals with SMA: nusinersen (brand name Spinraza, 2018), onasemnogene abeparvovec (brand name Zolgensma, 2020), and risdiplam (brand name Evrysdi, 2021). These genetic-based therapies aim to increase the production of the SMN protein and improve muscle function [14]. As a result of these new treatments, Ontario, Canada, has included SMA in newborn screening programs since 2020, enabling treatment shortly after birth [15]. Implementation of these genetic-based therapies has demonstrated significant and clinically meaningful gains in physical function in clinical trials in both individuals receiving a genetic-based therapy presymptomatically as well as after the onset of clinical symptoms, which was previously unheard of in the SMA population [16-24]. For example, presymptomatic infants who received nusinersen within 6 weeks of birth gained the ability to sit without support (100%), walk with assistance (92%), and walk independently (88%) [18]. Additionally, 57% of children with later-onset SMA treated with nusinersen saw increases in motor function compared to 26% of children in the placebo control group [22].

The most recent standards of care for SMA were published in 2018, before the widespread approval of genetic-based treatments internationally [14,22,25]. Additionally, there is minimal evidence-based guidance in the literature regarding rehabilitation interventions to proactively optimize function for children with SMA treated with genetic-based therapies [3]. With that, there is a paucity of published long-term evidence regarding rehabilitation programs and their impact on physical function in individuals with SMA treated with genetic-based therapies to guide program development and funding of rehabilitation programs. Few studies have explored the combined effects of genetic-based therapy and rehabilitation therapy for children with SMA; however, preliminary research indicates promising synergies [26]. For example, a retrospective study reported that individuals treated with nusinersen who attended physiotherapy (PT) 5 days per week experienced a 12.7% (P<.001) improvement in gross motor gains compared to a 5.4% increase in those who only received nusinersen and less than 1 PT session per week at 1 year after starting nusinersen [26].

Due to the progression of SMA, PT and occupational therapy (OT) historically focused on the provision of equipment, compensatory strategies, and reducing the risk of secondary complications, such as joint contractures [3]. With new disease-modifying treatments, families of young children with SMA are seeking proactive rehabilitation to enhance and optimize physical function [27,28]. The intervention presented in this protocol proposes rehabilitation therapy that draws upon models of service delivery used in pediatric populations at the delivering institution. Goal-directed therapy will be implemented, which has been shown to be the most effective type of therapy for commonly studied pediatric neurological conditions such as cerebral palsy [29-31]. Additionally, based on previous SMA exercise therapy intervention studies that were tolerable and safe [32], a 12-week therapy block duration has been proposed. Drawing from the aforementioned proposal, further evaluation of the effects of therapy and the efficacy of this rehabilitation program is crucial to improving the quality of care for this population and the optimization of their function [26].

The objective of the study is to assess the feasibility of a twice-weekly outpatient rehabilitation intervention focused on gross motor and manual function to inform the methodology and sample size of a definitive clinical trial according to specific feasibility indicators (process, resources, management, and scientific) [33]. This protocol will describe the pilot and feasibility trial for this evidence-informed outpatient rehabilitation intervention for children with SMA treated with genetic-based therapies. The Standard Protocol Items–Recommendations for Interventional Trials (SPIRIT) guidelines, the Consolidated Standards of Reporting Trials (CONSORT) extension for feasibility and pilot trials, and the Template for Intervention Description and Replication (TIDieR) checklist for intervention description and replication guided the reporting of this protocol.

Methods

Design

The study is a single-center nonrandomized pilot and feasibility trial to explore the feasibility of an outpatient rehabilitation intervention for children 6 months to 3 years of age with SMA treated with genetic-based therapies. Participation in the study will occur over a 25-week period, with a baseline assessment visit followed by a 12-week intervention period and a 12-week nonintervention period. The trial site will be a pediatric rehabilitation hospital in Toronto, Canada.

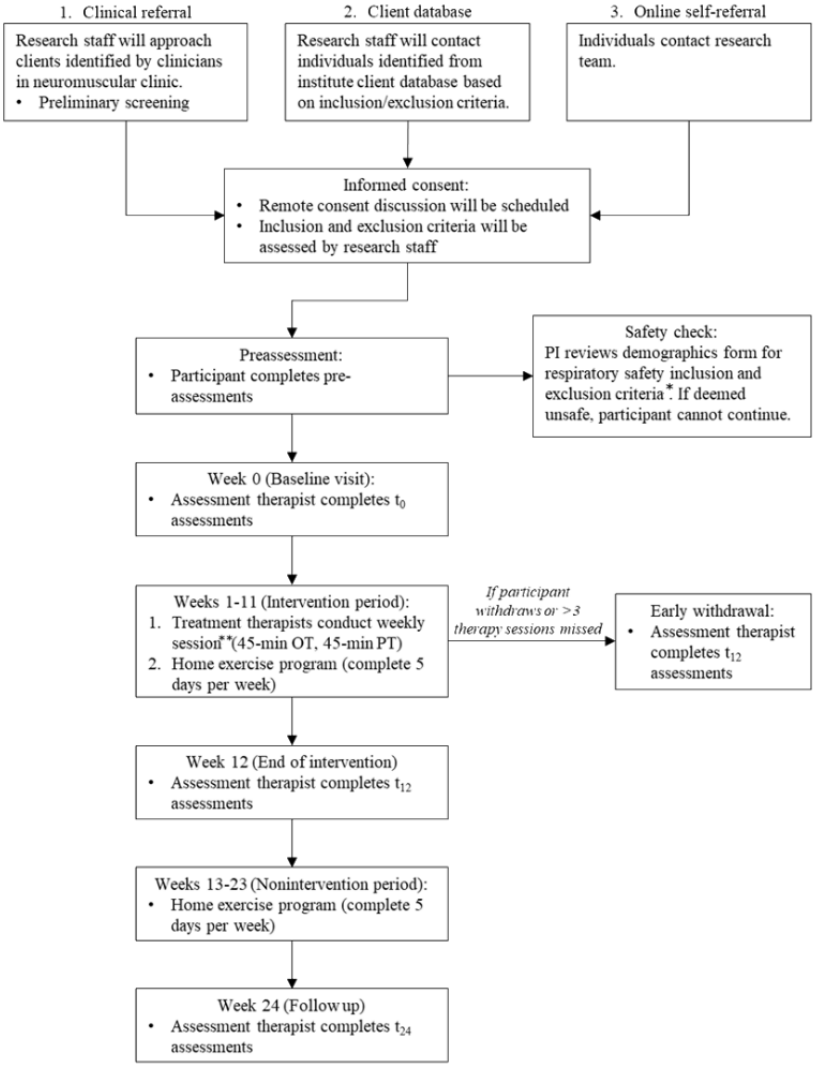
XSL•FO
RenderX

Participants

A convenience sample of 5-10 participants (children and parent or guardian dyads) will be enrolled. Current standards of practice deem formal sample size calculations unnecessary for feasibility trials since findings obtained from the small sample size in this study will allow for generalization to a larger definitive trial. Thus, a pragmatic approach will be undertaken, justifying the sample size used in this study [34]. This also supports the practicality of this study design, as the participant pool does not need to be exhausted to deliver the intervention.

Eligibility Criteria

The inclusion criteria are as follows: (1) SMA (type I, II, or III) diagnosis; (2) received or receiving a genetic-based therapy; (3) age 6 months to 3 years; (4) able to participate in twice-weekly therapy at the study site; (5) able to bring appropriate respiratory equipment to weekly therapy sessions, if required; (6) parent or guardian must be able to speak and read English; (7) child participant must be able to understand and follow directions in English, as age appropriate; and (8) parent or guardian must consent to participate on behalf of their child.



The exclusion criteria are as follows: (1) live outside of Ontario, and (2) tracheostomy or use of daytime ventilation (excluding ventilation used during naps).

Inclusion and exclusion criteria will be assessed during the recruitment process. Respiratory safety screening will be conducted by the principal investigator if the use of respiratory equipment is identified.

Recruitment

Participants will be recruited from across Ontario, Canada. A multipronged recruitment strategy will be implemented using active (clinical referrals and an institutional research client database) and passive (self-referral through web posts) approaches. Posts include institutional internet posts (social media and the institution's website) as well as social media sharing on websites commonly accessed by families with children with SMA. Figure 1 describes potential recruitment pathways and participant flow.

Figure 1. Recruitment path and participant flow for the twice-weekly outpatient intensive rehabilitation intervention for young children with spinal muscular atrophy treated with genetic-based therapies. *The respiratory safety inclusion and exclusion criteria include 5 inclusion criteria and 2 exclusion criteria. **Up to 3 weeks of therapy sessions can be missed or held on the internet (ie, 3 OT and 3 PT sessions may be missed or held virtually). OT: occupational therapy; PI: principal investigator; PT: physiotherapy.

XSL•FO
RenderX

Intervention

Parents will consent on behalf of their child before study visits are conducted by trained research staff. The intervention comprises a 12-week intervention period (OT and PT sessions plus a home exercise program) followed by a 12-week nonintervention period (home exercise program only). The 12-week intervention period was based on previous exercise therapy studies on pediatric neurological conditions such as cerebral palsy [29-31], and a small number of SMA exercise studies [23,32,35,36]. The on-off block structure is what is typically offered at the institution.

Participants will not be required to stop any additional private therapies during the study. However, participants will be asked not to start any new treatments or therapy during the study. All additional activities should be recorded in the home exercise diary.

In week 0, therapy goals will be set using the Canadian Occupational Performance Measure (COPM) and Goal Attainment Scaling (GAS) goals created with the participant's parents, and baseline functional assessments will be completed. OT and PT goals will be individual to each participant. With that, the therapy sessions are created and personalized to the participant and their goals.

During the intervention period, active therapy will be delivered in person through weeks 1-11. A total of 2 therapy sessions (one 45-minute PT and one 45-minute OT session) per week in addition to a home exercise program will be completed. It will be recommended that participants complete the home exercise program 5 days per week in addition to the 2 therapy sessions (OT and PT). During the nonintervention period, the home exercise program will be continued. Functional assessments will be reevaluated at week 12 and then again at week 24 to determine whether functional gains were maintained. See Figure 1 for a detailed participant flow. A total of 3 weeks of sessions will be permitted to be missed or conducted through video conferencing software over the intervention period.

During the nonintervention period, the participant will receive an updated home exercise program to be completed 5 days per week. A research team member will contact the participant every 2 weeks to review the home exercise diary and other activities in which the participant is participating and to reiterate the importance of the home exercise program.

All on-site therapy and assessment sessions will be completed in a private therapy room; however, sessions could occur in a group therapy room if needed.

Assessment

Assessments will be administered at prescribed time points, as described in Table 1.

XSL•FO
RenderX

Table 1. Intervention and assessment time points for the twice-weekly outpatient rehabilitation intervention for young children with spinal muscular atrophy treated with genetic-based therapies. The intervention period occurs between t_1 and t_{11}, and the nonintervention period occurs between t_{13} and t_{23}.

Measure	Assessment

AIM[k], IAM[l], FIM[c,m]			✓	

[a]EOI: end of intervention.

[b]EW: early withdrawal.

[c]Completed by participant parent or guardian.

[d]ITQOL: Infant Toddler Quality of Life Questionnaire.

[e]Conducted by assessment therapist.

[f]COPM: Canadian Occupational Performance Measure.

[g]GAS: Goal Attainment Scaling.

[h]CHOP-INTEND: Children's Hospital of Philadelphia Infant Test of Neuromuscular Disorders.

[i]CHOP-INTEND used with nonindependent sitters and HFMSE used with independent sitters.

[j]HFMSE: Hammersmith Functional Motor Scale-Expanded.

[k]AIM: Acceptability of Intervention Measure.

[l]IAM: Intervention Appropriateness Measure.

[m]FIM: Feasibility of Intervention Measure.

Intervention Providers

The intervention uses 2 types of providers: assessment therapists and treatment therapists. Assessment therapists will complete the listed outcome measures at week 0, end of intervention or early withdrawal (week 12), and follow-up (week 24). Treatment therapists will plan and conduct the therapy sessions based on the COPM and GAS goals created by the assessment therapists. For a participant, the assessment and treatment therapists will be different to avoid bias.

The assessment and treatment therapists will be OTs and PTs with previous experience and training working with young children with SMA. Assessment therapists will complete the standardized training for the respective assessments. Assessment OTs will complete the Bayley Scale (all sections except the gross motor function), COPM, and GAS. Assessment PTs will complete the Children's Hospital of Philadelphia Infant Test of Neuromuscular Disorders (CHOP-INTEND) or Hammersmith Functional Motor Scale-Expanded (HFMSE), gross motor section of the Bayley Scale, COPM, and GAS.

Outcome Measures

Demographics Survey

This 15-item purposefully developed survey will capture participant characteristics (eg, age at intervention commencement [year and month], sex, parent report of genetic condition, therapies received, and timing or frequency).

Infant Toddler Quality of Life Questionnaire

The ITQOL (Infant Toddler Quality of Life Questionnaire) [37] comprises 103 items on 12 scales pertaining to the past 4 weeks, covering physical and psychosocial domains and the impact of child health on parents. Scales include physical functioning, growth and development, bodily pain, temperament or moods, general behavior, getting along, general health perception, parental-emotional, parental time, family activities, family cohesion, and change in health. Multi-item scales showed adequate internal consistency (Cronbach α=.81). Overall, 4 scales showed adequate (intraclass correlation; ICC ≥0.70; P<.01), 6 scales showed moderate (ICC=0.50-0.70; P<.01), and 1 scale had poor test-retest reliability [37].

XSL•FO
RenderX

COPM Measure

The COPM [38,39] measures an individual's self-perception of occupational performance on self-care, productivity, and leisure and is used by OTs in initial assessments to set goals and plan treatment focusing on activities that an individual needs, wants, or is expected to do. The importance of activities is rated on a 10-point scale (1=not important at all to 10=extremely important). The individual selects the 5 most important activities, which are rated on a 10-point performance scale (1=not at all able to 10=able to perform extremely well) and for satisfaction (1=not at all satisfied to 10=extremely satisfied).

GAS Measure

GAS [40,41] will evaluate an individual's progress toward participant and family goals. Each scale is developed based on assessment and collaboration between the therapist and the participant and family. A 5-point scale, ranging from –2 to +2, is used. A numeric value is assigned to each level of performance. On the scale, 0 is used to represent the expected level of outcome, with +1 and +2 indicating greater than expected progress and –1 and –2 indicating less than expected progress.

CHOP-INTEND Measure

The CHOP-INTEND [42] evaluates the motor skills of individuals with SMA type I aged 3 months to 4 years or older over 16 items. Items are scored on a 4-point scale (0=no response, 1=partial level of response, 3=nearly full level of response, 4=complete level of response). The assessment has good internal consistency (Cronbach α>.70) and strong intrarater reliability (ICC=0.96). CHOP-INTEND will be used with participants who do not sit independently.

HFMSE Measure

The 33-item HFMSE [43] assesses the functional motor ability of individuals with SMA who are able to sit and walk using a 3-point scoring system (0=unable to perform, 1=performs with modification, adaptation, and compensation, 2=performs without modification, adaptation, and compensation). The HFMSE will be used with participants who are able to sit independently.

Bayley Scales of Infant and Toddler Development, 4th Edition

The Bayley Scale is a developmental assessment tool for diagnosing developmental delays in early childhood (16 days to 42 months) across 5 domains: cognitive, language, motor, social-emotional, and adaptive behavior. The entire Bayley Scale can take 30-70 minutes to administer, depending on the participant's age. The entire Bayley Scale will be completed at week 0, and only the motor scales will be completed at weeks 12 and 24.

Acceptability of Intervention Measure, Intervention Appropriateness Measure, Feasibility of Intervention Measure

The Acceptability of Intervention Measure (AIM), Intervention Appropriateness Measure (IAM), and Feasibility of Intervention Measure (FIM) [44] are each 4-item surveys to evaluate the acceptability, appropriateness, and feasibility of the intervention from a personal perspective using a 5-point Likert scale (1=completely disagree to 5=completely agree). Internal consistency (α) of the 3 measures ranged from .87 to .89, and they take less than 5 minutes each to complete.

Home Exercise Diary

This purposefully developed form will be completed by the participant's parent or guardian each time the home exercise program is completed. During the intervention period, the diary will be reviewed by the therapists weekly, and during the nonintervention period, a research team member will call the participant every 2 weeks to review the diary. For each time the home exercise program is completed, the participant will complete the intervention week, the day of the week (eg, Monday), OT and PT exercises completed, and any comments (ie, about the participant's mood, adverse events, and duration of the exercises). Additionally, the parent or guardian will indicate if any additional activities were completed.

Data Management

All assessment measures except the participant-facing measures (ie, demographics survey, ITQOL, AIM, IAM, and FIM) will be completed in hard copy. A trained research team member will input the data into Research Electronic Data Capture (REDCap) [45,46] forms for secure retention and ease of exportation and analysis. Participant-facing measures will be completed by parents or guardians electronically on REDCap.

Feasibility Indicators and Data Analysis

The trial's feasibility will be evaluated using process, resource, management, and scientific domains [33]. Specific feasibility indicators within the domains, their data management plan, and success criteria are described in Table 2.

Process indicators will examine key items to ensure the success of the trial. Recruitment rate, eligibility criteria, adherence rate, and retention rate data will be collected from recruitment logs. Results for these indicators will be reported as ratios, means, and frequencies. Questionnaire completion times and completion correctness will be reported as means and frequencies. Item scores for acceptability measures (AIM, FIM, and IAM) will be summed by each participant and reported as averages for each measure. Resource indicators will assess time and resource issues that could occur when running a definitive trial. Therapists will record session and documentation durations for all visits. These results will be presented as a ratio and compared to the success criteria. With the same data, session and documentation times will be compared to similar values in the literature as well as clinician reports. Last, protocol deviations will be reviewed by deductive content analysis to determine if protocol revisions are required. Management indicators will assess potential human and data management issues when running the trial and will be evaluated through deductive content analysis of completed measures and data analysis notes. Adverse events will be analyzed by deductive content analysis. Feasibility indicators will be compared to the success criteria, as appropriate.

XSL•FO
RenderX

From a scientific standpoint, a preliminary examination of the intervention's effectiveness will be assessed through safety and efficacy. Participant demographics and medical history collected from the demographics survey will be summarized descriptively. Preliminary efficacy will be evaluated through descriptive statistics and within-subject change scores of intervention assessment measures (ie, ITQOL, CHOP-INTEND or HFMSE, Bayley, COPM, and GAS goals). No between-subject analysis will be completed due to the small sample size. Change scores will measure functional gains and losses during the intervention period (t_{12}-t_0), nonintervention period (t_{24}-t_{12}), and the entire trial (t_{24}-t_0) for each participant separately.

XSL•FO
RenderX

Table 2. Feasibility indicators to measure the success of the twice-weekly outpatient intensive rehabilitation intervention for young children with spinal muscular atrophy treated with genetic-based therapies with data management (data collection methods and analysis) and a priori success criteria.

Feasibility indicator	Data management	Success criteria
Process		
Recruitment rates	• Ratio of enrolled participants vs approached potential participants; number screened and enrolled per month; and time from screening to enrollment to baseline visit	• ≥10% response rate from eligible participants [47]
Eligibility criteria	• Ratio of eligible vs screened participants	• >70% meet eligibility criteria
Adherence rates	• Therapist documentation (attendance at study visits) • Home exercise diary during intervention and nonintervention (weekly average completion rate of prescribed home exercise program)	• ≥75% attendance to therapy sessions[a] • At least three days per week
Retention rates	• Ratio of participants who successfully complete the study (including outcome measures) vs enrolled participants	• ≥70% retention of participants [48]
Questionnaires	• Participant-reported outcome measures (time to complete forms and correctly completed forms)	• Exploratory
Acceptability	• AIM[b], IAM[c], and FIM[d]	• ≥90% on the AIM, IAM, and FIM [49]
Resources		
Time	• Therapist documentation (ratio of actual vs estimated durations)	• Assessment: meets time prescribed in protocol (±5 min) • Documentation: ≤15 min
Implementation	• Therapist documentation (cost analysis of therapist time compared to standard care)	• Exploratory
Execution	• Protocol deviations (amount, frequency, and type)	• Exploratory
Management		
Materials	• Patient-facing materials and outcome measures (evaluate whether revisions are required)	• Exploratory
Data	• Data analysis notes (evaluate if additional data are required for efficacy analysis in a definitive trial)	• Exploratory
Scientific		
Safety and tolerability	• AE[e] and SAE[f] documentation (type and cause)	• Exploratory
Preliminary efficacy	• Efficacy (functional assessment change scores between t_0, t_{12}, and t_{24} time points for within-subject changes) • Sample size calculations for a larger definitive trial	• N/A[g]

[a]A total of 3 weeks of sessions will be permitted to be missed or conducted through video conferencing software over the course of the 12-week intervention period.

[b]AIM: Acceptability of Intervention Measure.

[c]IAM: Intervention Appropriateness Measure.

[d]FIM: Feasibility of Intervention Measure.

[e]AE: adverse event.

[f]SAE: serious adverse event.

[g]N/A: not applicable.

The sample size for a larger equivalence trial will be calculated [50]. Specifically, the trial will test whether the intervention (genetic-based therapy and the intervention) and standard treatment (genetic-based therapy only) are equally effective. With that, there are 2 null hypotheses:  and , where T=intervention, S=standard treatment, and δ=clinically admissible margin of equivalence. Using the information gained from the completed outcome measures, a primary end point will

XSL•FO
RenderX

be confirmed. Calculations for continuous outcome measures by Zhong will be used:

Where N=size per group; z_x=standard normal deviation for 1- or 2-sided  and ; δ_0=clinically acceptable margin; and s^2=polled SD of both comparison groups. As per convention, α will be set at .05 and β will be set at .80. δ_0 will be calculated as the difference between the mean changes in the chosen primary end point for the current intervention (taken from this feasibility study) and typical change scores for the age-matched populations from the literature minus one.

Monitoring

A data safety monitoring board (DSMB) will be established to review and evaluate the accumulated study data for participant safety. The DSMB will function independently from the study investigators and have no direct involvement with study conduct. Any recommendations regarding the continuation, modification, or termination of the trial will be made to the study investigators based on the received reviews. A DSMB term of reference was prepared and is available upon request.

Adverse events or serious adverse events will be collected and reported by therapists and research personnel. The study doctors will assess the seriousness of adverse events or other unintended effects and will propose a management plan as required. Serious adverse events will be reported to the DSMB.

Ethical Considerations

This study has been approved by the Research Ethics Board at Holland Bloorview Kids Rehabilitation Hospital in Toronto, Canada (REB#0550). All participants, through a substitute decision-maker, will partake in an informed consent discussion and sign an informed consent form before being enrolled in this study.

Results

This project was funded in March 2022, and data will be collected between March 2023 and December 2023. Data analysis will occur between January 2024 and March 2024, with publication expected in the fall of 2024.

This feasibility trial will be considered successful if it meets the success criteria set for the feasibility indicators. Indicators of specific interest include all process indicators as well as time. Exploratory indicators will be reported. Pragmatically, the results of the feasibility trial will inform updates to the design of the intervention and the protocol, as well as the start-up of a definitive multisite trial.

Discussion

This nonrandomized pilot and feasibility trial aims to assess the feasibility of the twice-weekly outpatient rehabilitation intervention for young children with SMA treated with genetic-based therapies. The description of this protocol and the future results are poised to make several valuable contributions to the functional and motor capabilities of children with SMA.

First, this innovative study is one of the first of its kind and will provide insight into the therapy potential for young children with SMA treated with genetic-based therapies. With the approval of genetic-based therapies to treat individuals with SMA as well as the introduction of newborn screening across Canada within the past 5 years, children are being diagnosed and treated earlier in the disease course [15]. With these previously unheard-of functional opportunities and the lack of knowledge of the long-term efficacy and tolerability of genetic-based therapies, it is important for children with SMA treated with genetic-based therapies to receive appropriate rehabilitation therapy. The current SMA standards of care include recommendations for exercise therapy as well as PT and OT involvement in bracing, positioning, and equipment [3,25]. However, these recommendations were published before the widespread approval of genetic-based therapies, and therefore the efficacy of PT and OT treatment blocks in this population has yet to be explored. This protocol will be a first step toward establishing an evidence-based rehabilitation intervention therapy program for children with SMA treated with genetic-based therapies.

Additionally, previous studies and therapy recommendations for children with SMA identify therapies to maintain function [23,32,35,36,51]. However, the proposed outpatient rehabilitation intervention is hypothesized to increase function in participants in combination with genetic-based therapies.

While there are several promising outcomes to the proposed pilot and feasibility trial, it does have its limitations. For instance, the implementation of the nonrandomized study design will not yield definitive efficacy data at this time. Additionally, the nonrandomized study design will not enable the measurement of subgroup differences. With that, nonrandomized pilot studies are still an effective method to evaluate a novel intervention, such as the trial outlined in this protocol [52]. It is expected that this pilot and feasibility trial will provide important insight into both the feasibility of the intervention itself and a future definitive trial.

Challenges to the implementation and feasibility of the intervention are foreseen. Recruitment will be a challenge due to the rarity of the disease and the large recruitment area (ie, anywhere in the province of Ontario, Canada). However, it is expected that families will travel far distances to receive therapy sessions at no cost with therapists with expertise working with young children with SMA. Additionally, the long potential travel distances may impact retention, adherence, and protocol deviations. However, the protocol includes that 3 OT and PT sessions can be held on video conferencing software or be missed. This allows families and therapists to be flexible in the delivery of the sessions without encountering large amounts of protocol deviation. Last, adherence to the home exercise program, particularly during the nonintervention period, may be a challenge. In past clinical experiences, the clinical team has seen functional gains lost when home exercises were not completed after a therapy block. Therefore, a research team member will contact the family every 2 weeks during the

XSL•FO
RenderX

nonintervention period to remind them of the importance of completing the home exercise program.

Overall, it is expected that when coupled with available genetic-based therapies, the consistent PT and OT provided as part of the proposed rehabilitation intervention will augment the functional gains being observed in this treated population. We aim for this feasibility trial to reflect the realities of participants and their families, as well as therapists and institutions that may deliver this intervention. In sharing this protocol, we hope to achieve widespread awareness of this new potential rehabilitation intervention with the future goal of making direct clinical impacts in the SMA community.

Abstract

Background: The earliest days of the COVID-19 pandemic in Canada were marked by a significant surge in COVID-19 cases and COVID-19–related deaths among residents of long-term care facilities (LTCFs). As part of Canada's response to the COVID-19 pandemic, Canadian Armed Forces (CAF) personnel were mobilized for an initial emergency domestic deployment to the hardest-hit LTCFs (Operation LASER LTCF) to support the remaining civilian staff in ensuring the continued delivery of care to residents. Akin to what was observed following past CAF international humanitarian missions, there was an expected increased risk of exposure to multiple stressors that may be psychologically traumatic and potentially morally injurious in nature (ie, related to core values, eg, witnessing human suffering). Emerging data from health care workers exposed to the unprecedented medical challenges and dilemmas of the early pandemic stages also indicated that such experiences were associated with increased risk of adverse mental health outcomes.

Objective: This study aims to identify and quantify the individual-, group-, and organizational-level risk and resilience factors associated with moral distress, moral injury, and traditional mental health and well-being outcomes of Operation LASER LTCF CAF personnel. This paper aimed to document the methodology, implementation procedures, and participation metrics.

Methods: A multimethod research initiative was conducted consisting of 2 primary data collection studies (a quantitative survey and qualitative interviews). The quantitative arm was a complete enumeration survey with web-based, self-report questionnaires administered at 3 time points (3, 6, and 12 mo after deployment). The qualitative arm consisted of individual, web-based interviews with a focus on understanding the nuanced lived experiences of individuals participating in the Operation LASER LTCF deployment.

XSL•FO
RenderX

Results: CAF personnel deployed to Operation LASER LTCF (N=2595) were invited to participate in the study. Data collection is now complete. Overall, of the 2595 deployed personnel, 1088 (41.93%), 582 (22.43%), and 497 (19.15%) responded to the survey at time point 1 (3 mo), time point 2 (6 mo), and time point 3 (12 mo) after deployment, respectively. The target sample size for the qualitative interviews was set at approximately 50 considering resourcing and data saturation. Interest in participating in qualitative interviews surpassed expectations, with >200 individuals expressing interest; this allowed for purposive sampling across key characteristics, including gender, rank, Operation LASER LTCF role, and province. In total, 53 interviews were conducted.

Conclusions: The data generated through this research have the potential to inform and promote better understanding of the well-being and mental health of Operation LASER LTCF personnel over time; identify general and Operation LASER LTCF–specific risk and protective factors; provide necessary support to the military personnel who served in this mission; and inform preparation and interventions for future missions, especially those more domestic and humanitarian in nature.

Introduction

Background

As part of Canada's response to the COVID-19 pandemic, Canadian Armed Forces (CAF) personnel were deployed on Operation LASER to support various aspects of the civilian health care sector in addressing and mitigating the impact of the COVID-19 pandemic across Canada. The scope of the mission expanded as the pandemic progressed, with activities that included contact tracing, CAF personnel vaccinations, COVID-19 testing at land ports of entry, and the subsequent deployment of intensive care unit nurses in several Canadian provinces.

The earliest days of the pandemic were marked by a significant surge in COVID-19 cases and COVID-19–related deaths among long-term care facility (LTCF) residents. In Canada, 3% of COVID-19 cases and 43% of COVID-19–related deaths occurred in LTCF residents, primarily in the provinces of Ontario and Québec [1]. The civilian staff were also falling ill with COVID-19 in high numbers and were unable to adequately mitigate the unprecedented challenges brought upon by the pandemic. Hence, on April 15, 2020, the CAF received a request for assistance to support the provision of care to residents of select LTCFs (also known as *centres d'hébergement et de soins de longue durée*) in the provinces of Québec and Ontario [2].

As part of this initial Operation LASER response, which occurred between April 2020 and July 2020, involved CAF personnel (ie, medical and support personnel, as well as command teams) were deployed to support the hardest-hit LTCFs: 47 *centres d'hébergement et de soins de longue durée* in Québec and 7 LTCFs in Ontario (all located in the Greater Toronto Area). The goal of this initial emergency deployment, hereafter referred to as *Operation LASER LTCF*, was to support the existing civilian staff in ensuring the safety of residents, maintain adequate staffing, and assist with infection control. The dire circumstances experienced in certain LTCFs were reported by the media and in CAF reports [3,4]. Similarly, anecdotal information was provided to our research team by CAF leadership.

These various reports highlighted that personnel deployed in support of the LTCFs may be exposed to multiple stressors that may be psychologically traumatic and potentially morally injurious (ie, related to important values) in nature (eg, witnessing human suffering); this is akin to what was observed in past CAF international humanitarian missions and recent experiences of health care workers (ie, medical challenges and dilemmas) during the early stages of the pandemic. More uniquely to Operation LASER, especially in the earliest days of the crisis, the COVID-19 pandemic posed a serious health and economic threat to people in Canada, not to people in a far-off land. As such, it held greater implications for the loved ones of Operation LASER personnel than perhaps any other domestic mission to date. Moreover, understanding concerning the lethality and transmissibility of the virus was unfolding and being updated on an almost daily basis at that time. Finally, the deployment was focused on assisting the most sick and vulnerable Canadian older adult patients and residents of LTCFs, a population that even seasoned CAF medical personnel were largely unfamiliar with. This combination of traditional and new stressors meant that the initial Operation LASER deployment was unique in many ways. Drawing on previous literature, such psychologically traumatic and morally injurious stressors may increase individuals' risk of adverse mental health outcomes such as posttraumatic stress disorder (PTSD), depression, and moral injury [5-9].

Previous deployments where CAF personnel were exposed to such psychological stressors were typically international, which came with inherent logistical challenges related to implementing timely, comprehensive, and secure research data collection [10]. These are typically overcome by a rigorous chain of command that allows for direct and efficient communication between researchers and the military chain of command. Although Operation LASER was a domestic deployment, the same challenges were encountered and mitigated by the CAF Surgeon General, Canadian Joint Operations Command (CJOC) chain

XSL•FO
RenderX

of command, and the Department of National Defence (DND). Understanding the challenges facing personnel in this deployment, the Surgeon General and Chief of Military Personnel, with the approval and facilitation of CJOC, requested research investigating the individual-, group-, and organizational-level risks, resilience factors, and mental health outcomes of Operation LASER LTCF personnel. In response, a multiorganizational collaborative Operation LASER research team was established to comprehensively capture and better understand the impact of this deployment on the well-being of Operation LASER LTCF personnel.

The Structure of the Initial Operation LASER LTCF Deployment

Operation LASER LTCF personnel were typically divided into teams comprising 1 senior medical authority and a number of medical workers and support personnel. They answered to various command teams from CJOC and Canadian Forces Health Services Group (CF H Svcs Gp), as well as Land Force Command. The total number of serving military personnel ranged from 14 to 60 per facility, and they liaised with and supported the civilian medical and administrative staff on-site. In accordance with provincial health care regulations, their responsibilities included accompanying and assisting residents with daily tasks (eg, building and personal hygiene and feeding), preparing and distributing medical products, preparing meals, and maintaining medical and nonmedical equipment. To limit the potential spread of COVID-19 to their social networks, most Operation LASER LTCF personnel stayed in hotels for the duration of their deployment. Through initial discussions with CJOC, CF H Svcs Gp, and Land Force Command, the research team identified 4 overarching duty types: group 1 (Operation LASER 1) comprised medical and health care personnel who worked inside the LTCFs, group 2 (Operation LASER 2) comprised nonclinical personnel who worked inside the LTCFs (ie, provided support to clinical personnel inside the LTCFs), group 3 (Operation LASER 3) comprised nonclinical personnel who did not enter LTCFs (eg, outside general duties), and group 4 (Operation LASER 4) comprised personnel who provided support roles involved in Operation LASER (eg, Headquarters or Command, support, resupply, Company Quarters, Military Police, and clinical leadership not embedded inside the LTCFs). Before deploying to the LTCFs, Operation LASER LTCF personnel received medical briefings and were trained to use appropriate personal protective equipment (PPE) according to the level of protection required for the tasks performed or depending on the availability of the material, keeping in mind the quickness of the CAF response to the pandemic. They also received training on the physical needs and psychological and spiritual reactions that might be experienced by personnel in the context of their Operation LASER LTCF work and ways to maintain resilience and well-being.

Most of the Operation LASER LTCF deployment occurred between April 20, 2020, and June 26, 2020, for Québec and between April 27, 2020, and July 3, 2020, for Ontario [2], although many military personnel saw their engagement continue until August 31, 2020. However, germane to the study and this paper, at the time of the study protocol development (between April 2020 and May 2020), the situation was still unfolding, and certain aspects of Operation LASER LTCF were still unknown or in flux. This presented the research team with particular challenges in identifying the optimal study design for this initiative, all under tight time frames (ie, because of incomplete awareness of Operation LASER LTCF details and changes to Operation LASER LTCF parameters that were assumed to be static; for more information on specific challenges and lessons learned, refer to the study by Fikretoglu et al [11]). For instance, the deployment start date and end date were not identical for all personnel; start and end dates depended on LTCF location, and staffing requirements may have fluctuated across time (requiring reallocation of personnel to more than one Operation LASER role). Following deployment, Operation LASER LTCF personnel should have participated in a 3-day decompression session, which included additional resilience training; they then should have undergone a 14-day isolation period. However, reports from CJOC and CF H Svcs Gp indicated that the redeployment processes were not consistent across Operation LASER LTCF personnel in different roles and LTCFs. These nuances required careful data collection, protocol adjustments from the first to the third iteration of the web-based survey, and analytical considerations throughout to allow for the most accurate characterization of the sample.

Risk and Resilience Factors and Mental Health Outcomes in Military Personnel

There is extensive research enumerating the factors that may affect short- and long-term psychological well-being and mental health outcomes following exposure to psychological trauma [12,13]. We approached the research questions by applying and testing key constructs from previous literature to the Operation LASER LTCF context and integrating them with the emerging literature on moral distress and injury. For instance, certain personal background characteristics, health status variables, and occupational roles may place military personnel at greater risk of experiencing negative reactions following Operation LASER LTCF [7,14,15]—those with prior trauma or preexisting physical or mental health conditions, those who become infected and enter extended self-isolation and quarantine, those with lower income, visible minority groups, and women may be at greater risk of adverse mental health outcomes [13]. In addition, individual-level factors such as exposure to stressful deployment experiences and maladaptive coping styles may also be associated with poorer outcomes [7,16].

Regarding stressful deployment experiences, we expected that, although some of these would be organizationally related and be commonly experienced in any deployment regardless of its nature (eg, logistical issues), other Operation LASER LTCF–specific experiences would be linked to fundamental values that an individual holds dear (eg, the need to provide care to the sick and vulnerable). Thus, we anticipated that at least some Operation LASER LTCF personnel would encounter morally laden experiences that could engender significant amounts of what is termed moral distress. Such moral distress can lead to moral injury (ie, profound and lingering psychological distress that is particularly associated with intense value conflicts [17]) and has been demonstrated to be a risk factor for depression and PTSD in CAF personnel [7,18]. Recent research with health care workers exposed to morally distressing

XSL•FO
RenderX

experiences during the COVID-19 pandemic highlights the strong association between moral distress and adverse mental health outcomes, including depressive symptoms and burnout [19]. The increased recognition of moral injury as a clinically important construct [20] and the challenges it poses during help seeking and treatment [21] further underscore the necessity to understand this issue and identify opportunities for early intervention, prevention, and support.

Other research suggests that many psychosocial dimensions at the social, unit, leader, and organizational levels may also influence the effect of stressful experiences on the well-being of military personnel. Specifically, findings sourced from previous DND Human Dimensions of Operations surveys have demonstrated that poor social support, as well as less trust in units and leaders and lower feelings of relatedness to others on the mission, are more likely to be associated with poorer psychological well-being and mental health outcomes (Michaud K, unpublished data, December 2021). Past research with CAF personnel has documented gaps in mental health service use [22,23] and several unique barriers to help seeking among CAF members [24]. Moreover, the literature also demonstrates that military personnel with prior experience, training, and preparation (both for crisis work and psychological reactions) and adequate social support from personal and organizational sources (during and after deployment) fare better after stressful experiences [12,25]. Finally, those who are able to derive a sense of meaning and accomplishment as a result of the mission may be better protected from negative reactions and more likely to experience positive outcomes such as posttraumatic growth [12,25].

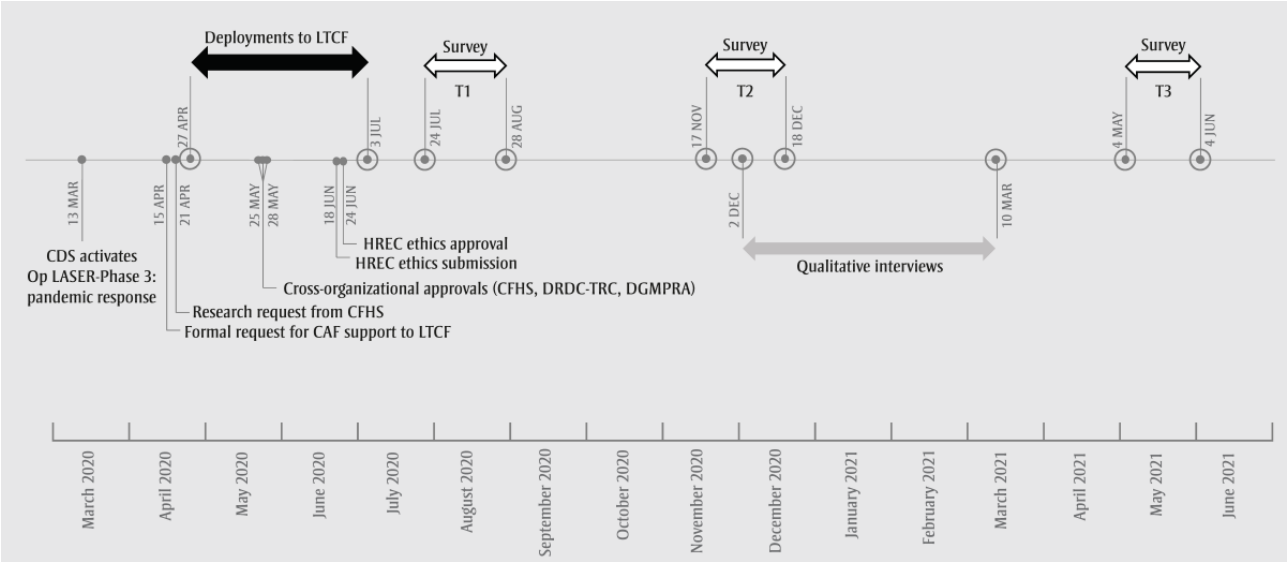
Given the many stressors that appear inherent to the Operation LASER LTCF deployment, lessons concerning risk and protective factors and effective preparation to promote psychological well-being following crisis work needed to be captured.

Research Objectives

The research objectives were as follows:

- Identify and quantify the individual-, group-, and organizational-level risk and resilience factors associated with moral distress, moral injury, and traditional mental health and well-being outcomes of Operation LASER LTCF CAF personnel and, to the extent possible, determine any changes that may occur over time.
- Gain a lived experience perspective through in-depth discussions with Operation LASER LTCF participants to develop a deeper understanding of their deployment experiences. Primary areas of exploration included views regarding particular risk (eg, Operation LASER LTCF COVID-19–specific stressors) and resilience (eg, predeployment Operation LASER LTCF training, prior CAF resilience training, and adaptive coping strategies) factors and the effects of these on mental health, well-being, and recovery.
- Identify lessons that can be used to inform the decisions of senior commanders in the event of similar future deployments.

In this paper, we document the protocol for this multimethod initiative (ie, composed of quantitative surveys and qualitative interviews) [26]. Specifically, we report on the study design, sampling details, measures used, sampling weight creation, and study implementation procedures. Considering that the data collection is complete, we also report on participation profiles and metrics, which provide insights into the nature of the sample and may be useful in guiding the protocol development of future research in this field and population.



Methods

Study Design

This multimethod research initiative comprised 2 interrelated arms: a quantitative arm (ie, survey) and a qualitative arm (ie, interviews). The quantitative arm was a complete enumeration (ie, census) survey (ie, email invitations to participate were sent to all Operation LASER LTCF personnel) with self-report questionnaires administered remotely at 3 time points (referred to as *Survey*), allowing for cross-sectional and, for a subset of respondents, longitudinal analyses. The qualitative arm was a collection of in-depth, individual interviews with a focus on understanding the nuanced lived experiences of individuals taking part in the Operation LASER LTCF deployment (referred to as *Interviews*). Figure 1 shows the deployment, administrative approval, and data collection timelines (adapted with permission from the study by Fikretoglu et al [11]). No remuneration was provided for research participation.

CAF: Canadian Armed Forces; CDS: Chief of Defence Staff; CFHS: Canadian Forces Health Services; DGMPRA: Director General Military Personnel Research and Analysis; DRDC-TRC: Defence Research and Development Canada–Toronto Research Centre; HREC: Human Research Ethics Committee; T1: time point 1; T2: time point 2; T3: time point 3.

Survey

Participants

The target population for this survey was the entire cohort of CAF personnel deployed to Ontario and Québec LTCFs as part of Operation LASER LTCF. A list of the names and email addresses of 2595 CAF personnel, representing the deployed cohort at the time (June 26, 2020), was provided to the research team; military personnel on this list were eligible for participation in the study. There were no exclusion criteria.

Recruitment

An administrative manifest of all Operation LASER LTCF personnel deployed to Ontario and Québec as of June 26, 2020 (provided by CJOC), was used to establish the sample frame and disseminate survey invitations. The administrative list contained names, contact email addresses, military rank, and deployment location (ie, Québec or Ontario) for all CAF personnel deployed to Operation LASER LTCF. Considering that many Operation LASER LTCF personnel were reservists (who may not always have immediate access to internal Defence Wide Area Network [DWAN] email accounts), the list contained a mix of personal or DWAN addresses. As the survey invitation was sent to all individuals intended to be deployed to Operation LASER LTCF, survey sampling (eg, stratified random sampling) was not required or implemented. All personnel with valid contact information received an invitation email written in English and French at each data collection time point sent from the dedicated positional Operation LASER LTCF research project DWAN email address. Emails were individually and personally addressed (ie, rank and name) and briefly outlined the research objectives, methods, participant rights, risks, risk mitigation measures, benefits of the study, and relevant contact information. If individuals wished to participate, they were able to access the web-based questionnaire via individualized hyperlinks (directed to either the French or English version of the survey), which were accessible through the personal or DWAN email account. At each time point, reminder emails were sent to all participants who had not yet completed the survey for that specific time point. Each individual received a maximum of 2 email reminders per time point, spaced approximately 2 weeks apart.

Survey Administration Time Points

Survey invitations were sent on July 24, 2020; November 17, 2020; and May 4, 2021, for time point 1 (T1; 3 mo), time point 2 (T2; 6 mo), and time point 3 (T3; 12 mo), respectively. The respective data collection windows for the survey were July 24, 2020, to August 28, 2020; November 17, 2020, to December 18, 2020; and May 4, 2021, to June 4, 2021.

Measures

Overview

An overview of the measures included in the survey is presented in Table 1. To reduce respondent burden, branching logic was implemented where appropriate (ie, displaying relevant and hiding irrelevant sections of the survey based on previous responses). Similarly, not all sections were necessary to repeat at follow-up sessions (ie, demographic information and predeployment training). Most of the included measures had been validated in both French and English. Scales were adapted only in cases in which the item wording was not appropriate for the CAF or Operation LASER LTCF context (see the following sections).

XSL•FO
RenderX

[m]Self-report assessment is a component of the Director General Military Personnel Research and Analysis (DGMPRA) Human Dimensions of Operations (HDO) data collection battery. Assessments were validated by the DGMPRA and designed specifically for administration to CAF personnel in HDO research.

Sociodemographic and Military Background

Information on age, gender, educational background, family status (ie, marital status, living arrangements, and dependents), military rank, length of military service, and component (ie, regular or reserve) was collected. These variables were selected based on previous research identifying them as potential predictors of psychological outcomes.

Operation LASER LTCF Roles and Duties

Participants were asked about the start and end dates of their Operation LASER LTCF deployment, military occupation (included only at T3), and the closest researcher-derived operational group they belonged to (Operation LASER 1, 2, 3, or 4; *other*; or *no role assigned*; the *no role assigned* option was available only at T3).

Predeployment Training and Postdeployment Decompression Satisfaction

Satisfaction with various aspects of predeployment training (ie, both for deployment duties and deployment psychological reactions) was assessed using 16 items that asked participants about their agreement with the following statement—*I am satisfied with my training for:*—for each of the 16 training components on a 7-point scale (ie, 1=*Strongly disagree*; 7=*Strongly agree*). A similar set of 5 questions assessed satisfaction with postdeployment training using an identical response format.

Prior CAF Mental Health or Resilience Training Questions

Exposure to and perceived utility of prior resilience training was assessed using items adapted from the 2013 Canadian Forces Mental Health Survey (CFMHS), a cross-sectional epidemiological survey conducted by Statistics Canada on behalf of the DND [27]. Items assessing the perceived utility of the training were adapted to be anchored to the Operation LASER LTCF context.

Coping

Various adaptive coping strategies were assessed using 16 items carefully selected from the well-established Brief Coping Orientation to Problems Experienced [28] based on the maximum relevance for Operation LASER LTCF as determined a priori by subject matter experts (SMEs). The selected items assess active coping, positive reframing, acceptance, use of emotional support, use of instrumental support, denial, substance use, and self-blame coping strategies. The following subscales were excluded: humor, venting, behavioral distraction, religion, behavioral disengagement, and self-distraction.

Social Support

Social support from various sources, including family, friends, employers, medical staff, religious or spiritual advisors, strangers, and online support groups, was assessed using a matrix of 7 items adapted from multiple sources, including the 2013 CFMHS [27]. Participants indicated their agreement with the following statement—*I received support from:*—on a 7-point scale (ie, 1=*Strongly disagree*; 7=*Strongly agree*).

Exposure to General Deployment Stressors

Exposure and perceived stress in response to general deployment stressors were captured using 9 items drawn from prior Human Dimensions of Operations surveys and from recent CAF Operation LASER LTCF reports [3,4] (Multimedia Appendix 1). Respondents indicated how stressed they felt in response to each of the situations (at the time of exposure) based on a 5-point scale (0=*No stress*; 4=*Extreme stress*, in addition to *N/A*=no exposure). The items were related to logistic support, accommodations, problems with infection control, lack of equipment and medication problems (eg, PPE), lack of civilian personnel, communication problems, absenteeism by civilian employees, and leadership or management issues. Participants were directed to indicate their degree of stress when the stressor was present (ie, at the time of deployment). Following T1 and T2 data collection, 3 items were excluded at T3 (ie, *problems with infection control*, *lack of equipment and medication problems (eg, PPE)*, and *civilian employee's absenteeism problem*) because of redundancy and overlap with moral distress items (see the following section).

Exposure to Morally Distressing Experiences in Operation LASER LTCF

To assess the potential for moral challenges and distress in Operation LASER LTCF, we adapted the Measure of Moral Distress for Healthcare Professionals (MMD-HP [29]) for the context of Operation LASER LTCF (the adapted version was named MMD-HP adapted to Operation LASER [MMD-LASER]; Multimedia Appendix 2). Accordingly, participants were asked to rate how distressed they currently felt according to a 4-point scale in response to 20 moral situations adapted from the MMD-HP and via input from Operation LASER LTCF SMEs (eg, leadership, chaplains, and reports from deployed personnel). Scale modifications included reducing the number of items to display only those situations that may be encountered during Operation LASER LTCF and only measuring the degree of distress to reduce respondent burden (the original MMD-HP scale captured both frequency and distress). Participants were instructed to rate their degree of moral distress on a 4-point scale (ie, 1=*No moral distress*; 4=*Extreme moral distress*, in addition to *N/A=I have not experienced this situation*) for each of the potentially morally distressing experiences. The English-language MMD-LASER and the translated French version were not psychometrically tested at the time of survey administration. However, considering the formative model of measurement for this type of scale, ensuring that the scale contains a breadth of relevant exposures through rigorous consultation with Operation LASER LTCF SMEs may be a better indicator of scale quality than common quantitative psychometrics (eg, factor analysis and indexes of model fit), which are more appropriate for reflective measurement models [30].

XSL•FO
RenderX

Meaning

Grounded in theoretical understanding of psychological empowerment in the workplace [31], participants rated the perceived meaning of their duties during the operation using 3 statements on a 5-point scale (ie, 1=*Strongly disagree*; 5=*Strongly agree*, eg, *the work I do is very important to me*).

Relatedness

Relatedness refers to the sense of belonging a person experiences with others in the workplace [32]. Such attachments lead to a sense of being supported and can reduce the adverse effects of workplace stressors on mental health. Participants were asked to assess the extent to which they felt connected to the people they worked with by rating their level of agreement with 7 statements pertaining to perceived social support using a 5-point scale (ie, 1=*Totally disagree*; 5=*Totally agree*, eg, *at work, I can talk with people about things that really matter to me*).

Trust in Teams and Trust in Leadership

Participants were asked to rate their trust in their peers or team (eg, *My teammates were capable of doing their job*) and immediate leaders (eg, *My leader performed his/her job well*) [33] each using 9 items rated on a 5-point scale (ie, 1=*Completely disagree*; 5=*Completely agree*).

Morale

Participants were asked to rate their level of agreement with 6 statements pertaining to their morale and enthusiasm for accomplishing the objectives of Operation LASER LTCF using a 5-point scale (ie, 1=*Very low*; 5=*Very high*, eg, [Please rate] *your level of motivation*) [34].

Psychological Distress

Psychological distress was assessed using a self-report measure, the Kessler Psychological Distress Scale (K-10) [35]. The K-10 is a 10-item questionnaire assessing nervousness, agitation, fatigue, and negative affect. Good internal consistency (Cronbach α=.89-.92) and construct validity of the K-10 have been established in general population and military samples [35,36]. The French version of the K-10 has also shown good reliability (Cronbach α=.84) and validity [37].

Anxiety

The Generalized Anxiety Disorder Scale (GAD-7) [38] was used as a measure of anxiety. The GAD-7 is a 1-factor, 7-item self-report questionnaire that has demonstrated good internal consistency (Cronbach α=.89) and validity in both general population and primary care samples [39-41]. The French version of the GAD-7 has demonstrated good reliability (Cronbach α=.86) in a general population sample of French Canadians [42].

Depression

Severity of current depressive symptoms (ie, past 2 wk) was assessed using the Patient Health Questionnaire–9 (PHQ-9) [38]. The PHQ-9 is a validated and widely used brief, single-factor, 9-item self-report questionnaire with well-established reliability, validity, and sensitivity [43-45]. The French version of the PHQ-9 has demonstrated good internal consistency (Cronbach α=.83) [42] that is comparable with that of the original instrument.

Posttraumatic Stress Symptoms

Posttraumatic stress symptoms were assessed using the most commonly used self-report instrument for research purposes, the 20-item PTSD Checklist [46], which is based on the most recent conceptualization included in the Diagnostic and Statistical Manual of Mental Disorders [47]. A French-Canadian version has also undergone validation [48]. A new item was added at the end to determine whether the reported symptoms were related to or exacerbated by Operation LASER LTCF.

Moral Injury

Moral injury expression was assessed using the 14-item Moral Injury Outcome Scale (MIOS) self-report questionnaire [49]. To date, assessing moral injury has been a significant challenge because of the lack of well-conceptualized measures [50,51]. To address this gap, the MIOS was developed by an international consortium of leading experts in moral injury (across the United States, United Kingdom, Israel, Canada, and Australia). On the basis of the most distressing, potentially morally injurious event, participants were asked to indicate whether they would agree or disagree with statements that capture 6 domains: alterations in self-perception (eg, *my actions don't fit with who I thought I was*), alterations in moral thinking (eg, *I have trouble seeing goodness in others*), social impacts (eg, *I feel rejected by people*), self-harming and self-sabotaging behaviors (eg, *I keep myself from having success*), emotional aftermath (eg, *I feel guilty*), and beliefs about life meaning and purpose (eg, *I lost a sense of meaning in life*). The MIOS has additional questions that further characterize the morally injurious event that the responses were based on. The version of the MIOS that was included in this study was a nonreduced 34-item version of the scale; scale validation on veteran samples has indicated a 14-item, 2-factor structure that will be used for scoring [49]. The French version of the MIOS has not yet been cross-validated.

Positive Reactions to Morally Challenging Situations

Haidt [52] has also suggested that, in addition to negative reactions such as moral injury, a number of positive reactions regarding oneself or others can result following the encounter of moral situations. As no validated measure exists for this construct, we created 7 items based on the description by Haidt [52], for instance, feeling pride in oneself or having faith in the goodness of humanity. Respondents were asked to indicate their agreement on a 5-point scale (ie, 0=*Strongly disagree*; 4=*Strongly agree*, eg, *I feel a sense of honour*) as to whether each of the statements characterized their reaction in the past month to their Operation LASER LTCF experience. This measure is currently not validated in English or French.

Posttraumatic Growth

Posttraumatic growth was assessed using 5 items drawn from the Posttraumatic Growth Inventory [53]. These items were selected to reflect the 5 factors assessed by the Posttraumatic Growth Inventory: stronger relationships, new possibilities, identification of personal strengths, spiritual change, and increased appreciation of life.

XSL•FO
RenderX

Perceived Need for Care

Participants were asked to indicate their subjective need for mental health care using a single, dichotomous self-report item adapted from the Canadian Community Health Survey [54] and the 2013 CFMHS [27] by Statistics Canada, which asked whether help for mental health problems (including emotions, mental health, or use of alcohol or drugs) was needed at any point since the start of Operation LASER LTCF.

Mental Health Service Use

A total of 3 items were taken from the 2013 CFMHS [27] to assess mental health service use at T2 and T3. The first item assessed access to formal and informal mental health support, and 2 follow-up items asked specifically about the Canadian Forces Member Assistance Program and web-based resources.

Barriers to Mental Health Service Use

Individuals may fail to seek care because of a denial of the need for treatment or because of perceived barriers to care [55]. Barriers to mental health care were measured using an 8-factor, self-report questionnaire developed by the Director General Military Personnel Research and Analysis (DGMPRA) in both French and English for a prior research project (Born, J, unpublished data, October 2021). Barriers to mental health care were explored using 29 items from the Operation LASER LTCF survey. A subset of 21 items was derived from the original 8-factor Barriers to Access to Care Evaluation, a 52-item scale that has demonstrated good internal consistency (Cronbach α=.86-.97) and validity (all factors predicted intention to seek care, and items are loaded in a theoretically logical manner) in a sample of CF H Svcs Gp personnel [24]. The abbreviated scale included 2 to 3 items per factor (8 factors in total: knowledge and ability to access care, organizational and social support, staffing and workload resources, concerns about privacy, alternative treatment options [eg, intention to self-treat], health care provider identity, conflict with career goals, and discomfort accessing care at work) selected from the larger Barriers to Access to Care Evaluation scale based on item factor loading scores, correlation of new factors with the original scale factor (r>0.90), and completeness of the factor's content while maximizing both internal consistency and validity within the original sample of CF H Svcs Gp personnel. In addition, 3 new items were included in the survey to explore concerns about moral discomfort (eg, *Not comfortable discussing experiences where I felt I/others could/should have done more/acted differently*), 3 new items were added to explore revisiting trauma (eg, *I did not want to revisit stressful or traumatic experiences that would make me feel distressed*), 1 new item was added to explore quality of care (eg, *I did not have access to quality care*), and 1 item was added to explore past experiences (eg, *I have had a negative experience getting help in the past*) as barriers to mental health service use. Barriers to mental health service use were assessed at T2 and T3 using a 7-point scale rating agreement (ie, −3=*Strongly disagree* to +3=*Strongly agree*). The text of the chosen items was modified to distinguish between barriers experienced in the Operation LASER LTCF context for those with a perceived need for care and hypothetical barriers for those without a perceived need. At this point, neither the French nor the English version of the scale have been fully validated; nevertheless, it represents the only applicable measure currently available.

Survey Programing and Presentation

The survey was programmed in Snap Surveys (Snap Surveys Ltd [56]), a web-based survey platform that adheres to the Government of Canada's quantitative research security policy. Individualized survey hyperlinks were given to each participant and were uniquely linked to each respondent's email address; the web-based survey platform linked and stored contact information and a survey ID number separately from survey research data. This procedure preserved the deidentification of respondents while allowing for the linkage of their data across questionnaire administrations (ie, across different time points).

The survey began with a question that asked participants to select their preferred language (materials were available in both official languages of Canada [ie, English and French]). Once their preferred language was selected, an information page was displayed that reviewed the instructions, aims of the study, participant rights, and confidentiality. This was followed by questions that assessed demographics, prior training (Operation LASER LTCF–specific training for deployment duties and for psychological reactions, as well as prior resilience training), exposure to stressful experiences, moral injury, risk and resilience, and psychological health outcomes. The last section of the survey thanked respondents for their participation, informed them of the opportunity to volunteer for interviews (ie, interview study), and provided a list of available CAF mental health resources (from the CAF Directorate of Mental Health).

Review of survey content for relevance and order of presentation of various measures, dry-run completion for timings (to estimate respondent burden), and proofreading were conducted by internal research team members, CAF members either deployed to or familiar with Operation LASER LTCF, and carefully selected DND SMEs.

Data Analysis Plan

Survey Weight Generation

Depending on the patterns of nonresponse, certain demographic or military characteristics could be under- or overrepresented in the final sample. Estimates produced using the final sample without any weight adjustment would be representative of the sample itself but not necessarily of the source population. To reduce nonresponse bias and improve the representativeness of the study findings to the source population, we generated survey weights based on available sociodemographic and military characteristics of the source population (see the *Data Linkage* section). A total of 5 characteristics were available for the source population: age, gender, force type, rank, and province deployed. Given our limited sample size, we could not conduct poststratification using all 5 weighting factors. To maximize the effect of using weights to adjust for nonresponse bias, we combined poststratification and propensity score inverse weighting in generating our survey weights [57]. We first used propensity score inverse weighting with all 5 weighting factors included in a binary logistic regression model predicting response at each time point. Given the sample size, the interaction terms of the weighting factors were not included.

XSL•FO
RenderX

For each respondent, a weight was created as the inverse of the propensity score of responding with the sum of the weights equal to the sample size of the source population. The second step was to poststratify weights from the first step based on age and gender information. A total of 4 cells were created, and weight adjustment was used for each participant according to which cell the participant fell into. For each cell, the weight adjustment factor was calculated as the ratio of the sum of the weights from the first step to the sample size of the source population in that cell. This step ensured that the weighted sample had the same distribution in terms of age and gender as the source population. The third step was to apply a weight adjustment to reflect the original sample size at each time point. This step served to avoid artificially inflating the sample size while preserving the representativeness of the source population. The last step was to give participants with missing information in the 5 weighting factors a weight of 1 (2.7% of the source population). This step allowed for keeping these participants in the data analysis in the absence of information by adjusting for their response bias. Analyses with the application of the generated survey weights are expected to provide estimates that are statistically adjusted to reflect key source population parameters, making the results generalizable to the source population. Using the same process, an alternative set of survey weights was generated based on a sample (981/1088, 90.17% at T1; 445/582, 76.5% at T2; and 403/497, 81.1% at T3) where the definition of a partial responder had a higher threshold for completion (ie, at least 1 section answered that related to a study outcome, defined as any of the assessments following Operation LASER LTCF Roles and Duties [see the *Measures* section for survey order]). This approach treated early *break-off* participants as unit nonresponders, similar to previously published guidelines [58]. A sensitivity analysis will be conducted to assess the effect of using different samples for weight generation on the study findings.

Data Linkage

To compute sample weights for source population representativeness, additional demographic variables (ie, date of birth, gender, force type, years of service, Operation LASER LTCF role, time in mission, occupation, unit name, deployment start date, and deployment end date) were required. In early March 2021, a Military ad hoc request was submitted to the office of the Assistant Deputy Minister (Information Management) to provide these additional variables, as well as variables for data linkage (ie, service number [SN], first name and last name), for all CAF personnel who were deployed on Operation LASER LTCF between April 1, 2020, and August 30, 2020. Typically, a unique identifier variable (ie, SN) would be used to link datasets; however, although SNs were provided in the ad hoc administrative file for all members, SNs were missing for 32% of members from the original administrative list. To confidently match as many members from the administrative list as possible, a sequence of automated and manual matching iterations was completed on the available identifiers, resulting in a total of 2536 (97.77% of the sample linked to administrative data) confirmed matches of 2595 possible matches. This allowed for a fairly accurate computation of sample weights for further weighted analyses.

Careless Responses

Checks for careless responders at each time point were conducted using a combination of post hoc methods following recommendations by Meade and Craig [59]. The *careless* R package (R Foundation for Statistical Computing) [60] was used to assist in computing carelessness indexes. Specifically, indexes included longest identical sequence, average identical sequence, intraindividual response variability split across 5 equal sections of the survey (starting with MMD-LASER, see the following rationale), psychometric synonym index, and Mahalanobis distance (for more information, see the study by Meade and Craig [59]). We avoided calculating carelessness indexes in sections where conditional question presentation (ie, display logic) was common (eg, training satisfaction and deployment details); as such, all scales including and following the MMD-LASER were used in the calculation of the indexes. These indexes were mapped to response times to identify individuals with unusual response patterns (ie, very short completion times in combination with significant outlier values [–2.5-+2.5 SD] on 1 or more of the carelessness indexes). The responses of these individuals were then manually checked by a research team member to confirm their response patterns and identify substantive evidence for careless responses. A conservative approach of not excluding any participants was taken in light of the nature of the sample (ie, largely psychologically healthy) and the measures (ie, largely clinical) that were included in calculating the indexes; a floor effect on these scales may create false positives for certain indexes, such as the longest and average identical sequence.

Statistical Analysis

Depending on the analytical objectives, the data will be analyzed cross-sectionally or longitudinally. Population-averaged approaches, such as generalized estimation equations, will be chosen for objectives that aim to assess population means. For objectives that aim to identify risk factors at the individual level, individual-specific approaches such as hierarchy regressions will be chosen. Sample weights will be used in all analyses to improve the representativeness of the study estimates for the source population. Considering the response rate and uncertainty of the reason for nonresponse, both weighted and unweighted estimates will be presented, and their discrepancies will be discussed. In addition, weights will be applied to all longitudinal analyses to account for bias owing to potential differential attrition. A 95% CI for estimates will be provided wherever possible.

No individual-level data or tables (eg, cross-tabulations) that may identify individuals will be produced. Cell sizes of <5 will not be reported. Descriptive statistics (eg, mean, SD, and frequencies) summarized at the group level will be used to capture key outcomes cross-sectionally (ie, at each of the 3 time points). Inferential statistics (eg, ANOVA, regression, and correlation) using T1 data will be conducted to examine the relationships between the risk and resilience factors and the key outcomes, as well as the differences that may exist between subgroups of the cohort (eg, differences in trust or relatedness between ranks).

XSL•FO
RenderX

Path analysis and structural equation modeling using T1 data will be used to analyze potential conceptual models. Predictive models (eg, linear and binary logistic regressions) using T1 data to capture changes over time will be used to assess associations between risk and resilience factors and the key outcomes. SPSS Statistics (version 23; IBM Corp), R (version 4.0.5), RStudio (version 1.4; Posit, PBC), and SAS (version 9.4; SAS Institute) will be used for all data management and analyses.

Interviews

Participants and Recruitment

The target population for the interview component of the project was the entire cohort of CAF personnel deployed to Ontario and Québec LTCFs as part of Operation LASER LTCF. Considerations regarding project resourcing and data saturation limited the maximum sample size of the qualitative interviews to approximately 50. Interviews were conducted in the participants' choice of French or English. There were no exclusion criteria.

On December 2, 2020, an email call for participants (written in English and French) was sent from the dedicated positional Operation LASER LTCF research project DWAN email address to the entire cohort of CAF personnel deployed to LTCFs (N=2595) to invite them to participate in a confidential interview with the research team. Similar to the survey study, emails were individually and personally addressed (ie, rank and name) and briefly outlined the study objectives, methods, participant rights, risks, risk mitigation measures, benefits of the study, and relevant contact information. Interested personnel were instructed to reply to the email to contact a member of the research team to obtain more information about the study or schedule an interview. The Operation LASER LTCF study email address was monitored by 2 members of the research team. Responses to prospective participants were provided in the same language as that used in their email inquiries.

In an effort to select a representative sample, from the pool of personnel who expressed interest in taking part in the interview study, participants were selected based on their Operation LASER LTCF role, rank, gender, component, province of deployment, and marital status. At the time of recruitment for the interview study, the research team did not have access to the ad hoc report, which provided demographic information for the entire population of Operation LASER LTCF personnel. As a result, participants were selected to ensure that the overall demographic breakdown of the interview study sample reflected that reported by respondents in the T1 survey. This sampling method yielded relatively representative proportions of the overall population (Table S1 in Multimedia Appendix 3) and ensured relative representation from subpopulations with a range of responsibilities and experiences. A member of the research team emailed the selected participants to schedule a 1-hour interview based on participants' availability and language of choice. A study information sheet was attached to the scheduling email to provide further details.

Interview Process

The interviews were conducted using Teams (Microsoft Corp), a DND-approved communication platform that allows for web-based synchronic audio and video discussions. Participants had the choice to join the web-based discussion, with their video turned on or off, or to dial in by telephone. At the outset of each scheduled interview, the research goals, as well as participant rights and protections stated in the information sheet, were outlined. Verbal consent to participate in the interview and to have their interview audio recorded (to assist the researchers with note taking) was obtained from each participant. Each interview was conducted in the official language of the respondents' choice. For consistency, one interviewer conducted most of the interviews while a second interviewer took notes, managed the audio recorder, and asked follow-up questions when applicable. Each interview was scheduled for 1 hour; however, an additional 30 minutes was scheduled between interview sessions in the event that a participant desired more time to share the details of their unique experiences. The duration of the interview was ultimately up to the participant. A semistructured interview approach was used, in which participants were guided by specific questions that aimed to explore their pre-, peri-, and postdeployment experiences. All interviews were conducted between December 2, 2020, and March 30, 2021.

Interview Content

The discussion domains are summarized in Multimedia Appendix 4 and fall under the general categories of (1) demographic and background variables, (2) predeployment experiences, (3) perideployment experiences, and (4) postdeployment experiences. These areas allowed for a nuanced view of demographic and background factors that may affect the Operation LASER LTCF experience [7,13,14]; Operation LASER LTCF–specific risk and protective factors, such as individual exposure and psychological reactions to stressful Operation LASER LTCF events; coping styles; and experiences related to moral challenges, moral emotions, moral distress [61], and potential moral injury [12,17,25,52,62]. Participants were also asked about group cohesion and leadership factors that may have affected their experience as past research has demonstrated that social-, unit-, leader-, and organizational-level factors may also affect team dynamics (Michaud K, unpublished data, December 2021). Participants were also asked about mental health service use and barriers to help seeking among CAF members [22-24]. Finally, participants were queried on any lessons learned that could be shared with military leadership to inform preparation and support for future missions of the same nature. Although these predefined topics guided the discussions, participants were free to raise additional issues to discuss in the interviews.

Analytical Approach to Qualitative Data

The audio recording of each discussion conducted in either French or English was transcribed verbatim into a text file. French transcriptions were translated into English for data analysis purposes, and the English transcriptions were uploaded to the NVivo qualitative analysis software (QSR International). Each discussion was first analyzed by the research team (who were also the interviewers) to identify the main topics addressed (called nodes) throughout the data. Once this coding scheme was complete, NVivo was used to generate a word search to

XSL•FO
RenderX

discover trends throughout the discussions. For example, the program identified how often certain words were used, especially with regard to military training, military experience, and postdeployment particularities. By choosing keywords or nodes, the software presented each of the references related to a specific node, which allowed for the comparison of the results across different keywords or nodes and the detection of trends throughout the discussions.

Each interview transcript was manually coded according to the following contexts: before deployment (eg, the military role in Operation LASER LTCF, the predeployment training according to that role, and the domestic operation dimension and expectations), during deployment (eg, location, duration, role, experience, competence, chain of command, communication with civilian staff and with other military personnel, and sanitary measures), and after deployment (eg, quarantine, postdeployment training, return home and family, and willingness to deploy to another similar domestic or overseas operation). Further details on the qualitative methodology will be reported in follow-up manuscripts specific to each analysis and research question.

Ethical Considerations

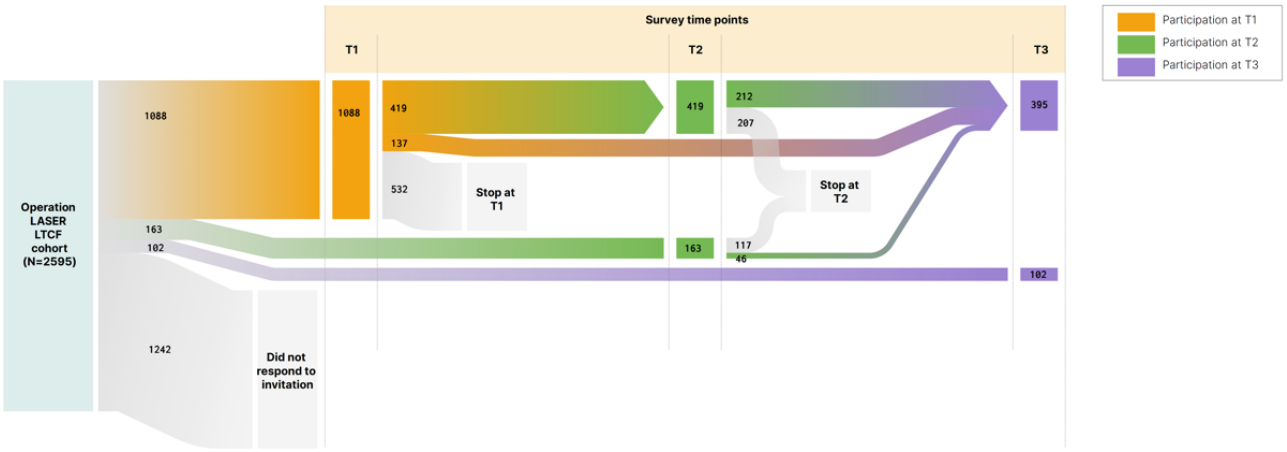
The CAF Surgeon General and Chief of Military Personnel were the sponsors of this research, and CJOC approved access to Operation LASER LTCF personnel. This survey was conducted jointly by Defence Research and Development Canada, DGMPRA, CF H Svcs Gp, and the Royal Military College of Canada. It was reviewed and approved by the Defence Research and Development Canada Human Research Ethics Committee (approval HREC 2020-026 and 2020-040) and coordinated by the DGMPRA Social Science Research Review Board in accordance with Defence Administrative Orders and Directives 5062-0 and 5062-1 (coordination 1897/20N). The questions asked in this research fell under the current Treasury Board of Canada Secretariat definition of public opinion research. Thus, public opinion research approval from the Deputy Minister was obtained before the survey launch (ie, July 21, 2020). Although CJOC approved and facilitated this study by coordinating the provision of contact information of potential participants, neither the research sponsors nor CJOC were directly involved in participant recruitment for any phase or aspect of the study, nor did they know the identities of the individuals who elected to participate. An unsigned consent procedure was used, consistent with the methodology used in previous surveys administered by DGMPRA. All data used for analysis were deidentified. No participant remuneration was provided.

Results

Survey

Cohort and Survey Frame Size

A total of 47, 12, and 13 invitations were not delivered because of automated email bounce messages for T1, T2, and T3, respectively (representing 13/2595, 0.5% to 47/2595, 1.81% of all eligible personnel). Both the Ontario and Québec points of contact were asked for updated email addresses for members whose email addresses were invalid. An updated Québec list was received soon after the initial T1 invitation email was distributed; thus, members with an updated email address were sent the initial T1 survey invitation and all subsequent reminders. For Ontario members, an updated list was received before the distribution of the initial T2 survey invitation, which accounts for the decrease in undeliverable emails between T1 and T2. Although most invalid email addresses were personal, a few emails to DWAN accounts also bounced; the reason for this issue was unknown. A total of 0.31% (8/2595) of the personnel asked to be removed from the distribution list after either the T2 or interview study emails were sent out; an additional member asked to be removed after the initial T3 email was sent. Ultimately, survey invitations were sent to 2595 members at T1 and T2 and 2587 individuals at T3.



Participation Metrics and Sample Characteristics

Participation Across Time Points

The participation flow across the 3 data collection time points is shown in Figure 2. Overall, 1088, 582, and 497 individuals responded in T1, T2, and T3, respectively (see Tables 2-4 for unweighted and weighted sample characteristics). An individual was classified as a responder if they completed at least one question in the first section of the survey (ie, demographics and Operation LASER LTCF role). Relative to the total cohort eligible for participation (N=2595), this represented a participation rate of 41.93% (1088/2595), 22.43% (582/2595), and 19.15% (497/2595) for T1, T2, and T3, respectively. Close to half (532/1088, 48.9%) of the T1 participants did not return for follow-up at T2 and T3. Of those 1088 who participated in T1, a total of 419 (38.5%) had data at T2, a total of 212 (19.5%) had data for all 3 time points, and 137 (12.6%) had data only for T1 and T3. Not all individuals who participated in the follow-up time points (ie, T2 and T3) participated in T1. At T2, a total of 28% (163/582) of all participants took part for the first time. More than a quarter of these T2 first-time participants (46/163, 28.2%) continued to T3. T3 had 20.5% (102/497) of first-time participants.

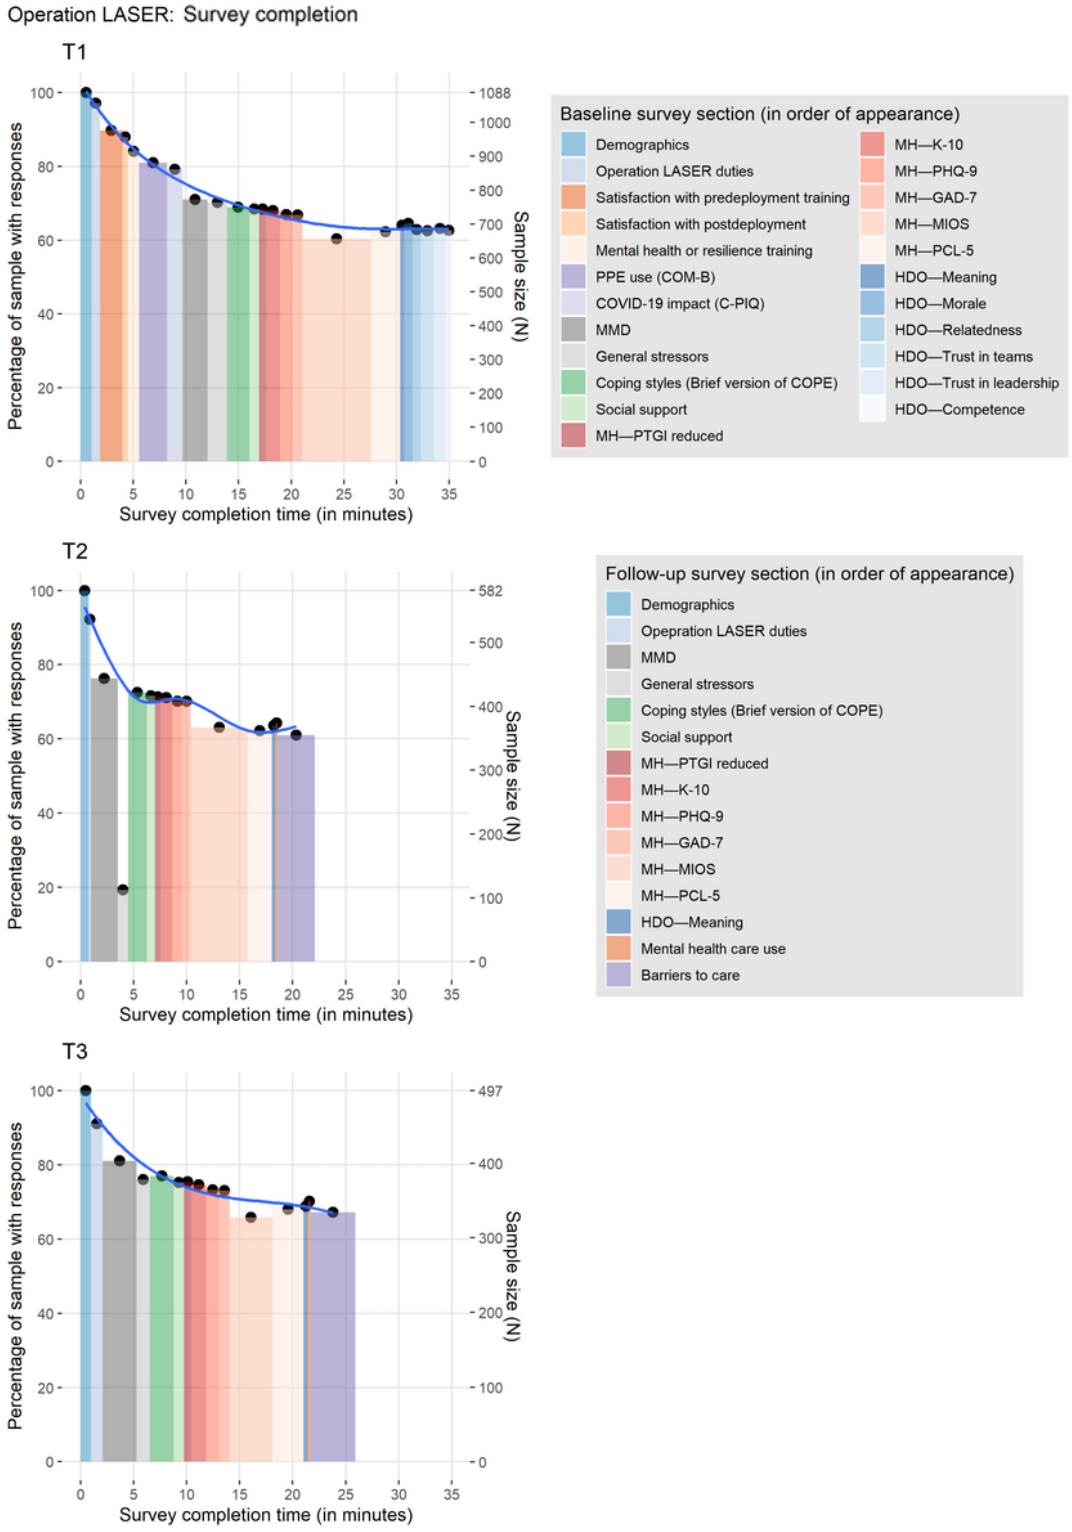
Completion Time

Multimedia Appendix 5 describes the quantiles of completion time for individuals who completed the survey (ie, reached and submitted the final page). Survey duration for partial completers (ie, completed at least one question in the first section of the survey and left the survey before reaching the final page) was not available because of the manner in which time stamps were established by the survey platform (ie, only recorded at the start

XSL•FO
RenderX



of the survey and once participants submitted the final page). After the removal of unreasonably long durations (ie, >500 min, likely because of participants completing the survey in multiple sittings), the median completion time for T1, T2, and T3 was 35.2 (IQR 26.3) minutes, 22.1 (IQR 16.0) minutes, and 25.9 (IQR 19.6) minutes, respectively. As expected, T1 had the longest completion duration because of the number of scales and items in the survey. Although T2 and T3 were very similar in content, additional questions were included in T3 that were not present in T2 (eg, additional items in the MMD-LASER). In reviewing the completion dates of the unusually long survey durations, it was evident that respondents returned to the survey on a different day to complete it as it aligned with the dates when reminder emails were sent. This pattern indicated that reminder emails were effective in encouraging a portion of partial completers to complete the survey at a later date (representing approximately 5%-10% of respondents at each time point).

Attrition Across Survey Sections

Common to many web-based surveys, not all participants in our study who started the survey completed it (see Figure 3 for attrition across survey sections). Survey completion at each time point was approximately 60% to 65% (relative to the number of individuals who completed the first section of the survey at each time point). Attrition across survey sections was largely a function of time spent in the survey, where approximately 80% of participants were retained at the 5-minute mark and 70% of participants were retained at the 10-minute mark.

XSL•FO
RenderX

Figure 3. Participant attrition across survey sections. Interview

A total of 208 members responded to our request for participants for the interview study, representing approximately 8.02% (208/2595) of the eligible cohort. Of the 208 participants who responded, 185 (88.9%) expressed interest in participating, 14 (6.7%) requested more information, and 9 (4.3%) declined the invitation to participate or requested to have their name removed from the distribution list for future Operation LASER LTCF research invitations. In total, 53 interviews were conducted

XSL•FO
RenderX

(n=23, 43% in French, n=27, 51% in English, and n=3, 6% in both languages). Multimedia Appendix 4 shows the characteristics of the interview participants.

All participants except 1 (52/53, 98%) consented to having their discussion audio recorded. In the case of the individual who declined audio recording, the investigator leading the discussion took detailed notes. The interviews ranged in duration from 34 to 98 minutes, lasting approximately 70 minutes on average. All discussions were transcribed verbatim (with the exception of the one interview in which the participant did not consent to audio recording). The number of words per transcript ranged from 3114 to 19,340, with a mean of 9779 words. Most of the personnel who participated in the interview study also completed the survey (51/53, 96%).

Discussion

This paper documents the methodology and implementation of a longitudinal study that aims to explore the psychological impact and mental health outcomes of CAF personnel deployed domestically to support civilian health care in LTCFs during the COVID-19 pandemic (as part of Operation LASER). Owing to the moral nature of the stressors encountered by personnel deployed to LTCFs and the insufficiently researched link between morally injurious experiences and mental health outcomes, it was important to understand their impact on mental health and well-being. The research objectives included identifying and quantifying individual, group, and organizational risk and resilience factors associated with these mental health outcomes; gaining an in-depth understanding of the personnel's lived experiences during deployment; and extracting lessons to inform decisions for similar future deployments.

Overall, the study rollout and data collection were successfully executed despite the complexity of the study design. The participant response rates, ranging from 19.15% (497/2595) to 41.93% (1088/2595) depending on the time point, are typical and consistent with those of other studies [63], including those in military populations [64-66]. Of those who started the survey, most completed it in its entirety. The likelihood of survey dropout was a function of survey length, with the largest dropout (approximately 20%) occurring within the first 5 minutes. This attrition across survey sections is comparable with that of other web-based surveys, suggesting that, as the time requirement for a survey increases, the completion rate decreases [67,68].

Among the several objectives of this study, a critical gap that this research intended to address lay in the area of moral injury. Military personnel often face situations that may be perceived to transgress deeply held moral beliefs and values; this includes through acts of commission of, omission of, learning about, or being a victim of betrayal [69,70]. Such experiences can lead to moral injury, causing intense feelings of guilt, shame, spiritual conflict, social alterations, and changes in moral thinking, which are distinct from PTSD but can coexist with it [71,72]. Understanding the nuances of moral injury (ie, its risk factors and mechanism of development) can help further differentiate it from PTSD and develop more tailored mental health interventions. These interventions can range from predeployment training programs that prepare military personnel for the moral complexities of operations to therapeutic approaches that can assist in the healing process for those experiencing moral injury. Finally, the identification and recognition of the scope and impact of moral injury can help foster a military culture that is more aware of and responsive to the moral and ethical challenges of military service, particularly when emerging research highlights the protective role of organizational support and sound leadership against the development of distress in the aftermath of exposure to potentially morally injurious events [19,73]. Addressing these gaps is not only a priority for military personnel [50,74] but also relevant to other high-stress occupational settings where individuals may be presented with moral conflicts in high-stakes environments (ie, first responders, health care workers, and the legal system) [75-77].

Despite the longitudinal and mixed methods nature of the study, the substantial effort made to optimize the study design mitigates bias (eg, attrition and nonresponse bias and careless responding). This study is not without limitations. Specifically, the lack of a time point preceding deployment limits the ability to draw strong causal inferences linked to the experiences during deployment. Data for this study were collected using web-based self-reports, which may carry the inherent bias associated with most self-reports, including measurement error, human error, response bias (eg, social desirability), memory recall bias, interpretation challenges, and lack of verifiability. Inherent to longitudinal surveys, attrition bias and panel conditioning may have been a factor. Finally, the 3–time point longitudinal design, although superior to trend study designs, has limited time resolution and restrains the granularity of temporal changes in the key outcomes captured in this survey.

The quantitative and qualitative data generated through this research provide an opportunity to characterize the well-being and mental health of Operation LASER LTCF personnel over the year after this deployment, identify general and Operation LASER LTCF–specific risk and protective factors, and inform preparation and interventions for future missions.

Abstract

Background: Disparities in cancer incidence, complex care needs, and poor health outcomes are largely driven by structural inequities stemming from social determinants of health. To date, no evidence-based clinical tool has been developed to identify newly diagnosed patients at risk of poorer outcomes. Specialist cancer nurses are well-positioned to ameliorate inequity of opportunity for optimal care, treatment, and outcomes through timely screening, assessment, and intervention. We designed a nursing complexity checklist (the "Checklist") to support these activities, with the ultimate goal of improving equitable experiences and outcomes of care. This study aims to generate evidence regarding the clinical utility of the Checklist.

Objective: The primary objectives of this study are to provide qualitative evidence regarding key aspects of the Checklist's clinical utility (appropriateness, acceptability, and practicability), informed by Smart's multidimensional model of clinical utility. Secondary objectives explore the predictive value of the Checklist and concordance between specific checklist items and patient-reported outcome measures.

Methods: This prospective mixed methods case series study will recruit up to 60 newly diagnosed patients with cancer and 10 specialist nurses from a specialist cancer center. Nurses will complete the Checklist with patient participants. Within 2 weeks of Checklist completion, patients will complete 5 patient-reported outcome measures with established psychometric properties that correspond to specific checklist items and an individual semistructured interview to explore Checklist clinical utility. Interviews with nurses will occur 12 and 24 weeks after they first complete a checklist, exploring perceptions of the Checklist's clinical utility including barriers and facilitators to implementation. Data describing planned and unplanned patient service use will be collected from patient follow-up interviews at 12 weeks and the electronic medical record at 24 weeks after Checklist completion. Descriptive statistics will summarize operational, checklist, and electronic medical record data. The predictive value of the Checklist and the relationship between specific checklist items and relevant patient-reported outcome measures will be examined using descriptive statistics, contingency tables, measures of association, and plots as appropriate. Qualitative data will be analyzed using a content analysis approach.

Results: This study was approved by the institution's ethics committee. The enrollment period commenced in May 2022 and ended in November 2022. In total, 37 patients with cancer and 7 specialist cancer nurses were recruited at this time. Data collection is scheduled for completion at the end of May 2023.

XSL•FO
RenderX

Conclusions: This study will evaluate key clinical utility dimensions of a nursing complexity checklist. It will also provide preliminary evidence on its predictive value and information to support its seamless implementation into everyday practice including, but not limited to, possible revisions to the Checklist, instructions, and training for relevant personnel. Future implementation of this Checklist may improve equity of opportunity of access to care for patients with cancer.

Introduction

The past decade saw remarkable advances in cancer care, treatment, and outcomes, but these benefits were not equitably realized. Concerningly, cancer disparities between populations of high and low socioeconomic status continue to widen, and those disadvantaged by social determinants of health experience a disproportionate burden of poorer cancer outcomes [1]. Social determinants of health, such as income and social protection, education, food security, and social inclusion and nondiscrimination, have major impacts on health and health outcomes of populations [2,3]. This is especially true for people affected by cancer, whereby those disadvantaged due to the impact of social determinants experience significantly more disease burden and are more likely to die from their cancer than others [2,4].

A significant proportion of this burden is due to systemic barriers influencing access to diagnosis, treatment, and care. For example, distance from treatment centers, out-of-pocket costs associated with accessing treatment and care, and overly complex health care systems that are difficult to navigate without adequate information and support [5,6]. In countries like Australia, health services inadequately address the requirements of the communities they serve; for example, insufficient provision of information in languages other than English, and institutional racism that particularly affects experiences and outcomes for Aboriginal and Torres Strait Islander patients [7]. The evolution of the concept of the "complex patient" acknowledges that individual patients are not inherently complex, but rather face a complex intersection of interrelating factors on multiple levels: biomedical (diagnoses and comorbidities), individual (language, literacy, and cultural), social (support, inclusion, and discrimination), and environmental (access to food, housing, and transportation) [8]. If unaddressed, these factors may manifest in a higher risk of morbidity, challenges to accessing appropriate health care, receipt of worse care, and consequently worse health outcomes. Although these findings are well recognized, few attempts exist to systematically integrate point-of-care interventions to rapidly identify people requiring early support or increased follow-up to address or mediate access barriers and systemic inequities that maximize health outcomes.

Evidence demonstrates that cancer nurses address critical gaps in care coordination for patients with cancer resulting in improved health outcomes and overall survival [9]. Cancer nurses are therefore ideally placed to identify and address these consequences flowing from structural inequities that impact equitable access to diagnosis, treatment, and care. However, there are considerable and increasing discrepancies between the available cancer nursing workforce and the demand for services, with a recent report published by the World Health Organization estimating a global shortage of 5.7 million nurses by 2030 [10]. There are also policy and funding barriers to innovations in care, such as nurse-led services.

Concurrently, there is a projected 47% increase in cancer burden expected from 2020 to 2040 across all settings globally, though particularly affecting low-resource settings [11]. With growing numbers of patients with cancer without a corresponding increase in specialist nurses, the ability to quickly identify and target those most in need of timely support is critical. Resourcing cancer nurses with validated tools to efficiently and systematically identify people with or at risk of complex care needs presents an overlooked opportunity to redress inequities in cancer care. For the purpose of this study, "complex care needs" are defined as the presence of access barriers to care and increased needs individuals newly diagnosed with cancer face due to the presence of social determinants of health and associated systemic barriers. The Complexity Checklist (the "Checklist") is a novel cancer nursing checklist developed to facilitate early identification of newly diagnosed patients with cancer at risk of poor experiences and outcomes due to complex care needs. In a review of internationally published papers, no similar checklist exists for oncology settings.

To generate evidence regarding the potential benefit of the Checklist, this study will undertake a comprehensive assessment of the Checklist's clinical utility. Clinical utility refers to the practical usefulness of an intervention to improve health outcomes. This study is informed by Smart's multidimensional model of clinical utility, which describes 4 dimensions that impact on an intervention's clinical utility: appropriateness, accessibility, acceptability, and practicability (Table 1) [12]. "Accessibility" will not be examined as it pertains to economic considerations of an intervention, which is out of the scope of this study. "Appropriateness" explores the evidence of the effectiveness and relevance of an intervention to clinical decision-making, and disruptions to current work and care [12]. Acceptability explores whether the intervention is acceptable to service users, providers, and broader society [12]. "Practicability" examines suitability, whether the intervention performs in real-world settings; functionality, whether the intervention, training, and instructions are complete and in

XSL•FO
RenderX

working order; as well as current and future training and knowledge requirements [12].

Table 1. Study objectives, type of data, and data source for a mixed methods case series study investigating the clinical utility of a nursing checklist for newly diagnosed patients with cancer in a specialist cancer hospital. Data collection activities occur over a 6-month period.

Study objective	Type of data	Data source
To determine patient and specialist nurse perspectives regarding the relevance or importance of the Checklist for decision-making, and disruptions to current work and care.	• Perspectives of patients and CNCs[a] of ease of use of Checklist and meaning and relevance of information obtained. • Time taken to complete the Checklist and make referrals.	• Interviews with patients (T1) and CNCs (T2 and T3). • CNC postchecklist survey, patient and CNC interviews.
To determine whether the Checklist is acceptable to patients newly diagnosed with cancer and specialist nurses delivering care.	• Perspectives of patients and CNCs. • Number of patients approached and recruited for the study. • Number of Checklists completed at T1.	• Interviews with patients and CNCs. • Checklist, operational, and EMR[b] data.
To determine whether the Checklist, training, and instructions are complete and in working order.	• Perspectives of patients and CNCs regarding whether the Checklist addresses all issues of importance/relevance to participants.	• Interviews with patients and CNCs.
To determine the perspectives of specialist nurses regarding the adequacy of training and current staff knowledge to use the Checklist and future needs.	• Perspectives of CNCs on the adequacy of training delivered to use the Checklist in practice and perceptions of future needs.	• Interviews with CNCs.
To explore the predictive value of the Checklist.	• CNC classification at enrollment and at 24-week follow-up.	• Checklist, operational and EMR data (internal and external referrals and internal uptake), and patient interview data (external uptake).
To explore concordance between specific checklist items and PROMs[c].	• Responses to prespecified Checklist items and relevant PROMs scores.	• Checklist, PROMs data.

[a]CNC: clinical nurse consultant.

[b]EMR: electronic medical record.

[c]PROMs: patient-reported outcome measures.

This study aims to provide an assessment of the clinical utility of the Checklist. Perspectives of newly diagnosed patients with cancer and specialist nurses will be used to explore the following 4 primary objectives:

- To determine patient and specialist nurse perspectives regarding the relevance or importance of the Checklist for decision-making, and disruptions to current work and care.
- To determine whether the Checklist is acceptable to patients newly diagnosed with cancer and specialist nurses delivering care.
- To determine whether the Checklist, training, and instructions are complete and in working order.
- To determine qualitative perspectives of specialist nurses regarding the adequacy of training and current staff knowledge to use the Checklist and future needs.

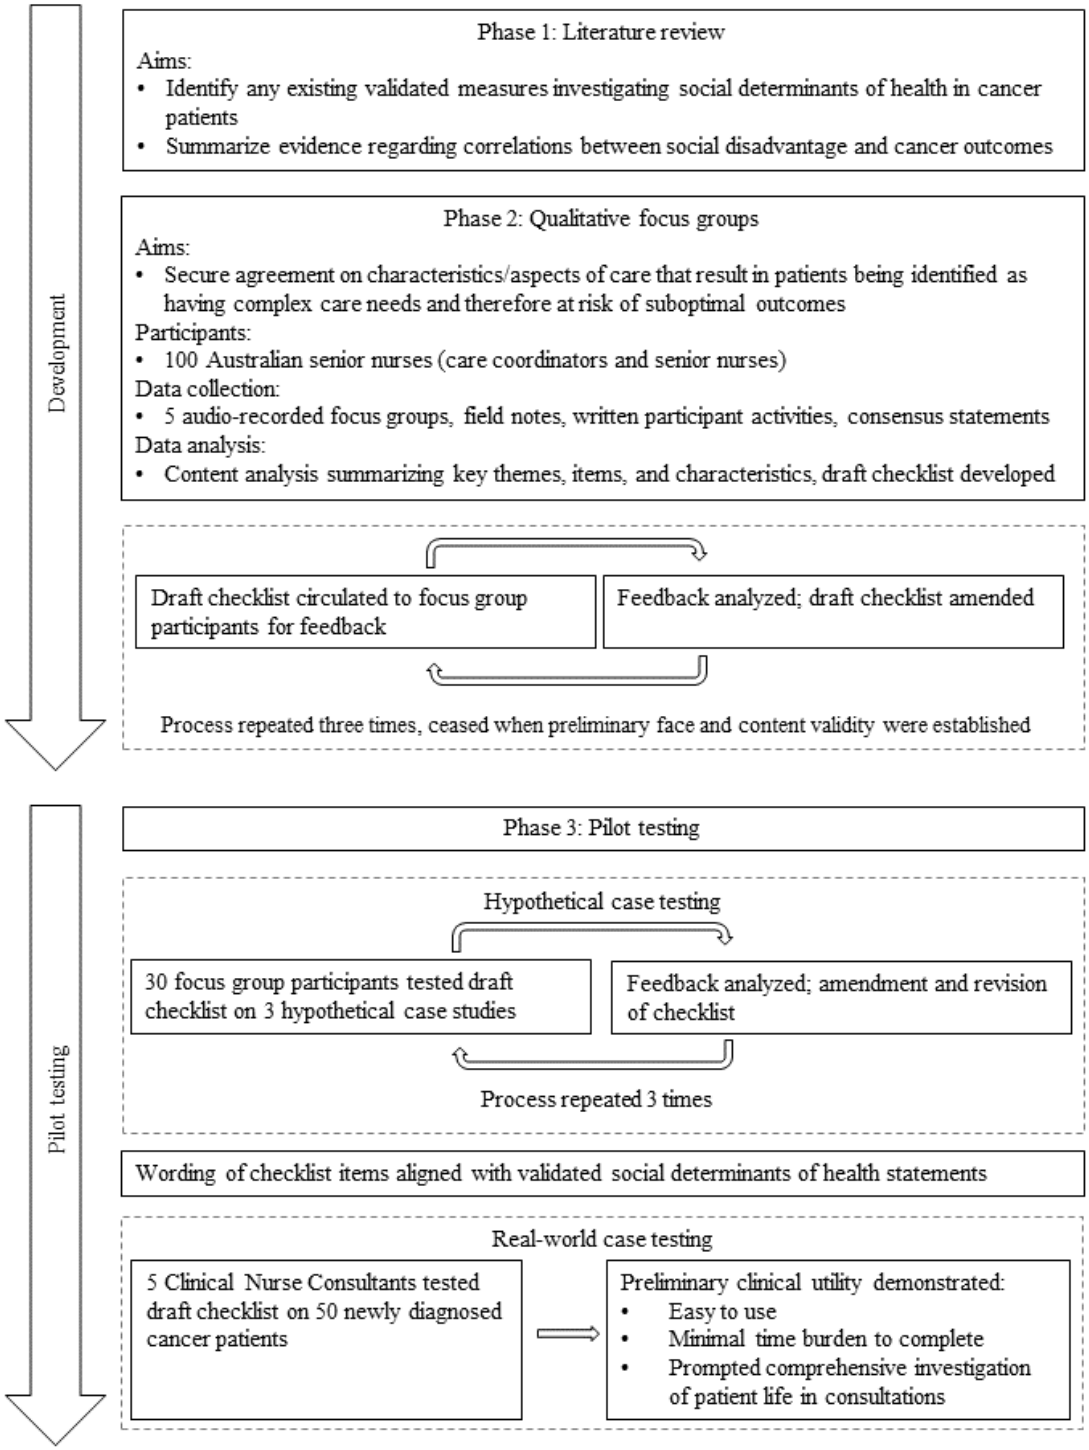
In addition, 2 secondary objectives have also been identified:

- To explore the predictive value of the Checklist.
- To explore concordance between specific checklist items and patient-reported outcome measures (PROMs).

Methods

Study Design and Setting

This prospective mixed methods case series study was designed to investigate the clinical utility of a nursing complexity checklist. The study will be conducted in accordance with the Joanna Briggs Checklist for Case Series [13]. Specialist nurses will complete the Checklist with consecutive patients newly diagnosed with cancer; then quantitative and qualitative data will be collected multiple times following completion of the Checklist at enrollment up to 24 weeks post Checklist completion. The study will be conducted at a specialist cancer center in Victoria, Australia. Ethical approval was granted by the institutional ethics committee (HREC/84219/PMCC).



Development

The Checklist was developed between 2016 and 2019 by members of our team (MK, DM, AH, and KG; Figure 1). A comprehensive review of published literature was undertaken to identify existing measures investigating social determinants of health in patients with cancer and to summarize evidence on associations between social disadvantage and cancer outcomes. Next, 100 Australian cancer nurses from Victoria, New South Wales, Queensland, South Australia, and Western Australia participated in 5 qualitative focus group consultations conducted face-to-face and digitally. Focus groups aimed to secure

XSL•FO
RenderX

agreement on characteristics or aspects of care that result in a patient having complex care coordination needs likely to increase their risk of suboptimal outcomes. Audio-recorded and written qualitative data were analyzed using content analysis. The first iteration of the Checklist was developed and circulated to nurse participants for feedback. This process occurred 3 times until no new characteristics or aspects of care were proposed for inclusion (preliminary content validity) and participants felt items included were easily understood (preliminary face validity).

Figure 1. Development of a nursing checklist to assess patients with cancer for risk of complex care needs with senior cancer nurses in Australia, 2016-2019.

The Checklist was then pilot-tested through hypothetical and real-world case testing. In total, 30 nurses (drawn from focus group participants) tested the Checklist with 3 hypothetical case studies to provide data on ease of use, and interpretation of the items when applied to a patient case. Feedback guided amendment and revision of the number of items included in the

XSL•FO
RenderX

Checklist (for example, items were collapsed or excluded as repetitive) over 3 iterative cycles until no further modifications were required. Following the establishment of Checklist constructs, a series of study team workshops were undertaken to operationalize constructs identified in the nurse workshops into quantitively measurable index items. Items were aligned items with existing psychometric and clinical assessments, as well as standardized definitions to enhance face and construct validity. The revised Checklist was then tested by 5 Clinical Nurse Consultants (CNCs) at a specialist cancer hospital in Australia who each used the Checklist in real-world consultations with 10 newly referred patients with cancer. Pilot-testing found the Checklist to be easy to use, took minimal time to complete, and prompted CNCs to ask their patients questions they may not otherwise have done.

Description

The Checklist comprises 15 items mapping to 4 domains: demographic, disease, health status, and symptomatology (Figure 2). Items are answered using a yes/no response format. The Checklist has been designed as a tool to prompt systematic assessment of newly diagnosed patients with cancer during consultations. This is achieved by guiding nurses through a comprehensive clinical consultation, to elicit all relevant information on factors that may add to a person's experiences of complexity. Data generated by the Checklist will be used by the CNCs to initiate referrals and with other members of the treating team; for example, through the electronic medical record or multidisciplinary team meetings.

Figure 2. The Complexity Checklist, a novel nursing checklist to identify patients with cancer at risk of complex care needs developed in Australia 2016-2019.

Demographic		
Social Support	Does the patient have adequate care support from family or friends?	Yes/No
Living arrangements	Do you consider the patient's current living arrangements or discharge destination suitable and able to meet their care needs?	Yes/No
Distance from Treatment	Is distance likely to impact on safety and accessibility of care?	Yes/No
Financial Toxicity	Does the patient have financial concerns which will require referral?	Yes/No
Indigenous or Torres Strait Islander	Does the patient identify as Aboriginal and/or Torres Strait Islander?	Yes/No
CALD	Does the patient require an interpreter?	Yes/No
Caregiver Anxiety	Nurse Assessment: Are close family or primary caregiver highly anxious or distressed by the cancer diagnosis?	Yes/No
Patient Capacity	Does the patient have family and/or work commitments which will be significantly impacted by their diagnosis and require extra intervention?	Yes/No
Disease Status		
Advanced Disease	Does the patient have advanced disease?	Yes/No
Diagnosis	Despite investigations, is the patient's diagnosis unknown?	Yes/No
Health Status		
Functional Capacity	Does the patient have a functional impairment (cognitive or physical) likely to complicate their care?	Yes/No
Psycho-pathology	Does the patient have a psychological illness which requires intervention or support?	Yes/No
Health/Lifestyle	Does the patient have health lifestyle factors likely to complicate their care including (tick which): Obesity Substance use/abuse (specify_____) Sedentary Lifestyle	Yes/No
Comorbidities	Does the patient have one or more comorbidities likely to complicate their cancer care? Specify:_____	Yes/No
Symptomology		
Uncontrolled symptoms	Does the patient have poorly or uncontrolled physical symptoms which require prompt intervention?	Yes/No

XSL•FO
RenderX

CNC Training

Nurses will participate in a training session on the use of the Checklist to optimize generalizability across observers (or raters). The session will provide guidance for specific items such as recommended daily exercise and guidelines regarding safe alcohol intake [14,15].

Patient and Public Involvement

This study builds upon preliminary clinical utility data from 5 CNCs who used the Checklist with 50 newly diagnosed patients with cancer. In addition, 2 consumer representatives were appointed to the study's steering committee following protocol development and have assisted with guiding the study amendments and direction.

Participants

A consecutive sample of newly diagnosed patients with cancer from 4 cancer streams (gynecological, urological, head and neck, and lung cancers) will be recruited. In accordance with the equity focus of the Checklist, support to enable participation of non-English speaking patients is provided. As this study investigates care delivery, the study targets people with a new diagnosis of cancer or where a previous diagnosis was managed with a simple excision. Patients attending the health service solely for the provision of clinical trial access are also excluded as trial care is not standard of care. Potential patient participants will be identified by participating CNCs from clinic and referral triage lists. A project officer (PO) will screen identified patients according to the following eligibility criteria:

- are 18 years or older
- have a histologically confirmed cancer diagnosis
- are expected to survive at least 24 weeks from the time of recruitment, as determined by tumor stream CNC
- are referred to the head and neck, gynecological, urological, or lung treating teams at the hospital for major surgery, more than a single fraction of radiotherapy or systemic therapy.
- are approached to participate within a 4-week window of their first appointment at the hospital or are approached within 4 weeks following a confirmed cancer diagnosis (for patients referred for diagnostic workup)
- are able to complete Checklist-related questions and take part in an audio-recorded semistructured interview either independently or with support (such as a caregiver, family member, or interpreter) as per usual clinical care
- are able to give informed consent
- have no previous cancer diagnosis (except basal cell carcinoma and squamous cell carcinoma type skin cancers and in situ carcinomas)
- have not been referred to Peter Mac solely to access treatment through a clinical trial

Eligible patients will be approached via telephone to introduce the study and invite participation via telephone. Interested eligible participants will be requested to provide written informed consent. CNCs from each participating cancer stream will be eligible to participate in the study. A maximum of 5 CNCs from each cancer stream will be recruited, to ensure all CNCs gain familiarity with delivering the tool.

Ethical Considerations

This study protocol has been approved by the relevant institution's Human Research Ethics Committee (22/39L). Written informed consent will be requested from all participants prior to study enrollment. Verbal reconfirmation of consent is audio-recorded at the beginning of semistructured interviews with all CNC and patient participants. Participants will not receive compensation for their involvement in this study. Participant data will be stored in accordance with National Health and Medical Research Council guidelines and deidentified where possible (refer to data management below for further detail).

Study Size

The study will aim to recruit 15 patients from each participating cancer stream (60 patient participants in total), and a minimum of 1 to a maximum of 5 CNCs working in each of the 4 participating cancer streams. The sample size is pragmatic based on study timeframes, clinical throughput and funds available These sample sizes will provide adequate information to achieve the primary study objectives, explored through qualitative interviews with patients and CNCs [16].

Data Sources and Measurement

Data collection activities will occur at 4 timepoints (Figure 3). Study enrollment of patient participants is confirmed once the intervention (the Checklist) is completed with their CNC (T0). Study enrollment for CNC participants is similarly confirmed the first time they complete a Checklist with a patient participant. Patients will complete 5 PROMs and an audio-recorded semistructured interview within 2 weeks of completing the checklist (T1), and a follow-up interview at 12 weeks post completion (T2). CNCs will complete 2 qualitative semistructured interviews at 12 weeks (T2) and 24 weeks (T3) after completing their first checklist. Medical record data to describe each patient's care events across the 24-week data collection period will be collected at T3. Qualitative and quantitative data collected will be used to evaluate multiple aspects of the clinical utility of the Checklist (Table 2).

XSL•FO
RenderX

Figure 3. Study schema for a mixed methods case-series study investigating the clinical utility of a nursing checklist for newly diagnosed patients with cancer in a specialist cancer hospital. Data collection activities occur over a 6-month period. CNC: clinical nurse consultant; PROM: patient-reported outcome measure.

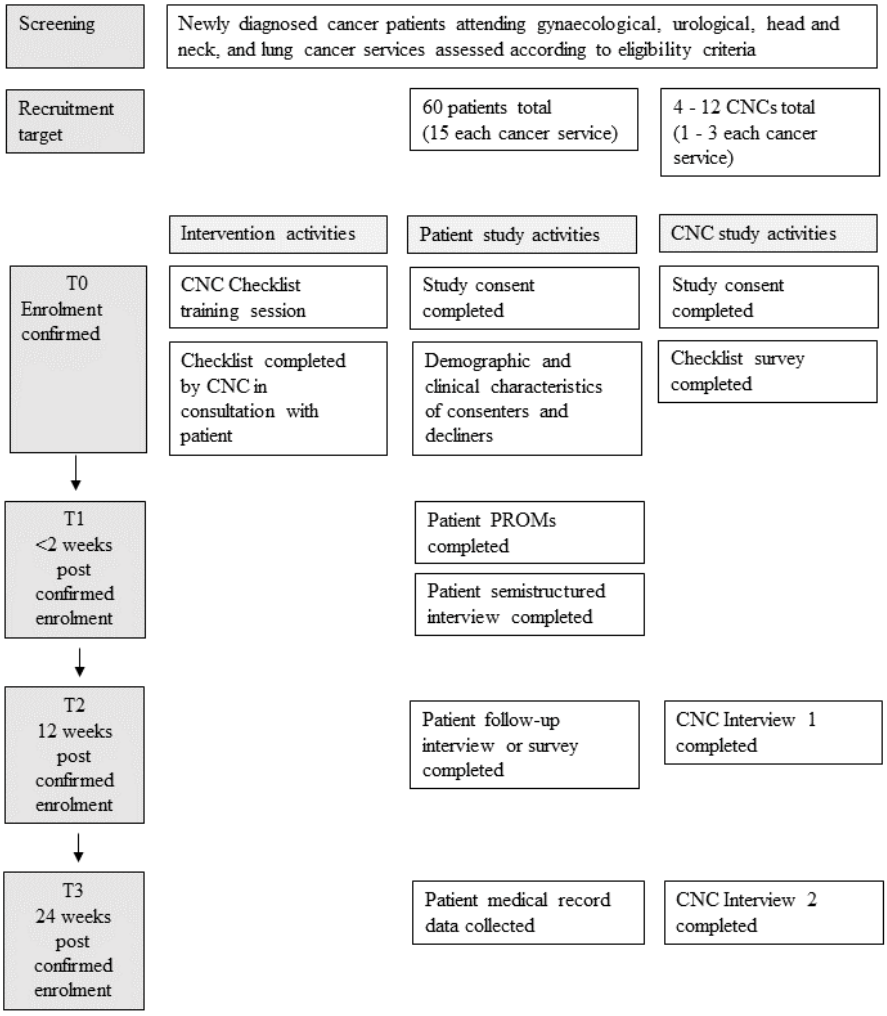


Table 2. Checklist items and corresponding PROMs[a] used to investigate concordance in a mixed methods case series study at a specialist cancer hospital.

Complexity Checklist item	Corresponding PROM
1) Social support	PROMIS[b] Instrumental Support SF[c] [17]
4) Financial toxicity	COST-FACIT [18]
8) Patient capacity	PROMIS ability to participate in social roles and activities—SF [17]
11) Functional capacity	PROMIS physical function SF [17]
15) Uncontrolled symptoms	PROMIS self-efficacy for managing symptoms SF [17]

[a]PROM: patient-reported outcome measure.

[b]PROMIS: patient-reported outcomes measurement information system.

[c]SF: short form.

T0 Data Collection Activities and Procedures

Operational Data

Details of patients screened, approached, consented, and declined will be entered into a password-protected Excel (Microsoft Corp) spreadsheet, hosted on a secure hospital server.

Patient Information

Demographic, disease, and treatment-related data will be extracted from the electronic medical record (EMR) by members of the project team (HC and EC) for all patient participants (consenters). Data will include sex, age, marital status, country of birth, primary language spoken, postcode, living situation, disease type and stage, comorbidities, treatment plan, and treatment intent and entered into Research Electronic Data

XSL•FO
RenderX

Capture (REDCap; Vanderbilt University)—a web-based electronic data capture tool hosted by the hospital [19,20]. Demographic and disease data will also be extracted from the EMR for all eligible participants who decline to participate (decliners) and entered into a separate REDCap database.

CNC Postchecklist Survey

CNCs will complete a paper-based or electronic checklist with patient participants. After completing each checklist, CNCs will also complete a study-specific survey to record: whether the checklist was completed face-to-face or digitally (telephone or telehealth); whether and from who the patient received assistance answering checklist items; and whether the CNC deemed the patient as having complex care needs based on Checklist items (response options: complex, not complex, and unsure). Checklist and CNC survey data will be entered into a web-based REDCap database by a study PO.

T1 Data Collection Activities

Initial Patient Interview

Patient participants will take part in an audio-recorded semistructured interview investigating patients' experiences and views regarding the acceptability, appropriateness, and practicability of the Checklist. Interviews will be conducted by a study PO face-to-face, by telephone, or via videoconferencing as per participant preference, and will take approximately 20-30 minutes to complete.

PROMs

Patient participants will complete 5 PROMs at the beginning of their semistructured interview (listed in Table 2). PROM data will be entered into a web-based REDCap database by a study PO. Four PROMS are drawn from the Patient-Reported Outcomes Measurement Information System, a system of widely used, highly reliable, and precise measures of patient-reported health status for physical, mental, and social well-being [17]. The fifth measure is the COST-FACIT scale, an 11-item measure of the impacts of chronic illness and its treatment on financial status [18].

T2 Data Collection Activities

Patient Follow-Up Interview

Approximately 12 weeks after administration of the Checklist, patient participants will be invited to complete a short follow-up interview. The purpose of this is to understand each patient's pattern of service use regarding uptake of internal and external referrals made at and following T1, and unplanned service use, particularly external care not captured by the hospital EMR.

Initial CNC Interview

CNCs will participate in an audio-recorded semistructured interview 12 weeks after they first administered a Checklist. This interview will explore the CNCs' perspectives on the appropriateness, acceptability, practicability, and clinical application of the Checklist. Demographic data will be collected at the start of interviews and comprise role title and discipline, years working at Peter Mac, and cancer stream affiliation. Interviews will be conducted face-to-face or by videoconferences as per participant preference and will take approximately 45-60 minutes to complete.

T3 Data Collection Activities

CNC Follow-Up Interview

Approximately 24 weeks after the first Checklist administration, CNCs will participate in a second audio-recorded semistructured interview. The purpose of this interview is to explore CNC perceptions of the discriminatory capacity of the Checklist, as well as its clinical utility and application. Additionally, checklist, operational and EMR data combined with CNC judgment will be used to determine complex care needs "caseness" at 24 weeks after enrollment. Interviews will be conducted as per participant preference and take approximately 20-30 minutes to complete.

Patient EMR Data

POs will complete a review of the patient's EMR to record treatment-related outcomes 24 weeks after patient participants complete the Checklist. These data include whether treatment was completed, amended, or the patient has withdrawn from treatment, transitioned to a clinical trial, or transitioned to palliative care. Referral data will also be collected, to add to and cross-check patient T2 follow-up. Data will capture types and dates of internal and external referrals, unplanned contacts with nurses and other health care professionals, and information regarding the uptake of internal referrals.

Data Analysis Plan

Qualitative Data

Audio-recorded interviews will be translated (as required), transcribed verbatim, and deidentified. NVivo 12 (QSR International) will be used to assist with data management. Three distinct tranches of semistructured interview data (patient T1, CNC T2, and CNC T3) will be analyzed separately using deductive and inductive content analysis. Content analysis allows for systematic and objective descriptions of phenomena such as views and perceptions of participants and is well-suited to informing clinical improvements [21].

An initial deductive approach will operationalize the prespecified study objectives (Table 1) to construct an initial, unconstrained, coding frame for each tranche of interviews. The coding frames will be tested and inductively revised to classify data into relevant codes and categories under clinical utility themes. In addition, 2 POs (HC and EC) trained in qualitative research will independently code 10% of each interview tranche to test and revise the coding frames. Iterations of the coding frames will be discussed, and discrepancies within coding frames will be resolved by consensus. The project principal investigator (MK) will be assigned a "third reviewer" role if HC and EC are unable to resolve discrepancies. Upon conclusion of the qualitative analysis, findings (codebooks and summaries) will be presented and discussed with members of the study team. Any divergence or disagreement with interpretation will be resolved by consensus. Following the completion of coding frames, qualitative data will be synthesized to explore similarities and disagreements between participant cohort perspectives regarding the clinical utility of the Checklist.

XSL•FO
RenderX

Quantitative Data

Data will be exported from REDCap, and then imported into R for scoring and analysis (reference index version 4.2.3 or higher). PROMs will be scored according to author guidelines and standard recodes applied as required [22-27]. T0 "caseness" classifications will be recoded to a discrete variable comprising 2 categories: case or noncase (noncase and unsure).

Counts and percentages will be used to summarize missing operational, participant characteristics (patient and CNC), checklist, EMR, and PROMs data. Missing data will not be imputed. Descriptive statistics (counts and percentages, means and SDs, medians and IQRs, and ranges, as appropriate) will be used to summarize the characteristics of patient consenters and decliners for the full sample and by cancer service, as well as the demographic and professional characteristics of CNC participants. Counts and percentages will be used to summarize "caseness" data (complex, not complex, unsure) from the CNC survey completed at enrollment. Contingency tables and conditional probabilities will be used to explore the predictive value of the Checklist by assessing agreement between T0 and T3 "caseness" variables. Descriptive statistics, measures of association, and graphical displays will be used to examine the concordance between prespecified checklist items and PROMs scores [28].

Data Management

Data Storage and Access

Demographic, Checklist, and PROMs data will be recorded onto hard-copy paper forms and entered into a study database developed and stored on the hospital REDCap platform. All study data (such as REDCap exports, qualitative data files, and analysis files) will be stored securely in password-protected electronic folders, housed on a secure hospital server. Quality checks will be undertaken at regular intervals by POs during data collection to ensure completeness, precision, and timeliness of data. Access to all hard-copy and electronic data will be restricted to the project principal investigator and POs directly involved in data collection and analysis.

Privacy

Study identification codes will be assigned to each participant and decliner and used to label data collected to protect privacy. Separate master lists, linking study identification codes to identifiable information (such as demographic and contact data) will be constructed for participants and decliners. Separate REDCap databases will be developed to store the participant master list, decliner master list, and Complexity study data. As above, only key project staff will be given access to these databases.

Data Retention and Disposal

At study closure, REDCap databases will be archived from the platform. Password-protected exports of all databases will be saved onto the secure hospital server, and hard-copy data placed into secure storage. All study data will be stored in accordance with National Health and Medical Research Council guidelines for the conduct of research for the duration of the study and 5 years post publication, in accordance with best practice research guidelines [29].

Results

This study received a grant from Perpetual's IMPACT Philanthropy Application Program in 2021 and was approved by the Peter MacCallum Cancer Centre Human Research Ethics Council in May 2022 (HREC/84219/PMCC). In total, 37 patient participants and 7 CNC participants were recruited across gynecological, head and neck, lung, and urological cancer streams from May 10, 2022, to October 19, 2022. Data collection, cleaning, and analysis activities are ongoing, and data collection will be concluded in April 2023. Study results are expected to be disseminated by the end of 2023.

Discussion

Principal Findings

This study will provide a comprehensive assessment of the Complexity Checklist's acceptability, appropriateness, and practicability (as defined by Smarts' multidimensional model of clinical utility) [12]. These data will provide understanding regarding patient and CNC perspectives on the Checklist's clinical utility and inform recommendations for changes to the Checklist (addition, removal, and modifications of items), and changes to training and instructions provided to clinicians delivering the Checklist. Findings from exploratory objectives will give early evidence of the Checklist's predictive capability and concordance with evidence-based measures. These findings will guide Checklist refinement, as well as justification and development of future studies assessing the Checklist's predictive capability and potential to impact clinical outcomes

Recent literature promotes the importance of understanding the impacts of social determinants of health (SDoH) on clinical care, though the definition and inclusion of SDoH in previous clinical checklists are varied [1,30]. The Complexity Checklist comprises structural (gender, education, and socioeconomic position) and intermediary determinants (psychosocial, behavioral, and biological factors), as well as individual medical factors that senior cancer nurses identified as contributing to worse patient experiences and outcomes [3]. This checklist has the potential to serve dual purposes: informing care for individual patients, while also gathering structured data that will enrich health service understanding of the distribution and impact of SDoH within their patient population to inform system and service level change.

Limitations

This mixed methods study is not sufficiently powered to establish statistical evidence for the Checklist, though the target sample size is suitable to inform qualitative findings. The case-series approach, with no control group, aims to describe the characteristics and outcomes of patient participants rather than investigate the effectiveness of the intervention. These limitations will be addressed in a future large-scale trial if this study supports justification for further investigation. Recruitment will occur at a specialist metropolitan cancer hospital in Victoria, and a lack of diversity in patient participants may result.

XSL•FO
RenderX

However, inclusion criteria have been developed to enable participation from non-English speaking persons. Future studies will specifically explore the clinical utility of the Checklist in culturally diverse cancer populations, acknowledging the importance of constructing cross-culturally valid measures [31].

Dissemination

Following data analysis, findings will be presented to the study funder as required by the funding agreement. Findings will be disseminated through standard scientific channels including peer-reviewed publications, conference presentations, and communities of practice, as well as to a broader audience including media, government, service users, and clinicians. The study investigators have a strong interest in promoting awareness of how social disadvantage affects cancer experiences and outcomes, and how inequities in cancer care can be addressed.

Conclusions

Structural and intermediatory determinants of health can result in access barriers to health care, posing a significant risk to achieving equity in cancer care. The Checklist aims to assist nurses to quickly and in a standardized manner, identify people disadvantaged due to social determinants of health at risk of complex care needs, so necessary supports can be provided. Pilot-testing had shown early evidence of potential. The study outlined above will assess the acceptability, appropriateness, and practicability of the measure, from the perspectives of newly diagnosed patients with cancer and specialist nurses involved in their care. Findings will inform further development and future studies to assess the Checklist. Integration of the Checklist into routine care offers the opportunity to improve patient care and outcomes, as well as create data sets with information regarding the SDoH to inform health service reform.

Acknowledgments

The authors acknowledge and thank all previous project team members and nurse participants who contributed to the development of the Checklist. We would also like to thank all nurse and patient participants for their willingness to take part and give their time to this study. This study has been funded by the Perpetual Foundations' IMPACT Philanthropy Application Program.

Data Availability

Data generated by this study will be available from the corresponding author upon reasonable request.

Authors' Contributions

MK, DM, AH, KG, and SA conceptualized the study. MK, KG, and SA designed the methodology. HC and EC are currently undertaking study activities outlined in this paper. All authors contributed to the preparation, reviewing, or editing of this paper.

Conflicts of Interest

None declared.

Abstract

Background: Only 5% of the molecules tested in oncology phase 1 trials reach the market after an average of 7.5 years of waiting and at a cost of tens of millions of dollars. To reduce the cost and shorten the time of discovery of new treatments, "drug repurposing" (research with molecules already approved for another indication) and the use of secondary data (not collected for the purpose of research) have been proposed. Due to advances in informatics in clinical care, secondary data can, in some cases, be of equal quality to primary data generated through prospective studies.

Objective: The objective of this study is to identify drugs currently marketed for other indications that may have an effect on the prognosis of patients with cancer.

Methods: We plan to monitor a cohort of patients with high-lethality cancers treated in the public health system of Catalonia between 2006 and 2012, retrospectively, for survival for 5 years after diagnosis or until death. A control cohort, comprising people without cancer, will also be retrospectively monitored for 5 years. The following study variables will be extracted from different population databases: type of cancer (patients with cancer cohort), date and cause of death, pharmacological treatment, sex, age, and place of residence. During the first stage of statistical analysis of the patients with cancer cohort, the drugs consumed by the long-term survivors (alive at 5 years) will be compared with those consumed by nonsurvivors. In the second stage, the survival associated with the consumption of each relevant drug will be analyzed. For the analyses, groups will be matched for potentially confounding variables, and multivariate analyses will be performed to adjust for residual confounding variables if necessary. The control cohort will be used to verify whether the associations found are exclusive to patients with cancer or whether they also occur in patients without cancer.

Results: We anticipate discovering multiple significant associations between commonly used drugs and the survival outcomes of patients with cancer. We expect to publish the initial results in the first half of 2024.

Conclusions: This retrospective study may identify several commonly used drugs as candidates for repurposing in the treatment of various cancers. All analyses are considered exploratory; therefore, the results will have to be confirmed in subsequent clinical trials. However, the results of this study may accelerate drug discovery in oncology.

Introduction

The usefulness of new cancer treatments is traditionally analyzed in clinical trials, which are considered the most rigorous design to study the effects of a treatment on a disease. Despite their strengths, clinical trials have significant limitations, such as cost and time. In a typical clinical trial, one or very few treatments are tested over a course of 7.5 years, and in oncology, the costs range from US $4.5 million (phase I) to US $22.1 million (phase III) [1-4]. Despite this, the clinical trials database ClinicalTrials.gov registers more than 22,000 trials each year, accounting for billions spent annually on clinical trials [5].

In oncology, the results of this substantial financial investment are modest, at best. As an example, only 5% of the molecules tested in phase 1 trials are marketed, and even if they are, they rarely generate a substantial change in the prognosis of patients [6,7]. In addition, the issue seems to be getting worse because the number of approved molecules has not increased in recent decades, but investment by the pharmaceutical industry has increased significantly [8].

Various strategies have been used to try to improve the efficiency of clinical trials. One of the most interesting is drug reuse (drug repurposing), with the aim of finding new uses for existing drugs approved for another therapeutic indication. This approach can, in most cases, allow research to begin with phase 2 trials because preclinical, pharmacokinetic, pharmacodynamic, and toxicity data are usually already known [7]. Looking for new treatments among already known molecules does not seem unreasonable, because in Spain alone, there are more than 2600 active ingredients approved and in use; it makes sense to think that some of them may have unknown effects on cancer. This approach, however, faces significant challenges since the complex and heterogeneous nature of cancer means that drugs with an effect on one type of cancer may not exhibit similar efficacy in several subtypes of cancer. Additionally, issues related to intellectual property, regulatory pathways, and the need for robust clinical evidence contribute to the complexity of drug repurposing efforts in oncology [9,10].

Another approach that substantially lowers the cost of pharmacological discoveries is the use of secondary data for research. Secondary data, which are used in some epidemiological designs, are those that are not collected for the purpose of the investigation but for another purpose, generally before the start of the study. Traditionally, data of this type are of poor quality because they are collected for other purposes, without the rigor of prospective studies. The number of variables may be incomplete because the data collection was not designed to address the research question. However, the technological revolution in recent decades has led to a paradigm shift, leading to reconsiderations of the classic axiom that secondary data are of low quality. New technologies and social networks produce a substantial amount of population data, which are not always of poor quality. The application of these technologies to medicine has led to the implementation of electronic health records and electronic prescription. Although the data in these 2 registries are not research data, they are of high quality, as they are used in clinical practice to manage people's health. Electronic prescription in Catalonia, for example, is how treatments are prescribed to users of the National Health System; therefore, it contains the drugs, doses, and guidelines actually prescribed to millions of people by their doctors. In addition, these doctors do not type the active ingredients in the prescription, which could lead to errors, but rather select them from lists in drop-down windows; therefore, the database is completely encrypted and does not contain transcription errors, in addition to being continuously updated. Other current databases, such as the mortality registry of the National Institute of Statistics (INE) or the Minimum Basic Data Set (CMBD) registry, where the diagnoses and procedures performed on hospitalized patients in Spain are recorded, can offer sufficient quality, in combination with electronic prescription, to draw conclusions about some of the effects of commercialized drugs [11,12].

Thus, combining the 2 strategies discussed above, we have designed a drug epidemiological study using population databases to identify drugs whose consumption is associated with changes in the survival of patients with cancer. For this, the pharmacological agents consumed by long-term survivors of incurable cancer will be compared with the drugs consumed by patients with shorter survival. We hope that this will allow, with a minimum investment of time and money, the identification of hitherto unknown effects of the molecules marketed in Spain on various oncological diseases.

This paper presents the general protocol for the study; the primary objective is to identify drugs whose consumption influences the survival of patients with high-lethality cancer (defined as those with a 5-year average survival of less than 20%, according to the statistics available at the time of database creation), and the secondary objective is to study the relationship between nonneoplastic diseases of patients with cancer and their survival. Given the diversity of the expected results with respect to different drugs and cancer diseases, we plan to publish the most relevant results in independent papers, in which the methodological details of each substudy will be described, as well as the specific interpretation of the results and their implications, depending on the nature of the findings and the associated cancer.

Methods

Design

This will be a retrospective cohort study in which a cohort of patients with high-lethality cancer (cohort 1) and another control cohort composed of people without cancer (cohort 2) will be studied.

Participants and Settings

The study population will be patients with the following cancers whose estimated survival at 5 years is less than 20%: lung, pancreas, esophagus, gastric carcinomas, hepatocarcinoma, and metastatic cancers.

Cohort 1 will include all patients registered in the databases of the public health system in Catalonia (Spain) who were diagnosed with any of the diseases under study between 2006 and 2012 (Textbox 1 contains the list of International

XSL•FO
RenderX

Classification of Diseases, Tenth Revision [ICD-10] codes) and who have complete data regarding the study variables (see "Outcome Measurements and Variables" section).

Textbox 1. Diagnostic codes (International Classification of Diseases, Tenth Revision [ICD-10]) for the pathologies under study.

Neoplasm lung

- C34.0, C34.00, C34.01, C34.02, C34.1, C34.10, C34.11, C34.12, C34.2, C34.3, C34.30, C34.31, C34.32, C34.8, C34.80, C34.81, C34.82, C 34.9, C34.90, C34.91, and C34.92

Neoplasm pancreas

- C25, C25.0, C25.1, C25.2, C25.3, C25.7, and C25.9

Neoplasm hepatic

- C22, C22.0, C22.1, C22.2, C22.3, C22.4, C22.7, C22.8, and C22.9

Neoplasm gastric

- C16, C16.0, C16.4, C16.3, C16.1, C16.2, C16.5, C16.6, C16.8, and C16.9

Neoplasm esophagus

- C15, C15.3, C15.4, C15.5, C15.8, and C15.9

Metastasis

- C78.0, C78.00, C78.01, C78.02, C78.1, C78.2, C78.3, C78.30, C78.39, C78.4, C78.5, C78.6, C78.7, C78.8, C78.80, C78.89, C79.0, C79.00, C79.01, C79.02, C79.1, C79.10, C79.11, C79.19, C79.2, C79.3, C79.31, C79.32, C79.4, C79.40, C79.49, C79.5, C79.51, C79.52, C79.6, C79.60, C79.61, C79.62, C79.7, C79.70, C79.71, C79.72, C79.8, C79.81, C79.82, C79.89, C79.9, and C80.0

In cohort 2, a total of 4 control participants will be included for each patient with cancer included in cohort 1. Control participants will be selected from those registered in the databases of the public health system in Catalonia whose diagnostic codes do not include neoplasm diseases (ICD-10 codes C00 to D49). The 4 control participants will be matched with the cases in cohort 1 by place of residence and date of birth, of which 2 controls will have been born in the same year and the other 2 controls will have been born 10 years earlier, with the aim of generating an older subcohort with, therefore, higher expected mortality.

Participants who, due to their unique health characteristics, including rare diseases or peculiar sociodemographic data such as extreme ages or residing in sparsely populated areas, were at risk of being identified were excluded from the sample.

Duration

The patients in cohort 1 will have been diagnosed with the cancer under study between 2006 and 2012, both inclusive, and their survival will be retrospectively monitored for 5 years after diagnosis or until death if it occurs earlier. Cohort 2 will include patients without cancer who have had any type of contact with the health care system between 2006 and 2012, and these individuals will be followed up retrospectively for 5 years or until death if it occurs earlier.

Data Sources

The study will be carried out using secondary data previously collected from various health databases at the population level. The researchers accessed the data set through the PADRIS program (Programa públic d'analítica de dades per a la recerca i la innovació en salut a Catalunya) of AQuAS (L'Agència de Qualitat i Avaluació Sanitàries de Catalunya) [13]. This program is designed to facilitate research by reusing data from the Catalan Public Utilization System (Sistema Sanitari Integral d'Utilització Pública de Catalunya [SISCAT]) with maximum ethical and data protection guarantees. The data will be pseudonymized and subjected to a study of the risk of reidentification of individuals from the data set, thus minimizing this risk before being used by the researchers.

The general characteristics of the original databases from which the study data will be obtained are summarized below:

- Hospital CMBD is a database in which diagnoses and procedures performed on hospitalized patients are recorded throughout the Spanish territory; all public hospitals and the majority of private hospitals (>95% hospital coverage) are included [14].
- Estació Clínica d'Atenció Primària (ECAP) is an electronic medical history program launched in 2001 and used by family doctors, pediatricians, and nurses from the Catalan Institute of Health (Institut Català de la Salut [ICS]) primary care centers when they visit patients; it includes all previous illnesses known to the primary care physician and records of the health care process in the outpatient setting, including assessments by health care personnel, diagnostic tests, and treatment, among others. The PADRIS program has only provided data since 2006, after which data are considered to be of good quality.
- The registry of causes of death is prepared by the INE using data from the Medical Certificate of Death or Statistical Bulletin of Death, Statistical Bulletin of Judicial Death, and Statistical Bulletin of Childbirth. It is prepared following the criteria established by the WHO (World Health

XSL•FO
RenderX

Organization) in the International Classification of Diseases (ICD), which includes more than 12,000 diseases.
- Electronic prescription has been implemented in Catalonia progressively since 2010 and is currently deployed in 100% of primary care centers, pharmacies, and public hospitals in Catalonia. Prescribing and dispensing data will be obtained from the Comprehensive Health Information System of the Catalan Health Service (Servei Català de la Salut [CatSalut]), which is a computerized system used by the doctors of the national health system in Catalonia to prescribe financed pharmacological treatments to their patients and the pharmacies to dispense them; it contains information on the date of the prescription, the active ingredient, and dose, among other variables. Unfunded treatments can be prescribed using this tool but are often prescribed by other means (paper prescriptions).

Outcome Variables and Measurements

The primary end point is survival, calculated from the date of entry in the database until death or until 5 years of follow-up are reached. For patients in cohort 1, the earliest date of cancer diagnosis for which they have been selected to be part of the cohort will be considered the date of entry into the study (inclusion criterion).

As study variables, the following data will be collected from all patients:

- List of diagnosed diseases (data source: CMBD and ICS ECAP diagnostic registry)
- Date of death (data source: INE cause of death registry)
- Cause of death (data source: INE cause of death registry)
- Pharmacological treatment (data source: Catalan electronic prescription), including all prescribed active ingredients, drug withdrawal dates from pharmacies, consumed doses, and prescribed regimen, during the entire follow-up period
- Sex (data source: Sistema Integral d'Informació de Salut)
- Date of birth (data source: Sistema Integral d'Informació de Salut)
- Basic health area (data source: Sistema Integral d'Informació de Salut)

For the patients included in the study with one of the cancers under study (cohort 1), the following variables will also be collected:

- Type of cancer and presence of metastases (data source: CMBD and ICS ECAP diagnostic registry)
- Date of diagnosis for which the patient is included in the cohort (data source: CMBD and ICS ECAP diagnosis registry)
- Surgical treatment of the cancer (data source: CMBD)
- Date of surgical treatment (data source: CMBD)

Data Curation

The data used in this study will be obtained from different databases, which must be merged for the analysis. None of the databases will be sorted by patient but by other types of entries (drugs, diagnoses, procedures performed, etc); therefore, the same patient could appear multiple times in each of them. Thus, first, a date will be associated with each event, and the information in the databases will be sorted by patient, with each patient as an entry that appears only once.

The coding of diseases and therapeutic procedures has undergone changes during the years of collection in the cohort, transitioning from using International Classification of Diseases, Ninth Revision (ICD-9) coding to ICD-10 coding. Consequently, all the data with ICD-9 coding will have to be converted to ICD-10 using the conversion tables provided by the Government of Catalonia (Generalitat de Catalunya) on their website [15].

In the pharmacological dispensing database, the active principles will be collected through the Anatomical Therapeutic Chemical (ATC) Classification System, and the amount dispensed monthly will be determined using the number of defined daily doses (DDDs) [16]. DDDs change over the years and are not uniform for different active ingredients or for drugs that form different groups as defined by the ATC4 codes. Thus, when necessary, DDDs will be transformed into units of mass for each of the drugs using the tables provided by the WHO with the evolution of DDDs over time [17].

One of the databases managed includes patients with metastases of any origin. For these patients, their previous diagnoses will be traced, and all the codes for both the CMBD and the ECAP will be analyzed to search for cancer diagnoses before metastasis to determine the origin of the cancer.

Finally, a patient rejection process will be applied based on the consistency of dates between the different databases. Following this principle, all those patients who, having been included in the database, do not have electronic prescription records will be rejected. In addition, all patients without registration or enumeration in the death databases will be excluded. Finally, patients with inconsistent dates will be excluded, for example, with postdeath records in the CMBD, ECAP, or electronic prescription.

Machine Learning

Machine learning techniques can reveal associations between variables, which are difficult to discover through statistical analyses [18]. Given the large volume of active ingredients to be analyzed and the high number of cases included in the database, in this study, as an additional step to the statistical analyses described below, machine learning techniques will be used to identify associations between the consumption of drugs and survival. The associations identified by machine learning techniques will later be confirmed by the classical statistical analyses described below.

Association rule mining (ARM), widely used for medical data analysis, will be used [19-21]. Through this method, association rules (ARs) are constructed that represent possible relationships between different elements within large data sets, identifying the most relevant ones. ARs consist of an antecedent (left hand side), which can be made up of several elements (drugs, age, etc), and a consequent (right hand side), which is made up of a single element, in the case of this study, survival at 5 years. In this study, a total of 2 sets of different ARs will be built using two approaches: (1) based on the amount of drug consumed, and (2) based on the time of drug consumption.

XSL•FO
RenderX

All variables will be previously categorized for use by the ARM technique. The survival variable will be treated dichotomously, depending on whether the patient has survived for at least 5 years. To obtain the set of rules based on the time of consumption of the drugs (active principles [ATC4] and families [ATC5]), the information will be categorically organized by quarters: whether the drug has been consumed during the quarter or not. To construct the set of rules related to the doses of drug consumed, the average DDD, discretized in 3 quantiles, will be used during the survival time of the patient.

Among all the rules generated by this methodology, the relevant ones will be selected. For this, an a priori algorithm [22] will be used to extract element frequencies, as it has been shown to be effective and is widely used in the literature [23].

Of all the rules produced using this methodology, only those that are met in at least 5 patients will be taken into consideration, and the most relevant will be selected using the following set of metrics:

- Support is a measure that indicates the frequency of the combination of the antecedent and consequent in the data set.
- Confidence is a measure that indicates the probability of obtaining a consequent given an antecedent.
- Lift is a measure that indicates how much more the combination of the antecedent and consequent occurs compared with what would be expected if they were statistically independent.
- Conviction is a measure that evaluates the relationship between the antecedent and the consequent of a rule [24]. This measure takes into account the occurrence of both independently. It is defined as the ratio of the expected frequency of incorrect predictions made by the rule to the actual frequency of incorrect predictions made by the rule. As a general rule, those values that are further from 1 usually indicate the most interesting rules.

First, the data are preprocessed to obtain a column for each active substance in each patient and, depending on the desired screening, the amount of the active substance taken in the different quarters. Other relevant data, such as age and sex, are also added.

Subsequently, AR search algorithms are run on the processed data, with a support threshold set to avoid generating nonrelevant rules, for example, less than 5 patients. However, this support can be filtered again later. Obtaining ARs that indicate static relationships between the different attributes, filtering now those that present survival.

Finally, the filtered rules are sorted by the desired metric (eg, lift). This metric was chosen especially for its ability to find active ingredients with a higher-than-expected survival rate. In the example shown in Table 1, active substance 3 in a medium dose leads to 6 times longer survival than expected in these patients.

Table 1. Example of the use of the association rule mining method for the analysis of survival associated with different active ingredients and combinations of active ingredients.

Antecedent	Quantity	Consequents	Support	n	Confidence	Lift	Conviction
Single active ingredient							
active-3	Medium	Survival	0.0079	30	0.5000	6.4054	1.8438
active-5	Low	Survival	0.0081	31	0.4366	5.5934	1.6364
active-1	Low	Survival	0.0013	5	0.4166	5.3378	1.5804
active-4	High	Survival	0.0013	5	0.4166	5.3378	1.5804
active-2	Low	Survival	0.0021	7	0.4000	5.1243	1.5365
Combination of active ingredients							
active-3 and active-2	Medium, low	Survival	0.0021	7	0.8888	11.3873	8.2974
active-5 and active-1	Low, low	Survival	0.0015	6	0.7500	9.6081	3.6877
active-4 and active-2	High, low	Survival	0.0013	5	0.7142	9.1505	3.2267

In addition, it is possible to filter by age, gender, or patient group, as well as search for relationships between them and their survival. Similarly, combinations of active ingredients can be sought that lead to increased survival (Table 1).

Statistical Analysis

To achieve the primary objective, several exploratory analyses will be performed. These will look for an association between the use of the different drugs available in the database (the exposure variable) and patient survival (the outcome variable). The exposure variable will be treated both dichotomously (exposed or not exposed) and quantitatively. The time exposed to the drug, the average monthly dose, the maximum dose, or the cumulative dose per unit of time will be considered. Specific analyses will be carried out on the effect of 2 or more drugs that have been shown to influence survival when they have been consumed, either simultaneously or sequentially, within the time unit being analyzed. The outcome variable is survival during the observation period. Patients who are censored, for whom no death is recorded during the follow-up time, are considered alive at the end of the period.

In addition to the machine-learning techniques described above, the association between exposure and outcome will be investigated using 2 different approaches. The exposure odds

XSL•FO
RenderX

for each drug will be calculated, and this exposure will be compared between patients considered alive at 5 years and those who have died using odds ratios (exposure odds ratio). The group of nonsurvivors will be selected with different time criteria in a sensitivity analysis: deceased in the 1st, 2nd, or 3rd year after diagnosis. Second, the survival time of participants exposed and unexposed to each drug available in the database (individual agents, ATC5 codes) or to each family of agents (ATC4 codes) will be compared.

To avoid bias due to a lack of randomization, in both approaches, matching will be carried out between the groups with respect to confounding variables. In addition, if residual confounding is suspected or an imbalance between groups remains after matching, adjustments for age, sex, and diagnostic groups will be performed. A Cox regression model will be constructed to estimate the effect of the evaluated drug. The hazard ratio (HR) and its 95% CI will be reported. Hazard proportionality will be assessed graphically by Schoenfeld residuals.

As a secondary objective, we plan to analyze the relationship between the presence of various nonneoplastic diseases and the survival of patients with cancer. To do this, we will compare the survival of patients with a specific disease to those who do not have it, adjusting multivariate models for age, gender, other conditions that may impact survival, and medications that have previously been shown to modify survival in previous analyses.

All analyses conducted in the cohort of patients with cancer will be replicated in a control patient group matched by age to the patients with cancer (with expected lower mortality) and in another group of older patients, where each control will be 10 years older than their cancer counterpart (with expected higher mortality). The findings that are reproduced in these groups of the control cohort will be discarded, as they are considered the result of uncontrolled biases or general effects on survival, not related to the cancers under study.

To consider a result statistically significant, the P value will be set at P=.05. All analyses are considered exploratory and hence subject to confirmation in new studies; therefore, no correction techniques will be applied to the P values obtained. All statistical analyses will be performed using R statistical software (version 4.1.0 or higher; R Core Team).

Methods to Address Potential Sources of Bias

This study, given its retrospective nature, is potentially affected by a series of biases, whose prevention or compensation will be attempted through various techniques. The 3 most important biases are discussed below:

- Reverse causality bias: drugs that are prescribed to patients near death to control their symptoms will appear associated with an increased risk of death in the analyses, with the prescription of these drugs not being the cause of death but a consequence of proximity to death. This bias will be alleviated by eliminating the drugs prescribed 3 months before death from the analysis.
- "Immortal patient" bias: the longer a patient survives, the more likely he or she is to be diagnosed with pathologies and to consume drugs. This can give the false appearance that the drugs consumed throughout life are the cause of prolonged survival. To control this effect, the analyses only considered the drugs consumed up to a certain date in the group of patients who survived until that same date. For example, in the group of patients who have survived at least 3 months after the diagnosis of their cancer, only drugs consumed at any time up to month 3 after the cancer diagnosis will be considered. Thus, the consumption of the drug will not be explained by longer survival because the entire group will have survived until the moment when the drugs under study are consumed. Patients who consume the study drugs after the established time cutoff point will be eliminated from the analysis. As a comparison group, only patients who have not consumed the drug at any point in their disease evolution will be taken into account.
- Diagnostic anticipation or "medical surveillance" bias: this bias occurs when patients are included in studies who are in a screening program for cancer because, in such programs, the cancer is diagnosed earlier, which causes the erroneous impression that the individuals live longer. In our database, patients with certain diseases may have undergone frequent diagnostic tests, thus triggering early cancer detection. For example, patients with chronic obstructive pulmonary disease (COPD) may have undergone periodic radiographs, in which lung cancer has been detected early. This may give the impression that COPD, or the drugs used by patients with COPD, are associated with increased survival from lung cancer. To control this bias, patients with a previous pathology that produces greater medical surveillance of the organ where the cancer developed will be eliminated from the analysis.

Sample Size Considerations

Based on a maximum 5-year survival probability of 20% (P=.2, *Q*=.8) and with a significance level of 5% (95% CI) and a power of 80%, it will be possible to detect a difference of 10% between 2 groups with 294 individuals per group. Table 2 shows an initial estimate of the number of survivors at 5 years available during the study period. According to preliminary data not shown, the database available for the study includes a total of 102,860 patients diagnosed with the cancers under study.

XSL•FO
RenderX

Table 2. Incidence and estimated survival for the main pathologies under study.

Cancer	New cases each year, n	Estimated 5-year survival, n (%)	Cumulative survivors throughout the study, n
Lung	4079	738 (18.1)	3691
Metastatic colon	6128	852 (13.9)	4259
Metastatic bladder	2444	122 (5)	611
Metastatic kidney	1094	131 (12)	656
Metastatic melanoma	860	171 (19.9)	856
Pancreas	1168	96 (8.2)	479
Esophagus	616	116 (18.8)	579
Metastatic stomach	1089	57 (5.2)	283
Liver	670	118 (17.6)	590

Ethical Considerations

Data handling will comply with Spanish Organic Law 03/2018 for data protection, the General Data Protection Regulation 2016/679, and local data protection regulations. Fundació Unio Catalana Hospitals' ethics committee reviewed the study (CEI 18/37) and waived patient consent due to anonymized retrospective data review.

Results

The study is currently in progress, with access to various databases. The data have undergone harmonization and curation, and they are now ready for analysis. We have initiated statistical and machine learning analyses. We anticipate discovering multiple significant associations between commonly used drugs and the survival outcomes of patients with cancer (the primary objective). Additionally, we aim to identify relevant associations between the presence of certain chronic diseases and survival outcomes in different cancer types (the secondary objective). There will be specific effects for particular cancers and general effects that impact the survival of a broad range of cancers. The initial publications containing the first relevant results are expected to be released in the first half of 2024.

Discussion

The aim of this study is to identify drugs for commercial use for pathologies with an effect on the survival of patients with cancer. For the study, diseases that have high lethality (survival rate <20% at 5 years) will be selected because they are a priority in terms of the search for new therapies and because for these diseases, conventional treatment has had little impact on survival, which facilitates the observation of additional survival effects from other drugs. The diseases have also been selected for their high frequency, so that, despite the high lethality, the group of survivors at 5 years will be large enough to allow comparisons with the deceased group with sufficient statistical power.

Despite the good quality of the data used, this study is based on analyses of secondary data and, therefore, has certain limitations that, although hypotheses can be established, make it necessary for these hypotheses to be tested through trials that generate primary data.

First, we do not have all the variables that can act as confounding factors in patient survival. For example, we do not have data on the histology of the various tumors, which can impact survival. Especially important is also the absence of data on hospital treatment for cancer, which does not appear in any of the available databases. Due to this limitation, the study has been designed to investigate "long survivors" (5 or more years) because, for the diseases studied, there are no treatments that have been shown to extend survival to the fifth year. For this reason, it is not probable that hospital treatments act as a confounding factor (because they have no known association with the outcome studied: survival after 5 years).

Second, patient registration in the databases does not coincide exactly with disease onset, resulting in a shortened estimated time to death. This limitation is greater in the CMBD than in the ECAP databases; therefore, one database will be complemented with the other to alleviate this limitation. However, this temporal bias has an established direction: registration in the databases always occurs after the diagnosis. This allows all cases to be classified correctly in the group of patients identified as long survivors because patients who lived 5 years since their inclusion in the database will have lived at least 5 years from disease diagnosis. However, there will be a classification error whereby some long survivors, for whom their data were entered late in the databases used, will fall within the comparison group (classified as "nonlong survivors"). This error will affect at most 20% of the comparison group because that is the maximum survival at 5 years estimated for the diseases under study. Therefore, the specificity of the classification will be at least 80%, and for some cancers, it will reach 95% (such as metastatic bladder cancer or metastatic stomach cancer). This classification error will bias the results toward the null hypothesis, not invalidating the differences ultimately found between groups, although it does detract from the power of the study. Given that the magnitude of the effect sought is very large, we do not believe that the decline in power due to classification bias prevents the observation of these differences.

XSL•FO
RenderX

Third, despite the shortening of the time frame of the data analysis for each patient to control for reverse causality and "immortal patient" biases, there may be a residual effect derived from these biases within the time frame not eliminated from the analysis; however, we expect this effect to be much smaller. In addition to the aforementioned biases, there may be information biases, mainly due to pathologies not registered in the database. We do not expect that these biases will significantly affect the main variables because cancer diagnoses are usually registered in the databases used as soon as they are known, the pharmacological registry includes drugs dispensed in pharmacies (not only prescribed), and registry mortality is very reliable.

Finally, such a broad exploration of variables and results will lead to the discovery of many random results due to biological variability that may not be able to be replicated in future research. The researchers will consider the implementation of adjustments such as the "false discovery rate." Notably, the study is exploratory, and the results must be confirmed in subsequent studies designed to test each hypothesis derived from this study.

In conclusion, this will be a pharmaco-epidemiological study with great potential to discover new drugs that influence cancer, but that, by design, will serve only as a preliminary step, guiding subsequent research aimed at the repurposing of active molecules for the treatment of cancer.

Acknowledgments

The authors would like to thank Dr Albert Samà and Dr Francisco Javier Ruiz for their contributions to the initial phases of the design of this research.

The authors declare that no artificial intelligence has been used to prepare any section of the text of this manuscript.

Data Availability

The databases used in this study are managed by the PADRIS program (Programa públic d'analítica de dades per a la recerca i la innovació en salut a Catalunya) of AQuAS (L'Agència de Qualitat i Avaluació Sanitàries de Catalunya). The authors cannot give access to the aforementioned databases. Any researcher interested in using data from the Catalan Public Utilization System (Sistema Sanitari Integral d'Utilització Pública de Catalunya [SISCAT]) must contact directly the PADRIS program [25].

Abstract

Background: Pre-exposure prophylaxis (PrEP) against HIV infection is a new approach that involves the prophylactic use of the anti-HIV drug Truvada (tenofovir disoproxil fumarate [TDF] and emtricitabine [FTC]) by people not infected with HIV.

Objective: The objective of this investigator-initiated clinical study of PrEP was to evaluate the incidence of HIV and sexually transmitted infection (STI), safety and efficacy of PrEP in PrEP users, and their compliance with PrEP medication. The social, medical, and economic benefits of PrEP in Japan was assessed.

Methods: This single-center feasibility study of PrEP was conducted at the National Center for Global Health and Medicine, Tokyo, Japan, where a cohort of men who have sex with men without HIV was established in January 2017. This single-arm interventional study compared the efficacy and safety of PrEP in a single group of men who have sex with men who participated in PrEP cohort studies. For reference, the cohort study participants who did not participate in the PrEP study were included for comparison. Blood samples were collected for storage at baseline and clinic visits at 1, 3, and 6 months after starting PrEP and every 3 months thereafter. The participants were administered with 1 tablet of Truvada once daily as PrEP. They underwent blood and anal swab tests 1 and 3 months after starting PrEP and then HIV and STI infection assessments at 3-month intervals. Blood samples were centrifuged at the AIDS Clinical Center Laboratory. PrEP safety was evaluated by monitoring serum creatinine levels for symptoms of renal function disorders. The primary end point was the incidence of HIV in PrEP users (100 person-years). The secondary end points were the incidence of STI in PrEP users (100 person-years), incidence of adverse events caused by Truvada, frequency of high-risk sexual activity, and adherence to periodic visits and medication.

Results: The study protocol was reviewed and approved by the certified review board of the National Center for Global Health and Medicine (NCGM-C-003129-03) on April 20, 2020. Changes to the study plan were submitted for review by the certified review board and approved before implementation. Recruitment was completed on March 28, 2019, and the study was completed (last adult participant and last time point) on March 31, 2021. The data were analyzed, and the main results of the study have been published in a peer-reviewed journal.

Conclusions: The findings indicated that PrEP is a highly effective and feasible strategy against HIV infection in terms of prophylactic response, retention, and compliance.

KEYWORDS

pre-exposure prophylaxis; human immunodeficiency virus infection; Truvada; men who have sex with men cohort; Japan

Introduction

The government of Japan formulated the "Tourism Vision for Graphics" in March 2016, in which a target of 40 million foreign visitors to Japan in 2020 and 60 million in 2030 was set to stimulate the travel economy; it is expected to result in a large number of foreigners entering Japan and increased cases of HIV and sexually transmitted infections (STIs). Our hospital is situated in Tokyo, the capital of Japan, and is one of the world's leading entertainment centers, attracting men who have sex with men (MSM). Given the importance of the MSM community to HIV transmission, there is an urgent need to address this issue in Tokyo [1]. Unfortunately, Japan's ongoing measures against HIV transmission have been inadequate, with approximately 1500 new HIV infections diagnosed each year. Lifetime medical expenses per case of HIV infection are approximately ¥100 million (approximately US $660,641.69 as of November 1, 2023) in Japan, making the introduction of effective measures against infection an urgent issue.

Pre-exposure prophylaxis (PrEP) against HIV infection is a new approach that is gaining popularity in many countries worldwide [2-4]. PrEP involves preventing HIV infection through the prophylactic use of the anti-HIV drug, Truvada (tenofovir disoproxil fumarate [TDF] and emtricitabine [FTC]), by people not infected with HIV and is expected to reduce HIV infections by approximately 90% [5-7]. It is recommended as an effective preventive strategy in the United States and by the World Health Organization, whereas Europe, Canada, Australia, Thailand, South Korea, Taiwan, and other Asian countries have started to introduce PrEP [8-10]. However, Truvada is not indicated or approved for PrEP use in Japan, and this strategy remains unexplored.

PrEP is aimed at populations at high risk of HIV infection, defined by the International AIDS Society as those with a new HIV infection rate of 2.0/100 person-years or higher and by the World Health Organization as with a new HIV infection rate of 3.0/100 person-years or higher [2,11]. The MSM population accounts for 2.9% to 4.6% of the male population in Japan. However, it accounted for 71% (670/940) of new HIV cases, and 54.4% (205/377) of new AIDS cases in 2018. These percentages are much higher than those in other Asian countries [12]. Thus, MSM may be considered a population at high risk of infection. By 2016, we had performed 1402 mail-based surveys among MSM in Tokyo. The results showed an HIV prevalence of 3% (13/429) among MSM in the study area (unpublished data). HIV incidence in a hospital sexual health (SH) outpatient target group has been reported to be 3.8/100 person-years of HIV incidence.[13]; however, given the increase in foreign visitors to Japan, MSM in Tokyo seems to be a sufficiently valid population for PrEP.

In PrEP, anti-HIV drugs are administered to healthy people not infected with HIV in an ongoing basis to prevent HIV infection; hence, people receiving PrEP must periodically visit a hospital to be tested for HIV and other STIs and check for adverse reactions to anti-HIV drugs. Healthy individuals receiving PrEP should be sufficiently prepared and knowledgeable to complete periodic hospital visits. Although success rates for PrEP vary greatly outside Japan, success or failure depends not only on PrEP providers but also on the degree of awareness and readiness of PrEP recipients [14]. Therefore, to ensure the effective implementation of PrEP, our hospital has been building an MSM cohort since the establishment of an SH outpatient clinic in January 2017 to facilitate the implementation of PrEP as a package that includes provider-side testing systems and education to build awareness among PrEP recipients. This investigator-initiated clinical study delivered PrEP as a strategic package to patients in a registered MSM cohort who wished to undergo PrEP. If the PrEP package is effective, it may lead to the regulatory approval for the PrEP use of Truvada, eventual establishment of PrEP in Japan, and decreased number of new HIV infections.

There is abundant evidence supporting the efficacy of PrEP, and PrEP has already been described in clinical guidelines [2]; therefore, a randomized controlled trial that compares PrEP with a placebo would be unethical. Our MSM cohort was scheduled to visit the SH outpatient clinic once every 3 months for a year as part of a phase of understanding and preparing for PrEP. Patients who were successfully checked for STIs and HIV during this period were deemed eligible for the study. Patients with a history of STIs were considered the preferred study candidates, although STI infection during the observation period had no bearing on study inclusion. The objectives of this investigator-initiated clinical study of PrEP were to evaluate HIV and STI incidence, safety, and efficacy of PrEP in PrEP users and compliance with PrEP medication. This study assessed the social, medical, and economic benefits of PrEP in Japan.

Regarding the effective implementation of PrEP, the hospital opened an SH-based outpatient clinic in January 2017. The MSM cohort study that preceded this study (establishment of the MSM cohort in Tokyo for the 2020 Tokyo Olympics and preparation for PrEP implementation and expansion; Human Research Ethics Committee of National Center for Global Health and Medicine [NCGM] [NCGM-G-002333-00]) was conducted. MSM cohort participants from the previous study who participated in this study received 1 Truvada tablet daily as PrEP and a single-arm intervention study to assess HIV and STI incidence before and after PrEP initiation. The patient population in the previous MSM cohort study enabled the development of a protocol for a clinical trial designed to assess the efficacy and safety of PrEP, even in a single-arm study.

Methods

Ethical Considerations

The study protocol was reviewed and approved by the certified review board of NCGM (NCGM-C-003129-03). Changes to the study plan were submitted for review to a certified review board and approved before implementation. This study was registered with Japan Registry of Clinical Trials (jRCTs031180134).

This study followed the principles of the Declaration of Helsinki and was conducted in accordance with the "Ethical Guidelines for Medical and Health Research Involving Human Subjects" and "Clinical Trials Act." All the researchers involved in this study adhered to the above ethical standards.

The SH outpatient intern who attended to the participants and a nurse clinical research coordinator obtained informed consent from the participants. In accordance with the "Clinical Trials Act," written materials were used to explain the study to the participants, and after confirming that the study candidates understood the details of the study, voluntary informed consent was obtained in writing. Study candidates were made fully aware that their decision to participate in the study was voluntary; that once consent was provided, it could be withdrawn at any time with no special disadvantage to the participant; and that results already presented at academic meetings or published in research papers prior to the withdrawal of consent would not be removed. The original copy of the consent form was kept by the study organizer, and a copy of the consent form was handed to each consenting participant. The participants did not receive compensation for the study.

Stored specimens were used in subsequent evaluations, provided more detailed information, was required only for this study, and were not allowed to be used for any other purpose. The use of stored specimens for any new study warranted additional written informed consent. The model consent form is written in Japanese and can be provided upon request.

Study Design and Setting

This single-center feasibility study of PrEP was conducted at the NCGM, Tokyo, Japan, where a cohort of MSM without HIV was established in January 2017. This single-arm interventional study compared the efficacy and safety of PrEP in a single group of MSM who participated in PrEP cohort studies. For reference, the cohort study participants who did not participate in the PrEP study were compared.

In a previous MSM cohort study (establishment of MSM cohort in Tokyo toward the 2020 Tokyo Olympics in preparation for PrEP implementation and expansion—approved by the Human Research Ethics Committee of the NCGM; NCGM-G-002333-00; unpublished), HIV-negative MSM attending the SH outpatient clinic at NCGM were tested every 3 months for HIV and STIs (syphilis, pharyngeal, rectal *Chlamydia trachomatis*, and gonorrhea) and received guidance on safer sex. Participants who wished to undergo PrEP were included in this study. Interns specializing in HIV treatment attended patients at the SH outpatient clinic. The schedule of enrollment, interventions, and assessments are shown in Table 1.

The participants were administered 1 tablet of Truvada once daily as a PrEP. The participants underwent blood tests and anal swab tests 1 and 3 months after starting PrEP and then at 3-month intervals were assessed for HIV and STI infection. Blood samples were centrifuged at the AIDS Clinical Center Laboratory. In total, 5 mL of blood serum was frozen and stored at –80 °C in a deep freezer. The specimens were managed based on study IDs. The safety of PrEP was evaluated by monitoring serum creatinine levels for symptoms of renal function disorder, which is a known adverse reaction to Truvada. Truvada was discontinued in subjects with an estimated glomerular filtration rate (eGFR) below 60 mL/min/1.73 m^2.

The feasibility of PrEP implementation in Japan was examined through a cohort analysis of patient behavior based on medication adherence and hospital visits. Sexual behavior was assessed every 3 months in MSM cohort participants using a questionnaire (Multimedia Appendices 1 and 2) to determine whether PrEP increases high-risk sexual activity.

HIV RNA testing and blood tenofovir levels						✓	

[a]Time points: patients were enrolled at premedication screening. The date of medication initiation will be day 0, with blood tests to confirm safety at the first month after medication initiation and every 3 months after that and at each yearly milestone to confirm infection. If necessary, HIV infection activity will be confirmed, and all tests will be confirmed at the end of the study. HIV RNA testing and blood tenofovir levels are performed when necessary.

[b]STI: sexually transmitted infection.

[c]TPHA: *Treponema pallidum* hemagglutination test.

[d]RPR: rapid plasma reagin.

[e]TMA: transcription-mediated amplification.

[f]HBs: hepatitis B surface antigen.

[g]HBc: hepatitis B core antigen.

[h]HCV: hepatitis C virus.

[i]eGFR: estimated glomerular filtration rate.

Study Participants

Sample Size Determination

Considering the HIV incidence of 7% without prophylactic drugs over the study period and possible decrease to approximately 0.7% by prophylactic treatment (90% effective), a minimum of 88 participants were needed for a binomial evaluation with a 1-tailed 5% level of significance and statistical power of 90%. A sample size of 120 was chosen to account for study dropouts and other factors.

Inclusion and Exclusion Criteria

The incidences of HIV and STI were analyzed in a sample of 120 participants using data collected for over 2 years. A previous MSM cohort study (NCGM-G-002333-00) had recruited approximately 500 participants. From this cohort, 120 participants were chosen for this study based on the statistical rationale described in the previous section.

Among the participants of a previous study performed at our hospital, those who adhered to regular hospital visits for 1 year and wished to receive PrEP were included in this study. Participants who met the inclusion criteria and none of the exclusion criteria (Textbox 1) were enrolled in this study. Enrollment took place between the approval of the ethics review committee and March 2019. Patients with suspected acute HIV infection were rescreened for study participation after a 1-month interval and could participate in the study if confirmed to be HIV-negative.

XSL•FO
RenderX

Textbox 1. Study participation criteria.

Inclusion criteria

- HIV-negative men who have sex with men who practices anal intercourse
- 20 years or older
- At high risk of HIV infection (any of the following apply):
  - Contracted a sexually transmitted infection within the past year
  - Practiced anal intercourse without a condom within the past 6 months (insertive or receptive)
  - Has an HIV-positive sex partner
  - Used stimulants within the past 6 months
- Lives in Japan and understands Japanese
- Is a participant in the men who have sex with men cohort study, has completed 1-year of periodic hospital visits, and understands the significance and importance of HIV prevention by pre-exposure prophylaxis
- Has read the patient information and consent form carefully and indicated their willingness to participate in the study by signing the consent form

Exclusion criteria

- Suspected symptoms of acute HIV infection
- Serious liver damage or renal dysfunction (estimated glomerular filtration rate <60 mL/min/1.73 m^2)
- Taking a nephrotoxic drug (high doses of nonsteroidal anti-inflammatory drugs)
- Allergic to tenofovir disoproxil fumarate or emtricitabine
- Taking a drug that includes tenofovir disoproxil fumarate or emtricitabine
- May not be unable to take Truvada throughout the study period
- Otherwise deemed unsuitable for pre-exposure prophylaxis

Before enrollment, it was confirmed that the study participants met all the inclusion criteria and none of the exclusion criteria, and all necessary information was entered into a case enrollment form (CRF-1) that was submitted to the data center. The data center used the CRF-1 to check for eligibility and enroll subjects. The data center assigned an enrollment number and issued an "Outpatient Visit Schedule." The patients were observed for a minimum of 2 years and a maximum of 3 years. The study duration ranged from the day of the ethics committee approval to March 2022.

Interventions

The PrEP used in this study was FTC-TDF combination tablets. The product name and distributor was Truvada Combination Tab, Torii Pharmaceutical Co, Ltd. Each blue film-coated tablet contained 200 mg FTC and 300 mg TDF. The drug identification code of the drug was GILEAD-701. The tablets were stored at room temperature in an airtight container containing a desiccant. Once opened, they were stored away from moisture. As this was a single-arm interventional study, the choice of comparator was not applicable. In this open-label study, allocation sequence generation, adoption of a concealment mechanism, or blinding were not required.

Considering the range of enrollment periods and different durations of treatment for each participant, and assuming treatment for 100 study participants for 3 years, 100 (participants) × 12 (months) × 3 (years) = 3600 bottles of the study drug were procured for the 120 participants. Each patient was administered with 1 tablet daily. Treatment was initiated from the point of enrollment until March 2021. The study drug could only be prescribed by physician collaborators and dispensed by pharmacists. Drug information was excerpted from the January 2016 revision of the drug package insert, and only the latest version of the drug package insert was used.

The study drugs were stored, managed, and tracked for records of the supply, dispensing, retrieval, disposal, and return of drugs by the Department of Pharmacy of the NCGM. All surplus drug bottles were retrieved.

Data Collection and Assessment

Patient information included age, sex, ethnicity, HIV status (infected or not infected), current and past history of STIs (yes or no), sexual behavior (anal intercourse, number of sex partners, condom use, drug use, frequency of injected drug use [yes or no], and HIV and STI status of partner), timing of the most recent HIV and STI tests, medical history, complications, concomitant medications, and study drug adherence.

Blood specimens were collected and stored for periodic investigation before starting PrEP, 1 and 3 months after starting PrEP, and every 3 months thereafter. These periodic investigations included HIV testing (fourth generation), *Treponema pallidum* hemagglutination test quantification, rapid plasma reagin quantification, pharyngeal or anal *C trachomatis*, gonococcal testing (genetic method of diagnosis: transcription-mediated amplification), serum creatinine, eGFR, hepatic function testing, and testing to confirm a positive HIV

XSL•FO
RenderX

test. HIV RNA testing, blood tenofovir levels, and other investigations should be performed when required. In addition to the above periodic investigations, hepatitis B surface antigen antibodies, hepatitis B core antigen antibodies, hepatitis C virus antibodies, and amoebic antibodies were assayed. Information on self-reported adherence rates and pill counts by pharmacists between visit intervals was collected every 3 months.

Outcomes

The primary and secondary end points that were assessed to evaluate HIV and STI incidence and the safety and efficacy of PrEP in Japanese PrEP users are listed in Textbox 2.

Textbox 2. End points of the study.

Primary end point

- HIV incidence in PrEP users (/100 person-years)

Secondary end points

- STI incidence in PrEP users (/100 person-years)
- Incidence of adverse events caused by Truvada
- Frequency of high-risk sexual activity
- Adherence to periodic visits and medication

Criteria for Discontinuing or Modifying Allocated Interventions

Participation was considered discontinued when a participant refused the use of their personal information and data, any deviation from an inclusion criterion or an applicable exclusion criterion was noticed, or when continuation of the study was otherwise deemed difficult by a supervising physician or the principal researcher. The entire study was subject to discontinuation on the order of the head of the study site or when the principal researcher deemed continuation of the study difficult.

Study drug treatment was scheduled for discontinuation or temporary suspension in cases of HIV infection. If the HIV test was positive, the patient was to be transferred to the AIDS Clinical Center for medical care. The initial examination at the AIDS Clinical Center included testing for anti-HIV drug resistance as part of the routine medical care to confirm whether the patient had acquired resistance to TDF or FTC. The drug resistance test results were to be collected as relevant information for this study. Other criteria for discontinuing the treatment were decrease in eGFR below 60 mL/min/1.73 m^2, report of adverse events related to the drug, and when the use of a prohibited concomitant drug was deemed essential. As the patient recovered from the adverse event or stopped requiring the prohibited concomitant drug, the prescription of the study drug could be restarted after rescreening the patient for eligibility and a negative HIV test result.

Relevant Concomitant Care Permitted or Prohibited During the Trial

Drugs that were prohibited from concomitant use included nephrotoxic drugs and drugs containing FTC or TDF, lamivudine, and adefovir. Drugs that could be used concomitantly were the ones that were excreted by active tubular transport, such as acyclovir, valacyclovir, ganciclovir, and valganciclovir. However, these drugs may compete with Truvada for the excretion pathway, thereby increasing the risk of adverse events. Therefore, the concomitant use of these drugs was permitted only temporarily. There is a risk that patients with chronic hepatitis B would experience reactivation upon discontinuing Truvada. Therefore, extreme caution was exercised when suspending treatment with this drug.

The blood concentrations of FTC and tenofovir can be elevated in patients with renal disorders. Patients with a past history, presence of, or risk of developing renal disorders with this drug were monitored carefully during treatment for changes in blood creatinine and blood phosphate, and appropriate measures were taken. A study on tenofovir preparations reported a loss of bone density in the lumbar spine and femoral neck after 144 weeks of treatment [15]. Although the clinical significance of this finding remains unclear, patients with a history of pathological fractures or other chronic bone diseases were carefully observed and appropriate measures, such as discontinuing treatment, were to be taken in case of any abnormalities.

Clinical indemnity and liability insurance were obtained prior to the start of the study. Insurance payments were made according to the insurance policy for nonfault deaths or disabilities resulting from participation in this study. However, medical expenses were not covered by the insurance and were borne by the patient. In the event of a study-related injury, there was provision for appropriate and immediate action to be taken within the scope of insured medical care. The duration of insurance coverage was until the end of the study in March 2021. Participants who wished to receive PrEP after the end of the study could purchase Truvada at their own expense and receive medical follow-up at the AIDS Clinical Center while continuing to take the drug. However, medical fees associated with this were not covered by insurance.

Safety Assurance and Reporting of Adverse Events

Although Japan has not approved Truvada for PrEP use, it is frequently used in the routine medical care of patients with HIV. Evidence has also demonstrated that Truvada for PrEP use is safe, though prompt medical care was to be provided in case of any adverse events.

XSL•FO
RenderX

In this study, adverse events that were grade 3 or more severe (grade determined using a grade table) or lead to suspension of treatment will be immediately reported to the principal researcher. An adverse event report form (CRF-4) was also to be completed and information was to be shared with the study group. Incidences of serious adverse events were reported by the principal researcher to the Clinical Study Quality Management Office; the ethics committee; and the Minister of Health, Labor and Welfare when necessary.

Serious adverse events were defined as those that resulted in death, were life-threatening, required hospitalization or prolongation of existing hospitalization for treatment, resulted in persistent or significant disability or incapacity, caused a genetic abnormality in children, or were otherwise judged serious based on the reports of the principal researcher.

Caution was exercised in patients with a history of renal function disorders and those taking nephrotoxic drugs. Since severe renal function disorders such as renal insufficiency, renal failure, acute renal failure, proximal renal tubular dysfunction, Fanconi syndrome, acute tubular necrosis, nephrogenic diabetes, and nephritis may occur, participants were observed carefully with periodic testing. If laboratory abnormalities were observed, appropriate measures were taken, such as discontinuing treatment.

Statistical Methods

The main analysis included the estimation of the rate of new HIV infections during the study, either by dividing the number of infections by the number of subjects or by using a Kaplan-Meier estimate, estimating the 90% CI, and deciding whether PrEP was effective if the upper bound of the CI did not exceed 7%. However, given the expected increase in high-risk sexual behaviors, a log-linear model was used to assess whether the ratio of HIV to STI incidence at the end of the study differed between the participant cohort who did not wish to receive PrEP and the PrEP cohort. Behavioral evaluation included a quantitative assessment of risky sexual behavior (HIV Incidence Risk Index for MSM) score and a Wilcoxon signed rank test to determine whether there was a significant difference in sexual behavior before and after PrEP. A sensitivity analysis was performed using the least-squares method with a linear model or mixed-effects models for repeated measures (MMRM).

Oversight and Monitoring

The study was approved by the certified review board of NCGM. The certification review board was established by the President of NCGM and Director of the Centre Hospital of the NCGM, and the members met once a month.

To confirm whether the study was conducted safely and according to the protocol as a general rule, all participants underwent individual monitoring 1 month after enrollment. Subsequently, 10% of enrolled participants underwent annual monitoring. The monitoring included the matters listed in Textbox 3. Monitoring was performed via direct verification of source materials. The principal researcher designated a monitor among the study collaborators. After monitoring, the monitor promptly prepared a report and submitted it to the principal researcher. Monitoring reports were stored in the study office. In the event of a serious violation or deviation, the principal investigator reports the violation to the President through the Office of Clinical Research Quality Management. No audits were conducted during the study.

As a general rule, periodic centralized monitoring was performed twice a year to confirm that the study was being conducted safely and according to the protocol. Centralized monitoring was performed using the data entered into the records (CRF) collected by the data center. A periodic monitoring report prepared by the data center was submitted to the principal researcher and the study office. The matters subjected to centralized monitoring are listed in Textbox 4.

Textbox 3. Matters subject to monitoring.

- Consent obtained in writing and retention of the patient information or consent form
- Eligibility of subject inclusion criteria
- Referencing of data entered into case report forms against medical records (direct verification of source materials)
- Occurrence and reporting of adverse events
- Occurrence of protocol deviations
- Circumstances of stored specimen management
- Circumstances of study-related stored documents and case files
- Any other problems related to study progress and safety

XSL•FO
RenderX

Textbox 4. Matters subject to centralized monitoring.

- Number of enrollees
- Subjects receiving protocol treatment, discontinued subjects, and reasons for discontinuation
- Serious adverse events
- Adverse events and adverse reactions
- Protocol deviations
- Other problems related to study progress and safety

Data and Information Confidentiality

The following steps were followed to ensure confidentiality:

- Personal information and data collected during this study were handled only by the researchers involved, and the information was meant to be used for any purpose other than this study. Researchers exercised due care in handling personal information and data, and the principal researcher took necessary measures to ensure the proper handling of personal information and data.
- Data were anonymized before being added to the database. The study database and all temporary digital files contained no personal identifying information other than study IDs.
- The study database was stored on a hard disk on a password-protected computer located in a lockable room. The keys and passwords were managed appropriately by the study groups. Other printed matter and materials generated during study-related tasks were also managed appropriately, such as being viewed in locations that were not accessible to third parties and stored in a lockable cabinet. Portable electronic media were avoided whenever possible; however, when the use of portable electronic media was unavoidable, it was reported to the principal researcher and handled with the utmost care.
- The principal investigator was responsible for managing the master key and supervising its use. After the data in the study database were locked, the master key was submitted to the director of the planning and strategy of the AIDS Clinical Center and was not retained by the study group.
- Personal information and data are planned to be retained up to the day when 5 years have elapsed from the day when the end of the study was reported to the director, or up to the day when 3 years have elapsed from the day when the final publication of study results is reported to the director, whichever occurs later. Any printed materials, and electronic media will be disposed of after the content is rendered physically unreadable. Rewritable electronic media can be reused after rendering the study data entirely unrecoverable by overwriting them multiple times using dummy data.
- Care was taken when publishing the study results to ensure that individuals could not be identified.
- No specific limit was placed on the retention duration of the stored specimens owing to the importance of the samples.

Reporting of Protocol Modification, Deviations, and Violations

Any amendments to the protocol, violations of the above ethical standards, or deviations from the protocol was to be promptly reported to the ethics committee, including details, reasons, and responses to the violation or deviation.

In principle, a “violation” was defined as any deviation from the protocol rules that fell under more than 1 of the following categories: influence the evaluation of study end points, intentional or systematic, the degree of risk or deviation is significant, and clinically inappropriate.

Permissible deviation was to be considered if any of the following occurred: deviation did not affect the evaluation of a study end point, deviation was unintentional, and the severity of danger or extent of deviation was not significant. Deviations were incidents of nonadherence that did not fall under violations or permissible deviations. Consent procedures for study participation, eligibility determinations, drug treatment, laboratory tests, adverse event reporting, and other matters not performed in accordance with the provisions of the protocol were considered protocol deviations.

In principle, the monitoring process included the need to describe instances of suspected violations and deviations in a monitoring report and published paper of the study. However, there were no incidences of protocol modifications, violations, or deviations.

Frequency and Plans for Auditing Trial Conduct

The following matters were reported to the director in a preestablished format: (1) a report on the state of the progress of the study was made once a year; (2) study discontinuation or temporary suspension, restarting the temporary suspension, and ending the study; (3) occurrence of serious adverse events; (4) annual report on the state of the study progress; and (5) publication of study results.

Under the Clinical Trial Act in Japan, auditing the trial proceedings is not required in the absence of any conflicts of interest. No audits were conducted in this study.

Dissemination Plans

The results of this study belong to the NCGM. The first author, coauthors, and order of the papers that published the findings from this study were decided by the study manager. The main published papers was submitted to an English-language journal upon the completion of the primary end point analysis. If multiple papers were to be published, the themes and authors

XSL•FO
RenderX

of the papers will be coordinated by the principal researcher. The materials and results to appear in the papers will also be agreed upon by the study group before submission. The main analysis paper of this study was published in a peer-reviewed journal [16].

Results

The study protocol was reviewed and approved by the certified review board of the NCGM (NCGM-C-003129-03) on April 20, 2020. Changes to the study plan were submitted for review by the certified review board and approved before implementation. Recruitment was completed on March 28, 2019, and the study was completed on (last adult participant and last time point) March 31, 2021. The data were analyzed and the main results of the study have already been published in a peer-reviewed journal [16]. The findings indicated that PrEP is a highly effective and feasible strategy against HIV infection in terms of prophylactic response, retention, and compliance.

Discussion

This protocol of an investigator-initiated clinical study was designed to evaluate the safety and efficacy of PrEP in PrEP users as well as the compliance with PrEP medication among the users. It also aimed to assess the social, medical, and economic benefits of PrEP in Japan.

In Japan, MSM population covers less than 5% of male population. However, in 2018, the MSM population disproportionately accounted for 75.4% of HIV cases and 58.1% of AIDS cases in men and 66% of new HIV reports [12]. Despite having an established and equitable health coverage system, funding for treatment and preventive initiatives against HIV in Japan is limited. The national health insurance system of the country does not subsidize PrEP and access and uptake of PrEP are scarce [17]. An ethnographic study has shown that awareness and the observable presence of PrEP in conservative Japanese community is sparse [17]. Furthermore, the country lacks publicly funded health services focused on MSM resulting in insufficient and uncoordinated preventive activities against HIV. These gaps reflect the vulnerability of Japanese population to HIV [17,18]. Therefore, conducting PrEP trials among MSM population are the need of the hour to nudge the Japanese policy makers to steer in the direction of a more comprehensive HIV response and management plan. Our planned trial design was an invasive interventional study that administered the anti-HIV drug Truvada to prevent HIV infection and evaluated HIV and STI tests.

The results of the feasibility study conducted on the basis of this protocol showed that among 309 MSM registered in the cohort, 124 were included in the study on the basis of defined inclusion criteria. However, the rest of the patients were continuously monitored. We found that the incidents of HIV infection reduced significantly among PrEP users (0 infections, 235.5 person-years) compared to non-PrEP users (11 infections [3.4%/y], 318.9 person-years; P=.01) [16].

The government of Japan is implementing rapid measures to increase the number of foreign visitors to Japan to stimulate the travel economy. To ensure public health and reduce the spread of HIV and other STIs, it is necessary to assess the social, medical, and economic effects of PrEP as an effective counter measure of these diseases. An analysis of an economic model developed with epidemiological estimates for each of the 47 prefectures in Japan showed that over a 30-year time horizon, once daily use of PrEP among MSM resulted in 48% to 69% reduction of HIV infections and AIDS cases across all prefectures in Japan in comparison to no PrEP. Daily use of PrEP was cost-effective, owing to lower monitoring costs and general medical costs across Japan, especially in the prefectures with higher incidence of HIV [19]. PrEP adherence differs considerably among by countries and regions [20]. Nevertheless, the study conducted based on this protocol showed that the adherence to PrEP was as high as 95% and the retention rate at 2 years was approximately 80%, probably due to increased awareness [16].

The major strength of this protocol was the provision of capturing detailed information regarding risk behavior and STI incidence not only from MSM before and after PrEP but also from non-PrEP users that acted as a reference group. The use of PrEP to counter HIV infection is often considered to be associated with reduced condom use and increase in number of sexual partners, eventually leading to higher risk of developing STIs [21,22]. The design of the trial helped to shed light on the sexual behavior of PrEP users. The study based on this trial revealed a decrease in condom use and an increase in the incidence of STIs, including syphilis, chlamydia, and gonorrhea infection after PrEP initiation.

While this protocol led to a successful clinical study that provided important insights, a few limitations were perceived. First, this single-center trial involved a relatively small sample size. Second, the single-arm study design made the comparison of effectiveness of PrEP in HIV prevention with other randomized control trials difficult. Nevertheless, we succeeded in recruiting high-risk participants as no other organizations in Japan offered SH services to HIV-free MSM population. In addition, although the preventive effects of PrEP against HIV were already demonstrated in a number of RCTs, and the local HIV incidence (3.8%/y) reflected a risk considerably high enough for PrEP indication [13].

Although the safety of Truvada has been demonstrated in HIV treatment as well as for prophylactic use in PrEP, adverse events caused by Truvada may be considered a disadvantage of study participation because there is no history of Truvada use for PrEP in Japan. Another disadvantage of participation is the minor invasiveness of blood collection and the need for an additional 7 mL of blood for storage.

Conversely, the participants were expected to obtain a potent prophylactic effect against HIV infection, which can be considered a major benefit of participation in this study. Regarding the burden of cost for the participants, the Truvada drug used for PrEP and some HIV and STI tests were free for the participants.

XSL•FO
RenderX

After completion of the study based on this protocol, 78% participants continued receiving PrEP by buying tenofovir or FTC themselves, reflecting a strong demand for PrEP in this population [16].

Overall, the outcomes of the study based on this protocol strongly supported the implementation of PrEP in Japan in addition to promoting the use of condoms and safe sexual behaviors. The results of this study may lead to the approval of Truvada for PrEP use in Japan, a development that promises to help stop the spread of HIV.

Acknowledgments

Editorial support in the form of medical writing, assembling tables based on the authors' detailed directions, collating author comments, copyediting, fact-checking, and referencing was provided by Editage and Cactus Communications. This study was supported in part by Health and Labour Sciences Research Grants (H29-AIDS-009 and 20HB1007) from the Ministry of Health, Labour, and Welfare of Japan (principal researcher: DM). Expenditure included testing fees (serum creatinine, syphilis, HIV testing, pharyngeal and anal gonorrhea, and chlamydia). Torii Pharmaceutical Co, Ltd and Japan Tobacco Inc provided 3600 bottles (30 tablets per bottle) of the study drug Truvada (tenofovir disoproxil fumarate [TDF] and emtricitabine [FTC]). Principal investigator responsible for all aspects of the study was done by DM. Study planning and operations was done by Yoshimi Kikuchi. Study support services (clinical research coodinator) was handled by MT. Preparing the paper was performed by JT-H and DT.

Data Availability

The data sets generated and analyzed during this study are available from the corresponding author on reasonable request.

Conflicts of Interest

Torii Pharmaceutical provided the study drug but was not involved in any way during the planning, analysis, and publication of the study. Conflicts of interest with companies providing the study drug were reviewed and managed appropriately by the National Center for Global Health and Medicine Conflict of Interest Management Committee. SO received research grants from ViiV Healthcare and Gilead Sciences, and honorariums for lectures from ViiV Healthcare and Gilead Sciences.

Abstract

Background: Hip and knee osteoarthritis is common and leads to pain, stiffness, and disability. Clinical practice guidelines provide recommendations based on the best available evidence to assist health care professionals and patients in clinical decision-making. However, several studies have reported a gap between guideline recommendations and clinical practice in physiotherapy. Improved implementation strategies and the removal of existing barriers may facilitate the transfer of evidence into clinical practice and contribute to optimized quality of care.

Objective: This paper presents the protocol for a study that aims to describe the current physiotherapy practice in patients with hip and knee osteoarthritis and to investigate physiotherapists' adherence to clinical practice guidelines, to identify and specify barriers to and facilitators of guideline use and implementation, and to develop and pilot test a theory-based tailored implementation intervention aiming to increase guideline use in osteoarthritis care.

Methods: The research project is divided into 4 parts. During the first part, we will conduct a nationwide web-based survey among German physiotherapists to evaluate the current management of hip and knee osteoarthritis and to evaluate whether treatment aligns with guideline recommendations. Subsequently, semistructured interviews will be conducted to specify barriers to and facilitators of guideline use and implementation among physiotherapists (part 2). On the basis of these findings, in part 3, we will develop a theory-driven implementation intervention based on the Theoretical Domains Framework and the Behavior Change Wheel, which will be evaluated in a controlled pilot study in terms of effectiveness, feasibility, and acceptability (part 4).

Results: Data collection of the web-based survey among German physiotherapists (part 1) was completed in December 2021. The semistructured interviews (part 2) were conducted between January and September 2023. Recruitment of physiotherapy practices to participate in the development of the implementation intervention is expected to start in January 2024.

Conclusions: This research project aims to develop a theory-driven implementation intervention to facilitate the transfer of evidence from hip and knee osteoarthritis guidelines in physiotherapy practice. We hypothesize that successful implementation will lead to increased guideline adherence in physiotherapists, which in turn will improve the quality of care. The results from our project will provide valuable knowledge concerning the development process and effectiveness of tailored implementation interventions.

KEYWORDS

osteoarthritis; physiotherapy; guideline; implementation; clinical practice

Introduction

Osteoarthritis is the most common chronic joint disease and is mainly present in the lower extremity joints such as hips and knees [1]. In Germany, the prevalence of outpatient diagnosed hip and knee osteoarthritis in older patients is 21.8%, whereas osteoarthritis is more common in women than in men and its prevalence increases with age [2]. Osteoarthritis is characterized by inflammation and degenerative changes in the joints, causing pain, stiffness, functional disability, and reduced quality of life [3]. In addition to its effects on individuals, osteoarthritis is associated with an enormous burden on the health care system. The average annual costs per patient living with osteoarthritis in the lower extremities worldwide were estimated to be €11,100 (US $11,722) [4]. In Germany, the direct costs for osteoarthritis (*International Classification of Diseases, 10th Revision*: M15-M19) amounted to €7.62 (US $8.05) billion in 2008. Data on indirect costs are not available, but with 114,975 cases of work incapacity owing to knee osteoarthritis and 44,637 cases owing to hip osteoarthritis (2011), an enormous burden on the national economy can be assumed [5].

There are numerous treatment options available including conservative (eg, physiotherapy) and operative methods to manage hip and knee osteoarthritis, which vary with respect to efficacy and costs. To facilitate the implementation of research findings in clinical practice, clinical practice guidelines (CPGs) summarizing study results have been developed. CPGs are described as "statements that include recommendations intended to optimize patient care that are informed by a systematic review of evidence and an assessment of the benefits and harms of alternative care options" [6].

In recent CPGs [7-9], conservative nonpharmacological methods, particularly education and therapeutic exercise (and weight loss if overweight or obese), are widely recommended and are seen as first-line treatment for patients with hip and knee osteoarthritis. Other interventions (eg, pain medication or gait aids) can be used to relieve pain and to support first-line treatment. Joint replacement surgery is usually considered when osteoarthritis symptoms become intolerable and significantly affect quality of life, and other nonsurgical therapies have been ineffective or unsuitable [9].

Physiotherapeutic interventions play a key role in the conservative management of hip and knee osteoarthritis and have been shown to be effective in improving pain, quality of life, and physical function [10]. On the basis of the German health insurance data, Postler et al [2] identified that approximately 63.4% of patients (aged ≥60 y) diagnosed with hip or knee osteoarthritis receive pain medication (44.1% of which are nonsteroidal anti-inflammatory drugs), whereas physiotherapy is prescribed only to 43.1% of the patients, with decreasing numbers with increasing age.

However, deficits in osteoarthritis management are not only evident in physicians' prescribing behavior. Recent studies involving physiotherapists from Italy [11] and Belgium [12] indicated a gap between clinical practice and research findings, as treatment of hip and knee osteoarthritis often is not in line with current guideline recommendations. Instead of providing first-line treatments, many physiotherapists include interventions that do not contribute to high-quality care. This is consistent with findings from a systematic review in which Zadro et al [13] found that the median percentage of physiotherapists who chose treatments recommended in CPGs (eg, advice to stay active, aerobic, and strengthening exercises) was 58%, whereas 98% of the physiotherapists provided treatments with low or conflicting evidence in the management of knee osteoarthritis (eg, exercise that is neither aerobic nor strengthening). With regard to the nonpharmacological treatment of people with osteoarthritis, Hagen et al [14] noted that there is substantial room for improvement in the care of individual patients.

The limited use of evidence in clinical practice is a well-known problem, and the reasons for not using CPGs are manifold. Important barriers to the implementation of CPGs in physiotherapy mentioned in the literature are, for example, lack of time, lack of generalizability of research findings to individual patients, conflicting patient preferences, and lack of support in the workplace [15-19]. In addition, physiotherapists are often unaware of current CPGs [20,21]. Owing to the characteristics of the German health care system and the education of most physiotherapists in Germany at vocational schools instead of at institutions of higher education, it can be assumed that there are further barriers specific to the German context.

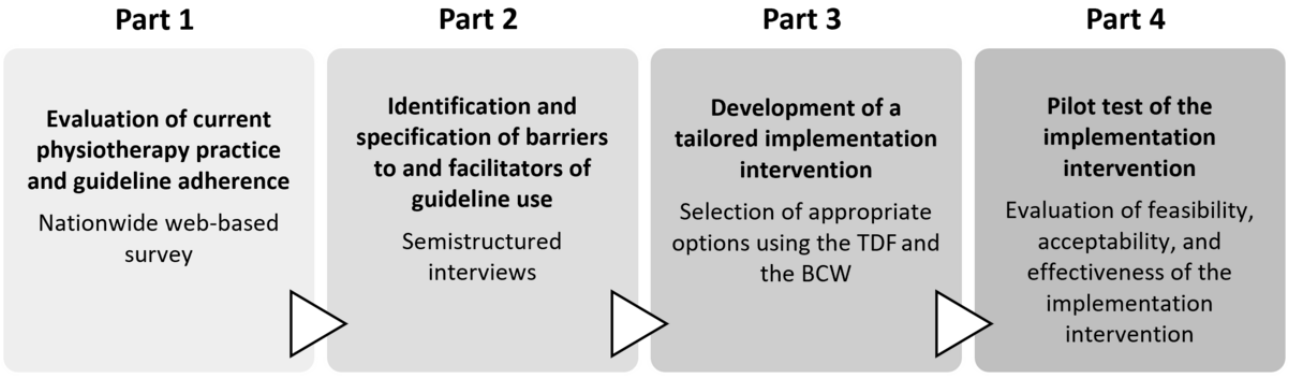
Publication and dissemination of guidelines alone is not sufficient to change clinical practice. It requires organizational change and behavioral change in individual health care professionals toward their use of guideline recommendations. Therefore, CPGs need to be accompanied by evidence-based implementation strategies [17]. There is evidence that tailored implementation programs targeting specific barriers and facilitators are more likely to improve professional practice than nontailored interventions or passive guideline dissemination [22,23]. It is recommended to use theories and frameworks to guide the implementation process and facilitate the identification of determining factors in health care professionals' behavior [24]. Moreover, using theories allows for a better understanding of the generalizability and replicability of implementation interventions [25].

A promising approach to developing a tailored, theory-driven implementation intervention might be the involvement of the Theoretical Domains Framework (TDF) and the Behavior Change Wheel (BCW). As one of the most commonly used theories in health care settings [26], the TDF synthesizes different theories of behavior change into one framework and is commonly used to explore factors that influence clinical behavior and guideline adherence. The 14 domains of the TDF include knowledge; skills; social or professional role and identity; beliefs about capabilities; optimism; beliefs about consequences; reinforcement; intentions; goals; memory, attention, and decision processes; environmental context and

XSL•FO
RenderX

resources; social influences; emotion; and behavioral regulation [27]. The BCW is a synthesis of 19 theoretical frameworks of behavior change and provides a systematic approach to developing a tailored guideline implementation intervention. The barriers and facilitators identified through the TDF can be used to expand the Capability, Opportunity, Motivation–Behavior components (COM-B), the core of the BCW, which indicates that behavior change occurs when there is a change in an individual's capability, opportunity, and motivation [28].

To date, little is known regarding the current physiotherapy practice for hip and knee osteoarthritis in Germany and whether its management is in line with guideline recommendations. We hypothesize that guideline adherence among physiotherapists is low, as in Germany, an academic level of physiotherapy education is not mandatory and only about 3% of the physiotherapists have graduated from higher educational institutions [29]. Most physiotherapists in Germany are trained at vocational schools where skills and knowledge regarding the implementation of guidelines and evidence-based practice are not an integral part of the curriculum. Given the burden of the disease and the high costs associated with osteoarthritis, as well as the importance of physiotherapy interventions in the treatment of hip and knee osteoarthritis, it is important to address this lack of research. Developing a tailored implementation intervention can increase evidence uptake in clinical practice and thus, improve quality of health care.



The objectives of the research project are (1) to describe the current physiotherapy practice in patients with hip and knee osteoarthritis in Germany and to investigate physiotherapists' adherence to CPG recommendations; (2) to identify and specify barriers to and facilitators of guideline use and implementation; and (3) to develop and (4) pilot test a theory-based tailored implementation intervention that aims to increase guideline use in the physiotherapy care of patients with hip and knee osteoarthritis in the German context.

Methods

Overview

The study was divided into 4 parts (Figure 1). In the first part, we will evaluate the current physiotherapy practice regarding the management of patients with hip and knee osteoarthritis. Subsequently, we will identify and specify barriers to and facilitators of guideline use among physiotherapists using a qualitative approach. On the basis of these findings, in part 3, we will develop a tailored implementation intervention to increase guideline use in clinical practice, which will be evaluated in a pilot study in part 4.

Figure 1. Flowchart of study parts. BCW: Behavior Change Wheel; TDF: Theoretical Domains Framework.

The evaluation and implementation of guideline-adherent care will be based on the German guidelines for hip and knee osteoarthritis [30,31]. These guidelines are aimed specifically at physicians working in musculoskeletal care and serve as information for general practitioners, physiotherapists, and occupational therapists, for example.

Part 1: Evaluation of Current Physiotherapy Practice and Guideline Adherence

A nationwide web-based survey among physiotherapists will be conducted to evaluate the current management of patients with hip and knee osteoarthritis and to explore adherence from physiotherapists to guideline recommendations. The reporting of the study will follow the Strengthening the Reporting of Observational Studies in Epidemiology statement [32] and the Consensus-Based Checklist for Reporting of Survey Studies [33].

A self-administered questionnaire will be developed based on the recommendations regarding conservative nonpharmacological management listed in the German CPGs for hip and knee osteoarthritis [30,31]. The questionnaire will be divided into three sections to assess (1) the demographic and working characteristics of the participants, (2) the current physiotherapy practice in patients with hip and knee osteoarthritis, and (3) perceived barriers to the implementation and clinical use of guidelines. We will use a mix of multiple choice questions and yes or no questions. To evaluate the current clinical practice, study participants will be asked to rate different treatment modalities for osteoarthritis on a 4-point Likert-type scale (1=never, 2=sometimes, 3=mostly, and 4=always). Specific barriers and facilitators regarding the German guidelines for hip and knee osteoarthritis will be assessed using the translated and cultural adapted version of "The Barriers and Facilitators Assessment Instrument" [34]. For participants who reject using CPGs in clinical practice, reasons against guideline use will be

XSL•FO
RenderX

explored based on barriers identified from literature. Adaptive questioning will be used to minimize the response burden and to reduce complexity of the questions. The web-based survey will be conducted using LimeSurvey, a free and open source web-based tool for research projects. The survey will be accessible without restrictions (password or registration) via an internet link to the LimeSurvey platform with no incentives offered. Before initiating the survey, the study participants have to read and accept written informed consent and are required to verify self-reported eligibility criteria. Participation will be voluntary and anonymous. To improve the quality and understanding of the questionnaire, a pretest of the web-based survey with 10 physiotherapists representative of the physiotherapists targeted with the survey will be conducted.

We will include physiotherapists mainly working in Germany who treat patients with hip or knee osteoarthritis in clinical practice and who are able to read and speak the German language. Only physiotherapists with a professional degree will be eligible; therefore, students will be excluded. The recruitment of participants will be initiated through announcements and calls on different physiotherapeutic networks, social media, and personal contacts of the study team. According to the snowball sampling approach, study participants will be invited to further distribute the participation invitation. As this study has an explorative character, no sample size calculation will be performed. There are approximately 203,000 physiotherapists working in Germany [29], but the number of physiotherapists involved in osteoarthritis care is unclear. We will target a total sample size of 1000 participants to allow regression analyses with subgroups of sufficient sample size. As survey participation is anonymous and different recruitment strategies will be used to maximize the response rate, there is a risk of duplicate responses. Therefore, we will systematically review all the responses to identify any surveys with matching demographics and answers.

Data analysis will be performed using the R software (version 4.0.3; R Foundation for Statistical Computing). Participants' characteristics and current clinical practice will be analyzed using descriptive statistics. Guideline adherence will be defined as accordance between recommendations retrieved from the German guidelines for knee and hip osteoarthritis [30,31] and the therapists' treatment choices. As there is no standardized method to evaluate guideline adherence, we will use 2 different approaches that have been recently used in previous studies. In the first approach, guideline adherence will be determined using a points system. The participant's treatment choices will be compared with the current guideline recommendations, and in case of adherent behavior, each will be scored with one point. The benchmarks for good adherence will be set at ≥80% of the maximally achievable points [20]. Assessing guideline adherence on the basis of the methods of Battista et al [11], participants will be considered as *delivering*, *partially delivering*, and *nondelivering* depending on their chosen treatment. For example, a participant will be classified *delivering* if all recommended interventions have been chosen without considering nonrecommended treatments. To assess possible determinants of guideline adherence, regression analyses will be conducted. The potential determinants will be selected based on the literature. The level of statistical significance will be set at $P<.05$.

Part 2: Identification and Specification of Barriers to and Facilitators of Guideline Use

A qualitative approach including semistructured interviews will be used to identify and specify barriers and facilitators to guideline use in the management of hip and knee osteoarthritis specifically for the German context. The reporting of this study will be in accordance with the Consolidated Criteria for Reporting Qualitative Research [35].

Purposive sampling will be used to gain a wide range of information. We aim to recruit a diverse sample of physiotherapists based on age, gender, work experience, and professional education level. Only physiotherapists mainly working in Germany who treat patients with hip or knee osteoarthritis in clinical practice and who are able to read and speak the German language will be included. The invitation to participate in one-to-one semistructured interviews will be distributed through announcements and calls on different physiotherapeutic networks, social media, and personal contacts of the study team. Recruitment will continue until data saturation has been reached (a minimum of 10 participants). Data saturation will be defined as the point when 3 consecutive interviews had been conducted with no additional information on barriers and facilitators emerging [36].

An interview guide will be developed based on the TDF [27]. Questions will be informed by key findings from the previous survey and information on barriers and facilitators to guideline use identified through literature. The guide will explore the domains of the TDF to understand the factors that influence guideline use in clinical practice in the management of hip or knee osteoarthritis. The interview guide will be pilot tested with 2 physiotherapists before use. Feedback on comprehension and content will subsequently be incorporated into the interview guide after discussion with the study team.

The interviews are anticipated to last approximately 45 to 60 minutes and will be conducted via telephone or video call. Before entering the study, the participants will receive a written informed consent. Interviews will be audio-recorded and transcribed verbatim. Data collection and storage will be done pseudonymously. To give participants the opportunity to review the transcript and to make any modifications, the transcripts will be sent to the participants for member checking.

Thematic analysis following the 6 stages from Braun and Clarke [37] will be used to analyze the interviews. The first transcript from the semistructured interview will be pilot coded independently by 2 researchers to develop a coding strategy. The remaining interviews will be analyzed iteratively by the first author who will discuss any difficulties with a second researcher. Finally, the barriers and facilitators will be mapped onto relevant domains from the TDF. Data will be analyzed using MAXQDA (version 22; VERBI GmbH) software.

Part 3: Development of a Tailored Implementation Intervention

Overview

In this step, 6 outpatient physiotherapy practices will be recruited, 3 of which will be randomly selected to participate in the development process of the tailored intervention. In these physiotherapy practices, the intervention will be implemented (study part 4), whereas the remaining practices will serve as a control group. We will include physiotherapy practices in the region of Brandenburg and Saxony (Germany) with >5 physiotherapists who treat patients with hip or knee osteoarthritis in clinical practice.

The development of the implementation intervention will be guided by the BCW and follows 3 stages, as outlined by Michie et al [28]: understand the target behavior, identify intervention options, and identify content and implementation options. These can be further divided into key substeps as illustrated in Figure 2 [28].

Figure 2. Stages and steps involved in the development of an intervention using the Behavior Change Wheel.

Stage 1: Understand the Target Behavior

The key barriers identified from the semistructured interviews (part 2) will be used to define the problem in behavioral terms and to specify the behavior and target population (step 1). From a list of all potential candidate behaviors, the study team will choose 1 or 2 core behaviors that appear to be promising in increasing guideline adherence in physiotherapists (step 2). The target behavior will be selected considering each potential impact, likelihood of change, spillover effect, and ease of measurement. After specifying the target behavior in detail and its context (who, what, when, where, how often, and with whom; step 3), focus groups will be conducted to identify what needs to change in the individual or the environment to achieve the desired behavior change (step 4).

The reporting of the focus groups will be guided by the Consolidated Criteria for Reporting Qualitative Research checklist [35]. One to 2 focus groups will be conducted at each participating physiotherapy practice. The focus groups will take place at the participants' worksite and will be moderated by 2 members of the research team. Mixed groups of 6 to 10 participants recruited from each physiotherapy practice representing different stakeholders (eg, physiotherapists, patients, management, administration, and other health professionals) will be invited to participate to promote diversity and to encourage a wide range of information on what needs to change regarding the target behavior. All participants will receive and approve a written informed consent before initiating the study. The topic guide will be developed using the TDF. The standardized guide will be used across all focus groups with some flexibility through open questions to allow further discussion between participants. Before the focus groups, basic demographics (eg, age, gender, job type, and working hours) will be collected from each participant. The focus group discussions will be audio-recorded while simultaneously handwritten field notes capturing relevant nonverbal responses or dynamics of the group will be documented. Data from the focus groups will be transcribed verbatim and will be analyzed following the same process used for the semistructured interviews described in the *Part 2: Identification and Specification of Barriers to and Facilitators of Guideline Use* section.

Stage 2: Identify Intervention Options

On the basis of the findings from the focus groups, relevant intervention functions will be identified using a matrix that systematically maps TDF domains to intervention functions (eg, education, training, persuasion; step 5). As changes at the policy level will be beyond the scope and time constraints of our project, and intervention programs targeting individual level and local barriers have been shown to be effective [38], policy categories (eg, regulation, communication or marketing, and service provision) provided by the BCW guidance will not be considered in this study (step 6). To select the most appropriate and effective intervention functions for our implementation intervention, the affordability, practicability, effectiveness and cost effectiveness, acceptability, side effects or safety, and equity criteria will be used [28].

Stage 3: Identify Content and Implementation Options

On the basis of the intervention functions selected in step 5, behavior change techniques (BCTs) will be identified (step 7). We will use BCT taxonomy (version 1; BCTTV1) [39] to generate a list of BCTs mapped to our intervention functions. Regarding the affordability, practicability, effectiveness and cost effectiveness, acceptability, side effects or safety, and equity criteria, the research team will work in close collaboration with

XSL•FO
RenderX

the stakeholders from the participating physiotherapy practices and discuss the included BCTs as well as possible modes of delivery for the intervention (step 8). Those that are likely to be the most effective and feasible to increase guideline adherence will be selected. Reporting of the intervention developed will be consistent with the recommendations for specifying and reporting implementation strategies in research studies proposed by Proctor et al [40] and the Template for Intervention Description and Replication checklist [41].

Part 4: Pilot Test of the Implementation Intervention

A controlled pilot study will be conducted to evaluate the effectiveness, feasibility, and acceptability of the tailored intervention implementation. The pilot study will simultaneously test a clinical intervention and an implementation intervention or strategy and thus will be a hybrid study [42]. The Standards for Reporting Implementation Studies statement [43] and the CONSORT (Consolidated Standards of Reporting Trials) statement [44] for pilot and feasibility trials will be used to guide the reporting of study methods and results.

The previously designed intervention will be implemented and evaluated at the 3 physiotherapy practices recruited in part 3 that participated in the development process, whereas the other 3 recruited practices will serve as the control group.

All physiotherapists involved in osteoarthritis management will be invited to participate. Patients will be eligible if they (1) are aged ≥18 years, (2) are primarily diagnosed with hip or knee osteoarthritis, and (3) have no restraint to receive physiotherapy. Participation will be voluntary, and informed consent will be obtained before the recruitment of any participant into the study.

To explore effectiveness at the patient level, the assessment of primary patient-relevant outcomes will follow the Outcome Measures in Rheumatology-Osteoarthritis Research Society International core domain set for clinical trials in hip and knee osteoarthritis and will include 5 domains: pain, physical function, quality of life, patient's global assessment of the target joint, and adverse events [45]. Patient outcomes will be assessed at baseline, at the end of physiotherapy treatment, and after 6 months. Physiotherapists' adherence to the osteoarthritis guidelines will be evaluated using a documentation questionnaire after each physiotherapy session. The implementation process will be evaluated using the Acceptability of Intervention Measure, Intervention Appropriateness Measure, and the Feasibility of Intervention Measure [46,47]. Additional outcomes will be the recruitment and retention rate [48]. Results from the pilot study will be used to inform sample size calculation for a subsequent study.

Patient and Public Involvement Statement

Patients and the public were not directly involved in the design or conduct, reporting, or dissemination plans of this research.

Ethical Considerations

Ethics approval for each part of the study will be sought from the ethics committee of the Brandenburg University of Technology Cottbus-Senftenberg, Germany. Permission for the nationwide web-based survey (study part 1) and the semistructured interviews (study part 2) has already been obtained from the ethics committee of the Brandenburg University of Technology Cottbus-Senftenberg, Germany (EK2021-10, EK2022-15). Throughout the research project, the principles established in the Declaration of Helsinki [49] will be strictly followed. Participants who are eligible for any part of the study will be informed about the respective objectives, content, and procedures of the study. Written informed consent will be obtained from all patients before enrollment. Participation will be voluntary, and participants are free to withdraw from the study at any moment.

The findings from this research project will be disseminated through open-access publications in international peer-reviewed journals and presentations at national and international scientific meetings. In addition, we will use social media (eg, X, formerly known as Twitter) to spread our findings to the public.

Results

In December 2021, the survey among German physiotherapists was completed, and results on the management of patients with hip and knee osteoarthritis and guideline adherence were published [50] (part 1 of the research project). Ethics approval for the second part of the research project was obtained in August 2022, and the semistructured interviews were conducted between January and September 2023. Recruitment of physiotherapy practices to participate in the development of the implementation intervention is expected to start in January 2024.

Discussion

Overview

The described research project aims to evaluate and improve the implementation of hip and knee osteoarthritis guidelines in physiotherapy in Germany, which to our knowledge has not been performed to date. Considering the burden of disease and the importance of physiotherapy interventions in the management of osteoarthritis, as well as findings from other countries indicating gaps between clinical practice and research findings [11,12], it seems important to address this lack of research.

The implementation of research findings into clinical practice is considered relevant for improving quality of care but is often hindered by various barriers [51]. Although guidelines are considered helpful in translating research findings into clinical practice by providing recommendations that can be used by health care professionals, patients, policy makers, and other stakeholders, many guidelines include no or a variety of guideline implementation tools for different stakeholders [52]. There are few studies on how to choose implementation strategies that address guideline-specific barriers, but education for clinicians or patients and printed materials were the most commonly used strategies for translating guidelines into practice [53]. Holm et al [54] reported that the limited use of CPGs may be because of insufficient knowledge of current evidence or that clinicians and patients may find it difficult to break old habits and abandon existing low-value treatment and also because the increasing number of frameworks and checklists

XSL•FO
RenderX

for guideline implementation makes implementation strategies too comprehensive and complicated.

For the management of people with osteoarthritis, pragmatic approaches to implementing osteoarthritis guidelines exist. For example, Good Life with osteoArthritis in Denmark (GLA:D) or Active with osteoArthritis (ActiveA) have been implemented in several countries [54]. GLA:D, which is currently being implemented in Germany, and ActiveA are both effective in reducing pain intensity and increasing quality of life, physical activity, or physical function [10,55-58]. Østerås et al [59] showed that a structured implementation of ActiveA in primary care resulted in a higher quality of osteoarthritis care as compared with usual care. However, it is unclear if such approaches can be implemented as standard care in the German health care system, as GLA:D does not fit into the German catalog of remedies, which defines the number and type of physiotherapeutic treatments, and is therefore only available based on special contracts with health insurance companies or must be paid for privately by patients. Furthermore, not all patients can (eg, owing to limited access to physiotherapy practices) or want to (eg, because they do not want to train in a group) participate in GLA:D. Therefore, it is necessary to evaluate how to increase guideline use in osteoarthritis care and thus improve the quality of care in addition to the ongoing implementation of GLA:D in Germany. With regard to physiotherapists in Germany, it was recently shown that the implementation of evidence-based practice in clinical practice is insufficient [60]. In a recent nationwide survey on physiotherapy management of low back pain, less than one-third of the participating physiotherapists reported being aware of the National Disease Management Guideline for “non-specific low back pain” or have dealt with its recommendations [20]. Similar results were shown by another survey, in which only 47% of the responding physiotherapists reported being aware of the German guidelines on stroke rehabilitation [61]. One reason for the low awareness of CPGs could be that the entry level for German physiotherapists is vocational school education. Furthermore, physiotherapists report limited access to guidelines [19] and often do not know where to find them [20]. We hypothesize that the physiotherapy management of persons with hip or knee osteoarthritis will most likely not be guideline adherent and therefore needs to be improved, which is the aim of this study.

There are numerous frameworks, models, and theories that provide guidance in developing strategies to facilitate guideline implementation [62]. However, many guideline implementation studies do not report explicit theory use or theory is not used consistently and transparently [26,63]. Choosing the most appropriate theory-driven approach is challenging as such models can be complex, that is, difficult for both researchers and health care practitioners to understand and operationalize, or lack comprehensiveness [64]. Although the TDF and BCW are comparatively new implementation frameworks, they have already been used in several studies to understand and promote the uptake of evidence in clinical practice [65-67], including in the field of physiotherapy [68]. For this research project, we decided to use the TDF as it has proven to be a comprehensive and accessible way to understand the barriers and facilitators to best practice in primary and secondary care in Western countries [64]. There is evidence that TDF-based interview schedules achieve a broader range of responses than when using a nontheoretical approach [69]. Therefore, the TDF is described as an “inclusive” rather than a “selective” approach [70]. The TDF works within the BCW framework as it provides a more detailed understanding of the behavior components of capability, opportunity, and motivation. The BCW provides a systematic and pragmatic approach to developing implementation interventions. It encourages intervention designers to comprehensively consider the full range of options and select those that are most promising for the context. In addition, it allows for a detailed specification of the content using agreed labels and definitions [28].

Conclusions

The results from our project will provide valuable knowledge concerning the development process and effectiveness of an intervention to implement hip or knee osteoarthritis guidelines in physiotherapy practice. We aim to develop an implementation intervention that can also be transferred to other health conditions, with modifications, if necessary. We hypothesize that successful implementation will lead to increased guideline adherence in physiotherapists, which in turn will improve the quality of care.

Acknowledgments

This research was funded by an intramural grant from the Brandenburg University of Technology, Cottbus-Senftenberg (award or grant number is not applicable). The funder had no role in the study design, data collection, analysis and interpretation, decision to publish, or preparation of the manuscript.

Data Availability

The data sets generated during the research project will be available on the Open Science Framework: 10.17605/OSF.IO/A7P3W.

Authors' Contributions

CB, BS, and CK conceptualized the design of the research project and drafted the manuscript. All authors contributed to the development of this manuscript and have read and approved the final version for publication.

Abstract

Background: “Interstitial lung disease” (ILD) is a broad term encompassing diseases of different backgrounds. “Interstitial pneumonia with autoimmune features” (IPAF) is a recent term that implies the presence of autoimmunity.

Objective: This study aims to determine the characteristics of Polish patients with IPAF, compare them with patients with other interstitial pneumonias, and search for the prognostic and diagnostic biomarkers of IPAF in serum and bronchoalveolar lavage fluid (BALF).

Methods: This multicenter prospective study plans to recruit 240 participants divided into 1 study group and 2 control groups. Biological fluid samples will be collected according to Polish Respiratory Society management guidelines and stored at –80°C for further tests. Prospective 5-year observations of 60 newly diagnosed individuals are planned. The study will be divided into subsections. First, we plan to characterize Polish patients with IPAF (study group) against their peers with other ILDs (2 control groups). Control group 1 will comprise patients with idiopathic ILDs, including mainly idiopathic pulmonary fibrosis and nonspecific interstitial pneumonia. Control group 2 will comprise patients with connective tissue disease–associated interstitial lung diseases, such as rheumatoid arthritis, systemic sclerosis, polymyositis, dermatomyositis, Sjögren’s syndrome, mixed connective tissue disease, and systemic lupus erythematosus. Radiological and functional parameters will be analyzed. Patients will be compared in terms of high-resolution computed tomography results, the 6-minute walking test performance, and pulmonary function test parameters. The diagnosis of IPAF will be reassessed on a regular basis through multidisciplinary discussion in order to determine its clinical stability. In the laboratory arm, inflammation and fibrosis pathways will be assessed. Cytokine levels (interleukin 8, transforming growth factor beta 1, chemokine C-C motif ligand [CXCL]18, CXCL1, surfactant protein [SP]-A, SP-D, Krebs von den Lungen-6 protein, and chitinase 1) will be measured in serum and BALF. A comparative analysis of serum and BALF cytokine levels will be performed in order to establish potential differences between systemic and local inflammatory pathways. In the quality of life (QoL) arm of the study, dyspnea and cough and their impact on various aspects of the QoL will be assessed. Depression and anxiety will be measured with the Hospital Anxiety and Depression Modified Scale and the 9-item Patient Health Questionnaire, and potential correlations with symptom prevalence will be assessed.

Results: This study will start recruiting patients to phase 1 in October 2023. The final results will be available in 2028. We plan to publish preliminary results after 2-3 years from the start of phase 1.

Conclusions: This study will be a step toward a better understanding of IPAF etiopathogenesis and outcomes.

KEYWORDS

IPAF; interstitial pneumonia with autoimmune features; CTD; connective tissue disease; interstitial lung disease; idiopathic interstitial pneumonia; lung disease; pneumonia; respiratory; radiology

Introduction

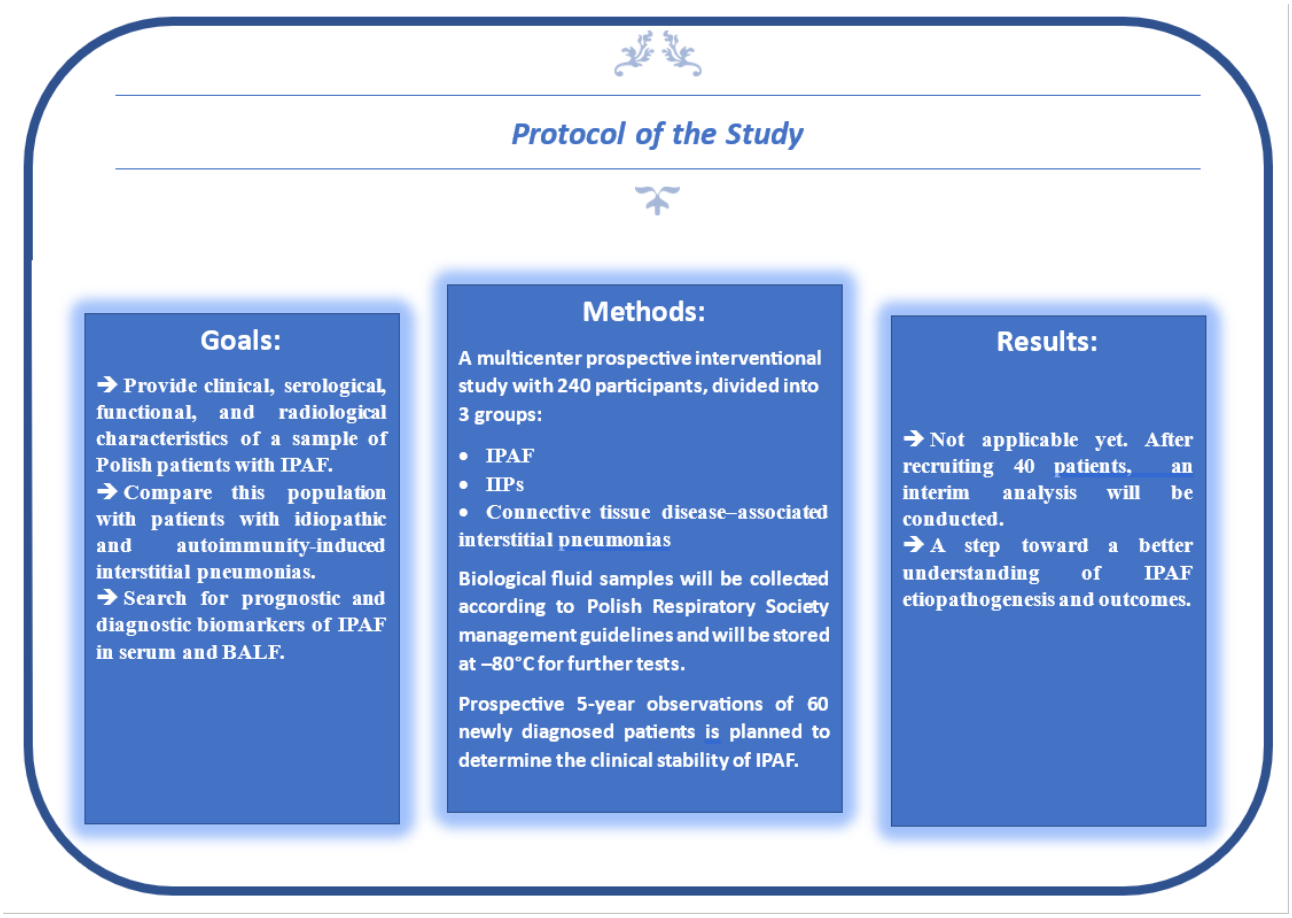
Background

Interstitial pneumonia with autoimmune features (IPAF) was defined in 2015 by the Working Group of the European Respiratory Society (ERS) and the American Thoracic Society (ATS) as interstitial pneumonia with some clinical or serological or both types of features suggesting the presence of an underlying autoimmune disorder. However, no diagnostic criteria for any autoimmune disease are met in these patients during thorough rheumatological workup [1].

"Interstitial lung disease" (ILD) is a broad term encompassing a varied group of disorders. This includes idiopathic interstitial pneumonias (IIPs) and ILDs stemming from environmental exposure or occurring during the course of systemic diseases [2,3].

Data regarding the etiopathogenesis and natural course of IPAF are still lacking. As this is a diagnosis at the crossroads of pulmonology and rheumatology, retrospective and optimally prospective observational studies may cast more light on this subject. Retrospective studies suggest that survival in IPAF does not substantially differ from that in connective tissue disease–associated interstitial lung disease (CTD-ILD) or idiopathic pulmonary fibrosis (IPF), and prospectively, merely 10% of patients with IPAF are reclassified as having CTD-ILD, mostly on the myositis spectrum [4].

Another clinical challenge is in establishing a subset of clinical traits associated with the development of progressive interstitial fibrosis and the loss of lung function. Another retrospective study [5] on individuals with IPAF and CTD-ILD revealed that yearly decline in the forced vital capacity (FVC) is significantly more pronounced in IPAF than in CTD-ILD. Progression is influenced by the presence of anti–Sjögren's syndrome–related antigen A (anti-SSA) antibodies and postexercise pulse increase in the 6-minute walking test (6MWT) [5].



Most available analyses of the ILD-related quality of life (QoL) and the influence of respiratory and psychological symptoms focus on the most prevalent entities (eg, IPF or sarcoidosis). Research on QoL evaluation in IPAF and its comparison with other ILDs is still scarce. Individuals with chronic disease often present with multiple symptoms, which results in decreased functioning and high medical and societal costs [6]. Depression and anxiety also contribute to the burden of chronic disease.

Objectives

The primary purpose of this study is to determine the incidence of IPAF in comparison with IIPs and ILDs occurring during the course of autoimmune diseases in 6 Polish pulmonological centers. Further objectives of this study include determination of the clinical, serological, functional, radiological, and histopathological characteristics of patients with IPAF; analysis of diagnostic strategies for specific IPAF subgroups; determination of the potential diagnostic, predictive, and prognostic features of IPAF; and prospective 5-year assessment of patients with IPAF in order to determine the stability of the diagnosis and potential progression to other diseases (eg, CTDs). Please see Figure 1 for the study protocol. To the best of our knowledge, this is the first prospective study focused on patients with IPAF, CTD-ILD, and IIP in Eastern Europe.

XSL•FO
RenderX

Figure 1. Study protocol. BALF: bronchoalveolar lavage fluid; IIP: idiopathic interstitial pneumonia; IPAF: interstitial pneumonia with autoimmune features.

Methods

Study Population

Inclusion criteria are as follows: individuals with ILDs, aged ≥18 years, and able to provide informed consent.

The study group will comprise patients with IPAF defined according to the criteria established by the Working Group of the ERS and the ATS [1]. Control group 1 will comprise patients with the following CTD-ILDs: rheumatoid arthritis (RA), systemic sclerosis (SSc), polymyositis (PM), dermatomyositis (DM), Sjögren's syndrome (SS), mixed connective tissue disease (MCTD), and systemic lupus erythematosus (SLE) diagnosed according to the diagnostic criteria issued by the European League Against Rheumatism (EULAR) or the American College of Rheumatology (ACR). Control group 2 will comprise patients with the following IIPs: IPF, nonspecific interstitial pneumonia (NSIP), cryptogenic organizing pneumonia (COP), acute interstitial pneumonia (AIP), respiratory bronchiolitis–associated interstitial lung disease (RB-ILD), desquamative interstitial pneumonia (DIP), and lymphocytic interstitial pneumonia (LIP). Previously untreated patients with a new diagnosis of ILD were recruited for a pilot study (a separate population of patients) [7].

Exclusion criteria include age<18 years; respiratory tract infection, including minor upper respiratory tract infections (eg, the common cold) 4 weeks prior to the diagnostic process; asthma; tuberculosis; asbestosis; chronic hypersensitivity pneumonia; Hermansky-Pudlak syndrome; and other causes of genetic ILDs (eg, lymphangioleiomyomatosis, tuberous sclerosis complex [TSC], Birt-Hogg-Dubé syndrome, dyskeratosis congenita, familial forms of ILD, immunodeficiency syndromes); a history of therapy for ILD, including systemic glucocorticosteroids (GCs; both pulsed and long-term low-dose therapy); pregnancy and nursing; malignancy; HIV seropositivity; and a lack of ability to provide informed consent. For the QoL arm of the study, we will also exclude participants unable to communicate verbally.

Ethical Considerations

The study will be carried out according to the Code of Ethics of the World Medical Association (Declaration of Helsinki). This protocol was reviewed and approved by the Ethical Board Committee of the Medical University of Silesia (decision no. KNW/0022/KB1/130/18/19). The trial is registered with reference number NCT03870828. All participants will sign the informed consent form prior to recruitment and will be informed of their right to waive consent at any time without a negative effect on their care. The informed consent form was reviewed and accepted by the Ethical Board Committee in terms of informativeness and understandability. The form allows for clinical data collection and secondary analysis. A copy of the form will be provided to each participant.

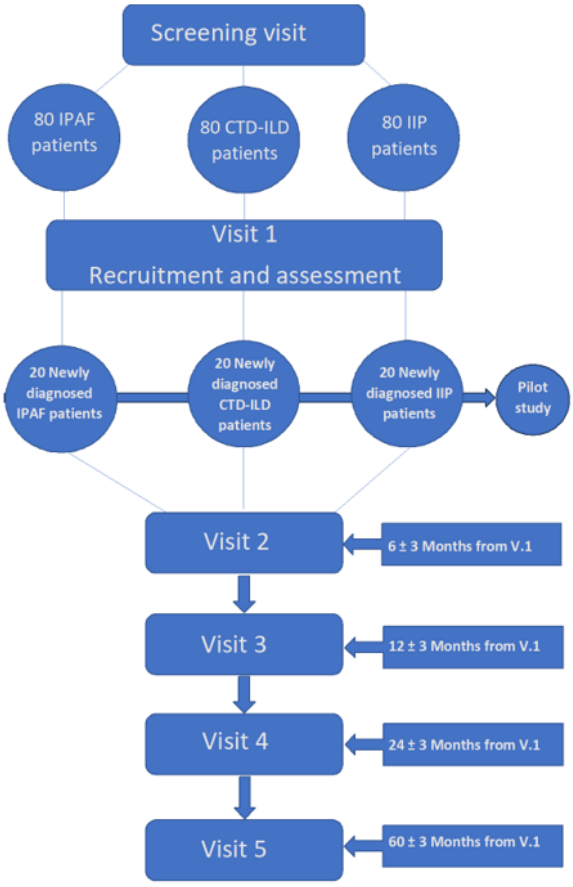
The study team will explain data analysis, the study duration, and objectives to the participants. We find it worth mentioning

XSL•FO
RenderX

that in addition to drawing larger volumes of blood, storing biological fluids, and completing the questionnaires, no procedures beyond standard care will be performed. Therefore, participants will not be burdened with additional risks or prolongation of hospitalization/outpatient clinic visits. Study data will be deidentified to protect the privacy of participants. Data confidentiality will be maintained. No monetary compensation will be given to the participants. Voluntary participation and the time of the participants will be respected.

Study Design

Phase 1



All patients meeting the inclusion criteria and not meeting the exclusion criteria regardless of prior treatment history will be recruited to phase 1 of the study. The recruitment process duration is estimated at 12 months. The previous recruitment of 40 patients led to a pilot study [7], which impacted further study design. The maximum number of patients included in this phase will be 80 (33.3%) in the IPAF group, 80 (33.3%) in the CTD-ILD group, and 80 (33.3%) in the IIP group.

Phase 2

Only patients with newly diagnosed disease (eg, no prior diagnosis of ILD and, hence, no prior treatment) will be recruited. The estimated recruitment duration is 36 months. The number of patients to be included in this phase will be 20 (33.3%) in the IPAF group, 20 (33.3%) in the CTD-ILD group (only those with RA, SSc, PM/DM), and 20 (33.3%) in the IIP group (only those with IPF, NSIP, COP, LIP; optimally 10, 50%, patients in the IPF subgroup and 10, 50%, in the non-IPF subgroup). Patients who were previously recruited to phase 1 of the study and meet the inclusion criteria of phase 2 may also be included.

Please see Figure 2 for a flowchart of the study design.

Figure 2. Flowchart of the study design. CTD-ILD: connective tissue disease–associated interstitial lung disease; IIP: idiopathic interstitial pneumonia; IPAF: interstitial pneumonia with autoimmune features; V: visit.

Visit 1

A thorough medical history will be obtained using the Visit 1 questionnaire. During the first hospitalization, the following procedures will be performed:

- Pulmonary function tests (PFTs)
- Depression and anxiety assessment
- Blood analysis
- Fiberoptic bronchoscopy (FOB) with bronchoalveolar lavage (BAL) and bronchial mucosa sampling
- The 6MWT
- Computed tomography (CT)
- Transthoracic echocardiography (TTE)

Visit 2

Only patients who qualify for phase 2 of the study will have further visits (60 newly diagnosed patients). The following

XSL•FO
RenderX

procedures will be performed after an average of 6 (SD 3) months from visit 1:

- The Visit 2 questionnaire
- Cough assessment
- Dyspnea assessment
- Depression and anxiety assessment
- PFTs, the 6MWT, and oxygen saturation (SpO2) measurement
- Arterial blood gas (ABG) analysis (if indicated)

Visit 3

The following procedures will be performed after an average of 12 (SD 3) months from visit 1:

- The Visit 2 questionnaire
- Cough assessment
- Dyspnea assessment
- Depression and anxiety assessment
- PFTs and the 6MWT
- High-resolution computed tomography (HRCT)
- Blood sampling (including testing for autoantibodies and potential biomarkers)
- FOB with BAL (optionally, if clinically indicated)
- Capillary blood gas (CBG) analysis
- TTE
- Rheumatological consultation

Visit 4

The following procedures will be performed after an average of 24 (SD 3) months from visit 1:

- The Visit 2 questionnaire
- Cough assessment
- Dyspnea assessment
- Depression and anxiety assessment
- PFTs and the 6MWT
- HRCT (if clinically indicated)
- Blood sampling (including testing for autoantibodies and potential biomarkers)
- FOB with BAL (if clinically indicated)
- CBG analysis

Visit 5

The following procedures will be performed after an average of 60 (SD 3) months from visit 1:

- The Visit 2 questionnaire
- Cough assessment
- Dyspnea assessment
- Depression and anxiety assessment
- PFTs and the 6MWT
- HRCT (if clinically indicated)
- Blood sampling (including testing for autoantibodies and potential biomarkers)
- FOB with BAL (if clinically indicated)
- CBG analysis
- Rheumatological consultation

Diagnostic Procedures

Pulmonary Function Tests

PFTs will include spirometry with a reversibility test (in the case of obstruction), body plethysmography, and diffusion capacity for carbon monoxide (DLCO). Both absolute and predicted values will be recorded: forced expiratory volume in 1 second (FEV_1), FVC, vital capacity (VC), FEV_1/VC ratio, total lung capacity (TLC), diffusing capacity for carbon monoxide measured by the single-breath method (DLCO SB), inspiratory thoracic gas volume (ITGV), and residual volume/total lung capacity (RV/TLC) ratio. Cough assessment will be conducted using the Leicester Cough Questionnaire and numeric scale. Dyspnea assessment will be performed using the Likert scale and the Modified Borg Scale.

Depression and Anxiety

Depression and anxiety assessment will be conducted using the Hospital Anxiety and Depression Modified Scale (HADS-M) and the 9-item Patient Health Questionnaire (PHQ-9).

Blood Analysis

Briefly, a vein will be punctured in order to take a blood sample, and 30 mL of blood will be drawn. Next, 15 mL of plasma and 15 mL of full blood will be stored separately at –80°C. The following will be analyzed: N-terminal prohormone of brain natriuretic peptide (NT-proBNP) biomarkers routinely used during rheumatological workup and potential IPAF biomarkers. For this, 15 mL of venous blood will be drawn and divided into 2 parts (10 mL and 5 mL), and no anticoagulant will be added to the samples.

The first sample (10 mL) will be sent to the local laboratory for routine analysis of NT-proBNP and rheumatological factor (RF) and for anti–cyclic citrullinated peptide (anti-CCP) and antinuclear antibody (ANA) screening tests. In the case of the confirmed presence of ANAs and the determination of a fluorescence pattern (eg, homogenous, speckled, peripheral, nucleolar), further tests will be ordered: anti–double-stranded DNA (anti-dsDNA), anti-Smith (anti-SM), anti-SSA/Ro, anti-SSB/La, anti–topoisomerase I (anti-Scl70), and antiribonucleoprotein (anti-RNP) antibodies and myositis-specific autoantibodies, such as anti–histidyl-tRNA synthetase (anti-Jo1), anti–threonyl-tRNA synthetase (anti-PL7), anti–alanyl-tRNA synthetase (anti-PL12), anti–Mi2 antigen (anti-Mi2), anti–human exosome complex (anti-PmScl), and anti–melanoma differentiation–associated 5 (anti-MDA5) antibodies.

From the second sample of 5 mL, after clot formation, approximately 2.5 mL of serum will be separated and then divided into 5 portions of 0.5 mL each and placed in Eppendorf tubes. The samples will be marked according to a system allowing for patient anonymization: medical center symbol (sample number - type of biological material - date of sample collection, eg, A12-S_10/04/18). The samples will be stored at –70°C. They will be then used for IPAF biomarkers' identification. This includes testing for chemokine C-C motif ligand 18 (CXCL18), surfactant protein (SP)-A, SP-D, Krebs von den Lungen-6 protein (KL-6), and chitinase 1 (CHIT1).

XSL•FO
RenderX

For genetic testing, 15 mL of full blood will be collected and divided into 10 Eppendorf tubes containing 1.5 mL of blood each. Samples will be marked according to the aforementioned organizational pattern and stored at –80°C.

Fiberoptic Bronchoscopy With Bronchoalveolar Lavage and Bronchial Mucosa Sampling

Before FOB, local anesthesia with lidocaine and conscious sedation with midazolam and optionally fentanyl will be performed according to detailed anesthesia protocols used in the endoscopy units of the respective medical centers taking part in the study. An intravenous cannula will be inserted prior to the procedure. During the endoscopy, the patient will be monitored according to safety protocols effective in the respective endoscopy units.

Bronchoalveolar lavage fluid (BALF) will be obtained from areas characterized by the greatest interstitial fibrosis involvement on HRCT. If such an area cannot be distinguished, BALF will be obtained from the middle lobe bronchus or the lingula on the side (B4, B5). Localization will be chosen based on HRCT results and will be recorded in the patients' medical files. Next, 200 mL of sterile 0.9% saline solution, previously warmed to body temperature, will be inserted in parts through a 25 mL syringe to perform BAL. For the test to be deemed diagnostic, the protocol will target BALF salvage of at least 60%.

BAL will be performed according to the guidelines of the ERS [8] and the practical guidelines of the Polish Respiratory Society [9]. A differential cell count will be performed in every sample. BALF samples will be processed by an experienced laboratory technician based on Polish Respiratory Society guidelines [9].

Microscopic slide preparation, determination of cell viability, and determination of the dominant population will be performed according to standard laboratory procedures in the Polish Respiratory Society guidelines. The whole-cell count and cell viability will be measured in a sample derived from fluid that has undergone filtration or the first centrifugation. Samples will be prepared with the cytospin method (routinely 1200-2000 rpm for 10 minutes), and cellular smears will be assessed in cytospin samples stained according to the May-Grünwald-Giemsa method.

BALF samples will be secured for further tests, including testing for potential IPAF biomarkers. Briefly, 15 mL of BALF will be divided into 10 Eppendorf tubes containing 1.5 mL of BALF each and stored at –70°C. Low-speed centrifugal supernatants of BALF will be obtained from each sample. We will measure the concentration of potential biomarkers in each sample using the sandwich enzyme-linked immunosorbent assay (ELISA) technique.

Next, 5 mucosa samples will be obtained from the middle lobe bronchus for histopathological assessment later. Directly after sample collection, they will be put into dry Eppendorf tubes and frozen at –80°C. In addition, transbronchial lung cryobiopsy may be used to obtain material for histopathological assessment.

The 6-Minute Walking Test

The submaximal exercise 6MWT, which entails the measurement of the distance walked over a span of 6 minutes, will be performed according to the detailed protocol used in the respective medical centers. The blood pressure (BP), heart rate (HR), and SpO_2 will be measured directly before and after the test. The following will be recorded: whether the patient completed the test, the distance walked (m), SpO_2, the SpO_2 nadir, and dyspnea sensation measured with the Modified Borg Scale and the Visual Analogue Scale (VAS). If the test is stopped or paused before 6 minutes, the reason (eg, dyspnea, high BP, cardiac arrythmia, limb pain, angina, or other) will be recorded.

The 6MWT will be performed according to Polish Respiratory Society guidelines [10]. Participants will be informed at 30-second intervals about the amount of time remaining. The predicted distance will be calculated based on the equation published in Polish Respiratory Society guidelines for the interpretation of the 6MWT as the most accurate for participants' characteristics [10].

Pulse oximetry will be performed for all patients. If $SpO_2<92\%$ or there are clinical indications for oxygen therapy, ABG analysis will be performed. For ABG analysis, an artery (radial or femoral) is punctured in order to take a sample of arterial blood. The artery is then compressed in order to prevent bleeding/hematoma. The procedure is performed according to ERS guidelines [11].

Computed Tomography

HRCT of the lung will be performed during hospitalization. If the patient provides a CT scan from up to 6 months prior to recruitment (eg, from the outpatient clinic), we will analyze both scans and the radiological descriptions. To ensure the patient's anonymity, a CD containing the patient's scans will be marked by the technician according to the aforementioned pattern. Radiological analysis will be performed using the OsiriXLite DICOM Viewer. The following densitometric values will be measured: mean lung attenuation (MLA), kurtosis, skewness, and deviation of lung radiodensity (SD_{IR}). Statistical analysis of the data will be performed using Statistica software. Data will be presented as the median value and IQRs. Differences between quantitative data will be analyzed using the Kruskal-Wallis test and the post hoc Dunn test.

Transthoracic Echocardiography

TTE with a thorough right heart description will be performed. The following parameters will be noted in the patient's medical file: main pulmonary artery diameter; acceleration time; pulmonary valve peak velocity, tricuspid annular peak systolic velocity (TAPSV), tricuspid annular plate systolic excursion (TAPSE), and tricuspid valve peak regurgitation velocity; right ventricular basal and right ventricular midcavity diameters; right ventricular outflow tract and proximal and distal right ventricular outflow; right atrial short- and long-axis, inferior vena cava, and superior vena cava diameters; and right ventricular wall thickness.

XSL•FO
RenderX

Rheumatological consultation will be provided to patients with IPAF and CTD-ILD to verify the diagnosis.

Choice of Candidate IPAF Biomarkers

KL-6 (mucin 1) is a glycoprotein encoded by the *MUC1* gene and is expressed on the outer surface of type II alveolar epithelial cells and the airway epithelium. It has been proposed as a biomarker of IPF [12]. KL-6 probably promotes fibroblasts' migration, proliferation, and survival in the respiratory system [12]. High serum KL-6 levels have been found in patients with IPF, NSIP, and other ILDs [13-15], which is associated with an aggressive clinical course and could also serve as a predictor of acute exacerbation [16]. High KL-6 levels have also been found in the BALF of individuals with various ILDs, including IPF [17].

Another proposed ILD activity biomarker is CC-chemokine ligand (CCL)18. In a population of patients with idiopathic ILD and SSc, it was revealed that the BALF CCL18 level was negatively correlated with the TLC and the DLCO and positively correlated with BALF neutrophil and eosinophil cell counts. During the follow-up period of ≥6 months, a negative correlation was observed between the decrease in the predicted TLC and the increase in serum CCL18 levels [18]. We hypothesize that such correlation also exists in IPAF, and we will test the theory that patients with IPAF with autoantibodies associated with SSc (anti-PmScl) have higher serum or BALF CCL18 levels than those who test negative for these autoantibodies.

Surfactant proteins SP-A and SP-D are large hydrophilic molecules produced by Clara cells and type II alveolar epithelial cells. SP-A and SP-D play an important role in innate immunity and modulate the excessive inflammatory response on the alveolar surface [19-21]. SP-A and SP-D levels are higher in patients with IPAF than in healthy individuals, patients with infectious pneumonia, or patients with nonfibrotic lung diseases [22-24]. Moreover, serum SP-D levels are lower in the IIP non-IPF group than in the IPAF group [22]. SP-A levels cannot be used to differentiate between patients with IPAF and CTD-ILD [24].

According to Xue et al [22], a negative correlation of serum SP-A levels and the DLCO was revealed in the IIP group (which included 27/69 patients with IPAF, although this subgroup was not separately analyzed). A negative correlation was also revealed with FEV_1 and the FVC [22]. This conclusion was partially confirmed by Wang et al [23], who revealed a negative correlation between serum SP-A levels and changes in the DLCO, FEV_1, and FVC values after treatment. Additionally, Wang et al [23] suggested a prognostic role of SP-A: the pretreatment levels were found to be significantly lower than the posttreatment ones in individuals with progressive fibrosis during the course of IPAF. Moreover, a positive correlation was found between shifts in KL-6 and SP-A levels [23]. In a prospective study, Xue et al [24] observed a significant difference in serum SP-A levels measured at baseline and after 1-year follow-up. In individuals whose condition had exacerbated, SP-A levels were correlated with lung involvement scores on HRCT [24].

These findings need to be validated in European populations. There is a need to determine whether there is a correlation between lung involvement and a decrease in pulmonary function and SP-A/SP-D levels in the bodily fluids of patients with IPAF.

CHIT1 is a member of the glycosyl hydrolase family 18. It is expressed predominantly in polarized and differentiated macrophages and acts as an innate immune mediator digesting cell walls of pathogens that contain chitin (eg, fungi). CHIT1, due to its dysregulated activity, is a proposed marker in granulomatous and fibrotic ILDs associated with interstitial inflammation and lung tissue remodeling.

A study by Bargagli et al [25] revealed elevated CHIT1 activity in the BALF of individuals with IPF in comparison with the healthy control group; however, no significant differences in the serum levels were noted. This suggests the role of CHIT1 expression in interstitial macrophages in tissue injury and remodeling. We hypothesize that CHIT1 may play an important role in the pathogenesis of other ILDs, including IPAF, especially with a progressive fibrosing phenotype.

Lee et al [26] revealed that in 2 different cohorts of individuals with SSc, CHIT1 activity and concentrations increased in the serum and BALF compared to demographically matched healthy controls. Individuals with SSc-ILD, in comparison with patients without lung involvement, were characterized by higher CHIT1 serum activity, which was also correlated with disease severity. The authors revealed that CHIT1 upregulates transforming growth factor beta 1 (TGF-β1) receptor expression and its signaling in fibroblasts, which makes CHIT1 a modulator of progressive interstitial lung fibrosis [27].

These findings raise the question whether CHIT1 or TGF-β1 and their interaction could be a potential target for SSc pharmacological therapy. As the etiopathogenesis of IPAF is still obscure, we plan to analyze both circulatory and lung activities of the enzyme to establish its potential role in the disease pathogenesis.

S100A9, also referred to as myeloid-related protein 14 or calgranulin B, is a member of the calcium-binding protein S100 family and is mostly expressed in neutrophils but also on vascular endothelial cells and mature macrophages. S1009A expression is enhanced by some chronic inflammatory factors [28]. It acts as an immunomodulatory, proinflammatory, and profibrotic agent [29]. It is mostly secreted in inflammatory lesions [30], and it has been suggested as a potential target for IPF treatment [31] and as a candidate biomarker to differentiate between IPF and other fibrotic ILDs [32]. However, convincing evidence from contemporary trials is yet scarce.

Elevated serum S100A9 levels have been reported in samples obtained from patients with RA, SLE, SSc, vasculitis, lung cancer, and various other diseases associated with chronic inflammation [33-35]. It has also been demonstrated that S1009A may promote atherosclerosis [36]. In an observational study by Lin et al [37], it was revealed that S100A9 levels were significantly elevated in BALF samples obtained from patients with severe IPF. It has also been demonstrated that S100A9 levels in the BALF of patients with IPF are positively correlated with the percentage of BALF neutrophils. This suggests a

XSL•FO
RenderX

relationship between S1009A levels and disease activity. Some studies have reported that BALF S100A9 levels are significantly elevated in individuals with pulmonary involvement during the course of SSc [38,39].

CCL2 is a protein that attracts T lymphocytes, natural killer lymphocytes, and fibrocytes [40]. It is associated with inflammatory processes, cell migration and activation, fibrosis, and angiogenesis [41] through its 7-transmembrane-spanning G-protein-coupled CC-chemokine receptor 2 [42]. CCL2 plays a significant role in the pathogenesis of various diseases, such as tuberculosis [43], asthma [44], and RA [45].

A connection was established between CCL2 polymorphism and the occurrence of autoimmune disorders. The *CCL2* gene (–2518G/A) single-nucleotide polymorphism has been shown to be associated with sarcoidosis [46]. Increased CCL2 levels have been found in the serum and BALF of patients with IPF [47]. In vitro and in vivo studies have revealed that CCL2 is associated with fibrosis by supporting monocyte-/macrophage-mediated inflammation, angiogenesis, collagen synthesis, myofibroblast cell differentiation, and fibroblast activation [48].

It remains unclear whether the chemokine profile of serum and BALF of individuals with IPAF, especially patients with progressive fibrosis, resembles that of patients with IPF.

Data Collection

Data will be collected via questionnaires: the Leicester Cough Questionnaire, St. George's Respiratory Questionnaire, the Fatigue Assessment Score and 36-item Short Form (SF-36) v.2 Quality of Life Questionnaire, the HADS-M, and the PHQ-9. To help unify data and due to copyright reasons, surveys for physicians will be set up on servers of the Medical University of Silesia. All the aforementioned documents will be provided to the patients in their native tongue and have been validated in the Polish population.

Statistical Analysis

Statistical tests will be chosen due to variable distribution. To verify the normality of variable distribution, the Shapiro-Wilk test will be performed. To compare parameters between the 1 study and 2 control groups, ANOVA or the Kruskal-Wallis test will be performed (for normal or nonnormal variable distribution, respectively). To correlate the variables, Pearson or Spearman correlation tests will be performed (for normal or nonnormal variable distribution, respectively). To determine the relationship between variables, the linear regression test will be performed.

Results

Although the study was designed and Ethical Board Committee approval granted in the past, we have experienced difficulties in the phase of patient recruitment due to the outbreak of the novel coronavirus.

It is worth noting that the majority of tests are routinely performed in the diagnostic workup of patients with ILDs; therefore, patients will not be subjected to additional risks. Discomfort may be caused by the drawing of more blood samples than usual; however, this will be reduced by the use of vacuum blood collection systems.

This study will start recruiting patients to phase 1 in October 2023. The final results will be available in 2028. We plan to publish preliminary results after 2-3 years from the start of phase 1.

Discussion

Summary

As IPAF is an exclusion diagnosis, we believe that in the era of genetic testing advancements, genetic disorders manifesting as ILDs should be considered as alternative etiologies. In our study, the local bioethics committee granted permission to perform genetic testing, and we plan to bank full blood, with the intention to perform such procedures.

There have been clinical reports of individuals with signal transducer and activator of transcription 3 (STAT3) gain-of-function syndrome [49] or cytotoxic T cell antigen 4 (CTL-A4) checkpoint haploinsufficiency [50], which could fulfill the 2015 criteria. Moreover, a newly discovered coatomer protein complex subunit alpha (COPA) syndrome causes progressive ILD [51]. The impaired COPA protein may contribute to endoplasmic reticulum stress and therefore trigger interferon signaling pathways and T cell–mediated inflammation [51].

Newton et al [52] revealed that the leukocyte telomere length is longer in individuals with IPAF and CTD-ILD than in those with IPF. The telomere length correlates with lung function and lung transplant outcomes in IPAF. Moreover, mucin 5B (MUC5B) and Toll-interacting protein (TOLLIP) polymorphisms are associated with both IPAF and IPF, which suggests that these 2 clinical entities have similar genetic backgrounds. Various polymorphisms are found in CTDs, such as RA, SS, and SSc, but to date, there are no data on whether the presence of these polymorphisms is associated with the development of IPAF. Hopefully, an in-depth understanding of molecular pathways could lead to the development of targeted therapies.

A practical question we are going to face stems from the fact that instructions for most ELISA kits that are available for research use in our area only contain suggestions/guidelines for serum dilution. Therefore, we will need to either predict the levels of the aforementioned proteins in BALF or experiment with dilution. As we are unsure how much time it will take to recruit the adequate number of individuals, we plan to perform a miniexperiment beforehand: First, we will test the serum according to the manufacturer's guidelines. If the standard 1:40 dilution does not lead to the detection of predicted concentrations, we will check the 1:20 dilution, 1:5 dilution, and undiluted samples. The next step will be testing BAL samples. We will test 1:20 dilution samples, and again, if this does not result in the detection of protein concentrations within the range provided in the kit instruction, we will test the 1:5 dilution and undiluted specimens.

XSL•FO
RenderX

The clinical stability of IPAF is an important subject, as the development of mild extrapulmonary symptoms may be overlooked. In our opinion, this specific population requires above-average clinical vigilance due to the fact that reclassification as definite CTD-ILD prompts a change in the therapeutic approach based on ACR/EULAR guidelines. This is why we plan to cooperate closely with rheumatologists regarding assessment of the extrapulmonary manifestations of autoimmunity. However, there is also a possibility that an entity that had been initially classified as idiopathic ILD may later be reclassified as IPAF. To test this hypothesis, we plan periodic rheumatological revaluations of this subgroup, together with retesting for ANAs (serological domain of IPAF).

Data on the progression of IPAF to CTDs are scarce and conflicting. Scirè et al [53] reported that 42% of patients with IPAF with antisynthetase antibody positivity were ultimately reclassified as RA-ILD, PM/DM-ILD, or myositis-RA overlap syndrome. Ito et al [54] also reported that 12.2% of individuals meeting IPAF serological and morphological criteria were diagnosed with CTD during a median follow-up period of 54 months. However, Chartrand et al [55] found that none of the 56 individuals with IPAF was rediagnosed over a follow-up period of 48 months.

Another question is when to initiate treatment during the course of IPAF. Before IPAF was defined, ILD with symptoms of underlying autoimmune disorder but without extrapulmonary manifestation could have been classified as IIP and therefore have delayed treatment initiation. In our prospective observational study, we will surely face a challenge in identifying patients with IPAF who require early clinical intervention. We hope that during the 60-month observation period, we will be able to identify molecular, radiological, and functional prognostic factors, which, in the future, will help lay the foundation for IPAF therapy guidelines.

In a study on 412 patients with CTD-ILD or IPAF, Li et al [56] analyzed the relationship between these 2 entities in order to identify which individuals with IPAF should commence treatment early. They concluded that based on similar yet milder symptoms and ANA positivity, IPAF is in fact an early stage of CTD-ILD and therefore treatment should commence early. After immunosuppressive treatment, they reported an increase in the FVC and DLCO in this population. The choice of adequate pharmacotherapy is another clinical question that we will face during prospective observation.

D'Silva et al [57] presented a case series of 50 patients from 2 centers who were treated with rituximab (RTX). The majority experienced either clinical improvement or stability understood as global assessment of performance in terms of oxygen requirement, unplanned hospitalization due to respiratory reasons, and 1-year survival, despite baseline differences regarding age, comorbidities, and prior treatment history.

Although we do not plan a randomized controlled trial, in prospective observation, we will face clinical decisions regarding treatment implementation. We hypothesize that some patients will have a history of treatment with systemic GCs or cyclophosphamide (CYC), and we wonder whether the results of studies on CTD-ILDs can be extrapolated to the IPAF population. The use of CYC is associated with an increased risk of malignancy, infections, and bone marrow suppression [58].

Some patients in this study had previously used mycophenolate mofetil (MMF) or tacrolimus, which may have impacted their performance on RTX. The implementation of RTX therapy, especially in patients with refractory ILD, should be considered due to its favorable safety profile [59]. We also hypothesize that a usual interstitial pneumonia (UIP) radiological pattern, which is associated with higher mortality in patients with IPAF [60], may impact treatment efficacy.

We wonder whether studies on patients with RA-ILD who generally have a UIP pattern may be extrapolated to this specific IPAF population, and in prospective observation, we plan to exteriorize 2 subpopulations (UIP-RA and UIP-IPAF) and compare patients' outcomes in terms of oxygen requirement, PFT results, 6MWT performance, and 1-, 3-, and 5-year survival.

We are looking forward to cooperating with rheumatologists for multidisciplinary discussion.

Impact of Pilot Study Results on the Protocol

In our pilot study [7], we revealed a greater prevalence of gastrointestinal reflux disease (GERD) in the CTD-ILD group than in the IPAF and IIP groups. Data on the impact of GERD on fibrosis pathogenesis are conflicting. There are data suggesting that exposure of the interstitial tissue to a low pH results in repeated lesions and, consequently, progressive fibrosis. However, there are also data supporting a hypothesis that GERD actually results from progressive fibrosis and a shift in intrathoracic pressure due to altered anatomy. Therefore, we decided to launch a substudy on patients with progressive fibrosing ILD (PF-ILD), focusing on the impact of GERD on the disease course. We will monitor 24-hour impedance-pH to objectify GERD episodes and correlate them with symptoms.

In the pilot study [7], it was also revealed that BALF levels of interleukin 8 (IL-8), CXCL1, and TGF-β1 were significantly higher in the CTD-ILD group than in the IPAF and IIP groups. We hope that the analysis of 240 subjects in this full-size study will reveal more defined differences between study groups. We plan to analyze subgroups (eg, RA-ILD or SSc-ILD) and compare them with their IPAF counterparts (based on the presence of clinical symptoms and specific autoantibodies). We also plan to distinguish an IPAF subgroup associated with the presence of antisynthetase autoantibodies and compare it with the PM/DM-ILD subgroup in terms of clinical stability and outcomes.

Our pilot study [7] also revealed that the BALF IL-8 concentration is associated with the presence of skin teleangiectasias. IL-8 is a known proangiogenic factor. In this full-size study, we plan to perform videocapillaroscopy to stratify participants according to the Cutolo nailfold capillaroscopy classification and measure the concentration of proangiogenic cytokines in both serum and BALF. We will be able to compare corresponding Cutolo subgroups of SSc-ILD and IPAF and determine the impact of proangiogenic factors on pathological angiogenesis.

XSL•FO
RenderX

We also hypothesize that there will be significant intergroup differences between the reported severity of cough and dyspnea as well as psychological symptoms and their impact on various aspects of the QoL.

Conclusion

This study will be a step toward a better understanding of IPAF etiopathogenesis and outcomes.

Abstract

Background: Endometrial cancer (EC) is the most common gynecological cancer in women globally. It is linked to increasing obesity rates and longer life spans. The molecular mechanisms leading to EC are unclear; however, women with polycystic ovary syndrome (PCOS) have a 3- to 5-fold increased EC risk. According to a pilot study conducted in the United Kingdom, insulin-like growth factor-1 (IGF-1) gene and protein were raised in the endometrium and blood of women with EC and PCOS, compared with those without PCOS (controls). Therefore, raised serum IGF-1 levels may contribute to an increased EC risk in women with PCOS, but it is necessary to test this hypothesis since not all studies have demonstrated this association.

Objective: This study aims to investigate the role of IGF-1 in mediating EC risk in PCOS. This will be achieved by evaluating the proliferative effects of PCOS serum, IGF-1, and IGF-1 antagonist on human endometrial cancer 1-A and 1-B cell lines, with a comparison to controls (using serum from women without PCOS and cell culture media). The study will also identify differentially expressed genes and pathways activated by various treatments.

Methods: We intend to recruit 20 women with PCOS and 20 women without PCOS for this cross-sectional study. All experiments will be carried out 4 times to ensure consistency. We will perform transcriptomic and phosphoproteomic profiling to identify differentially expressed genes and phosphoproteins between different treatments using RNA sequencing and phosphoproteomics. We will also perform bioinformatics pathway analysis to identify whether any unique collection of genes or phosphoproteins explains increased EC risk in PCOS. The primary outcome measure will be the cell proliferation (growth) difference measured by cell index values. Our protocol stands out due to its unique approach; no previous study has used this approach to investigate the oncogenic effect of serum from women with PCOS. Additionally, no previous study has considered the differential mutations of genes related to the insulin signaling pathway across various types of human EC cell lines and the potential impact of these variations on their experimental findings.

Results: Participants are currently being recruited. It is expected that preliminary findings suitable for analysis and publication will be available by the summer of 2024.

Conclusions: Although we currently do not have any results to report, sharing our protocol at this stage will aid in research collaboration, provide an opportunity for early feedback, and help reduce duplication of effort by other research groups. The findings of our study will have broader implications. A deeper understanding of the mechanisms underlying the regulation of the IGF system in PCOS and EC will improve our ability to develop effective treatment modalities for EC and will be a vital step toward reducing EC in women globally.

Introduction

Overview

Endometrial cancer (EC) was the sixth most diagnosed cancer in women globally, in 2020 [1], with 417,000 new cases and 97,000 deaths. The incidence is also increasing rapidly with rising rates of obesity [2] and longer life expectancy. It is estimated that the incidence will increase by more than 50% worldwide by the year 2040 [1]. EC was also the most common gynecological cancer in the United Arab Emirates in 2020, with a 5-year prevalence of 491 per 100,000 individuals [3]. The most common type of EC is type 1 (endometrioid), which is present in 80% of tumors. Treatment often involves hysterectomy—a major surgical operation with serious implications, such as infertility, for younger women [4], which is of growing concern in the United Arab Emirates [5]. There is, therefore, an urgent need for research to prevent and improve the management of EC in the United Arab Emirates and globally. However, uncertainty persists about the precise molecular mechanisms leading to EC, which hinders facilitating EC prevention and treatment.

Some of the known risk factors for EC include polycystic ovary syndrome (PCOS), diabetes, obesity, inflammation, insulin resistance, high estrogen concentrations, and possibly, high circulating insulin-like growth factor 1 (IGF-1) levels [6]. PCOS is, however, the most common female endocrinopathy [7] in women of reproductive age, and potentially, it could account for many cases of EC. PCOS is associated with obesity, infrequent menstrual periods, infertility, hirsutism, enlarged ovaries with many small follicles on ultrasound imaging, increased risks of type-2 diabetes in later life, and a 3- to 5-fold increased risk of EC [8,9], with higher risks in premenopausal women. Mechanisms thought to increase EC risk in PCOS include raised estrogen levels, obesity, anovulatory menstrual cycles, and unopposed (from progesterone) estrogen stimulation of the endometrium; however, the degree to which these mechanisms increase EC risk or interact with each other to underpin EC risk in PCOS is uncertain [10]. Genomic and proteomic approaches [11] have also identified potential new genes and proteins that might explain the link between PCOS and EC and could upregulate genes associated with the insulin signaling pathway in PCOS.

Over the past few years, research studies have investigated the potential role of insulin resistance and IGF-1 in the association between PCOS and EC [12,13]. The possible role of insulin resistance and IGF-1 in the association between PCOS and EC is supported by observations that endometrial dysfunction, causing miscarriages in PCOS, has been linked to insulin resistance and the associated elevation in serum IGF-1 levels in individuals with PCOS [14]. Epidermal growth factor, IGF-1, and IGF-2 were also found to stimulate a time-dependent mitogenic response in human EC cell lines [15]. The most frequently altered mutation in type 1 EC is the phosphoinositide 3-kinase (PI3K) pathway [16]. Elevated IGF-1 and insulin levels have been shown to directly stimulate cell proliferation by activating the phosphatidylinositol-4,5-bisphosphate 3-kinase catalytic subunit alpha pathway [17]. However, the precise association between serum IGF-1 and EC is still uncertain, and results from case-control studies are conflicting [18]. Multiple other molecular pathways also contribute to EC progression. Dysfunction in the TP53 pathway is common in type 2 EC, resulting in the loss of crucial p53 functions. Additionally, the overactivation of the mitogen-activated protein or extracellular signal-regulated kinase (ERK) pathway promotes EC cell proliferation and migration. These pathways, however, interact with IGF-1 signaling, and IGF-1 gene promoter polymorphisms are associated with EC [18].

The importance of investigating the IGF-1 pathway in the association between EC and PCOS is justified. This is because EC is a disease mainly driven by phosphoinositide 3-kinase (PI3K), as the PI3K pathway is aberrant in more than 90% of ECs. PI3K signaling is the main pathway cascade of insulin or IGF-1 signaling [19].

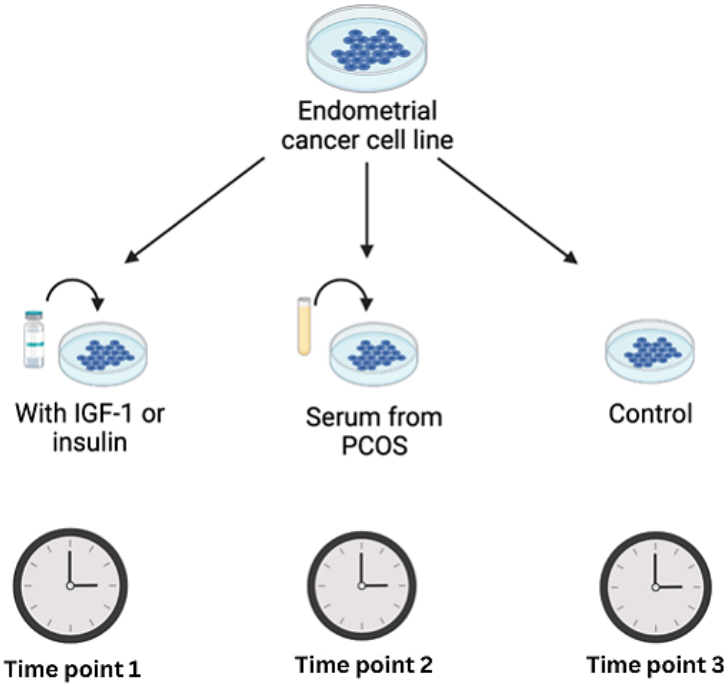
Prior Work

In a pilot study in which 102 women were recruited, the investigators found for the first time that IGF-1 gene and protein levels were raised in the endometrium and serum of women with PCOS and EC, compared with controls. These two groups exhibited similar levels of obesity [13]. Raised serum IGF-1 levels may, therefore, contribute to an increased risk of EC in women with PCOS; however, there is a need to test this hypothesis since not all studies have demonstrated an association between serum IGF-1, IGF-binding protein 1, IGF-binding protein 3, and insulin levels with EC [20]. A recently published systematic review [21] found that IGF-1 levels in women with PCOS were elevated compared with controls, as found in our pilot study. A total of 20 studies were included in the meta-analysis [21] involving 657 individuals: 362 patients with PCOS and 295 normal controls. The results of the meta-analysis showed that serum IGF-1 levels were significantly higher in patients with PCOS compared to controls (standard mean difference 0.89). Subgroup analysis based on BMI showed that elevated IGF-1 levels were associated with normal-weight and overweight patients in the PCOS group. Further clarification is required about the interplay between PCOS, IGF-1, and the endometrium as well as the impact they have on EC.

Aims

The aim of this study is to further investigate the possible role of IGF-1 in mediating the risk of EC in women with PCOS.

XSL•FO
RenderX



Objectives

The objectives of the study are as follows:

- To compare the oncogenic effect of PCOS serum, IGF-1, and IGF-1 antagonist on EC cell lines in women with PCOS and controls (using serum from women without PCOS and cell culture media)
- To identify differentially expressed genes and pathways activated by different treatments used in the previous objective
- Perform a bioinformatics pathway analysis to identify whether any unique genes or nodes can explain the increased EC risk in PCOS

Although using cell culture experiments, as described in this paper, is not a novel approach for studying molecular mechanisms to help the prevention and treatment of diseases [22], the unique aspects of our protocol lie in the fact that no previous study has used this approach to investigate the oncogenic effect of serum from women with PCOS. More importantly, no previous study has considered the differential mutations of genes related to the insulin signaling pathway in human endometrial cell lines, as identified in the Cancer Dependency Map Portal [23], and what impact this may have on their experimental findings (Figure 1).

Figure 1. Comparing the oncogenic effect of polycystic ovary syndrome (PCOS) serum on endometrial cancer cell lines with the effect of serum from women without PCOS (controls) and insulin-like growth factor 1 (IGF-1).

Methods

Ethics Approval

Ethics approval for this study has been obtained from the research ethics committees of Mohammed Bin Rashid University of Medicine and Health Sciences (MBRU IRB-2022-149) and Kings College London in Dubai (October 12, 2022). Approvals from other hospital sites (Latifa Women and Children's Hospital and Mediclinic Hospitals in Dubai) will be sought, as appropriate, based on participant recruitment rates.

Recruitment

The study will aim to recruit 20 women with PCOS and 20 women without PCOS aged between 18 and 45 years. We will recruit women with PCOS and controls into the study if they have a BMI below 30 and are not on any medications. This is to mitigate the possible confounding effect of obesity on EC risk. Inclusion criteria for women with PCOS will involve a diagnosis using the Rotterdam Criteria [24], which encompasses the presence of 2 or more of the following conditions: clinical or biochemical evidence of hyperandrogenism, chronic oligo-ovulation or anovulation, and the observation of polycystic ovaries on ultrasound, with the exclusion of other causes of chronic oligo-ovulation or anovulation (eg, hyperprolactinemia and hyperthyroidism). Controls will be women with regular menstrual cycles identified from a gynecology or other appropriate outpatient setting at Kings College Hospital, Latifa Women and Children's Hospital, or Mediclinic Hospital in Dubai, without a diagnosis of polycystic ovaries on ultrasound scan. Male patients will be excluded from this study, as they do not develop EC.

Women identified as having PCOS or controls will be identified by gynecologists in participating hospitals and provided a patient information sheet. If the patient agrees to participate, written consent will be obtained. One of the study investigators will then be informed by the clinician or gynecologist who recruited the patient into the study. The investigator will then contact the participant to arrange a mutually convenient time for sample collection. For women with and without PCOS recruited into the study, participation will not involve any extra visits to the hospital in addition to visits required as part of their clinical care. Fasting blood samples will be obtained following the

XSL•FO
RenderX

exclusion of a possible pregnancy. With the permission of the participants, we will review their electronic medical records to obtain details on their medical and gynecological history, including the reason for clinical presentation, menstrual history, date of last menstrual period before sample collection, past medical or surgical history, medication, allergies, and smoking history. The most recent height, weight, and blood pressure measurements in the electronic medical record will be recorded. The details of their last pelvic ultrasound scan will also be recorded to confirm if their ovaries did or did not look polycystic.

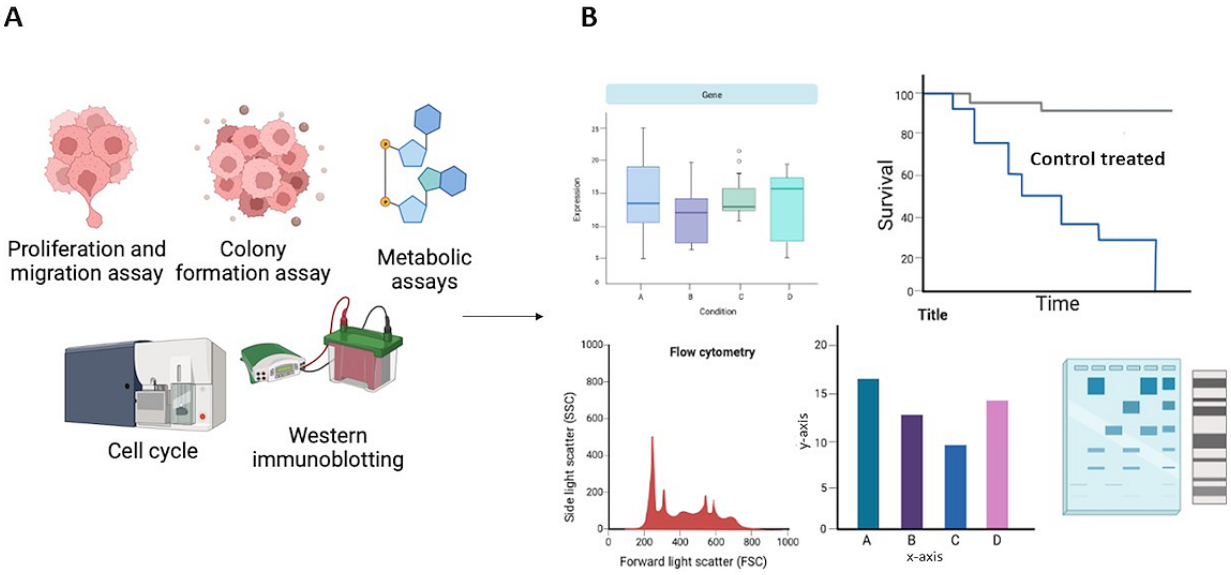
Participants can withdraw from the study at any stage without their clinical care being affected. We do not anticipate any issues with adverse effects; however, the research team aims to meet fortnightly as a research group during the study, with steering committee meetings arranged as indicated. The principal investigator will report any relevant data safety issues reported during these meetings or from any other sources to the Mohammed Bin Rashid University's Institutional Review Board (IRB).

Blood Tests

Following informed consent, 1 extra sample of blood (in addition to the other blood tests required as part of their clinical care) will be obtained from the participant's arm and collected into 1 vacutainer for the study. Whole blood collected from patients with PCOS and controls will be stored for a maximum of 24 hours before the serum is separated. Samples will be transported from the gynecology clinic to the laboratory at Mohammed Bin Rashid University, ideally within 6 hours of whole blood collection, in dry ice between 2˚C and 8˚C, with the tubes stored in specimen bags.

We anticipate no major problems with side effects; nonetheless, following the blood tests, the participants may experience minor bruising in the area from which blood was obtained. However, all the blood tests will be taken by an experienced staff member, which should help minimize this risk. Participants will be informed that during the cell culture studies, we may identify incidental factors that might be associated with an increased risk of EC. Should this occur, the results will be made available to participants and their general practitioners or family medicine doctors if they so wish, and they will be offered appropriate counseling. They will also be informed that we may not find any significant differences between blood samples taken from women with PCOS and controls and that there will be a need for further studies on more women to confirm any of our findings. The experiments will not involve any techniques that will put staff at risk or produce environmental contaminants. Participants will also be informed that the potential benefits are that this study might identify new genetic or chemical factors that may prove significant in future studies for the prevention and treatment of EC and that this will be a vital step in reducing the incidence of EC in women living in the United Arab Emirates.

Processing and Storage of Blood Samples



Whole blood will be allowed to clot for 15-30 minutes at room temperature or left at 4˚C until the reaction is complete. We will aim not to exceed 24 hours and isolate serum within 1 or 2 hours of blood collection. Once the blood has been clotted, it will be centrifuged at 1000 x gravitational units (g) for 10 minutes in a refrigerated centrifuge (at 4˚C) to facilitate the separation of the serum. A barrier will form between the serum and the cells; if no barrier is formed, the sample will be respun for 5 minutes. The serum will be carefully extracted using a fine-bore pipette to prevent the inclusion of red blood cells and will be aseptically transferred to a sterile vial. The samples will be kept at temperatures ranging from 2°C to 8°C during handling. The serum will then be stored without delay at –80˚C in 0.5 mL aliquots to prevent the disintegration of serum proteins. Upon completion of the initial studies with the blood tests obtained from the participants, with their consent, we will retain some of the remaining serum samples for long-term storage to allow further studies if newer technology for carrying out these studies becomes available. However, if participants do not wish to have their serum samples retained for this part of the study, the sample will be discarded in accordance with the established laboratory protocols immediately after the cell culture study. Permission will be sought from the research and ethics committee prior to conducting any further studies using the stored blood samples.

Objective 1: Comparing the Oncogenic Effect of PCOS Serum on EC Cell Lines With the Effect of Serum From Women Without PCOS (Controls) and IGF-1

To further investigate the possible role of IGF-1 in mediating the risk of EC in women with PCOS we will evaluate the proliferative effects of PCOS serum, IGF-1, and IGF-1 antagonists on human endometrial cancer 1-A and 1-B cell lines, through a comparison with controls (using serum from women without PCOS and cell culture media; Figure 2).

XSL•FO
RenderX

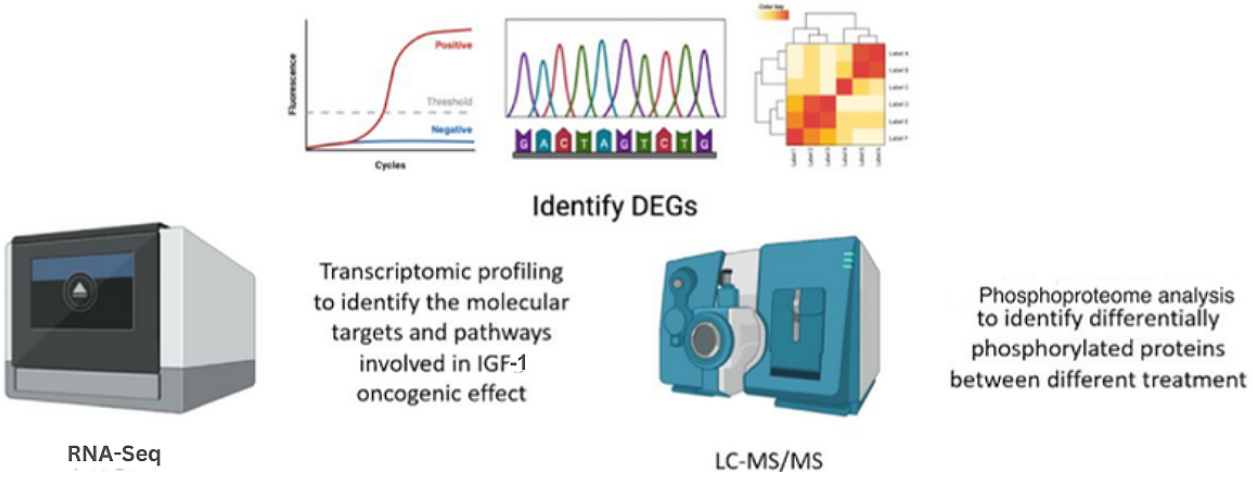
Figure 2. Comparing the oncogenic effect of polycystic ovary syndrome (PCOS) serum on endometrial cancer cell lines with the effect of with the effect of serum from women without PCOS (controls) and insulin-like growth factor 1 (IGF-1). (A) various assays. (B) measures to compare oncogenic effect.

Endometrial Carcinoma Cell Lines

Human endometrial cancer (HEC)-1-B and HEC-1-A cell lines will be used in this study. Cells will be treated with the study groups outlined below:

- PCOS serum alone
- PCOS serum and IGF-1
- PCOS serum with IGF-1 antagonist applied
- PCOS serum and IGF-1 with IGF antagonist applied
- Control serum alone
- Control serum and IGF-1
- Control serum with IGF-1 antagonist applied
- Control serum and IGF-1 with IGF antagonist applied
- Cell culture media alone
- Cell culture media and IGF-1
- Cell culture media with IGF-1 antagonist applied
- Cell culture media and IGF-1 with IGF antagonist applied

The treatment will be administered in different time periods, and all experiments will be carried out in quadruplicates. We will examine the effect of cell treatment on cell lines using proliferation, migration, cell cycle analysis, soft agar colony formation assays, and IGF cell signaling. Cell proliferation will be measured using xCELLigence real-time cell proliferation experiment; migration will be measured using xCELLigence real-time cell migration experiment and wound-healing assays; cell cycle analysis will be done using propidium iodide, flow cytometry, and IGF cell signaling, as previously described [25]. Activation of IGF or IGF receptor pathway will be assessed by western blots using the following: antibodies against phospho-IGF-1 receptor, IGF-1 receptor beta-subunit, insulin receptor, protein kinase B (AKT; a serine or threonine protein kinase encoded by the oncogene in the transforming retrovirus isolated from the thymoma cell line AKT-8, derived from the Stock A Strain k AKR mouse originally inbred in the laboratory of Doctor CP Rhoads by KB Rhoads at the Rockefeller Institute), phospho-AKT, phosphor–extracellular signal-regulated kinases (ERKs) 1/2, poly adenosine diphosphate ribose polymerase caspase 3, phosphor–adenosine monophosphate-activated protein kinase, adenosine monophosphate-activated protein kinase, mammalian target of rapamycin and phosphor–mammalian target of rapamycin, as well as PI3K, protein 85 (protein 85 refers to the regulatory subunit of phosphoinositide 3-kinase), ERK1, protein 21, B-cell lymphoma 2, tumor protein 53, phosphatase and tensin homolog, cyclin D1, and caspase 9.



The primary outcome measure will be the difference in cell proliferation measured by cell index values during the xCELLigence real-time cell proliferation experiment. Comparison of cell index values from cells treated in different groups will be performed by the Kruskal-Wallis test followed by multiple comparison tests.

Objective 2: Identifying Differentially Expressed Genes and Pathways Activated by the Treatment of Endometrial Cell Lines of the Different Study Groups Listed in Objective 1

We will perform transcriptomic profiling of endometrial cell lines to identify differentially expressed genes in response to different study conditions outlined previously, using RNA Sequencing (RNA-Seq) to identify the molecular targets and pathways involved in the oncogenic effects (Figure 3).

XSL•FO
RenderX

Figure 3. Identifying differentially expressed genes (DEGs) and pathways activated by the treatment in objective 1 of the study protocol. IGF-1: insulin-like growth factor 1. LC-MS/MS: Liquid chromatography with tandem mass spectrometry; RNA-Seq: RNA sequencing.

The steps for the RNA-Seq include the following:

- Total RNA will be extracted using a RNeasy extraction kit, with on-column DNase digestion.
- RNA quality will be assessed using an Agilent bioanalyzer.
- Samples will be analyzed on an Illumina HiSeq platform using standard protocols.
- For quantitative reverse transcriptase PCR validation of RNA-Seq results, a subset of the groups described in objective 1 will be used.
- The expression of identified differentially expressed genes will be compared in the publicly available RNA sequencing databases.

At the same time, we will use phosphoproteome analysis to identify differentially phosphorylated proteins between different study conditions using liquid chromatography with tandem mass spectrometry measurement.

The steps involved in the phosphoproteomics will be as outlined below:

- Cell lysis, protein digestion, and labelling
- Peptide enrichment, immunoprecipitation, and offline fractionation
- Mass spectrometry data acquisition
- Peptide and protein database searching
- Proteomics data analysis
- Phosphoproteomics and acetyl-immunoprecipitation data analysis

Objective 3: Bioinformatics

We will perform bioinformatics pathway analysis to identify any key genes and proteins involved in the association between PCOS and EC, after transcriptomic and phosphoproteomics profiling, as identified in objective 2 (Figure 4). The results from the same HEC-1-B and HEC-1-A cell lines and treatment groups, as outlined in objectives 1 and 2, will be used.

The methodology for the RNA-Seq data analysis will be as previously published [26], paired end raw reads (FASTQ format) will be quality- and adapter-filtered using Trim Galore wrapper for FastQC and Cutadapt [27]. The retained paired reads will be aligned to the Ensembl-annotated HG19 human Illumina iGenome build using Tophat2. Subsequently, differential gene expression will be calculated for the different cell culture study groups in comparison to the control specimen, using Cuffdiff, based on fold changes >1.5 and a *P* value <.05. Statistically significantly enriched gene ontologies and pathways for differentially expressed genes will be obtained using WebGestalt and the Cytoscape GeneMANIA plug-in. Next-generation RNA-Seq and associated clinical information will be obtained from publicly available data sets.

The methodology for the phosphoproteomics data analysis will also be as previously published data analysis for the phosphoproteomics data; label-free quantitative data will be filtered with a cutoff of ≥2 observations in the 4 repeats of at least 1 time point. Log transformation will be performed before any missing data points are imputed using random values generated from a normal distribution centered at the 1% quantile and the median SD. The abundance of phosphopeptides will be normalized to the abundance of corresponding parental proteins. The Limma package will be used in the R environment to identify differential proteins or phosphorylation with a false discovery rate–corrected ANOVA *P* value of .05. The k-means clustering approach will be used to analyze the patterns of the differential proteins and phosphorylation events. For functional annotation and network analysis, the differentially regulated proteins will be searched against the String database, and the networks will be visualized by using Cytoscape.

Although the study will aim to recruit 20 women with PCOS and 20 women without PCOS aged between 18 and 45 years, we will begin with a pilot study of samples from 3 women with PCOS and 2 controls and perform validation studies in the larger cohort of 20 women with PCOS and 20 women. The experimental plate design for the cell-culture studies in this feasibility study is illustrated in Table 1.

It will be 1 plate per cell line for each time point (24 h and 48 h). All experiments will be conducted in quadruplicates. We recognize that opinions differ about the ideal sample size for cell-culture experiments [28]; however, we believe our proposed experiments are stringent enough to make the results believable.

Results

In this study, we have described the protocol for an ongoing study to investigate the role of IGF-1 in mediating the risk of EC in women with PCOS. The study will aim to recruit 20 women with PCOS and 20 controls and measure the effect of serum from these women on cell proliferation and molecular pathways in human EC cell lines, compared with IGF-1 and IGF-1 antagonists. Recruitment for the study is currently ongoing. The project was funded in June 2022 and approved by the Mohammed Bin Rashid University of Medicine and Health Sciences' IRB in October 2022; funds were released in January 2023, and data collection began on 16 March 2023 and is ongoing. Three women with PCOS and 2 controls have been recruited as the date of this submission from 1 hospital site and IRB permission for further participant recruitment at a second hospital site was granted in October 2023. Data analysis has not yet commenced. We anticipate that initial results for analysis and publication will be available by the summer of 2024.

Discussion

Expected Outcomes

Although the protocol (using cell culture) described in this paper is not novel for studying molecular mechanisms to help in the prevention and treatment of diseases, the unique aspect of it is that no previous study has used this approach to investigate the oncogenic effect of serum from women with PCOS. More importantly, no previous study has considered the differential mutations of genes related to the insulin signaling pathway in human endometrial cell lines and the potential impact this may have on their experimental findings.

A possible limitation of our protocol includes the risk that the IGF-1 present in the serum of women with PCOS may become diluted in the cell culture media to an extent where the in vitro effects do not represent the in vivo activity. We will, however, aim to mitigate this risk by using Sep-Pak C18 for the extraction, concentration, and fractionation of peptides from PCOS and control serums [29]. We will also begin with a pilot study of samples from 3 women with PCOS and 2 controls to identify any other potential methodological problems before performing validation studies in the larger cohort of 20 women with PCOS and 20 women without PCOS. Another limitation of our protocol is that the use of these cell lines may limit the generalizability of the findings from our study. However, our results may inform future studies by independent research groups using primary cell lines or patient tumor samples.

We are aware of only 1 study [30] in which serum from women with PCOS has been used in experiments on EC cell lines. The study, however, was not designed to answer our research question, as it investigated the potential stimulatory effects of serum exosomes isolated from patients with PCOS on EC cell lines and explored the underlying mechanism. The study [30] found that EC cell lines exposed to exosomes derived from the serum of patients with PCOS exhibited an enhanced migration and invasion phenotype. The study also found that levels of 55 mature micro RNAs significantly differed in serum exosomes from patients with PCOS compared to those from normal controls and that MiR-27a-5p was the most significantly elevated in the serum exosomes of patients with PCOS. Furthermore, in vitro experiment results confirmed that MiR-27a-5p prohibited migration and invasion via Suppressor of Mothers Against Decapentaplegic-4 downregulation, suggesting that serum exosomal MiR-27a-5p may play a role in EC development in patients with PCOS. The implications of these findings for our study are that we may also find enhanced migration and invasion in our PCOS group compared to controls, independent of whether IGF-1 antagonist is present, which would imply that pathways other than IGF-1 may also be at play in the association between PCOS and EC. However, the planned transcriptomic profiling in our study will offer the opportunity to identify any interactions between messenger RNAs and IGF-1 in the possible association between PCOS and EC.

Conclusions

In conclusion, this study describes a protocol for an ongoing study to investigate the role of IGF-1 in mediating the risk of EC in women with PCOS, by investigating the effect of serum from women with PCOS and controls on cell proliferation and molecular pathways in human EC cell lines. Although we currently do not have any results to report, reporting our protocol should aid research collaboration and early feedback; it could also reduce duplication of effort by other research groups. The broader implications of the findings of our study, when available, are that a deeper understanding of the mechanisms underlying the regulation of the IGF system in PCOS and EC will improve our ability to develop effective treatment modalities for EC. Specifically, investigating how IGF-1 in PCOS participates in the development of EC may identify novel genetic associations between EC and PCOS. This will also facilitate future systems biology–based pathway analysis to explore further molecular mechanisms leading to EC and will be a vital step in reducing EC in women globally.

Data Availability

Data sharing is not applicable to this study, as no new data were created or analyzed.

Authors' Contributions

WA, MH, and FA conceptualized the study. WA, MH, and FA designed the methodology. WA prepared and wrote the original draft. WA, MH, FA, and SA contributed to the writing; they also reviewed and edited the manuscript. All authors have read and agreed to the published version of the manuscript.

Abstract

Background: Systematic monitoring of work atmosphere and patient safety incidents is a necessary part of a quality assurance system, particularly an accredited system like the Joint Commission International (JCI). How the implementation of quality assurance systems affects well-being at work and patient safety is unclear. Evidence shows that accreditation improves workplace atmosphere and well-being. Thus, the assumption that an increase in employees' well-being at work improves patient safety is reasonable.

Objective: This study aims to describe the protocol for monitoring the effects of implementing the quality assurance system of JCI at Orton Orthopedic Hospital on employees' well-being (primary outcome) and patient safety (secondary outcome).

Methods: Quantitative (questionnaires and register data) and qualitative (semistructured interviews) methods will be used. In addition, quantitative data will be collected from register data. Both quantitative and register data will be analyzed. Register data analysis will be performed using generalized linear models with an appropriate distribution and link function. The study timeline covers the time before, during, and after the start of the accreditation process. The collected data will be used to compare job satisfaction, as a part of the well-being questionnaire, and the development of patient safety during the accreditation process.

Results: The results of the quality assurance system implementation illuminate its possible effects on the patient's safety and job satisfaction. The repeatability and internal consistency reliability of the well-being questionnaire will be reported. Data collection will begin in May, 2024. It will be followed by data analysis and the results are expected to be published by 2025.

Conclusions: The planned study will contribute to the evaluation of the effects of JCI accreditation in terms of well-being at work and patient safety.

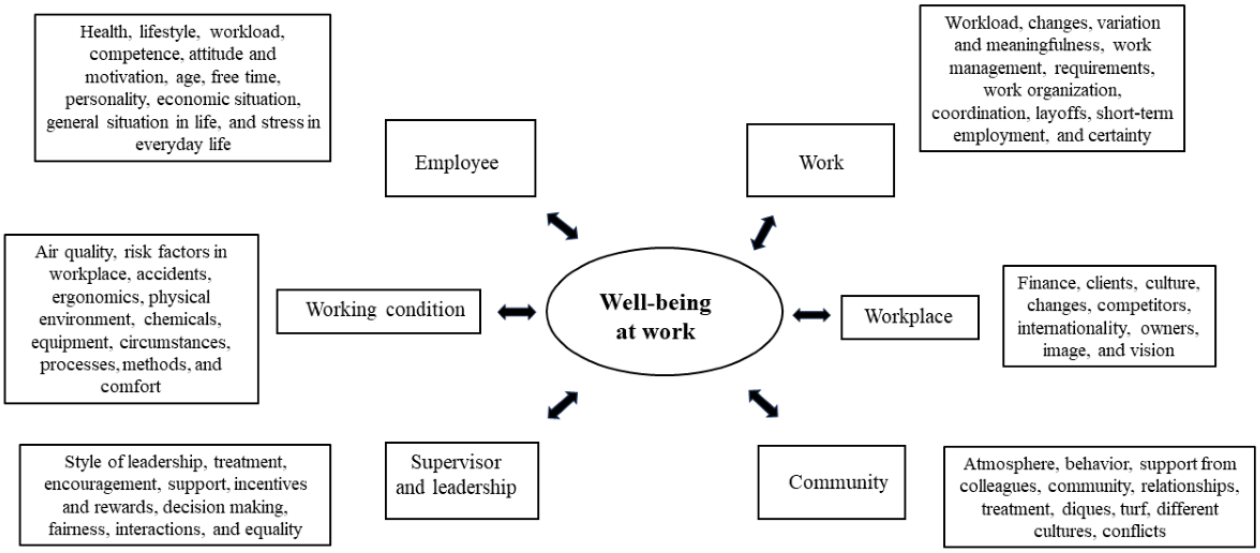
Introduction



Overview

Systematic monitoring of work atmosphere and patient safety incidents is a necessary part of a hospital's quality assurance systems, particularly an accredited system like the Joint Commission International (JCI) [1,2]. Accreditation and related education have been shown to increase motivation and improve work atmosphere and awareness of patient safety. Statistically significant improvements have been noted in defect management (particularly in the context of instrument cleaning and disinfection effectiveness) in a randomized controlled trial evaluating the impact of JCI accreditation [3]. Physician-nurse relations as well as management-line staff relations have been reported to improve along accreditation [4].

Accreditation is a costly and time-consuming process [5], causing a legitimacy problem for a hospital's management [6]. This situation raises a fundamental question: Is accreditation worth pursuing considering the time and effort it requires? Thus, further research is needed from a different view. How the implementation of quality assurance systems affects well-being at work and patient safety is not studied extensively [7]. The effects of quality assurance systems on work atmosphere and patient safety are challenging to determine due to numerous potentially confounding factors [8,9]. However, assuming that well-being at work and work satisfaction are strongly correlated with good outcomes in health care service delivery, including patient safety, is reasonable. This assumption is supported by Schwarz et al [10], who found that work-life integration among health care workers is associated with improvements in teamwork and safety across various safety culture domains [10]. In a study by Lopes et al [11], job satisfaction and safety culture were directly proportional. Better working conditions can provide a virtuous cycle of patient safety and occupational health [11].

The Finnish Institute of Occupational Health defines well-being at work as safe, healthy, and productive work, which is carried out by competent employees and work communities in a well-managed organization. Employees and work communities experience their work as meaningful and rewarding, and they consider work to support their life management [12]. The importance of well-being at work is highlighted in health care services, as labor input is directed toward patients. Well-being improves work performance, further promoting good workplace outcomes. For instance, well-being at work reduces the risks of exhaustion, workplace accidents, illnesses, and the loss of tacit knowledge regarding drug abuse [13]. The well-being of the working community is comprised of the performances of its members and linked to factors beyond each employee's performance and influence. In this study, the operationalization of well-being is based on a model that considers worker health, subjective well-being, capabilities, motivation, the organizational management model, management workload, company values, and the overall atmosphere as well as the conditions of the work environment, such as work content and instruments with which the work is executed (Figure 1) [14].

Figure 1. Domains well-being at work by Naumanen (2018) [14].

Aim and Objectives

This protocol will describe the procedure and methods for monitoring the effects of implementing the quality assurance system of JCI at Orton Orthopedic Hospital on employees' well-being (primary outcome) and patient safety (secondary outcome). The system implementation effects will be evaluated through work-related well-being surveys using direct and indirect evaluations, and patient safety will be evaluated using register data.

Methods

Overview

The study sample will include about 200 employees working in a hospital. The hospital is a private orthopedic hospital focused on joint replacements and back surgery and has a rehabilitation center. This hospital is owned by a large public health care hospital, which also performs JCI implementation. Table 1 illustrates the accreditation process and its monitoring. Textbox 1 [15] presents the registry data collection system. The

XSL•FO
RenderX

implementation will begin following a JCI orientation training organized by JCI. The company must organize their employees during the process. The JCI procedure is designed to be ready in 4 years. Baseline surveys (questionnaires and interviews) will be conducted, and all surveys will be repeated when the implementation is 50% complete.

Table 1. Methods and data collection system during the accreditation process.

Baseline surveys[a]	Data collection system
Questionnaires	• A total of 35 questions; registering and monitoring the well-being of the employees of the Orton Orthopedic Hospital • Repeatability test of the questionnaires
Register data	• HaiPro[b] • Absence due to illness • Employee turnover • Injuries of the employees • Cost of occupational health case • Patient insurance cases • Rate of wound infections • Revisions • Time of surgery
Qualitative method (semistructured interviews)	• A total of 4 groups (doctors, nurses, therapists and administration, and support staff)

[a]Surveys, including questionnaires and register data, as well as qualitative methods (semistructured interviews) will be repeated after half of the implementation and after finishing accreditation.

[b]HaiPro is a web-based tool for reporting patient safety incidents. Anonymous and voluntary input ensures confidential reporting and processing of the safety incidents. The HaiPro method does not seek to blame [15].

Textbox 1. Register data collection 2 years prior to implementation, when the implementation process is 50% complete, and when the facility is ready for accreditation. A web-based tool (HaiPro) will be used for reporting patient safety incidents and risk events, which are divided into near-miss and injurious events.

Register data collection

- HaiPro—near-misses and misses (n)
- Absence due to illness (days)
- Employee turnover (n)
- Employee injuries (n)
- Cost of occupational health care (€/year)
- Patient insurance cases (n)
- Rate of wound infections (n)
- Time per surgery (h/min)
- Revision surgery (%)

Quantitative Studies

Questionnaires

This study applies a mixed methods approach, including quantitative (questionnaires and register data) and qualitative (semistructured interviews) methods [16]. The study uses a convergent design, where both qualitative and quantitative data are collected as well as analyzed and results are reported at the same time [17]. The occupational well-being questionnaire in this hospital was developed before the planned study to facilitate good personnel management. In the questionnaire, job requirements and job resources have formed the theoretical framework of the survey [18-20]. It also included 4 questions designed to capture the participants' views on leadership, values, expertise, and work atmosphere, based on Otala and Ahonen [21].

The questions are divided into 3 sections: questions 1-6 ask for the participants' background information, questions 7-31 focus on physical and psychological well-being and connect to functional capacity, and questions 32-35 concern work satisfaction (Multimedia Appendix 1). The first section ascertains the employees' health and well-being regarding work burden and the effects of illnesses and strains on functional capability. The questions will be evaluated on a 10-point Numeric Rating Scale (1=no work-related problems; 10=completely unable to work). Questions 7-21 evaluate perceived health and mood, distress, anxiety, and the ability to take care of oneself on a 3-point Likert scale (1=no problems;

XSL•FO
RenderX

3=completely unable). These questions are evaluated on a 5-point Likert scale (1=completely agree; 5=completely disagree).

In the third section, question 32 describes management from the viewpoint of an immediate superior. Question 33 explores the know-how viewpoint, aiming at charting the perspective to improve one's competence and knowledge. Question 34 focuses on company values and acting upon them. Question 35 concerns team spirit, which is one of the company's most important values. Questions 32-35 are evaluated on a 5-point Likert scale (1=completely agree; 5=completely disagree).

Register Data

Register data, including the employees' sick leave and work accidents, will be collected from 2 years prior to implementation to 2 years after implementation. We will also use a web-based tool (HaiPro) for reporting patient safety incidents, which are all treatment events that either harmed or could have harmed them [15]. HaiPro is a web-based tool for reporting patient safety incidents. Anonymous and voluntary input ensures confidential reporting and processing of safety incidents and risk events. These events are called risk events and are divided into near-miss and injurious events [15]. In addition, the number of reoperations, the rate of wound infections, surgery times, and notices of injuries reported to the Finnish Patient Insurance Center will be collected. Textbox 1 shows the register data collection during the accreditation process.

Statistical Analysis

Primary and secondary end point analysis will be performed on all participants receiving 1 or more administrations of study treatment (the intent-to-treat population). However, no sample size calculation will be performed in advance due to the unavailability of accurate and reliable data for making such estimates. We will include all individuals who will respond to the questionnaire in this study. The descriptive statistics are presented as means (SDs), medians (IQRs), or counts with percentages. The groups will be compared using the *t* test, permutation test, and ANOVA for continuous variables and the Pearson chi - square test or Fisher exact test for categorical variables. Register data analysis will be performed using mixed-effect linear models with an appropriate distribution and link function; models do not require complete data and can be fit even when individuals or data do not have observations at all time points (missing data will be handled by using available-data analysis) [22]. Confounding factors will be adjusted. Models include age, sex, working time, education years, and employment status. In case there are violations of the assumptions or theoretical distribution of the test statistics (eg, nonnormality, skewness, kurtosis, or a small number of observations), a bootstrap- or permutation-type analysis will be used.

Traditional test theory analyses will be used to verify the reliability and validity of the questionnaire. These analyses include internal consistency using Cronbach α, inter-item correlations, and exploratory factor analysis (using the iterated principal-factor method for factoring and oblique promax-rotated factor loadings on polychoric correlation matrix). The test-retest reproducibility will be evaluated by intraclass correlation coefficients using the 1-way random effects model. Coefficients of reproducibility and their 95% CIs will be also calculated. Correlation coefficients will be calculated by the Pearson or Spearman method. Normal distributions will be evaluated graphically and with the Shapiro-Wilk W-test. Stata 17.0 (StataCorp LP) will be used for the analysis.

Qualitative Studies

Participants in the focus group interviews include working community members. The groups consist of multiprofessional individuals, and the interviews last about an hour. These qualitative interviews aim to broaden the baseline views, conceptions, and expectations of the personnel regarding quality assurance and their well-being before implementing the JCI quality assurance system. The semistructured interviews will be conducted by an external interviewer with knowledge of different quality assurance systems and conducting qualitative research.

Qualitative data are collected in 3 thematic group interviews that feature 12 participants. To create the groups for the interviews, a list of the hospital's employees will be collected and grouped into 4 categories: physicians; nurses; therapists, other medical staff, and the administration; as well as support staff and secretaries. The personnel will be listed in each category in alphabetical order. Consequently, random selections will be made from the staff at the hospital, stratified by occupation, for all groups. After the draw, each employee can opt out of their assigned group. In such cases, the group is supplemented with the next person on the list. The researchers conducting this study are exempted from the lists. After 3 semistructured focus group interviews, the main themes will presumably recur, and the point of saturation will be reached [23].

The interviews will be recorded with the participant's permission, and the tapes will be transcribed subsequently. The interviews will be analyzed using qualitative content analysis, a conventional content analysis [24]. The analysis aims to gain an understanding of how individuals in the small groups perceive the quality assurance system, assess its usefulness, and recognize the need for its development, all from the perspectives of different employees. The semistructured interviews ask participants about their expectations of the quality system, their involvement in the JCI orientation, as well as the perceived benefits and drawbacks of the quality system. In addition, the focus group interviews will ask about staff experiences in relation to safety, well-being, and motivation at work as well as the prospects of the hospital. The interviews will conclude with questions on quality factors related to surgery (eg, surgery times), patient safety, and experiences of patient care. Textbox 2 includes the semistructured interview questions.

The content of the open-ended questions will be coded according to the themes emerging from the data. The most prevalent themes will be selected and reported in the study. These themes will help explain and deepen the understanding of the responses to the quantitative approach of the study in describing the perceived conceptions of the quality system and its relationship to occupational safety, patient safety, and surgery.

XSL•FO
RenderX

The interviews will be renewed after half of the implementation is completed. The same groups will be requested to participate in the interviews; however, certain community members may change their working place or may not participate in the renewed test. Those members will be replaced by other members of the working community. If the point of saturation is not reached in the midterm interviews after 3 interviews, 4 or more interviews will be conducted [23].

Textbox 2. Semistructured interview questions.

Expectations from the quality assurance system, participation in orientation, perceived benefits of the quality assurance system, results, and their quality

- How have you participated in the quality assurance work?
- How have you experienced the training related to the quality assurance system and other orientations?
- What expectations do you have for the quality assurance system (ie, Joint Commission International)?
- What kind of benefits can the quality assurance system have? Do you think it might have some disadvantages as well?
- What kind of results can the quality assurance system have?
- How does it affect the quality of activities in the hospital?
- What kind of changes does the quality assurance system bring to your everyday work?
- In what state do you think the quality assurance system is right now?

Occupational safety of personnel, work motivation, and prospects of the hospital

- How does the quality system affect occupational safety?
- What about work motivation?

Occupational well-being

- What do you perceive as factors related to well-being at work?
- What are the driving forces of occupational well-being in our hospital?
- What kind of effects the quality assurance system can have on well-being at work?
- Which aspects of occupational well-being are affected by the quality assurance system?

Factors related to surgery (eg, surgery times), patient safety, and patient care

- What kind of effects does the quality assurance system have on factors related to surgeries?
- What kind of effects does the quality assurance system have on surgery times?
- What about patient safety?
- What other effects does the quality system have in relation to patient care?
- How do you think the quality assurance system will affect the future of the hospital?
- What else would you like to say about the quality assurance system or occupational well-being?

Ethical Considerations

The study was submitted to the University of Oulu Human Sciences Ethics Committee. An ethical review was not required based on their criteria. Participants will provide their written consent for the interviews.

Results

The results of the quality assurance implementation will illuminate the possible effects on patient safety and job satisfaction. The repeatability and internal consistency of the well-being questionnaire will be reported. The qualitative research results describe the employees' experiences with the quality implementation process. Data collection will begin in May, 2024. It will be followed by data analysis and the results are expected to be published by 2025.

Discussion

Expected Outcomes

The Finnish Institute of Occupational Health defines well-being at work in 3 different ways: the first one is based on doing in the sense of accomplishing, the second emphasizes experience, and the third provides a description of the experience [25]. Well-being results from the fulfilment of the important needs of individuals and the realization of goals and plans set for one's life. Goal-oriented activity and commitment to tasks lead to well-being. However, the history of well-being at work is short. The concept of quality and productivity in working life has only recently evolved and includes aspects such as learning and social activities [25]. Well-being at work is also subject to various perspectives in different countries and cultures and even in different workplaces within the same country. That is why we

XSL•FO
RenderX

believe it is crucial that in the planned study, we use a customized questionnaire for well-being at work; this questionnaire will encompass generic items from the Finnish working life context and will be supplemented with specific questions that are important for Orton Orthopedic Hospital.

The need for quality assurance systems in health care is widely accepted. However, the added value of an accredited quality assurance system has not been widely studied. When undertaking such a large task, the effects of pursuing an accredited quality assurance system should be evaluated. The analysis will be challenging in a comparative study design due to practical and ethical reasons, although a randomized controlled trial published recently offers some insight [3]. Therefore, in this study protocol, a quasi-experimental study design will be followed [26], with a focus on employee well-being and patient safety, under the assumption that they are interlinked. Therefore, procedures and practices will be clarified for workers to diminish errors and increase patient safety. The added value of branding and marketing will be ignored, but accredited quality influences these issues as well.

In this protocol, the primary and secondary outcomes are well-being at work and patient safety, respectively. Patient safety has 4 main items: all the HaiPro notices [15], the number of wound infections, the number of patient insurance cases, and the number of revision surgeries. Certain overlaps exist between these items and must be considered in the analysis. Worker well-being register data will also be collected, including information on illness-related absences, employee turnover, employee injuries, and the costs of occupational health care.

A staff survey is an efficient way to learn the views of all personnel. Surveys also help employees evaluate their efforts and input [27]. Our study will use various evaluations. The most important variable is employee well-being, which is evaluated through the questionnaire. This questionnaire is specifically developed for the study and complemented with the register data follow-up regarding sick leave, employee turnover, and costs of occupational health care.

We acknowledge the problem of presenteeism, which involves the act or culture of employees continuing to work as a performative measure, despite negative consequences); this is a rising issue in the workplace. If left unrecognized and unresolved, presenteeism can lead to poor well-being, low morale, burnout, and increased employee turnover. It also poses a huge threat to productivity because employees who show up to work when they are not feeling mentally or physically well cannot provide their best performance [28]. Indirectly, the effects of presenteeism can be evaluated in this study using specific questionnaire items and register data. However, due to the absence of readily available indicators to apply here, a more comprehensive examination of the issue may be reserved for future studies.

We are aware that some parts of the accreditation are demanding and require going over the allotted work-hour resources. The hospital may have to spend additional time in ensuring the smooth operation of new formats. There might be a need for extra personnel for accreditation-related work. We have the approval from the hospital management and the commitment of the staff to this endeavor.

Numerous confounding factors exist. Health care is greatly influenced by cultural norms and is strictly regulated by legislation. The strength of qualitative studies is to raise points of view that are formulated through study questions. The qualitative approach in research is exploratory and helps develop hypotheses for future studies. To the best of the authors' knowledge, the combination of the qualitative and quantitative approaches (ie, mixed methods) has not been used in research on hospital accreditation.

Limitations

This protocol has certain limitations. The study will be a monocentric study; thus, comparative data from other hospitals are not collected. The lack of a comparative design is a limiting factor in the study protocol. However, comparing 2 hospitals, one with quality assurance implementation and the other without, presents challenges. These 2 hospitals have different personnel, patient profiles, and managerial routines as well as different practices and philosophies in quality assurance work. Probably all the confounding factors cannot be considered in this planned comparison. To overcome the lack of a comparative design, we are planning to apply a mixed methods approach that includes quantitative (questionnaires and register data) and qualitative (semistructured interviews) methods. The study also uses a convergent design [17], where both qualitative and quantitative data are collected as well as analyzed and results are reported at the same time.

The application of a locally developed questionnaire can be considered a limitation of the study. We argue, however, that it is well reasoned to apply this occupational well-being questionnaire in the planned study. The results would facilitate the development of Orton Orthopedic Hospital presumably more accurately than using a generic questionnaire. The whole concept of occupational well-being is novel and strongly influenced by cultural factors, supporting the use of local applications [25]. It is also worth noticing that when we compared the Parker and Hyett [29] questionnaire with ours, there were multiple similarities. Personnel turnover is also a limiting factor to be considered in the analyses.

Acknowledgments

This work is supported by the Research Institute Orton through grants from the Ministry of Social Affairs and Health in Finland (A2500/495).

Abstract

Background: Maternal and newborn mortality in Pakistan remains as a major public health challenge. Pakistan faces significant infrastructure challenges and inadequate access to quality health care, exacerbated by sociocultural factors. Facility-based audit systems coupled with community engagement are key elements in achieving improved health system performance. We describe an implementation approach adapted from the World Health Organization audit cycle in real-world settings, with a plan to scale-up through mixed methods evaluation plan.

Objective: This study aims to implement a locally acceptable and relevant audit system and evaluate its feasibility within the rural health system of Pakistan for scale-up.

Methods: The implementation of the audit system comprises six phases: (1) identify facility and community leadership through consultative meetings with government district health offices, (2) establish the audit committee under the supervision of district health officer, (3) initiate audit with ongoing community engagement, (4) train the audit committee members, (5) launch the World Health Organization audit cycle (monthly meetings), and (6) quarterly review and refresher training. Data from all deliveries, live births, maternal deaths, maternal near misses, stillbirths, and neonatal deaths will be identified and recorded from four sources: (1) secondary-level care rural health facilities, (2) lady health workers' registers, (3) community representatives, and (4) project routine survey team. Concurrent quantitative and qualitative data will be drawn from case assessments, process analysis, and recommendations as components of iterative improvement cycles during the project. Outcomes will be the geographic distribution of mortality to measure the reach, proportion of facilities initiated to implement an audit system for measuring the adoption, proportion of audit committees with community representation, and proportion of audit committee members' sharing feedback regularly to measure acceptability and feasibility. In addition, outcomes of effectiveness will be measured based on data recording and reporting trends, identified modifiable factors for mortality and morbidity as underpinned by the Three Delays framework. Qualitative data will be analyzed based on perceived facilitators, barriers, and lessons learned for policy implications. Results will be summarized in frequencies and percentages and triangulated by the project team. Data will be analyzed using Stata (version 16; StataCorp) and NVivo (Lumivero) software.

Results: The study will be implemented for 20 months, followed by an additional 4-month period for follow-up. Initial results will be presented to the district health office and the District Health Program Management Team Meeting in the districts.

Conclusions: This study will generate evidence about the feasibility and potential scale-up of a facility-based mortality audit system with integrated community engagement in rural Pakistan. Audit committees will complete the feedback loop linking

XSL•FO
RenderX

health care providers, community representatives, and district health officials (policy makers). This implementation approach will serve decision makers in improving maternal and perinatal health outcomes.

Introduction

Background

Pakistan is a low-income country with significant infrastructure challenges, poor allocation of government funding for health, poor access to essential health care services, low-quality health care services [1], sociocultural constraints, and a feudal system that affects all aspects of province life [2]. One of the main impacts of these governance and funding challenges relates to the health of mothers and their newborn children—2 cohorts that are already categorized as populations at high risk. The manifestations of this burden include a persistently high neonatal mortality rate, accounting for 57% of child deaths across the nation [3], with 41 out of every 1000 born babies dying before the end of their first month [4] and a maternal mortality ratio of 186 per 100,000 live births [5]. Pakistan's perinatal, neonatal, infant, under 5 years, and maternal mortality rates remain unacceptably high, with estimates of >399,429 children dying per year [6]. Although efforts to improve the quality and timeliness of care in district and regional facilities are being made, progress has been painfully slow [7].

Audits and review systems, especially those with community engagement, are 2 key elements that have been shown to improve the health system's performance and maternal and perinatal health outcomes for at-risk populations [8]. Audits provide a documented history of the events leading up to the death and highlight process failures amenable to process redesign and teachable moments to prevent similar untoward events. Introducing audits and reviews can reduce inpatient maternal mortality (adjusted odds ratio 0.85, 95% CI 0.73-0.98; 191,167 deliveries; moderate certainty evidence) and likely inpatient neonatal mortality (adjusted odds ratio 0.74, 95% CI 0.61-0.90; moderate certainty evidence) [9]. Findings from a meta-analysis of 7 pre-post studies of facility-based perinatal mortality audits in low- and middle-income countries indicated a reduction in perinatal mortality of 30% (95% CI 21%-38%) after introduction of perinatal audits [10].

The District Health Information System (DHIS) seldom records and reports mortality (eg, maternal mortality and neonatal mortality) and severe morbidity indicators consistently and reliably (eg, birth asphyxia and preeclampsia), leading to challenges in data completeness in capturing vital statistics through routine health and administrative data. Audit systems at the facility levels can provide for sustained improvements in the quality of provision and delivery of services. Community linkages and engagement ensure proactive and detailed discussion of the causes and modifiable factors leading to the deaths, essential for improved working relationships between community members, health providers, and policy makers [11]. Audits of stillbirths and neonates also contribute to achieving Every Newborn Action Plan goal for reducing stillbirths and neonatal deaths to <12 newborn deaths per 1000 live births [12].

The Three Delays Framework for Maternal and Perinatal Mortality

Pregnancy-related maternal, neonatal, and infant mortality is attributed to delays in using the Three Delays framework [13] with time-related consequences—the "first delay" around the decision to seek medical care, "second delay" attributed to the time to reach the health facility, and "third delay" caused by receiving inappropriate care after reaching the medical facility [14-16]. In Pakistan, the "first delay" has been further divided into two subgroups: (1) delay in recognition of the severity of illness and danger signs contributed to 18% of all delays and (2) delays in decision-making by virtue of limited action of women to make decisions regarding their transfer to facilities contributed 34% [7].

The impacts of delays in care can be seen in the recent Verbal Autopsy and Social Autopsy mortality survey in Table 1. More than half of the deaths (26%-55%) occurred at the community level (the first delay), 4% to 13% of deaths occurred in route to the facility (the second delay), and the remaining occurred within health care systems (the third delay).

Table 1. Locations of neonatal, child, and maternal deaths according to the unpublished Verbal Autopsy and Social Autopsy results (2019).

Indicators	Hospital, %	Other health provider or facility, %	In route to health provider or facility, %	Home, %	Others, %
Location of neonatal deaths	55.3	2.3	4.1	38.2	0
Location of child deaths	35	0.9	7.1	54.7	2.2
Location of maternal deaths	56.8	11.4	12.5	26.4	3

History of Perinatal Audit Systems in Pakistan

Previous efforts to introduce facility audit systems by the Pakistan Ministry of National Health Services, Regulations, and Coordination have used the phased implementation of the Maternal and Perinatal Death Surveillance and Response to enhance reporting, recording, tracking, and auditing of deaths [17]. The World Health Organization (WHO) is currently assisting Khyber Pakhtunkhwa and Baluchistan provinces, and United Nations International Children's Emergency Fund (UNICEF) is helping the Sindh province in implementing audit mechanisms, but results have not been made public. The United Nations brief on COVID-19 [18] and the Pakistan Health Report 2020 [19] have stated that the Maternal and Perinatal Death Surveillance and Response has great potential for success.

We hypothesize that a WHO audit cycle that is locally acceptable in close consultation with local community representatives and health care providers is feasible for implementing a robust audit system in rural settings. Specifically, we asked the following questions:

1. Is the implementation of facility-based maternal and perinatal mortality audits in combination with targeted community engagement feasible in rural Pakistan?
2. Will the maternal and perinatal audits improve the reporting of deaths and maternal near misses at the DHIS health facilities?
3. Will the audit systems help better identify medical and nonmedical factors of deaths and near misses, and how doable recommendations are implemented through integration of feedback loops within the health facilities and communities?
4. Will the community-facility audit interaction improve the early referral proportions?

Primary Objectives

The primary objectives include the following:

1. Identify and establish audit committees at health facility levels with integrated community engagement, and
2. Determine the feasibility of implementing an acceptable audit system with community representation in existing secondary health facilities and serving catchment populations.

Secondary Objectives

The secondary objectives include the following:

1. Identification of "first delay" (care-seeking decision), "second delay" (identification and reaching the health facility), and "third delay" (receiving adequate care and treatment at facilities) among mortality and morbidity cases, and
2. Propose solutions and record actions taken to improve the access to quality of care through integrated feedback loops within health facilities and communities.

Primary Outcomes

The primary outcomes include the following:

1. Proportion of facilities initiated to implement an audit system for measuring the adoption of audit system,
2. Proportion of audit committees with community representation and proportion of committee audit members sharing feedback regularly to measure the feasibility of the audit system, and
3. Qualitative narrative approach for acceptability and exploring the facilitators of and challenges in implementing audit systems.

Secondary Outcomes

The secondary outcomes include the following:

1. Geographic distribution of mortality to measure the percentage coverage or reach in the implementation district,
2. Change in trends in data recording and reporting to measure effectiveness,
3. Categorization of mortality and maternal near-miss cases among Three Delays framework,
4. Number of awareness sessions covering the proportion of the catchment population,
5. Number of referrals in and out of the health facility,
6. Number of transport mechanisms linked to health facilities by audit committee members, and
7. Proportion of health facilities implementing actionable recommended actions at the facility level.

Methods

Overview

We will conduct a mixed methods study that integrates formative research and evaluative components into iterative improvement cycles. The planned interventions will examine the feasibility and document the process and challenges of implementing an audit system at scale. The study was also registered on ClinicalTrials.gov (NCT05640050).

Study Setting

The study will be conducted in 1 district—Matiari (Sindh) with a population of 770,040 (Pakistan Bureau of Statistics–2017). The district selection was based on the operational ease with past positive experiences in efficient rollout of health services. Moreover, the district health office (DHO) of Matiari is actively involved in DHIS feedback meetings to improve the data quality.

Study Population

The eligible population includes all women who had deliveries at community and health facilities that result in a maternal death or maternal "near miss," stillbirths, or neonatal death (perinatal death).

Inclusion Criteria

Women aged between 15 and 49 years who reside in the selected district are eligible to participate. Secondary-level public health facilities that offer obstetric and postnatal care and respective catchment areas supported by lady health workers (LHWs) are included in the study. Data for all maternal mortality, maternal "near misses," and perinatal and neonatal mortality recorded for all women and newborns delivered at home (through LHW monthly reports) and who contact the health facility within 42 days after delivery, regardless of whether they delivered at the health facility, will be collected.

XSL•FO
RenderX

Exclusion Criteria

Women who are nonresidents of the study district and who do not provide consent are not eligible to participate.

Operational Definitions

The outcomes are defined in Textbox 1, using the International Classification of Disease–10 classification system by WHO [20].

Textbox 1. Operational definitions—International Classification of Diseases–10.

Stillbirth

- Stillbirth is the delivery of baby with no signs of life after ≥22 weeks of gestation.

Neonatal mortality

- Neonatal mortality is the death of a newborn within the first 28 days of life.

Perinatal mortality or death

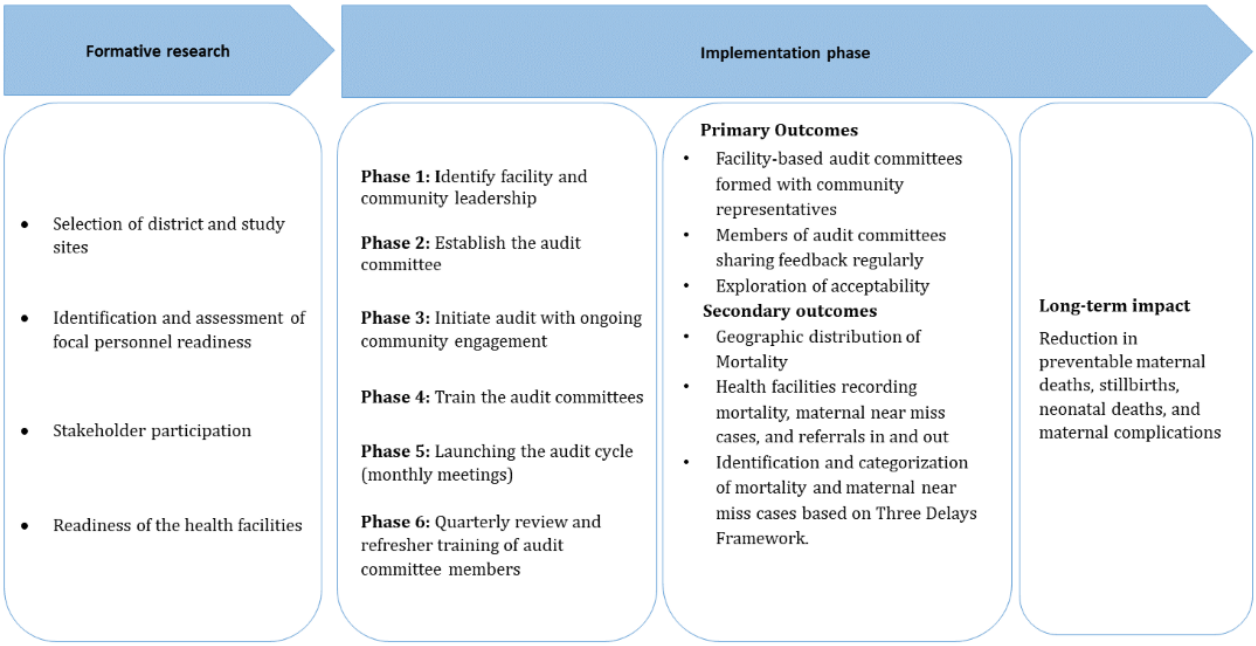
- Perinatal mortality or death is a death that occurs around the time of birth. It can involve a still birth or be an early neonatal death that occurs up to 7 days after birth.

Maternal *near miss*

- Maternal *near miss* is a situation in which a pregnant woman nearly dies but survives a complication that occurred during pregnancy, during childbirth, or within 42 days of the termination of pregnancy. It can involve severe pregnancy-related complications (severe postpartum hemorrhage, severe pre-eclampsia, eclampsia, sepsis, and ruptured uterus) or critical interventions (blood transfusion, laparotomy, admission to an intensive care unit, hysterectomy, and other emergency surgical interventions in the abdominal cavity).

Maternal mortality or death

- Maternal mortality or death is the death of a woman during pregnancy or within 42 days of delivery or the termination of pregnancy, irrespective of the duration or site of the pregnancy, from any cause related to or aggravated by the pregnancy or its management, but not from accidental or incidental causes.



Sample Size

Population size is a challenge in the rural setting, however this study intend to cover all records of stillbirths, neonatal deaths, maternal deaths, and maternal "near misses" from four sources: (1) secondary health facilities, (2) LHW registers, (3) audit committee's community representatives, and (4) project routine survey team.

Study Timeline

The implementation of the audit system intervention is planned for 20-month period. To account for the effects of maturation (ie, 28 days after delivery for neonatal outcomes and 42 days after pregnancy for maternal near-miss outcomes), an additional 4 months will be added to the end of the intervention. Figure 1 Illustrates the implementation framework.

Figure 1. Implementation framework.

XSL•FO
RenderX

Audit System Implementation Phases (6 Phases)

The project development is based on formative studies that identified the importance of health care providers' readiness, stakeholder and community participation, and health facilities' readiness. The process will include consultative meetings with project's core committee members, program advisory committee members, Director General of Health, and DHO staff.

Phase 1: Identify Facility and Community Leadership

The project's core team and district manager identify facilities and community representatives who will coordinate and liaise with other district stakeholders to implement the community audit interventions.

Phase 2: Establish the Audit Committee

The person in charge of the health facility will establish an audit committee using existing health committees at the Tehsil Head Quarters, quality control committees, medical inspection committees, health welfare committees, and joint health inspection committees in health facilities at Matiari. Audit committees will be led by the medical superintendent of the hospital, with a member from administration, 3 to 4 consultants or medical officers from various departments (gynecologist; pediatrician; ear, nose, and throat [ENT] specialist; pathologist; head of the emergency department; and head nurse), district magistrate, or focal person from DHOs. The community engagement and audit system for project audit committee will be established at each facility; preferably, members will be at least 2 obstetricians, 2 pediatricians, 1 administrator, project focal person, and community representatives as community audit representative. Responsibilities and audit committee structure will be described. Members of the audit committee will update their credentials every month, and trickle-down training will be conducted by audit committee members.

Phase 3: Initiate Audit With Ongoing Community Engagement

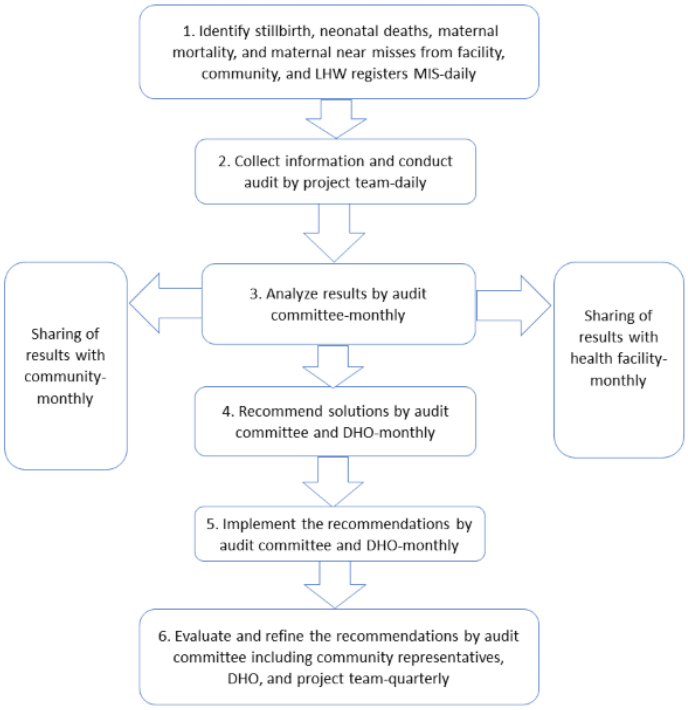
Community representatives (1-3 individuals) will be identified as community audit representatives. They will be invited to attend the monthly audit meetings with facility-based audit committee members to discuss the community perspectives (delays 1 and 2) and other issues pertaining to the negative maternal and perinatal outcomes. LHWs, lady health visitors, community midwives (CMWs), male community mobilizer (village or otaq leader or any other active member of village), or any other influential women in the village will be engaged for audit committee decisions. They will provide timely oversight, monitor, and respond to adverse events and later confer in the audit meetings.

Phase 4: Train the Audit Committees

Training for audit representatives and members of the audit committee, will be conducted using 3-day training workshop, which includes the following:

- Day 1: Maternal death, near misses, and perinatal death (stillbirth and neonatal deaths),
- Day 2: The Three Delays framework and identifying modifiable factors, and
- Day 3: Mentoring regarding the identification of the audit committees and initiating the audit implementation committee.

The audit committee will be trained to follow ethical guidelines in maintaining an empathetic gesture while recalling the adverse patient events by the respondents. Training will also include standardized case studies and completion of audit meeting minutes and action item tools.



Phase 5: Launch the Audit Cycle (Monthly Meetings)

Overview

The WHO audit system [20] will be adapted to assess maternal, perinatal, and neonatal deaths with 6 steps. Audit process in health facilities and communities is illustrated in Figure 2. Following are the steps and their processes involved in audit cycle.

XSL•FO
RenderX

Figure 2. World Health Organization audit cycle. DHO: district health officer; LHW: lady health worker; MIS: management information system.

Step 1: Identifying Cases for Review

The district supervisors will record all maternal deaths, maternal near misses, deliveries, births, stillbirths, and neonatal deaths that occur in the delivery ward, neonatal unit, and postnatal ward, ensuring the capture of the minimum set of perinatal indicators in a source register. Efforts to collect and record data on maternal deaths, near misses, and perinatal and neonatal deaths that occur in the community will be made through monthly reporting from LHWs or CMWs to their associated health facility or by women who contact the health facility after delivery. Specific strategies will be put in place to ensure that all deaths are captured and filtered to the mortality audit committee, so that cases can be selected for review and discussion at the mortality audit meetings.

Step 2: Collecting Information

The aim is to empower designated staff to collect a standardized set of information from the patient file or register as soon as possible after the death. For every death, decisions will be taken regarding what information is recorded, where the information is recorded, who records it, and who collates it on a periodic basis both for the death review process and for reporting to other levels within the health system. It should be noted that if the use for the data cannot be identified, the data will not be collected. Before collecting the information, the audit committee will have a clear understanding of the data analysis plan to help identify the data to collect. Data abstraction or collection forms will be either electronic or paper-based, depending on the infrastructure and capacity of the health facility. Clear directions about the exact data and qualitative information that should be collected will be included.

All data collected will be stored on password-protected laptops or tablets or locked cabinets in locked offices within the health facility. Before implementation, data collection forms will be piloted and revised as needed. The minimum data collected will include the following: information about the mother's condition, baby's condition on admission and at the onset of labor (for antepartum and intrapartum deaths), baby's condition at birth (stillbirth or live birth), baby's condition on discharge from the health facility (alive, transferred to another facility, or dead], and date and time of birth and death (so that the age at death can be calculated in hours rather than days).

As part of the intervention, each facility audit system is planned to be comprehensive to ensure that it captures data on each death and includes the relevant cause of death; link to maternal condition; demographic data; and a list of contributing, modifiable factors corresponding to codes for analysis and linked to recommendations. To ensure that phase-1 and phase-2 delays are captured, all efforts to link deaths that occur in the community to the facility audit system will be conducted by the trained LHWs, CMWs, and project team. The audit committee will hold follow-up monthly meetings with designated community engagement members to initiate the chain of notifications within the audit cycle as it relates to the implementation of recommendations and solutions.

Step 3: Analyzing the Information

The aim is to identify problems in the system that may have contributed to maternal death, stillbirths, and neonatal deaths, especially those that could have been averted. Data analysis will include quantitative components, such as identification of trends in rates and causes of death and geographic location. Qualitative analysis will provide additional insight into the problems that caused the deaths of individual cases and more general information about groups of deaths caused by similar contributing factors. The use of both types of data together will

XSL•FO
RenderX

provide a more robust analysis of the problems and aid the audit committee to identify priorities for action.

Step 4: Recommending Solutions

The aim of this critical step is to find ways to move from problems to action by identifying specific, measurable, attainable, relevant, and time-bound solutions. A formal platform will be created to present the findings of the audit process. The moderator will guide the discussion and present aggregated data and trends in addition to selected individual cases presented anonymously without bias. It is recommended that no more than 2 cases per 2-hour session shall be reviewed per month. After the presentation of the case summary, the main facts are analyzed by the audit members. Discussion will follow the presentation, reflecting on the modifiable factors of specific cases and any changes in trends from meeting to meeting.

A systematic and exhaustive analysis of the case should be conducted to effectively understand the chain of events related to the case. After identifying the main problems at the various steps described previously, the audit committee is invited to discuss and make the case for why a procedure or an act should be considered adequate or inadequate, by referring to the established standards of practice. Dysfunctions and their causes should be prioritized, and energy should be devoted to solving the most significant problems and those for which the implementation of a solution is feasible. Then, the committee will investigate what its causes and related factors may be, and these can be related to (1) personnel: qualification, skills, availability, attitude, and so on; (2) drugs, supplies, and equipment: availability, accessibility, and so on; (3) protocols: availability, knowledge, understanding, use, and so on; (4) management or care organization: coordination, communication, and so on; and (5) patient and his family: financial accessibility, misunderstanding, willingness, and so on. Final step will be the identification of cause of morbidity or death by (1) reviewing the medical cause of severe morbidity or death and identifying the various factors or events that may have contributed to the outcome, (2) comparing the cause of the morbidity or death documented in the patient's record with the audit committee findings, and (3) determining whether the death was preventable.

Following the abovementioned steps in analyzing the case, the moderator leads the discussion to select the problems to be solved in order of priority. Problems must be prioritized based on the significance of their effect on prognosis and the feasibility of the actions necessary to solve them. Through the moderator, the audit committee will then reach a consensus on appropriate, evidence-based strategies to address the main gaps at the health facility level (phase-3 delay). The solutions will balance the priorities based on burden and feasibility and may be related to ongoing or one-off activities.

In addition to possible solutions at the health care facility level, the audit committee in the community will identify cases that are closely linked to the community and agree on select cases to present during the postaudit community feedback meeting. Community-level solutions will be directly related to phase-1 and phase-2 delays. The audit committee will ensure that findings are shared in the appropriate forum and work with the community to develop solutions that are clear, attainable, and straightforward about the potential for improving care, without placing blame.

Recommending realistic solutions to reduce the factors associated with maternal, perinatal, and neonatal morbidity and mortality in the community can be challenging. Careful considerations regarding the capacity of the community to implement the recommendation and the method of communication will be prioritized. The 2016 WHO guidelines for audit and review of stillbirths and neonatal deaths advises formulating a recommendation in collaboration with community leaders empowered to make the recommended change to ensure it is effective. To alleviate the risk of developing distrust between the community and the health system, recommendations will not be "handed down" from the health facility audit committee but rather discussed as a partnership with the community. In addition, effective communication, relayed consistently and sensitively, will be developed through the early selection of appropriate community representatives to participate in the audit meetings. Through the deliberate selection of key community representatives, efforts will be made to encourage an open, synergetic, and nonjudgmental forum between the community and health facility to ensure that the chosen recommendation is attainable and will ultimately strengthen the community voice.

Our data suggest that the process of fostering active partnerships between health care providers and community members through dialogue, planning, and collective action by learning from what went wrong and emerging lessons can improve community trust and quality of care [21].

Step 5: Implementing Changes

The aim is to take immediate, medium-term, or long-term actions to prevent maternal deaths, stillbirths, and neonatal deaths, using successes to advocate for and spur further action. Implementing changes is the primary objective of the audit cycle. To be more effective, the audit committees will focus on the modifiable factors that are within the control of health workers and the community.

The findings of the audits will be shared with the concerned authorities in health facilities, program managers, and community representatives to spur policy and practice related change. DHO will be onboard to ensure that the decisions agreed upon are implemented at the facility and community levels. The decisions proposed by the audit committee and endorsed by DHO will be implemented to address the bottlenecks at the demand side (delay in care and financial and mobility challenges) and the supply side (lack of hospital supplies, staff, and resources).

Step 6: Monitoring and Evaluation

In addition to the monthly audits, the project committee will also collect administrative and survey data to capture the process and outcome indicators. From independent, third-party surveys and data sources such as DHIS, facility registers, and LHW management information system, the impact of the intervention will be evaluated based on the maternal perinatal and neonatal mortality and morbidity outcomes and rated for all pregnant women, mothers, and newborns.

XSL•FO
RenderX

The model will contain audit guidelines, protocols, and training materials and tools for effective monitoring at the facility level in the targeted districts with their respective catchment populations. A monthly monitoring cycle will be set up within the implementing facilities to ensure effective implementation of the audit systems.

Phase 6: Quarterly Review and Refresher Training of Audit Committee Members

For a sustainable audit system, recognition and reinforcement is inevitable. Refresher training and recertification will be conducted quarterly.

Data Management and Analysis

The data collection tool will be developed in English and then translated into the local language to be administered to the local community visiting the health facilities. Data will be collected manually and entered through a specifically designed application. The application will be installed on laptop or desktop at each health facility under the supervision of project leadership. The Aga Khan University Data Management Unit will develop an electronic database that includes the filters and data quality check indicators. Data will be entered at the end of every week and uploaded onto the Aga Khan University Data Management Unit server. All data files will be stored for 5 to 7 years and then deleted according to organizational procedures for the permanent destruction of electronic and paper data.

Descriptive statistics will be used to estimate maternal, neonatal, and other key quantitative variables. The Three Delays framework will be used to categorize the identified modifiable factors. Action reports will be submitted based on the recommendations proposed by the audit committee. The data will be analyzed using Stata (version 16; StataCorp) and NVivo (Lumivero) software and password-protected Excel (Microsoft Corp) files. A unique code identifier will be assigned for the cases to be selected for discussion in audit meetings. The village name and health facility name will be kept confidential in audit meetings and, instead, codes will be used. In addition, regular meetings, planned dissemination of study findings including manuscript publication, stakeholder knowledge sharing workshop including community participation, and conference presentations will be conducted.

Ethical Considerations

The study was approved by the ethical review committee of Aga Khan University (ethical review committee number 2021-6426-19638). The project committee will be trained in conducting human subject research keeping in mind the ethics guidelines and respecting the autonomy of the participants. Using a noncoercive attitude, informed consent and maintenance of privacy will be assured while collecting data. Respondents will be asked to participate voluntarily after giving written informed consent. Respondents will be free to ask any questions or may ask to skip any question or may withdraw from interview at any moment without incurring any penalties.

Results

The study implementation will be for 20 months, followed by an additional 4-month period for follow-up. Initial results will be presented to DHO and the District Health Program Management Team Meeting in the districts.

Discussion

Expected Outcomes

The study introduced a research protocol that outlines an intent to establish a systematic audit system for recording, assessing, and evaluating maternal deaths, near misses, stillbirths, and neonatal deaths in rural Pakistan. Previous endeavors of similar nature have been conducted in high-income countries and various low- and middle-income countries [22]. These initiatives underscore the significance of executing a thorough audit cycle, involving effective leadership, engaging relevant health care practitioners, and using participatory methods within communities. Targeting all cases through mortality audits to enhance the standard of care for mothers and newborns. Hence, this subject holds considerable importance for Pakistan's health care system, particularly for this type of project, which has not been pursued previously to enhance feasibility, continuity, and sustainability.

Risk Management

There are minimal risks associated with this study. Community members and health care providers may experience some psychological and social risks associated with recalling the consequences surrounding a death. In the event a woman becomes emotionally distressed during the survey, participants will be provided the opportunity to stop and take a break or discontinue the interview completely. Similarly, through the identification and discussion of causes resulting in specific deaths, there is the risk of blaming and shaming of potential health facility staff or community members. All efforts to allay these risks and the repercussions will be made by ensuring that all names of the health care staff who provided care and patients remain anonymous.

The goal of the audit approach is to identify why a death or severe outcome occurred, so that changes can be made to prevent similar events in the future. The purpose is not to cast blame or punish individuals, groups, or institutions. Audit committee members will be encouraged to develop a code of practice to foster an environment of collaboration rather than blame. Accountability for adverse actions will be encouraged through approaches that seek to improve care by educating both the health care provider and community. There is the potential risk that given the size of a catchment area, community representatives may have immediate knowledge about the case under discussion. To create an environment for change in the community, in addition to anonymizing all providers and patients, community representatives will be strategically selected to ensure that they are well respected and have strong, effective communication skills. As the primary factors related to patient-level, family-level, or community-level delays 1 and 2 are associated with knowledge about danger signs and plans for

XSL•FO
RenderX

delivery, such as transportation, there is minimal risk associated with individual blaming or shaming. Approaches for implementing the recommendations will be enhanced through the form of media favored by the community, such as radio, television, theater, and murals, in addition to written materials. No unexpected or adverse events are anticipated as a result of the audit reviews.

Policy and Practice Change Implications of the Audit System

Initially, based on the advice of the district health officer, the meetings will be conducted monthly. Later, dissemination of the implementation study findings will be shared quarterly at the District Health Program Management Team Meeting. This meeting comprises key stakeholders including those in charge of health facilities, DHIS focal person, LHW program focal individuals, and other members involved in and contributing to the design, implementation, and rollout of the audit system delivery model. Consistent liaison with these provincial-level stakeholders will allow for the integration of infrastructural changes and practice changes at the facility level, conducive to the effective implementation of the audit system. Conducting audits focused on maternal and perinatal mortality presents an opportunity to implement effective actionable actions for improving the well-being of mothers and children in limited-resource communities. The implementation approach will be used for integration of decision makers, health care providers, and community members, as they are vital components of the comprehensive audit cycle proposal.

Limitations

Our project is unique with its focus on community engagement and representation integrated into the facility-based audit system. As such, it has strong implications for scale-up and uptake across Pakistan's regional districts. Nevertheless, the primary limitation of this study is the recording of neonatal and maternal deaths and their complete medical history from health facilities. To overcome this challenge, there will be planned quarterly refresher training for the facility staff regarding source register apprising and DHIS. Moreover, in monthly audit cycles, the cases will be presented by audit committee members including community representatives. This will help support local ownership for facilitating and using existing resources. DHOs will ensure the presence, retention, and participating attitude of audit committee members. The implementation design includes quantitative and qualitative approaches, which can provide strong evidence for the impact generated by the audit system implementation.

Patient and Public Involvement

The public was not involved in the development of the study design, but they are an integral part of the implementation of this study, and their perspectives and engagement are key components of the study. The key findings will be regularly shared with the public sector authorities.

Conclusions

The study will generate evidence about the feasibility and potential scale-up of a facility-based mortality audit system with integrated community engagement in rural Pakistan. Audit committees will complete the feedback loop linking health care providers, community representatives, and district health officials (policy makers). Analyzing the burden of deaths in the area and delving into individual cases aid in identifying the causes and modifiable factors to prevent future adverse events. This implementation approach also serves the purpose of establishing a regular dissemination platform for decision makers to prioritize the actionable recommendations for improving maternal and perinatal health outcomes.

Acknowledgments

This study is funded by the Bill and Malinda Gates Foundation (grant OPP1148892). The authors acknowledge the support of the Department of Health, Sindh, Pakistan, for collaboration in implementing this project. The funding source had no role in the design of this study and will not have any role during its execution, analyses, interpretation of the data, or decision to submit the results.

Data Availability

The data set will be available upon request. The data will be restored under Aga Khan University data security and retention policy.

Authors' Contributions

ZAB led the funding acquisition for this implementation study under the large grant of Umeed e Nau (New Hope) project. ZM conceptualized this study with guidance from PB and ZAB. WA, SM, SS, and AR provided theoretical and technical support in the development of this protocol. SC provided the input for drafting the phases of the study. ZM drafted the first version of the manuscript and incorporated feedback from all coauthors. ZM, WA, SM, SS, SC, AR, PB, and ZAB reviewed the subsequent drafts of the manuscript. The final manuscript has been reviewed and approved by all the authors.

Conflicts of Interest

None declared.

Abstract

Background: Mental health problems during pregnancy and post partum are common and associated with negative short- and long-term impacts on pregnant individuals, obstetric outcomes, and child socioemotional development. Socio-environmental factors are important predictors of perinatal mental health, but the effects of the environment on mental health are heterogeneous. The differential susceptibility theory and the environmental sensitivity framework suggest that individuals differ in their degree of sensitivity to positive and negative environments, which can be captured by individual phenotypes such as temperament and personality. While there is strong evidence for these models in childhood, few studies examined them in adults, and they were not examined in pregnancy.

Objective: The primary objective of the Experiences of Pregnancy study is to explore whether childhood and current environments are associated with mental health and well-being in pregnancy and whether these effects depend on individual sensitivity phenotypes (personality). This study also aims to gather important psychosocial and health data for potential secondary data analyses and integrative data analyses.

Methods: We will conduct a longitudinal cohort study. The study was not registered elsewhere, other than this protocol. Participants will be recruited through social media advertisements linking to the study website, followed by an eligibility call on Zoom (Zoom Video Communications). Participants must be aged 18 years or older, currently residing in the United States as citizens or permanent residents, and currently planning to continue the pregnancy. A minimum of 512 participants will be recruited based on power analyses for the main objectives. Since the data will also be a resource for secondary analyses, up to 1000 participants will be recruited based on the available budget. Participants will be in their first trimester of pregnancy, and they will be followed at each trimester and once post partum. Data will be obtained through self-reported questionnaires assessing demographic factors; pregnancy-related factors; delivery, labor, and birth outcomes; early infant feeding; individual personality factors; childhood and current environments; mental health and well-being; attachment; and infant temperament. A series of measures were taken to safeguard the study from web robots and fraudulent participants, as well as to reduce legal and social risks for participants following *Dobbs v. Jackson*.

Results: The study received ethics approval in April 2023 from the University of Oklahoma-Norman Campus Institutional Review Board. Recruitment occurred from May to August 2023, with 3 follow-ups occurring over 10 months.

Conclusions: The Experiences of Pregnancy study will extend theories of environmental sensitivity, mainly applied in children to the perinatal period. This will help better understand individual sensitivity factors associated with risk, resilience, plasticity, and receptivity to negative and positive environmental influences during pregnancy for pregnant individuals.

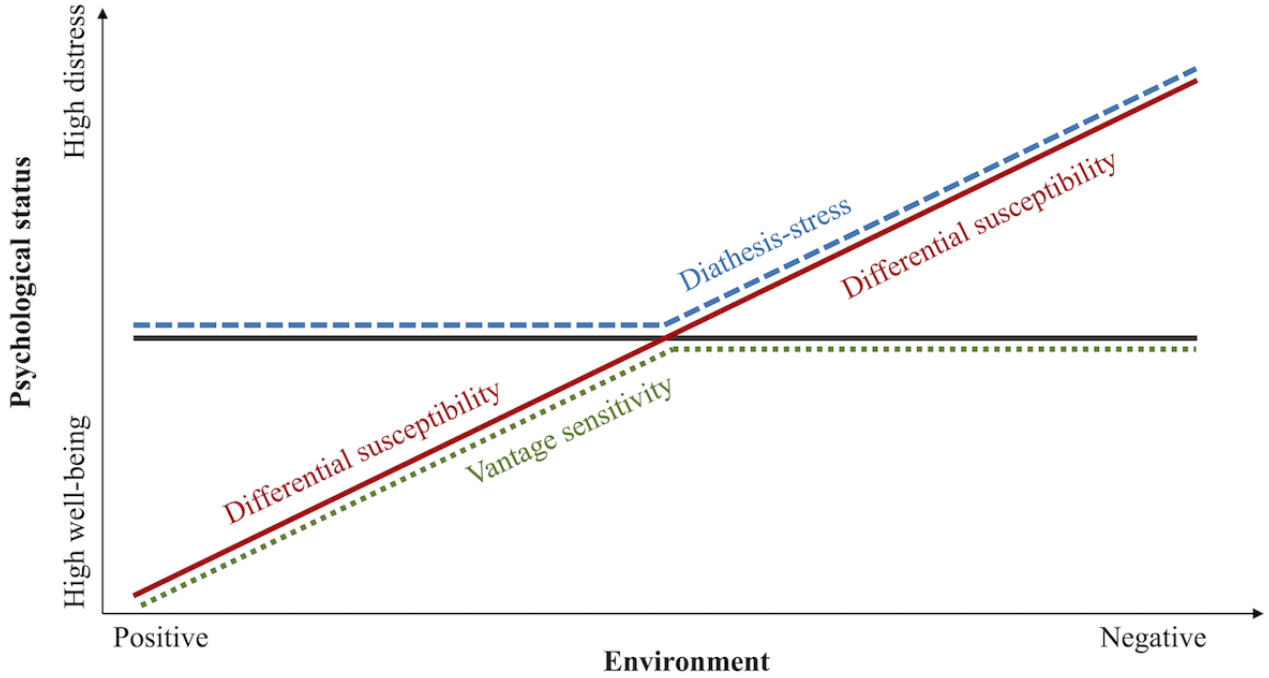
Introduction

Background

Pregnancy is a period of increased risk for mental health problems, which are one of the leading preventable causes of morbidity and mortality during the perinatal period in high-income nations [1-3]. Among people who are pregnant, approximately 20% to 30% experience elevated symptoms of anxiety or depression [4-6]. In turn, these symptoms are associated with short- and long-term parental and child health and well-being. Elevated and sustained prenatal psychological distress can often lead to long-term disturbing emotional experiences such as anger, anxiety, and depression in the postpartum period and beyond [7-9]. Prenatal stress and distress may impair bonding with the fetus and child [10,11] and may lead to strained familial and social relationships. In infants, exposure to prenatal stress and mental health problems has been found to be associated with a more difficult temperament and impaired cognitive and motor development [12]. Impacts on children may be long-term, with prenatal stress and distress being associated with disorganized attachment, poorer socioemotional development, learning deficits, and mental health problems across the internalizing and externalizing spectrums in children and adolescents, including attention-deficit/hyperactivity disorder, anxiety, depression, and behavioral problems [12-15]. Finally, prenatal stress and distress are also associated with obstetric and birth outcomes, with research showing links with early gestational age, low weight at birth, preeclampsia, hypertension, and reduced lactation [8,12,16-19].

Considering these broad negative impacts, understanding the risk and protective factors for mental health problems during pregnancy, as well as factors associated with well-being, is essential to promoting parental and child health. Environmental factors, both in early life and during pregnancy, have been found to be associated with perinatal mental health. For example, a meta-analysis found that adverse childhood experiences are a risk factor for prenatal and postpartum depression and anxiety, with the number of adverse childhood experiences being positively associated with symptom severity [20]. Sociodemographic factors are also important, with a meta-analysis showing that lower educational level and poor economic status are risk factors for perinatal depression [21]. Finally, research on current social environment factors shows that low social support from family members, friends, or community members [22], as well as poor romantic relationship satisfaction [23,24], are risk factors for perinatal depression, anxiety, and self-harm. The effects of the environment on mental health are, however, heterogeneous.

A proper understanding of the associations between environmental factors and mental health requires studying for whom the environment is influential. In turn, this can inform better targeted prevention efforts when psychosocial resources are limited. A frequently used theoretical model in psychiatry is the diathesis-stress model of vulnerability and resilience [25,26]. According to this model, some pregnant individuals would be vulnerable to adverse environments, leading to higher levels of psychological distress, while others would be resilient to such environments, leading to low levels of psychological distress despite negative environmental conditions. An alternative model, the differential susceptibility model [27,28], suggests that pregnant individuals who are sensitive to their environment would have higher levels of psychological distress than their peers in adverse environments but also lower levels of psychological distress and higher levels of well-being than their peers in positive environments. Thus, rather than being only vulnerable to adverse environments, individuals could be sensitive to both positive and negative environments, “for better or for worse” [29]. Individuals could also, however, be sensitive only to positive environmental influences, which was proposed in the vantage sensitivity model [30].



The environmental sensitivity framework [31] (Figure 1 [32]) comprehensively integrates these theoretical models of psychosocial person-environment interactions. According to this model, individuals differ in their degree of sensitivity to the environment. Based on an individual sensitivity factor, individuals may differ in their sensitivity to adverse or negative environments only (diathesis-stress), to enriched or positive environments only (vantage sensitivity), or to both (differential susceptibility) [31]. Furthermore, some evidence suggests that this sensitivity may be domain specific rather than domain general, meaning different individual characteristics may capture sensitivity to different environments [33]. It is thus important to further elucidate for whom, when, and under which environmental conditions diathesis-stress, vantage sensitivity, and differential susceptibility apply. This is important because individuals’ differences in their receptivity to environmental inputs can influence their response to treatment interventions [34]. A better understanding of environmental sensitivity can thus help determine the best intervention and treatment on an individual basis, as well as inform targeted prevention efforts and psychoeducation [34,35].

The differential susceptibility and environmental sensitivity models were proposed by developmental psychologists and have been thoroughly studied in children, with several reviews showing that individual-level factors originally thought to be vulnerability factors to adverse environments supported differential susceptibility, reflecting sensitivity to certain positive and negative environments [27,28,36]. We still know very little,

XSL•FO
RenderX

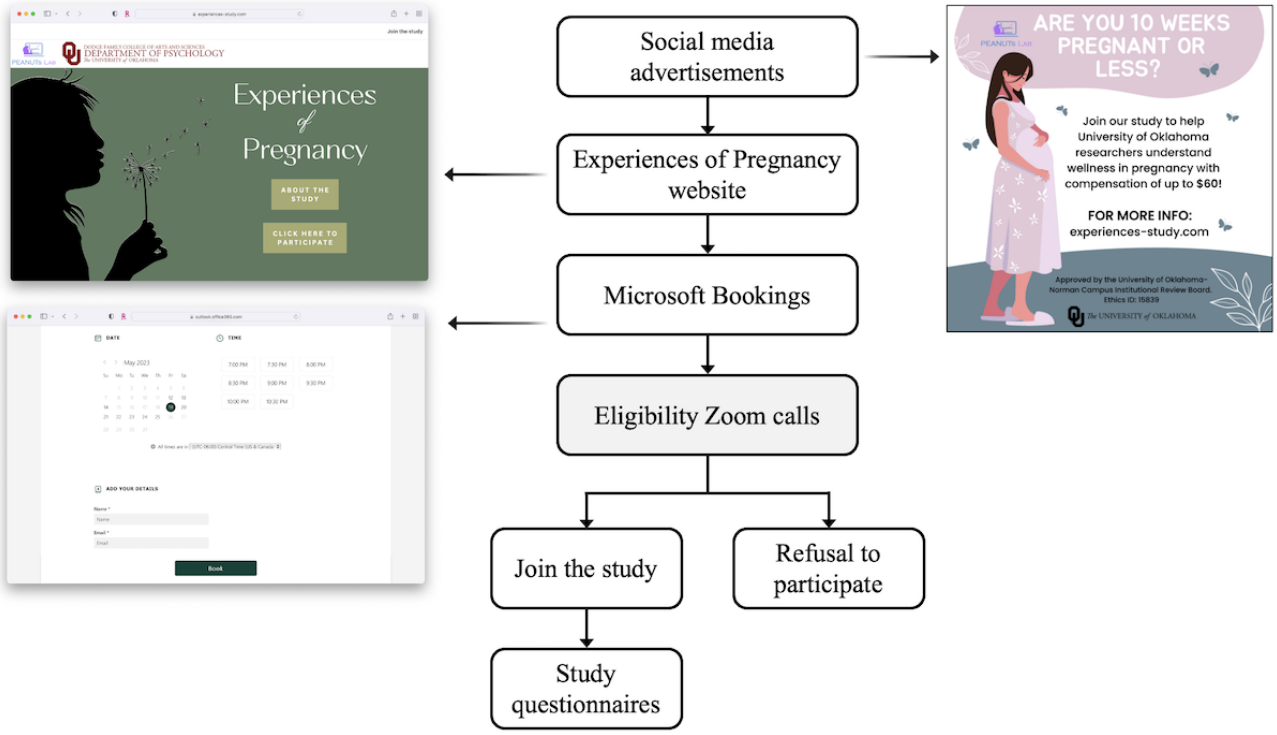
however, about how these models apply to adults. Theory suggests that some adults are sensitive to positive and negative environmental conditions in the prediction of mental health, but very few empirical studies have examined the patterns of interaction of the environmental sensitivity framework based on phenotype in adults [37-39]. Thus, research is needed to elucidate environmental sensitivity factors in adulthood, including during pregnancy, a key period of heightened risk for psychological distress [1,5,40].

Figure 1. Integrated model of environmental sensitivity. The diathesis-stress model captures individual sensitivity to negative environments only. The vantage sensitivity model captures individual sensitivity to positive environments only. The differential susceptibility captures sensitivity to both negative and positive environments within the same individuals (adapted from Belsky et al [32], which is published under Creative Commons Attribution 4.0 International License [41]).

Objectives

The primary objective of the Experiences of Pregnancy study is to explore whether childhood and current environments are associated with mental health and well-being in pregnancy and whether these effects depend on individual sensitivity phenotypes (personality) through a longitudinal cohort study design. Considering there are few empirical studies on this topic in adulthood in general and no data to our knowledge in pregnancy, the study aims to document a variety of individual, environmental, and mental health factors to clarify models of sensitivity in adults and pregnant people. Following epidemiological cohort principles, this study also aims to gather important psychosocial and health data for potential secondary data analyses [42] and integrative data analyses [43].

Methods



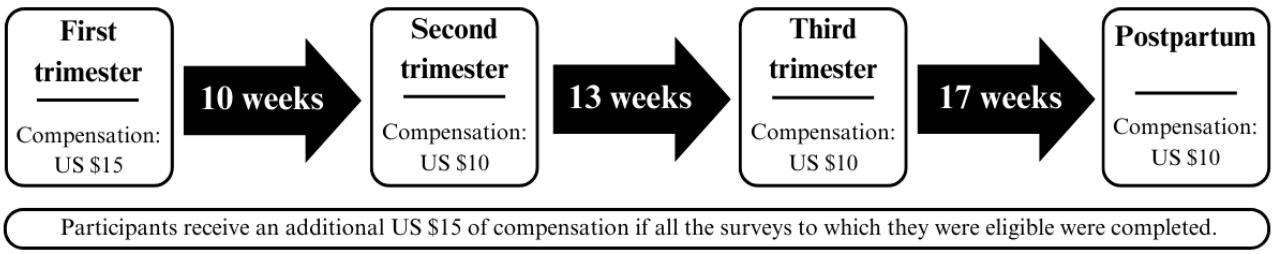
Participants and Recruitment

Figure 2 shows the recruitment process to occur from May to August 2023. Participants will be recruited on the web through advertisements (Figure 2) on Facebook, Instagram, Twitter (subsequently rebranded X), and Reddit, as well as posts on the Reddit forums “r/Maternity” and “r/lgbtstudies.” Participants will be directed to the study website [44], where they will find general information about the study, eligibility criteria, and a link to join the study. Through this link, interested participants will be directed to a REDCap (Research Electronic Data Capture; Vanderbilt University) [45,46] survey protected by a reCAPTCHA Inc (Google) verification and redirecting to a Microsoft Bookings (Microsoft Corporation) page to schedule their call, with availabilities open for the next 14 days. Zoom (Zoom Video Communications) calls with undergraduate and graduate research assistants (RAs) will confirm their eligibility and go over the study process. Eligible and interested participants will receive their personal survey link through email after their call.

Participants are eligible to enroll if they are aged 18 years or older, currently live in the United States, are citizens or permanent residents of the United States, and can read and write in English. Pregnant people of all gender identities are eligible to enroll in the study [47]. Furthermore, participants have to be currently planning to continue the pregnancy (see the *Ethical Considerations* section) and be in their first pregnancy trimester to join the study. Eligibility is to be 10 weeks pregnant or less when they signal their interest in the study (make their appointment through Microsoft Bookings) to allow time for their Zoom call confirming eligibility and for filling out the first survey. They remain eligible if they are 12 weeks pregnant or less by the time of their Zoom call. Overall, this allows for 2 weeks to schedule the Zoom call and gives them at least 1 week to fill out the first survey.

XSL•FO
RenderX

Figure 2. Flowchart of the study procedure for participant enrollment for the Experiences of Pregnancy longitudinal cohort study, United States, planned for 2023-2024.



Follow-Ups and Study Design

Participants will fill out 4 questionnaires: 1 questionnaire per trimester of pregnancy (3 first questionnaires) and 1 after birth (Figure 3). This follow-up schedule will allow collection of data during each key developmental period (trimester) of pregnancy. For this study, this follow-up schedule was also based on research showing individual differences in how mental health changes across each trimester [48-51] and highlighting the importance of repeated measurements at each pregnancy trimester in assessing prenatal mental health.

At each follow-up survey, participants will first be asked if they are still pregnant. In the event that a participant experiences pregnancy loss or premature birth, they will remain eligible to fill out the current survey as their last assessment (ie, 1 survey after loss or after birth). Depending on group sample sizes, this may allow for the examination of mental health and resilience factors after a pregnancy loss. At the end of each survey, the "submit" button redirects participants to resources on the study website, with resource lists for pregnancy, pregnancy loss, and post partum that include crisis lines, mental health services, information, and networks.

Based on an estimate of 4 to 7 items per minute for participants who do not regularly participate in survey studies [52], the first survey is expected to take between 50 and 70 minutes. The following 3 questionnaires are expected to take between 40 and 60 minutes; participants will be informed of these time estimates during their Zoom call. Based on the upper range of US minimum wages, participants will be compensated for their time, receiving US $15 of compensation for the first questionnaire (longer questionnaire) and US $10 for each subsequent questionnaire. As an incentive to complete the study and to reduce attrition, participants who complete all 4 questionnaires (or all questionnaires for which they are eligible in the event of a pregnancy loss or premature birth) will receive an additional US $15. Compensation will be in the form of Amazon or Giftogram e-gift cards sent by email within 2 weeks of each questionnaire's completion. To receive compensation, participants must submit the survey but are free not to answer questions they are uncomfortable with or do not wish to answer.

Figure 3. The timeline of completion of the study questionnaires for the Experiences of Pregnancy longitudinal cohort study, United States, planned for 2023-2024.

Study Measures

All study data will be obtained through self-reported questionnaires. Table 1 summarizes study measures across assessments. All personality measures will be collected at survey 1 only as potential moderators. Childhood environments will be retrospectively self-reported once as potential predictors. Adverse and benevolent childhood experiences will be assessed at survey 1, but parental bonding (a retrospective measure of the parenting styles of participants' parents in their childhood) will be assessed at survey 2 to reduce the burden of the longer first questionnaire. Current environments will be measured repeatedly at each assessment and include recent stressful experiences, everyday discrimination, social support, couple satisfaction, romantic intimate bonding, and social and digital media use. Mental health and well-being measures will be measured repeatedly at each assessment and include depressive symptoms, anxiety symptoms, anger, well-being, life satisfaction, sleep, disturbed dreaming, substance use (alcohol, tobacco, cannabis, and other drugs), and mental health service use. The initial (survey 1) substance use questionnaires will also assess substance use in the year before pregnancy as well as the age of onset for each substance. Attachment (prenatal or postnatal) will also be measured at all assessments. Finally, infant temperament will be measured after birth. Both postnatal attachment and infant temperament will be measured only for singleton pregnancies, as these questionnaires are specific to 1 baby, and the surveys would be much longer if asked for multiple babies.

[a]All: study measure is included in regular follow-ups and shown to all participants regardless of pregnancy status.

[b]P: pregnant; this indicates study measure is included for participants who are still pregnant at the time of that questionnaire.

[c]LD: live delivery; this indicates study measure is included for participants who experienced a (term or preterm) live delivery at the time of that questionnaire. Participants who experience a pregnancy loss or neonatal death are only shown instruments labeled "All" and are not shown instruments related to pregnancy, labor, delivery, or the child.

[d]PROMIS: Patient-Reported Outcomes Measurement Information System.

[e]Only the subscales "Rhythmicity," "Intensity," and "Threshold" are included.

[f]See the *Missing Data Mitigation* section for details.

Sample Size Considerations

We aim to recruit between 512 and 1000 participants. This study's main objective is to explore person-environment interactions in the prediction of perinatal mental health and well-being. We examined power for the simplest model to meet these objectives (1 interaction effect in a multiple regression model). Power analyses were run using the *InteractionPoweR* Shiny app [77], with moderate main effect sizes and small interaction effect sizes based on our previous differential susceptibility research [78-80]. Measurement reliability was integrated into the power analyses, with good (environmental and personality variables) and excellent (mental health) reliabilities [23,56,80,81]. This analysis indicated that the minimum sample size to detect the interaction effects with 80% power is 341. Simulation studies suggest that for tests of differential susceptibility, 50% more cases are required to achieve 80% power compared with power for the interaction effect [82], yielding a minimum sample size of 512. This study is also designed to serve as a secondary data analyses related to mental health and well-being during pregnancy and post partum. To maximize possibilities for longitudinal modeling, we will be recruiting up to 1000 participants, with the maximum being based on budgetary considerations.

Web-Based Data Integrity

Measures were used to safeguard the study against web robots (bots). To prevent enrollment from bots and fraudulent participants, participants will be individually screened through Zoom calls. Individually screening participants has been deemed one of the most reliable methods to protect web-based data collections [83,84]. Considering recent advances in artificial intelligence (AI) language, calls were deemed more secure than emails for participant screening. Zoom calls were easier to implement administratively than phone calls, as there were already organizational accounts set up for Zoom, but phone accounts had to be purchased. Finally, appointments were expected to be more efficient than trying to reach participants through phone calls after they provided their information without a set time.

To safeguard the Zoom call bookings from being targeted by bots, which could prevent genuine participants from enrolling due to appointments being unavailable, a total of 4 measures recommended to deter bots from studies were used. First, because bots are particularly interested in studies with financial incentives [83], monetary compensation was included in the images of the social media advertisements but will not be mentioned in any of the text accompanying the advertisements. Second, a total of 2 links will have to be accessed to get to the call bookings (the social media advertisement link and the link to join the study on the website). Direct links to Microsoft Bookings will not be posted on social media [83,85]. Third, a reCAPTCHA verification will protect the REDCap survey leading to the bookings page [83,85]. Finally, Microsoft Bookings settings will include 1-time passwords, where a numeric code will be sent to each participant's email address to complete the booking.

RAs conducting Zoom calls will complete 2 trainings. The first training (in person) will go over the study protocol, the steps for confirming calls with participants through email, conducting the call, and sending surveys, including how to use Microsoft Bookings, the study email account, and REDCap. Each RA will have a printed copy of a manual covering all these steps, along with access to a digital version of the manual. RAs will also practice all steps, including the calls, during the first training. The second training will be on Zoom, where RAs will practice calls further in a more similar setting to calls with participants. The principal investigator (CR) will have weekly scheduled meetings with RAs to discuss progress, questions, and any perceived issues during the calls, including potential fraud. RAs will also be able to share any perceived issues with a call in a

XSL•FO
RenderX

rapid manner through the laboratory's communication platform, Slack (Slack Technologies). This will allow the identification of any unforeseen issues during recruitment and the adaptation of call protocols if needed.

Missing Data Mitigation

To reduce attrition rates, an incentive of US $15 is offered for completing all 4 surveys (or all surveys a participant is eligible to in the event of a pregnancy loss or premature birth; see the *Follow-Ups and Study Design* section). Because participants are actively recruited and join the study through a Zoom call instead of only filling out the survey on the web, we expect more participant investment in the study than traditional web-based questionnaires.

In analyses with missing data rates up to 10%, deletion techniques may be used as they are not associated with increased bias [86]. In analyses above this missing data rate (which can be expected for longitudinal analyses), recommended missing data treatments, including full information maximum likelihood (FIML) and multiple imputation, will be used [87]. These missing data treatments are most effective at preventing biased results when predictors of missing data (ie, predictors of the missing at random [MAR] mechanism) are included as auxiliary variables [87]. At the first 2 assessments, we provided a study timeline of the next surveys and their associated compensation and included 1 question asking participants "Currently, how likely do you think you are to complete the follow-up surveys?" with answers ranging from "very unlikely" (score 1) to "very likely" (score 4), presented in Table 1. This question was included to serve as a potential predictor of the MAR mechanism (ie, potential auxiliary variable) in addition to the main survey questions.

Data Management

All data will be collected and managed using REDCap tools hosted at the University of Oklahoma Health Sciences Center [45,46]. REDCap is a secure, web-based software platform designed to support data capture for research studies, providing (1) an intuitive interface for validated data capture, (2) audit trails for tracking data manipulation and export procedures, (3) automated export procedures for seamless data downloads to common statistical packages, and (4) procedures for data integration and interoperability with external sources. Metadata will be submitted to the Maelstrom Catalogue [88] to support harmonization initiatives among epidemiological cohorts. The research team welcomes collaboration on the study; access to the data dictionary and data request form will be available upon reasonable request made to the corresponding author.

Data Analyses

Analyses for the primary aim will follow recommendations for testing person-environment interactions based on the environmental sensitivity framework and differential susceptibility. Linear moderated regressions will be conducted. To test for diathesis-stress, vantage sensitivity, and differential susceptibility, the nature of significant interactions will be further examined using regions of significance analyses, the proportion of interaction (PoI) index, and the proportion affected (PA) index [89]. The best-practice recommendations are to use a combination of these indices to confirm support for one of the environmental sensitivity models [82,89].

Regions of significance analyses use the Johnson-Neyman technique to identify at what levels of the environmental variable individuals differ in their mental health based on their phenotype [89]. The PoI index will quantify the "proportion of the total area of the interaction" that is attributable to the positive environment. Prototypical models would have a PoI of 0.5 for differential susceptibility, 0.0 for diathesis-stress, and 1.0 for vantage sensitivity. Proposed criteria are that a PoI of 0.2-0.8 supports differential susceptibility [82], with a PoI <0.2 supporting diathesis-stress and a PoI >0.8 supporting vantage sensitivity. The PA index will quantify the "proportion of participants" who benefit from the positive environment. Similar to the PoI index, prototypical models would have a PA of 0.5 for differential susceptibility, 0.0 for diathesis-stress, and 1.0 for vantage sensitivity. Proposed criteria are that a PA value <0.16 is considered as indicative of diathesis–stress [89], making a PA value >0.84 indicative of vantage sensitivity.

Ethical Considerations

The study received ethics approval from the University of Oklahoma-Norman Campus Institutional Review Board (IRB #15839). All participants will sign an electronic informed consent form once during the study through the REDCap eConsent framework [90] before completing the first questionnaire.

Special considerations were taken to reduce the legal and social risks and protect participants from their data being used in legal proceedings related to abortion. First, a National Institutes of Health Certificate of Confidentiality was obtained. Second, inclusion criteria explicitly include the intention to keep the pregnancy, so that pregnancy losses recorded in the study would not be assumed to be from intentional abortion. Third, while our pregnancy-information questionnaire would have typically included the following questions—(1) How many total times have you been pregnant? (2) Have you ever had a miscarriage? and (3) How many children do you currently have at home?—in order to avoid combined answers to these questions being used to deduce the possibility of a past abortion, questions 2 and 3 were removed, and question 1 was changed to "Is this your first pregnancy?" Fourth, while we initially planned an open-ended question following pregnancy losses where participants could tell us about their experience, we opted to remove that open-text field to avoid inadvertently recording liable information.

Results

The study received ethics approval in April 2023. Recruitment occurred from May to August 2023. After the first survey, participant follow-ups will occur over 10 months.

Discussion

The Experiences of Pregnancy study will assess individual personality factors, social environmental factors, and psychological distress and well-being factors throughout pregnancy and post partum. The Experiences of Pregnancy study will allow extending theories of environmental sensitivity

XSL•FO
RenderX

mainly applied in children to the perinatal period. This will help better understand individual characteristics associated with risk, resilience, plasticity, and receptivity to negative and positive environmental influences during pregnancy. In turn, this could help inform intervention and prevention efforts tailored to peoples' individual sensitivity to their environment [34,35]. While measures on individual phenotypes, social environments, and mental health outcomes were prioritized, the principal investigator's (CR) expertise in longitudinal study designs, population studies, and advanced quantitative analyses allowed the integration of a broader set of measures that will allow secondary data analyses and could contribute to data harmonization efforts addressing related developmental and epidemiological questions.

Recruitment for Experiences of Pregnancy is occurring nationwide, is completely web based, and will be carefully tracked. The infiltration of web-based data by bots and fraudulent participants has been a major concern in recent years [91,92]. In this study, we implemented many steps to ensure data integrity and protect the study from bots and fraudulent participants while ensuring feasibility, including not linking surveys directly on social media, reCAPTCHA verification, email verification, and a Zoom call. The study has the potential to contribute to the design of future studies looking to conduct reliable and safe web-based data collection. This could help future epidemiological and medical research since web-based data collection can have advantages in collecting data from minority populations and from hard-to-reach populations [93-96]. This is not limited to self-report surveys such as ours since many aspects of data collection, including, for example, some biological assays [97-100], neurobehavioral and cognitive assessments [101-103], stress tests [104,105], and parent-child observations [106], have been successfully adapted to be conducted remotely. Finally, our data on social media advertisement costs and success will also be documented and could help inform recruitment budgets for future web-based studies on pregnant populations.

The main weakness of the Experiences of Pregnancy study at the design stage is that all data will be self-reported. However, initial insights into environmental sensitivity and differential susceptibility in pregnancy stemming from this study could inform future investments in research integrating other measurement methods, such as examining genotypic and endophenotypic sensitivity factors [28,107]; recruiting participants' social network (eg, parents, siblings, friends, and romantic partners) to measure their social environment through multiple informants [108]; integrating objective stress measures; or accessing medical record information for participants' health, mental health, and birth outcomes. The generalizability of the results stemming from this study will also be limited to English-speaking US residents and citizens.

Overall, the Experiences of Pregnancy study will help improve our understanding of risk and protection factors for perinatal distress, as well as how different factors interact with each other to predict mental health and well-being. In turn, this can help inform efforts aiming to reduce the high prevalence rates of mental health problems during the perinatal period.

Acknowledgments

The Experiences of Pregnancy Study was funded through start-up funds to CR. No external funding agencies or sponsors were involved in the study.

We thank the research assistants who will be involved in the recruitment process of our study: Nicole Barton, Chloe Biggers, Emily Flesher, Riggs Gorman, Zoe Rockey, Jacob Stephens, Annika Testerman, Fily Wahidin, and Megan Waldron.

Data Availability

The data sets generated during this study are not publicly available as this study is not completed. Data will be available from the corresponding author on reasonable request upon conclusion of the study.

Authors' Contributions

CR conceptualized the study. All authors contributed to the design of the study. CR, DCF, and PNH programmed the study questionnaires. CR, DCF, JLL, MEA, KKL, and MTD are contributing to the investigation process through participant recruitment. CR, PNH, and NTM prepared visualizations and figures for the study and this paper. CR wrote the initial draft. All authors reviewed and edited the paper. CR provided resources, supervised the research team, and coordinated the project.

Conflicts of Interest

None declared.

Abstract

Background: The phenomenon of sexual harassment (SH) is a complex issue with multiple prongs that concerns all members of academia and raises serious challenges, particularly regarding prevention and response. SH in tertiary institutions remains a huge problem worldwide, leading to severe emotional, academic, and career difficulties, as well as undue suffering. Institutions have responded in various ways to alleviate the burden of SH with little success, especially in Nigeria. The prevalence is high but reportage is low because of the culture of silence around SH in most educational institutions. This study aims to identify factors associated with SH in tertiary institutions in Nigeria and explore factors surrounding reportage or nonreportage following the experience of SH, the institutional mechanisms to prevent and respond to SH, and the lived experience of survivors of SH.

Objective: The objective of this study was to present a study protocol that is designed to identify factors associated with the experience of SH in tertiary institutions in Nigeria, the institutional mechanisms to prevent and respond to SH, and the lived experience of survivors of SH.

Methods: A mixed (quantitative and qualitative) methods approach is used consisting of a policy review of existing antisexual harassment policies in the selected universities, a quantitative survey to determine the correlates of SH, focus group discussions to explore the perspectives of the university community concerning SH, in-depth interviews to explore the lived experiences of survivors of SH, and key informant interviews to understand the perspectives of people who provide interventions to survivors.

Results: This study was funded in July 2022 by the Consortium for Advanced Research Training in Africa, and data collection started in November 2022. The SH policies were comprehensive, with clear policy statements and definitions, and recognized a wide range of survivors and perpetrators. However, there was no clear mention of prevention and response to same-sex SH. Lived experiences showed negative psychological and social sequelae and little institutional support.

Conclusions: This is the first study that has a component investigating same-sex SH in tertiary institutions in Nigeria. This is also one of the first studies to explore the lived experiences of survivors of SH in Nigerian universities. The findings from this study suggest that periodic evaluation of SH policy implementation will improve institutional support, thus creating safe spaces for survivors and will thereby encourage reportage and support; prevention and response strategies need to be more inclusive; and more interventions should focus on strengthening prosocial skills and healthy, equitable relationships.

Introduction

Background

Sexual harassment (SH) in educational institutions remains a pervasive problem, and the institutional climate is still the best predictor of the occurrence of SH [1]. SH is not easy to define, partly because it does not involve a homogenous set of behaviors [2]. However, it includes requests for sexual favors and verbal or physical sexual activities in exchange for using or awarding academic marks [3]. When the advances are rejected, a hostile learning environment is created.

There are 2 main types of SH that are recognized in the literature. These include quid pro quo harassment, which is typically exchanging sex for benefits (usually performance or academic favors) or to avoid some detriment (demotion at work or academic failure), and a hostile environment (when speech or conduct creates an intimidating or humiliating environment that negatively affects an individual's academic or job performance) [4]. Till [5] categorized SH as gender harassment when general sexist or offensive remarks and jokes were made, seductive behavior when inappropriate flirting and sexual advances were made without threat of sanctions, sexual bribery when there was a reward for sexual activity, sexual coercion when the conditions of education were contingent upon sexual cooperation, and sexual imposition also known as sexual assault. Although it is usually easy to identify less ambiguous forms of SH (sexual bribery, sexual coercion, and sexual imposition), it is more difficult to define the more ambiguous forms of SH (gender harassment and seductive behavior), especially gender harassment, which is by far the most prevalent type of SH [1].

The global prevalence of SH in tertiary institutions is high. More than a third of university women in the United Kingdom reported having experienced unwelcome sexual advances (touching, including inappropriate groping) [6]. Nearly 18% of 221 Lebanese women in educational institutions reported being harassed by their professors [7]. In Canada, >80% of the female students surveyed had been sexually harassed in a school setting [8].

In Nigeria, SH came into the limelight through the Cookey Commission panel that was established to address allegations of female students failing examinations for reasons not based on their scholastic abilities [9]. The prevalence of SH in tertiary institutions is higher in Nigeria, ranging from 68% to 80% among female participants [10-12]. The wide range of prevalence rates may reflect the use of diverse instruments to measure SH.

Survivors and perpetrators of SH can be lecturers, students, administrative staff, and any gender [13], although more women than men experience SH and more men than women are likely to be perpetrators [1,8,14]. There are also cases of same-sex SH in tertiary institutions [15], although this experience is less explored. It must be noted that more studies have focused on female students as survivors and men as perpetrators [16,17].

Macrolevel factors for SH range from weak educational systems; low levels of institutional accountability; high population levels of poverty; gender inequality; and poorly trained, underpaid, and understaffed educators [18]. Factors that have been linked to SH in Nigerian universities include contextual societal factors such as gender stereotypes, oppression of women, the patriarchal construct of manhood, the patriarchal configuration of many African societies, communal pressure to secrecy, and the lack of specific policies that address the problem of SH [11,19].

Indecent dressing has been cited in the Nigerian literature as a factor in whether an individual will experience SH or not. This often leads to "victim-blaming." A common recommendation in the literature is the propriety of dressing for females as a means to prevent SH [12,20-25]. However, confounding factors such as a high sex drive of individual perpetrators have not been fully investigated in this setting [26].

SH in tertiary institutions is a huge concern because of its associated adverse effects [1] such as suboptimal academic fulfillment and withdrawal from academic activities [27,28]; psychological distress with symptoms of depression, stress and anxiety, self-blame, lowered self-esteem, and generally impaired psychological well-being [29-32]; and physical health issues such as headaches, exhaustion, sleep problems, gastric problems, nausea, respiratory complaints, musculoskeletal pain, and weight loss or gain [33,34].

It is known that because of the complexity of SH, the timing, duration, and severity of these effects will vary depending on the individuals affected. Adverse effects are found with gender harassment (the most common) as well as unwanted sexual attention and sexual coercion [35]. These adverse effects seem to be worse when SH is committed by a superior than when committed by peers [36], but it is established that individual reactions vary greatly [37].

SH in colleges and universities is grossly underreported [2]. Survivors rarely report their SH experiences. This is often because of unequal power relations; the fear of loss of status, marks, or job as retaliation; and the associated stigma that it brings [38,39]. Survivors cope with SH in many ways, including by ignoring or appeasing the harasser or seeking social support [1].

The prevalence and associated factors of SH in Nigeria have been investigated [6,7,10,11] but few studies have explored the reasons why SH is underreported and what can be done to improve reporting. In addition, there are no methodical studies on the assertion that indecent dressing is a risk factor for SH [12,20-22], and most studies on SH in Nigeria have focused almost exclusively on heterosexual SH, despite the possible risk of same-sex SH. This study will investigate the culture associated with SH in universities in Nigeria.

This study is based on the integrated conceptualization of SH, founded on the synthesis of the work by Hofstede [40] and Schwartz [41], which explored behaviors directed toward women in different countries and cultures. Luthar and Luthar [42] proposed that the likelihood of experiencing SH perpetrated by men, as well as the tolerance of SH by women, vary between different countries because of the fundamental differences in cultures and values. This study seeks to explore how culture may influence the perception and response to SH experiences in tertiary institutions in Nigeria. However, the study will expand

XSL•FO
RenderX

its inquiry to explore how the sociocultural context of same-sex relationships may affect the perception and response of people in same-sex relationships who experience SH in tertiary institutions in Nigeria.

This Study

This study aimed to identify factors associated with the experience of SH in tertiary institutions in Nigeria, the institutional mechanisms to prevent and respond to SH, and the lived experiences of survivors of SH; explore how the experiences of SH survivors differ between men and women in heterosexual and same-sex relationships; and interrogate how sociocultural contexts and perceptions about dressing, including institutional practices, may influence the experience and responses of survivors to SH perpetrated in tertiary institutions in Nigeria.

Methods

Research Design

This study used a concurrent mixed methods design that consisted of a policy review, a quantitative survey, focus group discussions (FGDs), in-depth interviews (IDIs), and key informant interviews (KIIs).

Study Sites

The study focused on the experiences of staff and students at tertiary educational institutions in Nigeria. There are >170 universities in Nigeria, of which 79 are privately owned and 43 are funded by the federal government [43]. The study recruited participants from 3 public universities owned by the Federal Government of Nigeria, located in southwest Nigeria. The study focused on public tertiary institutions that have existed for >60 years and have a large student and staff population.

The study was also limited to southwest Nigeria because of the homogeneity in the cultural norms and practices of this region. The 3 institutions selected for this study are in the Yoruba-speaking area of southwest Nigeria. Common ties in the language and practices of the community in which the 3 institutions are located may enhance the use of a sociocultural lens to explore the findings of this study.

Study Population

The target population for this study comprised staff and students of the selected institutions. Study participants were staff or students of the 3 selected universities who were aged >18 years and who gave consent to participate in the study. Staff or students who were severely physically or mentally ill and who lacked the capacity to participate in the study were excluded.

Quantitative Study

Sample Size Determination

The sample size for the survey was computed based on a sample size formula using a margin of error of 2.5%, a confidence level of 95%, and a population estimate of 120,000. The minimum sample per institution was 506 participants and 1518 participants for the study. This was increased to 550 participants per institution to adjust for possible incomplete responses to the questionnaire and to increase the power for subanalyses such as for sex differences. Thus, 1650 participants were surveyed from the 3 institutions using a proportionate sampling technique.

Data Collection Procedures

Overview

The quantitative survey was developed to explore the perceptions of university community members about SH. The survey focused on the experience of and risk indicators for SH (including mental health determinants) and the reporting of cases within the university community. The survey also explored perceptions of the link between dressing and SH. The questionnaire consisted of questions from validated instruments that measure the phenomena of interest. These were (1) the Sexual Experiences Questionnaire (SEQ) to measure the experience of SH, (2) the Administrator - Researcher Campus Climate Collaborative tool to measure the campus climate, (3) the Campus Conduct Survey on Sexual Assault and Sexual Misconduct tool to measure the institutional response, (4) pictures and questionnaire items to assess the tendency to perceive a link between provocative dressing and SH, (5) the Changes in Sexual Functioning Questionnaire to measure sexual desire, (6) the Patient Health Questionnaire-4 (PHQ-4) to measure anxiety and depression, and (7) the Suicidal Behavior Questionnaire-Revised (SBQ-R) to measure suicidal behavior.

SEQ Measure

The SEQ is the most widely used and validated measure of SH to date [44]. It was developed and validated by Fitzgerald et al [45]. The SEQ has been used in different settings and with different population groups over time. It has been noted that the factor structure of the SEQ (gender harassment, unwanted sexual attention, and sexual coercion) has remained stable across time, culture, and the occupational sector, even when there were variations in the specific items assessing each construct with good psychometric properties [46].

Administrator - Researcher Campus Climate Collaborative Tool

The Administrator - Researcher Campus Climate Collaborative tool is the result of collaborative efforts by students, legal affairs professionals, campus advocates, campus law enforcement, and sexual assault and harassment researchers [47]. The tool is organized into different modules that allow researchers to determine the length and content of their surveys. They include modules on possible outcomes (which encompasses a standardized 4-item measure of depression and anxiety [PHQ-4]), demographics, campus safety, SH by students and staff (which used questions from the SEQ), and institutional response [46]. All the measures mentioned above were used in this study.

Campus Conduct Survey on Sexual Assault and Sexual Misconduct

The Campus Conduct Survey on Sexual Assault and Sexual Misconduct is a survey questionnaire developed by the Association of American Universities [48]. This questionnaire assessed students' perceptions of experiencing sexual assault

XSL•FO
RenderX

or sexual misconduct and their perceptions of institutional response to reporting.

The Provocativeness of Dressing

The sexual provocativeness of dressing was assessed by presenting the research participants with 4 pictures, comprising 2 each of a male and a female dressed provocatively and nonprovocatively. Each respondent was shown each of the 4 pictures separately and asked a series of questions concerning them. A total of 2 pictures were shown, each for males and females, respectively. There was 1 picture per sex that depicted a nonprovocative dressing and a sexually provocative dressing. The pictures were taken by a professional photographer using the same background and similar postures as the models. The faces of the models were pixelated to ensure anonymity. The participants were asked to rate the 4 pictures for sexual provocativeness of dressing on a 7-point Likert scale ranging from 1 (not provocative at all) to 7 (extremely provocative) [49,50]. The participants were further asked to indicate the extent to which they expected the individual in the picture to experience SH. This was assessed with the single-item question scored on a Likert scale, such as "How likely is the person in the photograph to be sexually harassed?" (7=likely and 1=not likely).

A pilot study was conducted among 70 students of the Obafemi Awolowo University who were not included in the main study to select the pictures to be used for assessing the sexual provocativeness of dressing. These were selected as follows: 6 pictures each of male and female models in different forms of dressing were taken by a professional photographer with a similar background. The faces of the models were pixelated to ensure anonymity. Each picture was graded based on the level of sexual provocativeness of the dressing on a Likert scale ranging from 1 (not provocative at all) to 7 (extremely provocative). A total of 4 pictures labeled the most provocative and least provocative, 2 each for both males and females were then used in the main study.

Using questions adapted from Moor [51], participants' perceptions about the motivation of people for wearing provocative clothing as well as their reaction to people wearing such clothing items, were assessed. Participants were instructed to rate motivations for wearing provocative clothes by indicating how much they agreed with 10 statements such as "they wish to feel attractive" or "they intend to convey an interest in sex," on a 5-point Likert scale from 1 (strongly disagree) to 5 (strongly agree). Participants were also asked about their own customary style of dress and their own motivations for that style. Participants were instructed to respond to 7 questions on a 3-point scale (1 indicating "no," 2 "sometimes," and 3 "yes"), such as "Do you dress provocatively in order to feel attractive?" or "Do you dress provocatively to be seductive?"

Furthermore, they were asked about their responses to people who wear what they perceive to be provocative clothing. Items included such questions as "Do you feel that provocatively dressed people are attempting to tempt you?" or "Are you aroused by provocatively dressed people?"

Sexual Desire

Sexual desire was assessed using 6 questions from the Changes in Sexual Functioning Questionnaire [52], which assessed sexual desire and ease of arousal. Each item was rated on a 5-point Likert scale ranging from 1 (never) to 5 (always). Higher scores indicated higher sexual motivation and attribution for personal or others' dressing.

PHQ-4 Questionnaire

The PHQ-4 to measure anxiety and depression [53] is a 4-item self-screening measure that combines the items of the Patient Health Questionnaire-2 and Generalized Anxiety Disorder Scale-2, which both contain the 2 core items of depressive and generalized anxiety disorder symptoms. It is used to assess anxiety and depression. It is scored on a 4-point Likert scale, with responses ranging from 0 ("not at all") to 1 ("several days"), 2 ("more than half of the days"), or 3 ("nearly every day"), with a maximum possible score of 12.

The PHQ-4 compares favorably to the Medical Outcomes Study Short-Form Health Survey subscales in that increasing PHQ-4 scores correlate significantly with declining functional status [53]. It has a high internal consistency, with a Cronbach α of >.80 among the patient population in the United States [53], which compares to a study in Tanzania by Materu et al [54], who reported a Cronbach α of .81. It has good construct validity and has been validated in Germany [55], the United States [56], and Africa [54].

SBQ-R Questionnaire

The SBQ-R is a 4-item self-administered questionnaire designed to assess the lifetime and 1-year history, frequency, and severity of suicidal behaviors [57]. Each item in the SBQ-R scale measures a different dimension of suicidal behavior, and it has been found to be straightforward, brief, and easy for participants to complete [58]. The total score on the SBQ-R ranges from 3 to 18, with higher scores reflecting a greater risk of suicidal behavior. The questionnaire exhibited a sensitivity of 80% and a specificity of 91% at a cutoff point of 8 in a sample of adult American psychiatric inpatients [58]. In Nigeria, the questionnaire has been shown to be a valid and reliable suicide risk assessment tool among adolescents and young adults, with a cutoff point of 8 [59].

The data were collected using a secured web-based platform—Google Docs platform. Study participants who were recruited had the option of self-administering the questionnaire using a shared link or using a tablet operated by research assistants (RAs). Students and staff in each institution were categorized by faculties into 3 clusters: Science, Social science, and Arts. In total, 5 Departments were randomly selected from the faculties in each faculty cluster using a ballot. The RAs attended the lecture halls of the selected departments and approached the students. The RAs ensured that all the levels in any chosen department were represented. In addition, links were shared when more than 1 participant was eligible to fill out the questionnaire at the same time. Informed consent was obtained verbally before sending links to the participants, which was also the first question on the web-based questionnaire page.

XSL•FO
RenderX

Data Analyses

All quantitative data were coded and entered into SPSS (version 20; IBM Corp) for descriptive analyses. All continuous variables were expressed as means (SD), and categorical variables were summarized using frequencies and percentages. Bivariate and multivariate regression analyses with SH as the outcome variable were used to investigate the relationships between the predictors and SH, as stated in the objectives of the study. Bivariate and multivariate regression analyses with the likelihood of SH as the outcome variable and sociodemographic characteristics, dressing perception, and sex drive as the predictors were performed. For all quantitative analyses, we repeated the analyses with male and female participants to test for sex differences. Differences in sex and sexual orientation were investigated at all levels of the analyses. A P value of <.05 was considered statistically significant.

Qualitative Study

Sample Size and Technique

This had two levels:

1. Desk review: a purposive sampling approach was adopted to identify, screen, and select policy documents on SH across the 3 institutions. All the documents were analyzed based on their contents.
2. IDIs, KIIs, and FGDs: participants were recruited for the interviews and the FGDs. Purposive sampling was adopted to identify and recruit key informants from the Directorate of Student Affairs and from members of the antisexual harassment and disciplinary committees in each of the 3 universities. A total of 5 KIIs were conducted in each institution. Both students and staff who had survived SH were targeted for the IDIs. Recruitment was conducted through interactions with the core units of each university, such as the Directorate of Student Affairs, the security unit, the personnel unit, and nongovernmental organizations that have had interactions with SH survivors across the 3 universities. The recruitment and interview processes ensured privacy, confidentiality, and the freedom to share experiences without reservation. In total, 4 IDIs were conducted in each institution. The medium for conducting the interviews (face-to-face, through telephone, or through video calls) was chosen by the study participants.

The FGD participants were randomly selected through multiple calls on identified portals for students and staff at the targeted universities to join a FGD on SH. Participants were chosen based on their consent to participate. Equal gender representation was prioritized. The sample size for the FGDs ranged from 6 to 10 participants per session. A total of 2 student and 1 staff FGD session were held per university.

Data Collection Procedures

IDIs, KIIs, and FGDs: The IDIs focused on the experience of SH from the perspective of the survivor, the consequences, whether it was reported, the outcomes, and how the survivor felt about the outcome. The KIIs focused on the perceptions of counselors, SH committee members, and student and faculty on disciplinary committees on SH, institutional response, their experiences, and issues around vicarious trauma. The FGDs were conducted to explore the university community's perception of SH, its determinants, and how it can be prevented. The focus was also on how dressing is related to SH and the perceptions around same-sex SH.

Data Analysis

Desk review consisted of a content analysis of existing SH policies in the 3 selected universities, conducted between September 2022 and February 2023. Common themes and areas of divergence will be highlighted. In addition, the analysis attempted to determine how well the policies aligned with global best practices in the SH field. This was performed by the principal investigator (PI) and coinvestigators.

Analysis of the IDIs, the KIIs, and the FGDs commenced with verbatim transcription of the audio recordings to a Word (Microsoft Corporation) document to avoid misrepresentation and minimize bias. The accuracy, integrity, and completeness of all transcriptions were verified by the PI and coinvestigators by passing them through a 2-level proofreading. At each level, the recordings were listened to and read along with the typed transcripts, ensuring that all discrepancies were corrected. Then, a thematic analysis was conducted, all transcripts were coded by 3 experts, areas of divergence were resolved, and the analysis was managed using NVivo 12 Pro (QSR International). The interviews and the FGDs were synthesized and presented under subheadings to answer the research questions.

Data Management and Storage

The data collected using web-based surveys was stored on a secure, password-protected laptop. The audio recordings were destroyed immediately after transcription, and deidentified transcripts were saved on a password-protected computer that only the PI, coinvestigator, and statistician had access to. An external hard drive was used as the backup and was stored using a password. The transcripts were shared only with the other members of the research team.

Ethical Considerations

The research protocol was submitted for ethical review, and approval was received from the Institute of Public Health Research Ethics Committee (IPH/OAU/12/2028), Obafemi Awolowo University, the University of Ibadan Health Research Ethics Committee (UI/EC/22/0313), and the University of Lagos Health Research Ethics Committee (CMUL/HREC/08/22/1082). Written consent was obtained from the participants. Ethics approval at all 3 institutions was obtained between August and September 2022. Preliminary meetings with stakeholders across the 3 universities took place between September and October 2022. Training for the RAs took place in September 2022. Confidentiality was ensured and psychological first aid was offered to interview participants. Furthermore, referrals for therapy were offered to participants who exhibited or reported distress, although none of them took up the offer.

Knowledge Dissemination

The findings of the project will be summarized and disseminated through the development of institution-specific policy briefs detailing SH issues revealed during the study, which will be

XSL•FO
RenderX

given to each institution during a dissemination meeting with recommendations on how to improve prevention and response to SH. In addition, findings from the study will be shared with the scientific community through the presentation of papers at regional or international conference(s) and the publication of scientific papers in peer-reviewed journals. The findings will also be shared with the general public on the project website.

Results

This study was funded in July 2022 by the Consortium for Advanced Research Training in Africa, and data collection started in November 2022. Ethical approval at all 3 institutions was obtained between August and September 2022. Preliminary meetings with stakeholders across the 3 universities took place between September and October 2022. Training for the RAs took place in September 2022. Content analysis of the antisexual harassment policies of the 3 selected universities took place between September 2022 and February 2023. Recruitment and data collection for both the quantitative survey and the qualitative study took place concurrently between November 2022 and February 2023.

The data from the IDIs has been developed into a manuscript titled "Stifled screams: experiences of survivors of SH in first-generation southwestern Nigerian universities," which has been published in the *Social Sciences* (Multidisciplinary Digital Publishing Institute).

The SH policies were comprehensive with clear policy statements and definitions, and recognized a wide range of survivors and perpetrators. However, there was no clear mention of the prevention and response to same-sex SH. The forms of SH experienced ranged from physical touch to assault, attempted rape, and rape. The locations of the incidents included the perpetrator's abode, office, lecture theater, library, and a party. Survivors used several coping mechanisms, including talking with peers, joining social clubs, and heavy drinking. Consequences included not trusting others, blaming themselves, and feeling sad, suicidal, angry, and guilty.

The data analysis for the quantitative survey is ongoing. Dissemination meetings for the selected universities, presentations at scientific conferences, and subsequent publications in peer-reviewed journals are expected to be completed before the end of 2023.

Discussion

Principal Findings

To our knowledge, this is the first study that has a component investigating same-sex SH in tertiary institutions in Nigeria. It is also one of the first studies to explore the lived experiences of survivors of SH in Nigerian universities. This study hypothesizes that there will be a high prevalence of SH in the selected institutions; however, there will be underreportage of SH, and many students will find the institutional measures inadequate to curb SH. Globally, most studies have shown mixed results on the prevalence of SH in tertiary institutions [10,60-65]. Numerous studies have shown that both males and females are survivors of SH, although females are more affected [66,67]. Factors that influence nonreportage among students include shame, fear of retribution by the lecturer, and godfatherism, among others [38,39,68]. There has been extensive research regarding dressing and SH [12,20-25,51], with mixed results; some studies found that provocative dressing increased the likelihood of an individual being sexually harassed [69,70].

Although the 3 universities have antisexual harassment policies, reports of SH still appear in the news from these universities [60-62] signifying that the existence of SH policies is not enough to curb SH. It is hoped that the dissemination of content analysis will emphasize the need to supervise the implementation of institutional SH policies to improve prevention and response. In addition, the reports from lived experiences highlighted survivors' experiences of SH, the mental health consequences, how they have coped, the responses from their institutions, and barriers to reporting both to the institutions and law enforcement agencies. It has been shown that the lived experiences of survivors can be a powerful tool for advocacy and action in the response to SH [66]. The survey focused on the prevalence and correlates of SH, focusing on gender differences and differentiating between same-sex and heterosexual SH. It also examined the campus climate and how it influenced the experience of SH for the campus community.

Limitations

One of the limitations of this study is that the quantitative aspect is cross-sectional and cannot be used to determine causality. The qualitative aspect of the study regarding the lived experiences of survivors is retrospective in nature and may be subject to recall bias.

Conclusions

It is hoped that the findings from this study will improve our understanding of the factors that drive SH among staff and students in tertiary education institutions in Nigeria and the risks susceptible populations face. This information will help with the design and implementation of policies and programs that can reduce the risk of susceptible populations to SH, in view of the long-term and or lifetime mental health consequences and social effects of SH on survivors and improve reportage among survivors. Future research needs to focus on contextualized interventions for the prevention and response to SH in tertiary institutions.

Acknowledgments

The research team would like to acknowledge the tremendous support received from the 3 selected universities and every survivor who spoke their truth. The authors acknowledge the support of Prof Morenike Afolayan.

Abstract

Background: Food insecurity is a risk factor for multiple chronic diseases, including obesity. Importantly, both food insecurity and obesity are more prevalent in African American women than in other groups. Furthermore, food insecurity is considered a *cyclic phenomenon*, with episodes of food adequacy (ie, enough food to eat) and food shortage (ie, not enough food to eat). More research is needed to better understand why food insecurity is linked to obesity, including acknowledging the episodic nature of food insecurity as a stressor and identifying underlying mechanisms.

Objective: The objective of this study is to investigate the episodic nature of food insecurity as a stressor via responses in body weight and psychological and physiological parameters longitudinally and do so in a health-disparate population—African American women.

Methods: We enrolled 60 African American women (food-insecure cohort: n=30, 50%; food-secure cohort: n=30, 50%) aged 18-65 years with obesity (BMI 30-50 kg/m^2) to measure (1) daily body weight remotely over 22 weeks and (2) psychological and physiological parameters via clinic assessments at the beginning and end of the 22-week study. Furthermore, we are assessing episodes of food insecurity, stress, hedonic eating, and appetite on a weekly basis. We hypothesize that food-insecure African American women with obesity will demonstrate increased body weight and changes in psychological and physiological end points, whereas food-secure African American women with obesity will not. We are also examining associations between changes in psychological and physiological parameters and changes in body weight and performing a mediation analysis on the psychological parameters assessed at the study midpoint. Psychological questionnaires are used to assess stress; executive function, decision-making, and motivation; and affect and nonhomeostatic eating. Physiological measurements are used to evaluate the levels of cortisol, dehydroepiandrosterone-sulfate (DHEA-S), C-reactive protein, thyroid hormones, blood glucose, glycated hemoglobin, and insulin, as well as allostatic load.

Results: This study has completed participant recruitment (n=60). At the time of study enrollment, the mean age of the participants was almost 47 (SD 10.8) years, and they had a mean BMI of 39.6 (SD 5.31) kg/m^2. All data are anticipated to be collected by the end of 2023.

Conclusions: We believe that this is the first study to examine changes in body weight and psychological and physiological factors in food-insecure African American women with obesity. This study has significant public health implications because it addresses the cyclic nature of food insecurity to identify underlying mechanisms that can be targeted to mitigate the adverse relationship between food insecurity and obesity and reduce health disparities in minority populations.

Introduction

Background

Food insecurity, or the lack of sufficient food in both quality and quantity for an active and healthy life, is a prevalent public health concern in the United States, with >10% of households reporting food insecurity in 2021 [1,2]. Experiencing food insecurity can lead to adverse chronic health effects, including an increased risk of cardiovascular disease [3-7], type 2 diabetes [7-9], and mortality [10-12]. These associations are important considering chronic disease prevalence among American adults, including >9% with diabetes [13], approximately 33% with hypertension, and another 33% with prehypertension [14]. Because of this, health care spending in the United States is greater in food-insecure adults than in those who are food secure [15].

Food insecurity is linked to poor diet quality [16-19], maladaptive eating behaviors [20-22], and weight gain [23]. Importantly, food insecurity is linked to greater body weight and adiposity among American adults [24-27], with this relationship being the most unequivocal in women [27,28]. The burden of obesity is disparate across population subgroups. By 2030, severe obesity will become the most common BMI category among women, non-Hispanic African American adults, and adults with low income in the United States [29]. Both food insecurity and obesity are more prevalent in African American women than in other racial and ethnic and biological sex groups [30,31]. The prevalence of obesity has been shown to be almost 50% greater in African American women with food insecurity (52.1%) than in White women with food insecurity (26.5%) [32]. These data highlight African American women as a health-disparate population when considering the food insecurity–obesity linkage.

Research on the episodic nature of food insecurity, which is largely understudied in the literature (yet broadly hypothesized), may help elucidate its association with greater body weight (ie, obesity). Most studies that associate food insecurity and obesity are cross-sectional studies [24-28], which is a major limitation, given that food insecurity is considered a *cyclic phenomenon*, with episodes of food adequacy and food shortage [24,33,34]. Those who are food insecure may experience periods when food is more readily available and overconsume during this time, as well as periods of food scarcity that cause restricted food consumption [33,35,36]; for example, the largest federal nutrition assistance program, Supplemental Nutrition Assistance Program (SNAP), provides monthly benefits that are typically dispensed within the first 2 weeks of a month. Given this, food-insecure households may experience food availability in the first weeks of a month and overeat during this time, followed by food scarcity in the latter weeks of the month and constrained food consumption until the beginning of a new month [24,34,35]. Further evidence shows that soup kitchens see an increase in meals served toward the end of the month [37]. This highlights the need for longitudinal studies examining the episodic nature of food insecurity. Furthermore, alternating episodes of food adequacy and food shortage potentially shape body weight response in food-insecure individuals by increasing stress, which has both psychological and physiological manifestations [38].

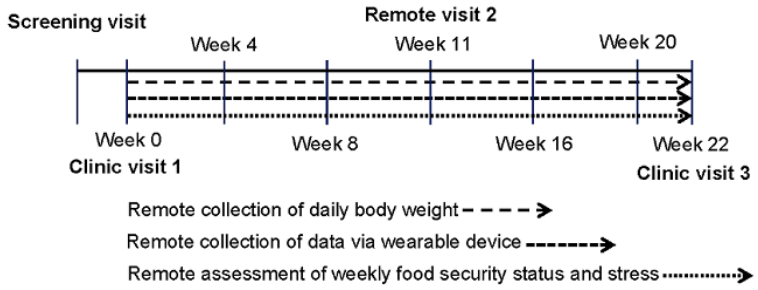
Stress is a central component in the pathway leading from food insecurity to chronic disease [33,39]. Specifically, "weight gain in food-insecure environments may actually represent a complex network of stress-related reactions" [40]. Experiencing food insecurity can elicit a stress response that leads to the activation of the hypothalamus-pituitary-adrenal (HPA) axis and the release of cortisol [34,41]. Allostasis is the ability to adaptively react to perceived challenges by activating these stress-response processes [42]. Chronic stress and repeated activation of these processes, as brought upon by cycles of food insecurity, can result in maladaptive response, including elevated cortisol levels and higher allostatic load [43]. This has both psychological and physiological costs, leading to increased disease risk [44-46]. Physiological parameters that play a mechanistic role in body weight accretion, such as metabolic and endocrine processes and allostatic load, have not been well assessed in relation to food insecurity. Furthermore, although researchers have found cross-sectional associations between food insecurity and psychological factors, such as poorer cognitive-based decision-making [47,48] and disordered eating [21,22], these associations were not triangulated with body weight. Psychological pathologies and physiological processes may hold insight for elucidating the food insecurity–obesity linkage.

Objectives

The primary objective of the RESPONSES (Effects of Episodic Food Insecurity on Psychological and Physiological *Responses* in African American Women With Obesity) study is to investigate the association between food insecurity as a stressor and obesity in African American women by assessing longitudinal responses in body weight and psychological and physiological parameters.

Methods

Overview of Study Design



This study is a 22-week longitudinal observation cohort study conducted at Pennington Biomedical Research Center in Baton Rouge, Louisiana. A total of 60 African American women with obesity—30 (50%) who report being food insecure and 30 (50%) who report being food secure at baseline—have been enrolled in the study. Daily body weights are remotely obtained from participants. Wearable devices are also given to participants to wear throughout the duration of the study to collect additional

data. Weekly food security status and stress assessments are remotely conducted to ascertain episodes of food insecurity and self-reported stress. Psychological and physiological parameters are measured at the beginning (week 0 at clinic visit 1) and conclusion (week 22 at clinic visit 3) of the study. There is also a midpoint remote assessment of selected psychological parameters (week 11 at remote visit 2). Figure 1 presents the RESPONSES study design and timeline.

The study was registered at ClinicalTrials.gov (NCT05076487) on September 30, 2021.

Figure 1. RESPONSES (Effects of Episodic Food Insecurity on Psychological and Physiological Responses in African American Women With Obesity) study design and timeline.

Aims

The RESPONSES study will address the following aims.

- Aim 1: the study will longitudinally assess body weight in addition to psychological and physiological parameters in food-insecure and food-secure African American women with obesity. Body weight is collected to assess the change from week 0 to week 22. Psychological parameters (stress; executive function, decision-making, and motivation; and affect and nonhomeostatic eating) are measured via validated questionnaires. Physiological parameters are measured via 24-hour urine (cortisol) and blood (dehydroepiandrosterone-sulfate [DHEA-S], C-reactive protein [CRP], thyroid hormones, blood glucose, glycated hemoglobin, and insulin) samples as well as an allostatic load total score. These parameters are measured at week 0 and week 22 to examine changes in psychological and physiological mechanisms. We hypothesize that food-insecure African American women with obesity will demonstrate increased body weight and changes in psychological and physiological parameters consistent with elevated stress over 22 weeks compared with food-secure African American women with obesity.
- Aim 2: the study will examine associations between changes in body weight and psychological and physiological parameters in food-insecure and food-secure African American women with obesity. We are examining associations between (1) change in body weight collected over 22 weeks and change in psychological and physiological parameters collected 22 weeks apart and (2) changes in psychological and physiological parameters.
- Exploratory aim: the study will longitudinally examine cyclic patterns in body weight, food insecurity, and stress in food-insecure and food-secure African American women with obesity. Body weight is collected daily to assess average weekly change. Food insecurity and stress are assessed weekly via questionnaires. We are examining weekly patterns of body weight, food insecurity, and stress to determine how changes in body weight are related to episodes of food insecurity and stress. Finally, we are assessing mediation analysis of the psychological questionnaires.

Recruitment and Screening

The target sample is 60 food-secure and food-insecure African American women with obesity; participants are enrolled 1 (food-insecure cohort: n=30, 50%) to 1 (food-secure cohort: n=30, 50%) for an equal number of food-insecure and food-secure participants (1:1) with reported income ≤250% of the federal poverty level. Participants are being recruited from the Greater Baton Rouge, Louisiana, area in designated community locations by trained study staff who assess each prospective participant's potential eligibility and interest in participating in the study. Community-based recruitment allows for engagement with potential participants in a setting that is familiar and comfortable. Recruitment sites include partnering food pantries, local YMCAs, and other community centers. Community recruitment efforts include, but are not limited to, flyers, presentations, health fairs, and attendance at site-specific community events. Additional recruitment efforts include email blasts, social media posts, and newsletters.

For prescreening, investigators at Pennington Biomedical Research Center use a telephone screener and/or an initial web screener to determine whether potential participants meet basic eligibility criteria. Study staff follow up with potential participants via telephone call to schedule a screening visit to determine eligibility. Ridesharing (eg, Uber and Lyft) is offered to all participants to travel to and from all clinic visits. During the screening visit, potential participants provide written informed consent before the collection of measurements.

Eligibility is assessed using the criteria presented in Textbox 1 (if eligible, participants are enrolled into the study).

XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Willing to provide written informed consent
- Female
- Self-reported race of African American or >1 race in which African American is identified
- Aged 18 to 65 y
- BMI 30 to 50 kg/m^2 (inclusive)
- Reported income ≤250% of the federal poverty level
- Ability to complete questionnaires in English
- Willing to archive blood and urine samples
- Willing to fast for a minimum of 8 to 10 h before clinic visits

Exclusion criteria

- Male
- Self-reported race other than African American or >1 race in which African American is not identified
- Reported income >250% of the federal poverty level
- Given birth within the past 6 mo, currently pregnant, or plans to become pregnant within 6 mo
- Currently breastfeeding
- Currently participating in a weight loss program
- Current use of prescription or over-the-counter medication specifically for weight loss
- Recent weight loss (+5% to −5% weight change in last 6 mo by self-report; if participant is on a prescription medication that impacts weight but meets weight stability criteria [+5% to −5% weight change in last 6 mo by self-report], participant will be deemed eligible)
- Past bariatric surgery or plans for bariatric surgery within 3 mo
- Active cancer or cancer treatment
- Serious digestive disorders that significantly alter metabolism and weight (such as uncontrolled inflammatory bowel disease)
- Current diagnosis of, and active treatment for, alcoholism or other illicit drugs of abuse
- Uncontrolled significant thyroid disorder
- Uncontrolled significant diabetes (fasting blood glucose level >250 mg/dL) or hypertension (blood pressure >180/100 mm Hg)
- Current diagnosis of, or treatment for, heart failure
- Serious psychiatric illness, including bipolar disorder and schizophrenia
- Current or recent diagnosis (within last 5 y) of an eating disorder
- Persons who weigh >380 pounds (172 kg; due to scale requirements)
- Not willing to be recontacted
- Are unable to use devices and applications as required for study participation
- Have another member of the household (same address) who is a participant in the study
- Other conditions that affect metabolism or body weight as determined by the principal investigators and medical investigator
- Presence of any cognitive, psychiatric, behavioral, or medical disorder that, in the opinion of the principal investigators or medical investigator may interfere with study participation

Outcome Measures and Study Procedures

Overview

The primary outcome of the RESPONSES study is the change in *body weight*. The secondary outcomes include *psychological parameters* (stress; executive function, decision-making, and motivation; and affect and nonhomeostatic eating measured via psychological questionnaires) and *physiological parameters* (cortisol, DHEA-S, CRP, thyroid hormones [thyroid-stimulating hormone, free tri-iodothyronine, and free thyroxine], blood glucose, glycated hemoglobin, and insulin levels measured via blood and urine samples, as well as an allostatic load total score). Table 1 summarizes the data collection schedule of study procedures.

Textbox 2. Psychological and physiological parameters assessed in the RESPONSES (Effects of Episodic Food Insecurity on Psychological and Physiological Responses in African American Women With Obesity) study.

Psychological parameters and questionnaires

- Stress
  - Perceived Stress Scale (PSS): PSS-10 (clinic visits) and PSS-4 (weekly remote assessment)
- Subjective social status
  - MacArthur Scale of Subjective Social Status
- Executive function
  - Delay discounting: Kirby 27-item Monetary Choice Questionnaire
- Decision-making
  - Grit: 8-item Short Grit Scale
  - Future time orientation: Zimbardo Time Perspective Inventory, Consideration of Future Consequences Scale-14
  - Financial planning
  - Longevity
- Motivation
  - Retrospective Visual Analog Scale
- Affect
  - Positive and Negative Affect Schedule
- Psychological distress
  - 6-item Kessler Psychological Distress Scale
- Nonhomeostatic eating
  - Food craving: Food Craving Inventory (trait) and Food Craving Questionnaire-State
  - Eating disorder: Eating Disorder Diagnostic Scale
  - Food addiction: Yale Food Addiction Scale
  - Restraint, disinhibition, and hunger: Eating Inventory and Power of Food Scale
- Well-being
  - Patient-Reported Outcomes Measurement Information System-43
- Physical activity
  - International Physical Activity Questionnaire–Long Form
- Sleep
  - Pittsburgh Sleep Quality Index

Physiological parameters and measures and assessments

- Stress
  - Cortisol: 24-h urine collection
  - Dehydroepiandrosterone-sulfate (DHEA-S): fasting blood sample
- Metabolic or endocrine marker
  - C-reactive protein, thyroid-stimulating hormone, free tri-iodothyronine, free thyroxine, blood glucose, glycated hemoglobin, and insulin levels: fasting blood sample
- Allostatic load total score

XSL•FO
RenderX

- Cardiovascular health: systolic blood pressure, diastolic blood pressure, pulse, high-density lipoprotein, and total cholesterol levels
- Metabolic markers: albumin levels, waist to hip ratio, and glycated hemoglobin levels
- Immune markers: C-reactive protein levels

Screening Visit

All participants undergo a screening visit to determine eligibility. At the screening visit, medical history information is collected, and medications are assessed. Anthropometrics, including height, weight, waist and hip circumference, and blood pressure, are obtained. Height is measured with a standard stadiometer. Measurements are taken without shoes and recorded to the nearest 0.1 cm. For screening purposes, a fasting blood sample was obtained to measure blood glucose, triglycerides, and total cholesterol levels, as well as standard clinical indicators of liver and kidney function.

Remote Daily Assessments

Body Weight

Body weight is obtained remotely via scales given to participants to take home and weigh themselves at approximately the same time each day. The scales transmit each participant's body weight data to a secure website to which study staff have access. Participants are given instructions on how to weigh themselves on the scale (eg, flat surface) to obtain accurate data. Ideally, weights are collected in a fasted state. Study staff inspect scale data and contact participants when necessary to ensure compliance with daily weighing.

Wearable Device

A wearable device (Fitbit Sense) is provided to each participant at clinic visit 1 to be worn throughout the duration of the study to collect physical activity, sleep, and other device-specific accessible data. The wearable device is used as a monitoring tool, and data are automatically and wirelessly sent to the Fitbit device database. Participants are trained in how to use the device, including how to sync it and charge it regularly.

Remote Weekly Assessments

Food Security Status

This is assessed via a 2-item food insecurity screener [49,50], which references the previous week, to measure episodes of food insecurity. Weekly food assistance use (eg, SNAP and Special Supplemental Nutrition Program for Women, Infants, and Children benefits, as well as visits to food banks, food pantries, or soup kitchens) and receipt of income from any source (eg, traditional employment and federal financial assistance [Supplemental Security Income, Temporary Assistance for Needy Families, and unemployment benefits]) are also assessed to further augment the assessment of episodic food insecurity.

Self-Reported Stress

This is measured using the Perceived Stress Scale-4 (PSS-4).

Nonhomeostatic Eating

We also assess nonhomeostatic eating in tandem with weekly assessments of food security status and stress by measuring appetitive drive to consume palatable foods in the absence of hunger via the Power of Food Scale (PFS) [51].

Hunger and Fullness

Last, we examine hunger and fullness with 2 questions from the Retrospective Visual Analog Scale [52,53]. These assessments are conducted remotely (eg, via telephone, text, email, or video) on anchor days (eg, Wednesday) for each participant.

Clinic Visits 1 and 3

Anthropometrics

Fasting *weight* is measured using a standard digital scale. Measurements are taken without shoes and recorded to the nearest 0.1 kg. Measures are taken twice and if not within 0.5 kg are taken a third time. BMI is calculated. *Waist* and *hip circumference* are measured using standardized procedures. Waist circumference is taken from the natural waist. This area is midway between the inferior border of the rib cage and the superior aspect of the iliac crest. The hip circumference is measured at the level of the trochanters, which is usually the maximal extension of the buttocks. Both measures are taken twice and if not within 0.5 cm are taken a third time. Average values are calculated for weight, waist circumference, and hip circumference measurements. Body fat and lean mass are assessed using a body composition analyzer and bioelectrical impedance analysis, which is accurate to within 5% of body fat estimation by dual energy x-ray absorptiometry with a reliability of <1% in variation within itself [54]. *Blood pressure* and *pulse* are taken.

Blood Collection

Fasting blood draws are collected. From a chemistry 15 panel, blood glucose, albumin, triglycerides, and cholesterol (total, low-density lipoprotein, and high-density lipoprotein) levels are measured. In addition, DHEA-S, CRP, thyroid-stimulating hormone, free tri-iodothyronine, free thyroxine, and insulin levels are measured.

Urinary Cortisol

Urinary cortisol level is obtained from 24-hour urine collections. Participants are provided instructions, a urine hat, and a urine jug. Participants perform the first 24-hour urine collection within 3 days (ideally within 24-48 h) before clinic visit 1. An immunoassay with chemiluminescent detection is used to determine cortisol concentration from urine.

Allostatic Load

An *allostatic load total score* is calculated from selected clinic assessments described previously [55].

XSL•FO
RenderX

Textbox 2 presents each psychological and physiological parameter assessed in the RESPONSES study, as well as the relevant questionnaire or metabolic or endocrine assessment used to measure each parameter.

Questionnaires

Health Literacy

The Rapid Estimate of Adult Literacy in Medicine–Short Form (REALM-SF) is used to measure health literacy in participants. This assessment is a standardized series of 7 words. The score (0-7) provides an assessment of how well a participant will be able to understand the additional questionnaires. Participants scoring 0 to 3 on the REALM-SF are aided by study staff in completing the other questionnaires. Patients scoring 4 to 7 on the REALM-SF complete the other questionnaires on their own but are offered assistance as needed.

Food Security Status

This is measured using a modified version of the 6-item Food Security Scale [56,57]. This scale is a well-validated measure of food security developed by researchers at the National Center for Health Statistics. Two or more affirmative answers indicate food insecurity.

Food Assistance

Participants will be asked about their use of federal food assistance (eg, SNAP [food stamps] and Special Supplemental Nutrition Program for Women, Infants, and Children) and other forms of nonfederal food assistance (eg, visits to food pantries and soup kitchens).

Sociodemographics

Participants complete a questionnaire that assesses age (date of birth), race, ethnicity, sex, marital status, the highest level of education completed, annual household income, the number of people in the household, occupation, employment status, home street address (including city and zip code), sources of financial support, dependent status, insurance and health care coverage, and smoking status.

Dietary Quality

A screener that assesses dietary fat, fruit, vegetable, and alcohol intake is completed by participants. The screener contains scales from several sources. The National Cancer Institute fat screener estimates the percentage of energy from fat by asking participants to report the frequency of consuming specific foods over the past 12 months [58,59]. A standard 7-item fruit and vegetable screener developed by the National Cancer Institute and the National 5 a Day Program asks how often fruit and vegetables were consumed in the past month [60,61]. Three questions related to the frequency of alcohol (beer, wine, and hard liquor) intake were adapted from the Brief Questionnaire to Assess Habitual Beverage Intake [62].

Psychological Questionnaires

Participants also complete multiple self-report questionnaires to measure psychological constructs related to stress; executive function, decision-making, and motivation; and affect and nonhomeostatic eating, as well as overall well-being, physical activity, and sleep. All questionnaires are reliable and valid as described in the following subsections.

Perceived Stress Scale

The Perceived Stress Scale-10 (PSS-10) is the most widely used psychological instrument to measure the perception of stress [63]. This questionnaire includes 10 items that measure the degree to which situations in one's life are appraised as stressful. The PSS-4 is a shortened version of the PSS-10 designed for telephone interviews. Items are designed to tap how unpredictable, uncontrollable, and overloaded respondents find their lives. Higher scores on the PSS-10 and PSS-4 indicate greater stress.

Subjective Social Status

This construct indicates one's self-perceived social position in American society and will be measured using the MacArthur Scale of Subjective Social Status [64]. This scale presents a *ladder* and asks participants to select a rung on which they feel they stand compared with other people in the United States. Scores range from 1 to 10, with higher scores representing higher subjective social status.

Kirby 27-Item Monetary Choice Questionnaire

Delay discounting is a bias toward smaller immediate rewards versus larger delayed rewards [65] and will be assessed via the Kirby 27-item Monetary Choice Questionnaire [66]. This questionnaire presents participants with a set of choices between smaller immediate monetary rewards and larger delayed monetary rewards. Participants who discount the value of the delayed rewards more steeply are considered to be more impulsive [66].

8-Item Short Grit Scale

Grit is a measure of trait-level perseverance and passion for long-term goals and will be assessed using the 8-item Short Grit Scale [67]. Scores range from 1 (not at all gritty) to 5 (extremely gritty).

Zimbardo Time Perspective Inventory–Future Scale

Future time perspective is a comprehensive assessment of one's orientation toward the future [47,68]. The *future* scale of the Zimbardo Time Perspective Inventory measures psychological orientation toward the future [69]. This scale comprises 13 statements with Likert-type responses. Higher scores indicate greater future time perspective.

Consideration of Future Consequences Scale

This scale is a valid and reliable 14-item measure of the extent to which a participant considers future outcomes in relation to current behaviors. The measure assesses two subscales—(1) consideration of immediate consequences and (2) consideration of future consequences—to assess the extent to which a participant feels that they may be influenced by an abstract consequence. The participant indicates how much they agree with the statement on a scale from 1 (not at all like you) to 7 (very much like you) [70-72]. Higher scores indicate greater consideration of future consequences.

XSL•FO
RenderX

Financial Planning

Participants will be asked a single question to assess the time period considered for financial planning: "In planning your, or your family's, saving and spending, which of the following time periods is more important to you and your partner, if you have one?" with the following response options: no planning, day to day, the next few weeks, the next few months, the next year, the next few years, the next 5 to 10 years, longer than 10 years [73,74]. Higher values indicate greater future time perspective.

Longevity

Participants' subjective appraisal of longevity will also be assessed via a single question: "What do you think are the chances you will live to age 75 or more (where 0 means there is not a chance you will live to 75 or more, and 100 means you will definitely live to 75 or more)?" [73,74]. Higher values indicate greater future time perspective.

Retrospective Visual Analog Scale

This scale contains 9 items to measure the average ratings of appetitive sensations that participants experienced over the past week. This method of collecting visual analog scale data has been found to be consistent with daily assessments of satiety [52], and support has been found for the reliability and validity of the visual analog scale for measuring subjective states related to energy intake [53].

Positive and Negative Affect Schedule

This is a self-report measure that is made up of 2 mood scales, 1 measuring positive affect and 1 measuring negative affect [75]. It has 10 items measuring positive affect and 10 items measuring negative affect on a 5-point Likert scale ranging from 1 (very slightly or not at all) to 5 (extremely). Scores can range from 10 to 50 on each scale, with higher scores representing higher levels of positive affect and lower scores representing lower levels of negative affect.

Psychological Distress

The Kessler Psychological Distress Scale (short version) is a 6-item self-report measure of psychological distress [76]. Respondents indicate how often they have had 6 different feelings or experiences during the past 30 days using a 5-point Likert scale: 4 (all of the time), 3 (most of the time), 2 (some of the time), 1 (a little of the time), and 0 (none of the time). The feelings and experiences are the following: *nervous*, *hopeless*, *restless or fidgety*, *so depressed that nothing could cheer you up*, *that everything was an effort*, and *worthless*. The score ranges from 0 to 24, with higher scores indicating greater psychological distress.

Food Craving Inventory

This is a 33-item measure of food craving [77,78] and assesses the frequency with which an individual experiences a craving for a particular food. The measure consists of 5 empirically derived factors: high fats, sweets, carbohydrates and starches, fruits and vegetables, and fast-food fats.

Food Craving Questionnaire-State

This questionnaire was developed to measure state (at the moment) craving for food using 15 items [79]. The reliability and validity of the state version of the Food Craving Questionnaire have been established.

Eating Disorder Diagnostic Scale

This brief scale contains 18 self-report items to assess eating disorder pathology and has been shown to be reliable and valid [80]. This measure can diagnose anorexia nervosa, bulimia nervosa, and binge eating disorder.

Yale Food Addiction Scale

This is a 27-item self-report questionnaire [81] used to identify individuals showing tendencies for addictive-like behaviors toward certain types of foods, such as those high in fat or sugar. The measure also allows participants to subjectively identify specific problem foods.

Eating Inventory

The Three-Factor Eating Inventory is designed to measure different dimensions of eating behavior. Three factor-analyzed subscales (cognitive restraint, disinhibition, and hunger) are derived from the questionnaire [82]. The 51-item questionnaire is divided into 2 parts: part I is composed of 36 true-false items, and part II is composed of 15 rating scale items.

Power of Food Survey

The PFS measures loss-of-control, or nonhomeostatic, eating. The PFS comprises 15 items that use a 5-point Likert scale to assess the intensity of desire to consume delicious food when not hungry [51]. Higher scores indicate greater hedonic hunger.

Patient-Reported Outcomes Measurement Information System-43

The Patient-Reported Outcomes Measurement Information System (PROMIS) is a system of highly reliable and precise measures of patient-reported health status for physical, mental, and social well-being [83,84]. The PROMIS-43 is a 43-item health-related quality-of-life questionnaire that includes questions covering the health-related domains of physical function, anxiety, depression, fatigue, sleep disturbance, ability to participate in social roles and activities, pain interference, and pain intensity.

International Physical Activity Questionnaire–Long Form

This is a 7-day recall of the intensity of physical activity and has acceptable reliability [85]. The results are reported as a continuous measure in median metabolic equivalent of task minutes per week.

Pittsburgh Sleep Quality Index

This is a self-rated questionnaire to assess sleep quality and disturbance over a 1-month time interval [86]. A total of 19 individual items generate 7 *component* scores: subjective sleep quality, sleep latency, sleep duration, habitual sleep efficiency, sleep disturbances, the use of sleeping medication, and daytime dysfunction. The sum of the scores for these 7 components yields 1 global score. Acceptable measures of internal homogeneity, consistency (test-retest reliability), and validity have been obtained [86].

XSL•FO
RenderX

Resource Packet

Given the focus on women who experience food insecurity, a resource packet was developed for the RESPONSES study that identifies community resources and services available to participants who may face resource deficits that compromise their overall health. Importantly, participants may identify multiple resource deficits beyond food insecurity during their participation in the study. The resource packet includes relevant community resources and services that address a range of health-related issues and concerns, including food insecurity, medical and dental care, mental health, substance abuse, and domestic violence. The resource packet is given to all participants regardless of study completion or food security status.

Management of Study Data

Portions of RESPONSES study data are collected and managed using Research Electronic Data Capture (REDCap; Vanderbilt University) hosted at Pennington Biomedical Research Center. REDCap is a secure Health Insurance Portability and Accountability Act–compliant web-based application designed to support data capture for research studies, providing (1) an intuitive interface for validated data entry, (2) audit trails for tracking data manipulation and export procedures, (3) automated export procedures for seamless data downloads to common statistical packages, and (4) procedures for importing data from external sources [87].

Sample Size and Statistical Power

Change in body weight was used to compute a minimum sample size for at least 80% power to examine response to episodic food insecurity longitudinally in African American women with obesity. Specifically, the power analysis is based on a study by Wilde and Peterman [23], which used nationally representative data to examine change in body weight over a 1-year period by food security status in women and men. We chose these data on body weight because we expect this measure to be responsive to episodic food insecurity. Wilde and Peterman [23] found that food-secure women had a 10.4% chance of gaining between 2.27 kg and 4.54 kg and a 20.7% chance of gaining >4.54 kg during a 1-year period. Food-insecure women had a 13% chance and a 31.7% chance of gaining between 2.27 kg and 4.54 kg and >4.54 kg, respectively. Using these estimates, an expected change over 22 weeks in the food-secure group is 0.54 kg, and an expected change in the food-insecure group is 0.80 kg. An SD of 22-week change in body weight, 0.24 kg [88], was increased to 0.30 kg to account for higher variability and ensure that the proposed study is well powered. Thus, with 60 participants, the study is well powered (>80%) to detect differences in body weight changes for aim 1. Furthermore, this study is also powered to detect a correlation as small as 0.40 for aim 2.

Planned Statistical Analysis

All available daily body weights will be used for analyses. For aim 1, body weight and psychological and physiological parameters will be analyzed using a mixed effects model with time, food security status, baseline BMI, and age. Models will be checked for both normality and heterogeneity of variance in potential subgroups (eg, age and BMI category). Least squares means and tests for differences by food security group will be the primary results. The analysis of aim 2 will focus on correlations among the outcomes from aim 1. Both Spearman and Pearson correlation coefficients will be used to determine the pairwise relationships among outcomes. Depending on the collinearity among outcomes, factor analysis will also be used to explore these relationships. Analysis of the exploratory aim will determine whether the weekly patterns of change in body weight, food security status, and perceived stress are different by food security group and how well these measures are associated with each other over time.

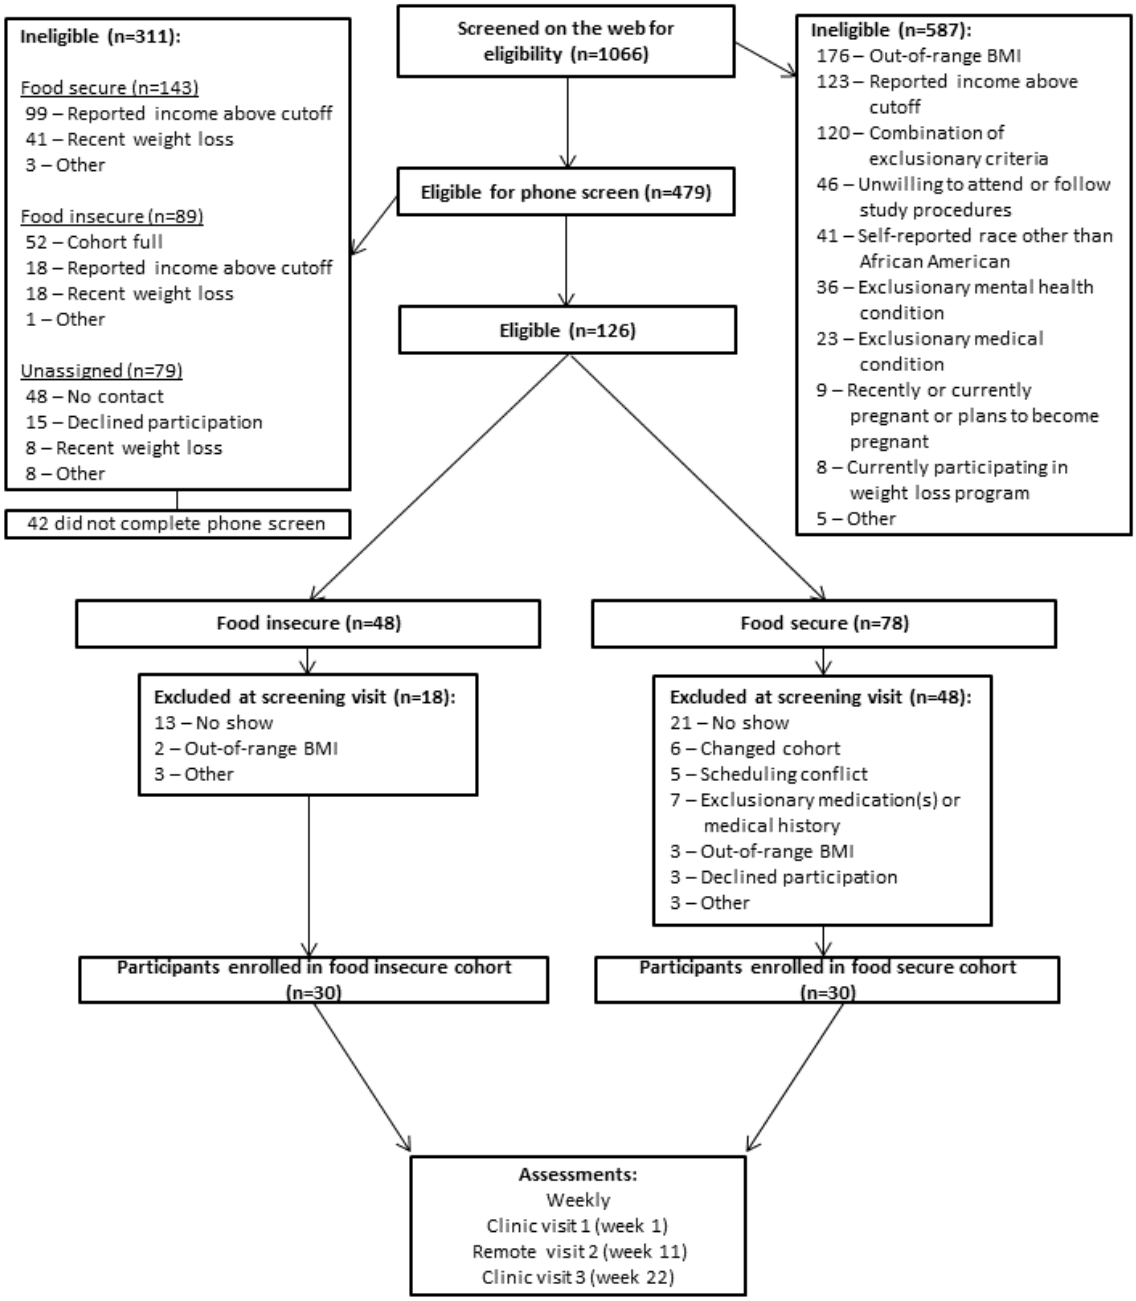
For aim 1, mixed effects models will be used to model psychological and physiological parameters. Furthermore, a linear mixed effects model will be used to model the daily weight over time. In addition to overall changes in body weight between the groups adjusted for BMI, age, and other baseline covariates, smaller temporal changes (ie, weekly) will also be a focus. Modeling these smaller changes should account for the increased fluctuations in the weight of the food-insecure women.

For aim 2, mixed effects models will assess how daily weight change is associated with changes in psychological and physiological parameters. Initial weight, overall weight change, and weekly weight change will all be considered as predictors in addition to more exploratory weight variables, such as the number of days significantly above or below starting weight or average absolute daily weight changes. These variables will be interacted with food security status (group) to determine whether the weight changes have greater effect on food-insecure women.

Analysis of the exploratory aim will determine whether the weekly patterns of change in body weight, food security status, and perceived stress are different by food security group and how well these measures are associated with each other over time. The first part of this analysis will use a mixed effects model, testing food security group differences at each week, whereas the second part will test correlations. Mediation analyses will be applied using both structural mean models and principal stratification [89]. Weekly food assistance use may be used for subgroup analyses to explore how food assistance use influences body weight.

Ethical Considerations

The Pennington Biomedical Research Center Institutional Review Board approved the study protocol (2021-022-PBRC), and all patients provided written informed consent. All attempts are made to maintain participant privacy and confidentiality. Safeguards such as password-protected computers and networks are in place to limit access to participant data. Study data are labeled with a unique series of letters and numbers. Pennington Biomedical Research Center stores data with this unique identifier. Participants receive up to US $300 for completed participation in the study. This includes compensation of US $50 for completion of visit 1, US $50 for completion of visit 2, and US $125 for completion of visit 3. Participants also receive the wearable device upon completion of the study.



XSL•FO
RenderX

Results

Overview

The RESPONSES study has completed participant recruitment (n=60). The flow of participants from screening to enrollment is shown in Figure 2. A total of 1066 potential participants were screened via a web screener for enrollment, and 587 (55.07%) were ineligible for study participation; the most common exclusionary criteria were out-of-range BMI (n=176, 30%) and having a reported income above the cutoff (n=123, 21%). Of the 479 potential participants who were screened via a telephone call, 311 (64.9%) were ineligible owing to exclusionary criteria. Of the 126 potential participants who were eligible after the telephone screener, 48 (38.1%) were food insecure, and 78 (61.9%) were food secure. At screening visits, of the 126 potential participants, a combined 66 (52.4%) were excluded from study participation to reach the target sample size of 60 (47.6%; food-insecure cohort: n=30, 50%; food-secure cohort: n=30, 50%). All data are anticipated to be collected by the end of 2023.

Figure 2. RESPONSES (Effects of Episodic Food Insecurity on Psychological and Physiological Responses in African American Women With Obesity) participant flow diagram.

Participant Characteristics

Table 2 presents the baseline characteristics of the participants enrolled in the RESPONSES study. On average, participants were aged almost 47 (SD 10.8) years with a mean BMI of 39.6 (SD 5.31) kg/m^2 at the time of study enrollment. Regarding marital status, 76% (45/59) of the participants were divorced, separated, widowed, or never married. In terms of education level, 58% (35/60) of the participants had a high school diploma,

XSL•FO
RenderX

General Educational Development Test certificate, or 1 to 3 years of college. Regarding income, 31% (17/55) of the participants reported an annual income of <US $30,000, and 24% (13/55) reported an annual income of >US $50,000. In terms of employment status, 58% (33/57) of the participants reported being employed full time. The mean poverty-to-income ratio (PIR) among all participants was 1.96 (SD 0.83), whereas the food-insecure cohort reported an average PIR of 2.03 (SD 0.79), and the food-secure cohort reported an average PIR of 1.88 (SD 0.89).

XSL•FO
RenderX

Table 2. Baseline characteristics of participants enrolled in the RESPONSES (Effects of Episodic Food Insecurity on Psychological and Physiological Responses in African American Women With Obesity) study.

Characteristics	Food-insecure cohort	Food-secure cohort	Overall
Age (y)

Discussion

Summary

The RESPONSES study is investigating the association between food insecurity and obesity in African American women by measuring the episodic nature of food insecurity, related stress, and the role of psychological and physiological mechanisms. We have completed participant enrollment with 60 African American women (food-insecure cohort: n=30, 50%; food-secure cohort: n=30, 50%). The mean age of participants at enrollment was almost 47 (SD 10.8) years, and they had a mean BMI of 39.6 (SD 5.31) kg/m^2. Once data collection is complete by the end of 2023, we will fulfill the study aims to (1) longitudinally assess body weight in addition to psychological and physiological parameters in food-insecure and food-secure African American women with obesity, to test our hypothesis that food-insecure African American women with obesity will demonstrate increased body weight and changes in psychological and physiological parameters consistent with elevated stress compared with food-secure African American women with obesity; (2) examine associations between changes in body weight and psychological and physiological parameters in food-insecure and food-secure African American women with obesity; and (3) longitudinally examine cyclic patterns in body weight, food insecurity, and stress in food-insecure and food-secure African American women with obesity and carry out a mediation analysis using the results from the psychological questionnaires.

The significance of the RESPONSES study is evidenced by a number of factors, including (1) an explicit focus on health disparities driven by both sex and race or ethnicity as evidenced in African American women, who experience a greater prevalence of both food insecurity and obesity; (2) the assessment of episodic food insecurity via longitudinal observational data collection; and (3) the triangulation of body weight and psychological and physiological parameters in the context of episodic food insecurity as a stressor. These points of significance directly relate to the *Strategic Plan for NIH Nutrition Research* by addressing the multiple recommendations highlighted in the position paper on food insecurity and obesity by Brown et al [90]. This study explicitly acknowledges the *episodic nature* of food insecurity by using a longitudinal study design to examine how the cyclic nature of food insecurity relates to body weight. Furthermore, this study will investigate the mechanisms underlying the linkage between food insecurity and obesity by focusing on a range of relevant psychological and physiological factors. Examining the interplay between psychological and physiological factors may be important to understanding the disparate rates of obesity-related comorbidities (eg, diabetes and hypertension) in African American women. Finally, the results from the RESPONSES study will hold important considerations for the assessment of

XSL•FO
RenderX

body weight and psychological and physiological parameters in studies, wherein the assessment of these markers might need to consider corresponding episodes of food insecurity.

The RESPONSES study uses a longitudinal observational cohort design. Given the study objective, it is important not to intervene; thus, this study would not be possible with a randomized controlled trial design. Interventions should occur after a thorough understanding of the episodic nature of food insecurity and its impact on body weight and psychological and physiological processes. We recognize that only screening for dietary quality and not obtaining food intake data are study limitations, but this aspect of food insecurity (ie, energy-dense and nutrient-poor diet) is very well established in the literature, and body weight can serve as a proxy for food intake [19,20,91]. We are also measuring more tertiary constructs (eg, physical activity) that could be measured via more rigorous methods in future studies, such as energy intake via dietary recall or food pictures and energy expenditure via metabolic chamber or other methodology (eg, doubly labeled water and metabolic cart) to better assess energy metabolism.

Conclusions

To our knowledge, the RESPONSES study will be the first to examine changes in body weight and psychological and physiological factors in food-insecure African American women with obesity during episodes of food insecurity. The findings from this study will provide a range of novel data with significant public health implications by addressing the cyclic nature of food insecurity to identify underlying mechanisms that can be targeted to mitigate the adverse relationship between food insecurity and obesity and reduce health disparities in racially minoritized populations.

Acknowledgments

The authors would like to acknowledge several key community partners who aided in the successful development and recruitment of the RESPONSES (Effects of Episodic Food Insecurity on Psychological and Physiological Responses in African American Women With Obesity) study. This includes Dr Tiffany Wesley Ardoin, Dr Marla Cannatella, and Dr Michelle Nelson, as well as the Louisiana Clinical & Translational Science Center Community Advisory Board. The authors are also thankful to the participants who consented to participate in the RESPONSES study. The research reported in this publication was supported by the National Institute on Minority Health and Health Disparities of the National Institutes of Health (NIH; R21MD015791). The content is solely the responsibility of the authors and does not necessarily represent the official views of the NIH. Additional support was provided by the National Institute of General Medical Sciences of the NIH (1 U54 GM104940) that funds the Louisiana Clinical & Translational Science Center and a Nutrition Obesity Research Centers grant (P30DK072476) entitled “Nutrition and Metabolic Health Through the Lifespan,” sponsored by the National Institute of Diabetes and Digestive and Kidney Diseases.

Data Availability

RESPONSES (Effects of Episodic Food Insecurity on Psychological and Physiological Responses in African American Women With Obesity) study data will be a deidentified participant-level data set that will include all data points necessary to validate the anticipated research findings. A cleaned, deidentified data set will be encrypted and stored on a secure server at Pennington Biomedical Research Center. At study completion, data will be made available to users via request from the Pennington Nutrition Obesity Data Repository. The mission of the Pennington Nutrition Obesity Research Centers Biorepository is to advance the knowledge of obesity, nutrition, and human health through the sharing of deidentified data and biospecimens collected from human participant research at Pennington Biomedical Research Center.

Abstract

Background: Although results from in vitro studies and small randomized controlled trials have shown positive effects of Dazhu hongjingtian injection (DZHJTI) on acute ischemic stroke (AIS), their generalizability to routine clinical practice remains to be established.

Objective: The primary aim of this study is to evaluate the effectiveness of DZHJTI treatment for AIS with regard to changes in the stroke-related neurological deficit from baseline to outpatient follow-up, mortality, subsequent vascular events, disability, and traditional Chinese medicine syndrome in real-world clinical settings. By monitoring for adverse events or significant changes in vital signs and laboratory parameters, we also aim to assess the safety of DZHJTI.

Methods: This prospective, multicenter cohort study plans to enroll 2000 patients with AIS within 14 days of symptom onset from 30 hospitals across China. Eligible patients will be followed up for 6 months after initiating medication treatments. The primary outcome will be the change in the National Institute of Health Stroke Scale score from baseline to outpatient follow-up. The secondary outcomes include overall mortality, stroke recurrence, new-onset major vascular events, global disability, and improvement of traditional Chinese medicine syndrome in 6 months. Adverse events or clinically significant changes in vital signs and laboratory parameters, regardless of the severity, will be recorded during the trial to assess the safety of DZHJTI. An augmented inverse propensity weighted estimator will be used to reduce variability and improve accuracy in average treatment effects estimation.

Results: The clinical trial registration was approved in October 2022, and the recruitment and enrollment of participants started in November 2022. The study's outcomes are expected to be published in 2025 in reputable, peer-reviewed health-related research journals.

Conclusions: This real-world cohort study is the first to assess the effectiveness and safety of DZHJTI in treating AIS. It may provide additional clinical evidence, including the duration of response, long-term drug effectiveness, and subgroup efficacy data. The study results will be valuable for clinicians and patients seeking optimal treatment for AIS and could lead to better use of DZHJTI and improved patient outcomes.

Introduction

The high morbidity, mortality, and disability rates associated with stroke impose a significant health and economic burden not only in China but globally [1]. The annual stroke mortality rate in China is approximately 153.9 per 100,000 people, which is 4 times that of American and European countries [1-3]. As the most common subtype of stroke, ischemic strokes accounted for 82.6% (2,818,875/3,411,168) of stroke cases in China admitted in 2019 [4]. Despite receiving guideline-recommended care, including intravenous thrombolysis and endovascular therapy, many patients with stroke continue to experience nerve dysfunction. Recent research conducted in 30 provinces of China revealed that up to 78.7% of first-ever stroke survivors developed poststroke cognitive impairment within 3-6 months following the initial stroke event [5]. This highlights the urgent need to identify a medication with proven efficiency and safety in improving neurofunctional recovery, thereby alleviating the substantial burden on patients and the health care system.

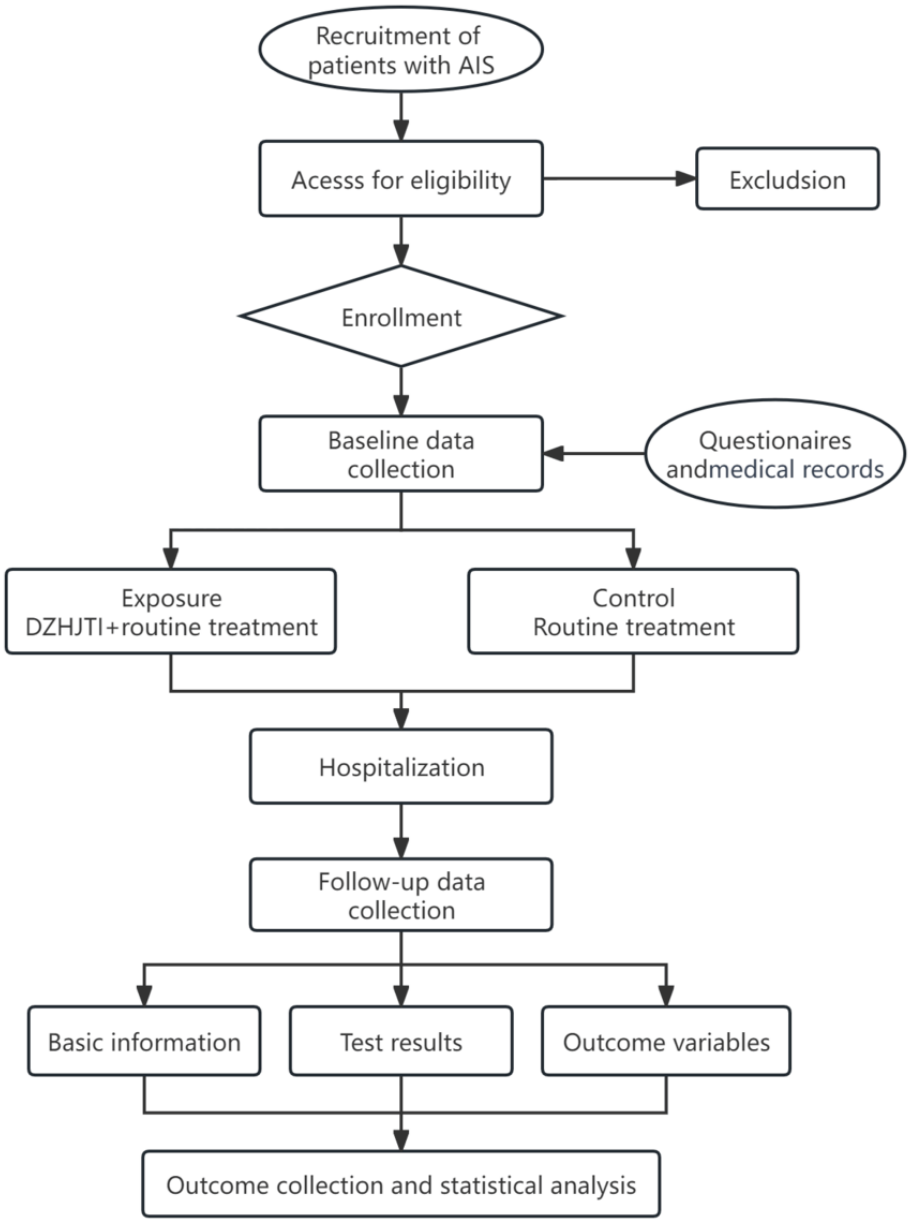
Dazhu hongjingtian (DZHJT) or *Rhodiola wallichiana* var *cholaensis* (Praeger) SH Fu belongs to the family Crassulaceae in the genus *Rhodiola*. Plants of this genus have a long history of traditional use and are included in the official pharmacopeia of Asia, Europe, North America, Latin America, Oceania, and Africa, which is attributed to their proven efficacy in stimulating the nervous system, alleviating fatigue, and preventing high altitude sickness [6,7] (Figure 1). Rhodiola dietary supplements have been recognized by the European Food Safety Authority for their contribution to optimal mental and cognitive activity [8]. DZHJT injection (DZHJTI) is produced from dried roots and stems of DZHJT using processes approved by the Food and Drug Administration of China. Extensive research on the chemical constituents of DZHJTI has identified a total of 49 compounds using ultra-high–performance liquid chromatography coupled with quadrupole time-of-flight mass spectrometry analysis, and a fingerprint has been established by high performance liquid chromatography [9,10]. The primary active constituent of DZHJT, salidroside, has demonstrated various biological activities in both in vitro and in vivo studies, including effects on the central nervous system, cardiac vessel dilation, antihypoxia, and anti-inflammatory properties, among others [11-13].

Figure 1. Worldwide patent application for Rhodiola. Data collected from the Lens (searching term: Rhodiola) as of July 20, 2023.

Several clinical studies have investigated the effects of DZHJTI on acute ischemic stroke (AIS). A pooled analysis of 18 trials involving 1713 participants demonstrated that DZHJTI combined with guideline-recommended therapy was superior to the control group in decreasing the National Institute of Health Stroke Scale (NIHSS; standardized mean difference –0.77, 95% CI –1.52 to –0.02). Moreover, when combined with basic therapy, DZHJTI can also significantly improve the whole blood viscosity, plasma viscosity, and level of fibrinogen, as well as decrease fasting blood glucose and levels of total cholesterol [14]. However, the relatively insufficient sample sizes and ambiguous study designs of previous studies urge high-quality real-world evidence from a rigorous research process.

To enhance the quality of clinical evidence and promote standardized development in clinical research related to traditional medicine on a global scale, we have established the International Traditional Medicine Clinical Trial Registry (ITMCTR), the world's first international clinical trial registration platform for traditional medicine. This accomplishment has earned ITMCTR the distinction of being

XSL•FO
RenderX



approved as a level 1 World Health Organization international clinical trial registration institution. ITMCTR became a member of the Primary Registry Network of the International Clinical Trials Registry Platform and the trials registered with ITMCTR have been added to the International Clinical Trials Registry Platform database. Building upon the foundation of this endeavor, we conducted a multicenter, prospective cohort study to assess the effectiveness and safety of DZHJTI as adjuvant therapy for patients with AIS in a real-world setting. With a complete and accurate study design and prospective registration, this study will provide qualified evidence for DZHJTI.

Methods

Study Design

Our study is a prospective, multicenter cohort study conducted in a real-world setting. An overview of the study flowchart is presented in Figure 2. It is planned to enroll 2000 patients with AIS, as defined in the *Chinese Guidelines for Diagnosis and Treatment of Acute Ischemic Stroke 2018* [15] and *Stroke Diagnosis and Effectiveness Evaluation Standards* [16]. A total of 3 visits will be carried out within a 6-month follow-up period. Baseline demographic data, therapeutic effects, adverse events, and complications associated with DZHJTI will be analyzed.

Figure 2. Flowchart of the study design. AIS: acute ischemic stroke; DZHJTI: Dazhu hongjingtian injection.

Participants

To collect a representative sample, the nephrology departments of 30 secondary or tertiary hospitals in multiple regions of China will continuously recruit and enroll patients. Recruitment began in November 2022 and will continue until at least 2000 participants are recruited. Potential patients will undergo eligibility screening based on the inclusion and exclusion criteria. Eligible patients or their legally authorized representatives will provide written informed consent before undergoing any study-specific procedures. Textbox 1 provides detailed information on the inclusion and exclusion criteria.

Textbox 1. Inclusion and exclusion criteria of the cohort study.

Inclusion criteria

- Female or male patients aged ≥18 years
- Meeting the acute ischemic stroke diagnostic criteria
- Time from symptom onset to the hospital admission ≤14 days
- Willingly participates in the clinical study and signs the informed consent

Exclusion criteria

- Clinically silent acute ischemic stroke
- Minor stroke or minor neurological deficit (National Institute of Health Stroke Scale score of 0-5), nondisabling or rapidly improving transient cerebral ischemia
- Severe hypertension or diabetes that is still unable to control the disease after treatment
- Other conditions that cause motor dysfunction (claudication, severe osteoarthrosis, rheumatoid arthritis, gouty arthritis, etc)
- Unable to complete daily activities independently due to various diseases and physical weakness before this disease, which seriously affects the effectiveness evaluation
- Known complications affecting drug evaluation, including severe cardiac insufficiency, renal insufficiency, severe mental illness, depression after stroke, dementia, cerebral hemorrhage after cerebral infarction, and so forth
- Known contraindications of Dazhu hongjingtian injection: pregnancy, allergic constitution, multiple drug allergies, allergy to ingredients in Dazhu hongjingtian injection, known adverse reactions to any component of the Dazhu hongjingtian injection
- Controls who used other dosage forms of Dazhu hongjingtian injection (tablets, capsules, etc)
- Unsuitability for participation as judged by the investigators

Treatment Regimens

All patients will receive current guideline-recommended treatments according to *Chinese Guidelines for the Diagnosis and Treatment of Acute Ischemic Stroke 2018* [15]. The most commonly used medications and treatments include intravenous thrombolysis drugs, antiplatelets, anticoagulants, drugs for volume expansion, neuroprotectants, medicines for improving cerebral blood flow, and traditional Chinese medicine. Cases will be recruited from patients who receive DZHJTI according to the physician's order. The DZHJTI will be manufactured and supplied by Tonghua Yusheng Pharmaceutical Co, Ltd (approvals Z20060361 and Z20060362), with identical appearance, color, and flavor. The fingerprint-based quality control and ingredient identification met the Chinese pharmacopeia's reference requirements (detailed information is provided in Multimedia Appendix 1). The administration and dosage of DZHJTI will be determined by the attending physicians based on the patients' medical history and clinical manifestations.

Data Collection and Monitoring

Trained research personnel at each participating site will collect baseline data during patient admission, including prehospital care and treatment, prestroke symptoms, and the NIHSS. They will also conduct assessments using the prestroke modified Rankin Scale scores and Barthel Index. Patient information, including demographics, medical and family history, physical examination, auxiliary examination, risk factor assessment, and clinical diagnosis, will be obtained from medical records. The classification of stroke etiology, related complications, and new cerebrovascular events will be documented, and the etiology of AIS will be determined according to the Trial of Org 10172 in Acute Stroke Treatment criteria [17]. Besides standard therapies, the administration of DJHJTI during hospitalization will be documented by the research team.

The collection and reporting of data will use a secure electronic data capture (EDC) system that follows the current clinical protocol and provides each patient with a unique ID. Authorized research personnel can access the EDC system both on personal computers and smartphones, enabling them to complete data collection during daily ward rounds. An overview of the measurement data collection schedule is shown in Table 1. In the EDC system, personal identifiers such as names, ID numbers, and contact information are removed or replaced with unique codes to ensure participant anonymity.

[a]Required data.

[b]TCM: traditional Chinese medicine.

[c]NIHSS: National Institutes of Health Stroke Scale.

[d]mRS: modified Rankin Scale.

[e]BI: Barthel Index.

[f]Optional data to be collected based on the actual occurrence of related events in patients.

[g]AE: adverse events.

Follow-Up Procedures

All patients will be identified and followed up using individual identity cards, which are mandatory for all Chinese citizens, enabling unambiguous linkages. Research personnel will conduct regular face-to-face or telephone follow-up at 1, 3, and 6 months after stroke onset. Information on patient outcomes, including mortality, functional status, activities of daily living, cognitive function, and cardiovascular or cerebrovascular events, will be obtained during follow-up. Mortality will be confirmed through a death certificate issued by the local civil registry or the attending hospital. New cardiovascular or cerebrovascular events requiring rehospitalization will be verified by the discharge diagnosis. In the absence of hospitalization, a committee responsible for determining end points will evaluate suspected recurrent cardiovascular or cerebrovascular events [18].

Outcomes

In this study, the primary outcome will be the distribution of scores on the NIHSS before and after treatment among patients. Secondary outcomes will be assessed at different follow-up visits and will include death, a composite of new clinical vascular events, neurological function, and improvement of traditional Chinese medicine syndrome. Safety assessment will be performed by monitoring adverse events. The complete study outcomes are illustrated in Table 2.

XSL•FO

Table 2. Outcome variables and definitions.

Outcome variables	Definitions
Primary outcome	
Improvement degree of clinical NIHSS[a] scores	• Basic recovery (NIHSS score decreased by more than 90%) • Significant improvement (NIHSS score decreased by 46%-89%) • Improvement (NIHSS score decreased by 18%-45%) • No change (NIHSS score decreased 0%-18% or increased<18%) • Deterioration (NIHSS score increased more than 18%) • The basic recovery, significant improvement, and improvement were regarded as effective. The no change, deterioration, and death were regarded as inefficient [19]
Secondary outcomes	
Overall mortality	—[b]
Stroke recurrence	—
New-onset major vascular events	• Major adverse vascular events include ischemic stroke, hemorrhagic stroke, transient ischemic attack, myocardial infarction, and vascular-related death
Global disability	• Measured by BI[c] and mRS[d] scale
improvement of TCM[e] syndrome	• Measured by TCM questionnaire
Adverse events	• Undesirable experiences occurring to participants during the trial are considered to be related to the DJHJTIf

[a]NIHSS: National Institute of Health Stroke Scale.

[b]Not available.

[c]BI: Barthel Index.

[d]mRS: modified Rankin Scale.

[e]TCM: traditional Chinese medicine.

[f]DZHJTI: Dazhu hongjingtian injection.

Study Sites and Data Source

The cohort study's steering committee will conduct a rigorous screening process of hospitals nationwide, aiming to represent the population from each region in mainland China. Only hospitals admitting over 100 patients with stroke annually, experienced in multicenter studies, and equipped with magnetic resonance imaging or computed tomography machines will be considered. After a thorough evaluation, 30 participating sites with proven research capabilities and a demonstrated commitment to the study will be selected.

Quality Control and Management

Before the study begins, the steering committee will create training materials outlining the study protocol and standard operating procedures for patient screening, recruitment, informed consent, and data collection. Research personnel must complete the training videos and pass an examination to obtain a study permit. The end-point judgment committee will establish standard operating procedures for the proper use of scales, outcome assessment, and reporting procedures. An independent data safety and monitoring board will oversee data monitoring to guarantee adherence to the study documentation, reporting procedures, and the study protocol. This board will be responsible for ensuring that the study is conducted in accordance with good clinical practice guidelines.

Sample Size

According to the previous studies, the ineffective rate assessed by NIHSS score (percentage of patients experiencing no change and deterioration) in controls was 8.75% (7/80), and the ratio of cases to controls was 0.31 [14]. To test the hypothesis that adjuvant treatment with DZHJTI significantly reduces the ineffective rate with a 2-sided α of .05, power of 0.80, and a 20% (n=248) dropout rate, a sample size of 619 cases in each group is required. Nevertheless, a sufficiently large sample size is also necessary to reduce the bias in real-world studies. Therefore, a total of 1000 case participants per group will be included.

Statistical Analysis

A statistical analysis plan was developed prior to initiating the cohort study. Continuous data will be summarized using mean, median, standard deviation, or IQR, while categorical data will be presented as counts and percentages. Between-group comparisons will be conducted using appropriate parametric tests (such as the 2-tailed Student *t* test) or nonparametric tests (such as the chi-square test, Fisher exact test, or Mann-Whitney *U* test). Time-to-event analysis will involve censoring patients at their last follow-up assessment when experiencing a clinical event, at the end of the study, or at the time of withdrawal from the study. Cumulative clinical events will be reported as Kaplan-Meier estimates. Hazard ratios will be calculated at 95% CIs using Cox proportional hazard regression methods.

XSL•FO
RenderX

During data analysis, both confounding factors and missing values will be taken into account. The augmented inverse propensity weighted (AIPW) estimator will be used to obtain a marginal estimate of the treatment effect rather than a conditional estimate. AIPW analysis creates a pseudopopulation in which the relationship between the confounders and the exposure is blocked. Multiple imputation will be used to handle missing values of covariates, and both complete case and imputed data sets will be analyzed. For each imputed data set, the AIPW estimator will be used to estimate the treatment effect, and Rubin rules will be used to combine these estimates and obtain an overall estimate [20]. Sensitivity analyses for unmeasured confounding in observational studies will be performed using the methodology proposed by VanderWeele and Ding [21]. All statistical tests will be 2-sided with statistical significance set at $P<.05$. Statistical analyses will be conducted using SAS software (version 9.4; SAS Institute Inc).

Ethical Considerations

This clinical trial will be conducted in accordance with the principles outlined in the Declaration of Helsinki. Prior to enrollment, all participants or their authorized representatives will be provided with a written informed consent form and will be required to provide their consent. The ethics committee of the Institute of Basic Clinical Research, China Academy of Chinese Medical Sciences (P22004/PJ04) granted approval for the trial on July 18, 2022. The authors declare that the results will be submitted to an international peer-reviewed journal for their prompt dissemination.

Results

The clinical trial registration for this study was approved in October 2022, and recruitment and enrollment of participants commenced in November 2022. We anticipate that the future outcomes of this study will be published in reputable, peer-reviewed health-related research journals around 2025.

Discussion

We present the rationale and design of a prospective, multicenter observational study that aims to evaluate the clinical effectiveness and safety of DZHJTI in the treatment of AIS in real-world settings. Rhodiola has long been used in Eurasian traditional medicine as a natural tonic, but DZHJTI's efficiency in treating AIS is not well known because previous studies had limited external validity [22,23]. Thus, it is necessary to collect large longitudinal data to confirm the practical benefits and disadvantages of DZHJTI treatment in patients with stroke. These data can then be used to develop initiatives to improve evidence-based care and patient outcomes.

Adjuvant treatment with DZHJTI has been shown to have an additional positive effect on improving clinical symptoms and hemodynamic indexes in patients with AIS [14,24]. This beneficial effect may be attributed to the ability of its ingredients, including salidroside, tyrosol, and *Rhodiola* polysaccharide, and the fact that it contains flavonoids, phenolic compounds, trace elements, and amino acids. This has been demonstrated to activate antioxidant enzymes' activity in brain tissue, reduce the oxidative damage of free radicals to cells, and improve glucose and lipid metabolism [25,26]. However, the evidence for the effectiveness of DZHJTI is still limited due to a lack of large controlled studies, and the strict treatment regimes in randomized controlled trials may be not applicable in clinical practice [14]. Therefore, well-designed prospective real-world studies with large sample sizes are necessary to evaluate the evidence.

Our study uses an observational design, and the treatments will not be specified by the study protocol. This approach has the advantage of reflecting real-world clinical practice, including therapy switches and concomitant medications, which can provide valuable insights into treatment effectiveness in diverse patient populations. Additionally, studying how DZHJTI is prescribed by health care providers and used in everyday environments can offer valuable information about the people and settings that are often underrepresented in randomized controlled trials, potentially leading to improvements in the way medicines are prescribed and used among these patient populations.

However, it is important to note that biases are common in real-world studies. Participants from different study sites may differ in characteristics, and combined treatments can vary widely. Additionally, incomplete data can be a significant issue with real-world data sources. Therefore, we plan to use the AIPW estimator, which involves a doubly robust procedure to minimize bias if either the treatment or outcome model is correctly specified [27]. The accuracy of the AIPW estimator for the average treatment effect has been demonstrated under different scenarios of misspecification [27]. To perform propensity score analysis when data are missing, we will conduct the analysis in each imputed data set and then combine the estimates of the treatment effect to obtain an overall estimate. This method has been demonstrated to be unbiased under a missing at random mechanism, and Rubin rules have been shown to provide reliable variance estimates and show good balancing properties [20].

Another key consideration in this trial is selecting an appropriate primary outcome, which depends largely on the disease and should reflect the treatment effect and expected mechanism. NIHSS is a tool used to objectively quantify neurological impairment after stroke [28], while the modified Rankin Scale and modified Barthel Index are commonly used scales to measure disability or dependence in daily activities in patients with stroke or other neurological dysfunction [29]. Previous studies on herbal injection often have limited follow-up periods of up to 3 months due to drug metabolism. However, since AIS neurological function recovery is a slow process, with the main recovery period occurring within 2 to 6 months after onset [30], we evaluated the effects of DZHJTI on neurological recovery for a period of 6 months after discharge from the hospital.

To our knowledge, this is the first and largest prospective cohort study in China that evaluates the real-world effectiveness and safety of DZHJTI in the treatment of AIS. It may provide additional clinical evidence, including the duration of response, long-term drug effectiveness, and subgroup efficacy data of DZHJTI treatment for patients with AIS under the influence of

XSL•FO
RenderX

other confounding factors. Ultimately, the results of this study will help optimize individualized interventions with DZHJTI for the treatment of AIS in China, leading to better patient outcomes and more standardized treatment practices.

Acknowledgments

The study received grants from the China Academy of Chinese Medical Sciences Innovation Fund (CI2021A00702-3), the National Key Research and Development Project of China (2022YFC3501104), the National Natural Science Foundation of China (82174532), and the 2022 Qi Huang Young Scholar program of the National Administration of Traditional Chinese Medicine (Z0841). The support of this work is gratefully acknowledged by all the hospitals and individuals who will participate in the study. We used the generative artificial intelligence tool ChatGPT by OpenAI [31] to polish the drafted manuscript, which was further reviewed and revised by the study group.

Data Availability

The data sets generated and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

All authors participated in the design of the study and will perform the trial. QZC, TS, and NL contributed equally to the drafting of the manuscript and were listed as cofirst authors. YPW and NNS proposed and coordinated the clinical trial. ZC helped to modify this prospective trial. JG performed the statistical analysis and estimated the sample size. XYL provided assistance with data administration and collection. LY was in charge of the trial's quality assurance. YJ kept track of the trial's progress. All coauthors have read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Veteran community reintegration (CR) has been defined as participation in community life, including employment or other productive activities, independent living, and social relationships. Veteran CR is a Veterans Health Administration priority, as a substantial proportion of veterans report difficulties with veteran CR following discharge from military service.

Objective: Enhancing Veteran Community Reintegration Research (ENCORE) is a project funded by Veterans Health Administration's Health Service Research and Development Service. The goal of ENCORE is to maximize veteran and family reintegration by promoting innovative research and knowledge translation (KT) that informs and improves equitable Department of Veterans Affairs (VA) policies, programs, and services. Overall, 2 strategic objectives guide ENCORE activities: mobilize veteran CR research and promote innovation, relevance, and acceleration of veteran CR research and KT.

Methods: ENCORE uses a mixed methods and stakeholder-engaged approach to achieve objectives and to ensure that the KT products generated are inclusive, innovative, and meaningful to stakeholders. Project activities will occur over 5 years (2019-2024) in 5 phases: plan, engage, mobilize, promote, and evaluate. All activities will be conducted remotely owing to the ongoing COVID-19 pandemic. Methods used will include reviewing research funding and literature examining the gaps in veteran CR research, conducting expert informant interviews with VA program office representatives, and assembling and working with a Multistakeholder Partnership (MSP). MSP meetings will use external facilitation services, group facilitation techniques adapted for virtual settings, and a 6-step group facilitation process to ensure successful execution of meetings and accomplishment of goals.

Results: As of December 2022, data collection for ENCORE is ongoing, with the team completing interviews with 20 stakeholders from 16 VA program offices providing veteran CR–related services. ENCORE developed and assembled the MSP, reviewed the VA funding portfolio and veteran CR research literature, and conducted a scientific gap analysis. The MSP developed a veteran CR research agenda in 2021 and continues to work with the ENCORE team to prepare materials for dissemination.

Conclusions: The goal of this program is to improve the impact of veteran CR research on policies and programs. Using a stakeholder-engaged process, insights from key stakeholder groups are being incorporated to set a research agenda that is more likely to result in a relevant and responsive veteran CR research program. Future products will include the development of an effective and relevant dissemination plan and the generation of innovative and relevant dissemination products designed for rapid KT.

Introduction

Overview

Enhancing Veteran Community Reintegration Research (ENCORE) is a 5-year project funded by Veterans Health Administration (VHA) in July 2019. The goal of ENCORE is to improve the Department of Veterans Affairs (VA) policies, programs, and services related to veteran community reintegration (CR), which is a VHA priority [1]. Veteran CR has often been defined as participation in community life, including employment or other productive activities, independent living, and social relationships [2]. ENCORE will achieve its goal by (1) mobilizing veteran CR research and (2) promoting innovation, relevance, and acceleration of veteran CR research and knowledge translation (KT). The ENCORE team developed a road map establishing how these 2 strategic objectives will guide activities to meet the project's impact goal. This protocol paper outlines this road map, including the methods that will be used to determine the current state of veteran CR research, engage stakeholders in shared decision-making using a Multistakeholder Partnership (MSP), and communicate with diverse audiences about veteran CR research needs and priorities. This protocol paper is intended to inform researchers and other professionals on underused methods to engage multiple stakeholders while prioritizing research, program, and policy needs of specific populations.

Veteran CR is a key determinant of veteran health, functioning, and quality of life [3]. A substantial proportion of veterans report difficulties with veteran CR following discharge from military service including poor social and family relationships, unemployment, financial strain, homelessness, and decreased physical and mental health [4,5]. These difficulties are further compounded for veterans with disabilities including the approximately 4.9 million veterans having a service-connected disability [6,7]. Successful veteran CR for all populations emphasizes engagement with community, peers, and family. VHA strategic initiatives outline the importance of establishing and enhancing community relationships that affect and promote veteran CR health [4,5].

ENCORE focuses on two critical domains of veteran CR: (1) work and other productive activities and (2) social relationships and activities (eg, interaction with family members and friends, parental or marital relationships, and marital issues). Employment or other meaningful and productive activity is directly related to income stability, independence, health, and a sense of meaning and purpose in life [8-10]. Evidence demonstrates that the strength and quality of one's social relationships and perceived social support also play key roles in health and well-being [8,11].

Background

KT Strategies

KT, defined "as a dynamic and iterative process that includes the synthesis, dissemination, exchange and ethically sound application of knowledge to improve health, provide more effective health services and products, and strengthen the health care system" [12], is a key component that underpins ENCORE's strategic objectives. Knowledge creation, distillation, and dissemination alone are not sufficient to ensure evidence-informed decision-making [12]. KT is widely used to ensure that decision makers at all levels of the health system (eg, consumers, patients, practitioners, managers, and policy makers) are aware of and can access and use research evidence to inform health-related decision-making [13-16]. Critical considerations suggest that KT should include all stakeholder groups (eg, patients, health care providers, and policy makers) in the actual process of using knowledge to facilitate decision-making [17,18]. Strategies for KT must vary according to the target audience (eg, researchers, clinicians, policy makers, and public) and the type of knowledge being translated (ie, clinical, biomedical, and policy-related) [18-20].

Stakeholder Engagement

Stakeholder engagement in KT is increasingly recognized as important [21,22]. Stakeholders are defined as "individuals, organizations or communities that have a direct interest in the process and outcomes of a project, research or policy endeavor" [23]. The Institute of Medicine, Agency for Healthcare Research and Quality, James Lind Alliance, and Patient Centered Outcomes Research Institute have all developed frameworks for systematically including patients in research, from topic generation to dissemination of results [24-28]. The involvement of relevant stakeholders in all phases of research has been called authentic stakeholder engagement [29].

Authentic engagement includes stakeholders as full partners in setting research priorities; forming research questions; and shaping the design, funding, conduct, and dissemination of studies. Authentic stakeholder engagement must be built on a foundation of trust between researchers and stakeholders [29,30]. In their review of the literature in 2018, Boaz et al [21] described 3 broad categories of important requirements for building this trust and authentically engaging stakeholders: organizational, value, and practice requirements. At the organizational level, researchers should begin by embedding stakeholder engagement into the frameworks of their projects and then allocating resources to support not only the engagement activities but also the evaluation of engagement and rewarding successes [21]. Next, researchers should foster shared values among researchers and stakeholders, including understanding roles, expectations, and activities and encouraging commitment to sustained and continuous engagement [21]. Finally, Boaz et al [21] identified 5 practices focused on ensuring that stakeholder engagement

XSL•FO
RenderX

activities are flexible and systematically enacted and that stakeholder feedback is collected and applied to improvement efforts.

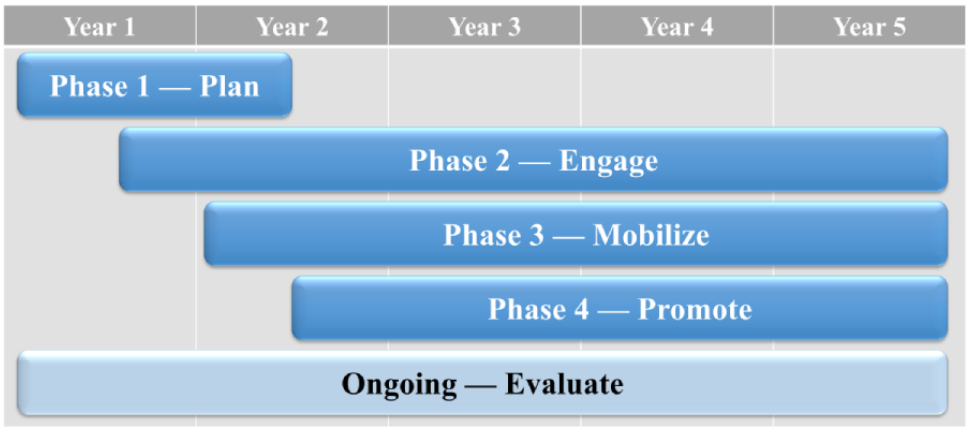
Within VHA, the use of stakeholder engagement methods has steadily increased in the past 2 decades [22]. Methods including the use of advisory councils, veteran engagement groups (VEGs), community-based participatory research, action research, patient-centered research, and human-centered design have become popular within VHA [22]. There is still a need to identify ways to measure and evaluate the quality of stakeholder engagement and its outcomes [31-33]. However, the impacts of stakeholder engagement on research have been documented in the literature both within the VHA [22] and within the broader scientific community [21]. Partnerships among those who produce research and those who use it are likely to enhance the relevance of research and facilitate its use [30]. An engaged stakeholder-driven process to generate and prioritize a research agenda increases the relevance and utility of sustainable interventions and services [34].

The Need to Assess Gaps in Current CR Research

In 2010, a Rehabilitation Research and Development (RR&D) state-of-the-art (SOTA) conference was convened on *issues in defining and measuring veteran CR* [9]. At the SOTA conference, researchers discussed ways to improve the measurement of outcomes for veteran CR, including outlining goals to accomplish this, based on current gaps in the literature.

Since the SOTA conference, the bulk of veteran CR research has focused on assessing CR among individuals with mental health conditions, including projects focusing specifically on posttraumatic stress disorder (PTSD), traumatic brain injury (TBI), and polytrauma [11,35-51]. Some of the SOTA goals have received limited attention, such as the need for more comprehensive measurement approaches for veteran CR. Although new measurements were in development at the time of the SOTA conference (eg, Military to Civilian Questionnaire [M2CQ], [52]; Community Reintegration of Injured Service Members [CRIS], [9]; and Community Reintegration of Injured Service Members Computer Adaptive Test [CRIS-CAT], [9]), other measures are yet to be developed and validated within the VA [52-55]. Moreover, little research has been conducted to complete head-to-head comparisons of CR measurements and instruments [55,56].

Another goal that has received limited attention is the need to measure veteran CR across the life span. Given that veteran CR is often a cyclical process that occurs throughout the lifetime of a veteran, this is an aspect of veteran CR research that requires more attention in coming years [51,57]. Similarly, the effect of veteran CR on society also needs to be studied more, as the CR struggles of veterans may have ripple effects within their communities [58-60].



Since Resnik et al [9] published the SOTA proceedings in 2012, it has become a seminal reference in veteran CR research, particularly for VA-funded research. In support of the goal of this project to enhance the impact of VA research for improving veteran CR, the SOTA conference became a natural point of reference. It became a starting point for the need to assess where the current gaps in the science of veteran CR research remain.

Methods

Design and Overview

The ENCORE project's 5-year road map contains five phases of activities designed to accomplish project objectives (Figure 1): (1) plan, (2) engage, (3) mobilize, (4) promote, and (5) evaluate. This project uses primary and secondary data and stakeholder engagement activities. The methods used during these phases will be described in detail in the following sections.

Figure 1. Timeline for the Enhancing Veteran Community Reintegration Research project's 5-year road map.

Phase 1 (Plan): Review of Research and Assemble the MSP

Review of Research

The findings of the 2010 RR&D SOTA conference on *issues in defining and measuring veteran CR* will be used as a starting point for the review of veteran CR research [9]. At the SOTA conference, researchers discussed ways to improve the measurement of outcomes for veteran CR, including discussions of how veteran CR should be measured, challenges that arise when measuring veteran CR, and recommendations for improving veteran CR measurement. In addition, recommendations were made for future research and policies on veteran CR.

For VA-funded veteran CR grants, the review will focus on grants funded by the VA's Office of Research and Development

XSL•FO
RenderX

and specifically through the following service lines: Health Services Research and Development, RR&D, and Clinical Science Research and Development. For non–VA-funded veteran CR grants, the review will identify grants sponsored by the National Institutes of Health, Department of Defense, and private foundations (eg, Robert Wood Johnson Foundation). Searches will be conducted within VA research databases (including Office of Research and Development) and the National Institutes of Health Reporter and PubMed databases. Research that examined veteran CR issues will be inputted into a Microsoft Excel (Microsoft Corp) tracking sheet. Additional searches for veteran CR research projects will be conducted within Google Scholar for investigators who were known to be linked to VA veteran CR research (VA principal investigators) to identify any missing studies. As the identified literature is reviewed, the reference lists will also be reviewed for relevant publications that did not appear in the literature searches.

The VA Evidence Synthesis Program (ESP) is a resource program that provides timely and accurate syntheses of targeted health care topics of importance to clinicians, managers, and policy makers, as they work to improve the health and health care of veterans [61]. The project team will collaborate with the VA ESP to conduct a search for published literature on veteran CR research focusing on the following question: What studies have examined interventions for promoting veteran CR (eg, reintegration into work, school, or other productive activities or reintegration into social relationships) among Operation Enduring Freedom, Operation Iraqi Freedom, and Operation New Dawn veterans with PTSD, TBI, spinal cord injury (SCI), or polytrauma? This ESP review focused on this selected group of veterans for both pragmatic and scientific reasons. Most of the studies reviewed for the SOTA conference consisted of studies conducted in rehabilitation populations, which include veterans with diagnoses such as PTSD, TBI, SCI, and polytrauma. The ESP review will enable a targeted review of interventions for these populations that have been published since the SOTA conference was conducted. In addition, focusing the ESP review on these populations will enable the team to conduct a more comprehensive review of the veteran CR literature, which includes work involving the military to civilian transition and other CR-related topics. Finally, the general review of the veteran CR literature will focus on the following questions: (1) What are the gaps in evidence that could be informed by future research? and (2) What are the recommendations for future research? This review will include search results from PubMed, VA research databases, Google, and Google Scholar and will focus on published peer-reviewed journals and the *gray literature* (eg, congressional reports and technical reports).

Assemble the MSP

The MSP was strategically assembled to set a veteran CR research agenda for the VA. An MSP is a collaboration across multiple sectors with vested interests in an issue [22,34,62].

Sampling

Overview

Members of the MSP will have experience in veteran CR and a vested interest in advancing impactful research in this field. The MSP will comprise (1) VA CR program leaders; (2) representatives from community-based veteran service organizations (VSOs); (3) veterans, their families, and caregivers; and (4) researchers with expertise in veteran CR. ENCORE can provide stipends to 16 non-VA employee members of the MSP. Microsoft Excel will be used to build a database of potential MSP members. The database will be organized according to member type. A nonexhaustive list of potential MSP members will be added to the database using a set of inclusion criteria (Textbox 1).

XSL•FO
RenderX

Textbox 1. Inclusion criteria for the Multistakeholder Partnership member groups.

Inclusion criteria for Department of Veterans Affairs community reintegration (CR) program leaders

- Program office goals and services align with at least one of the primary veteran CR domains of focus: (1) work and other productive activities and (2) social relationships and activities
- Program office supports either one of the following:
  - Priority populations that are at great risk for veteran CR challenges
  - Priority populations that are underrepresented in veteran CR research
  - Services that address specific diagnoses that place veterans at great risk for veteran CR challenges
  - Nominated by operational partner during expert interview

Inclusion criteria for community-based veteran service organizations

- Organization passes Department of Veterans Affairs due diligence criteria
- Organization has specific veteran-focused programming that addresses primary veteran CR domains of focus: (1) work and other productive activities or (2) social relationships and activities
- Organization supports priority populations that are at great risk for veteran CR challenges or those that are underrepresented in veteran CR research
- Organization is not engaged in lobbying, for-profit activities, or sponsoring research
- Organization has transparent financial and affiliate information

Inclusion criteria for veterans, their families, and caregivers

- Expressed interest in veteran CR
- Commitment to collaborate with Multistakeholder Partnership by sharing CR experiences and abiding by rules of group engagement
- Willing to participate in the Multistakeholder Partnership for 1-2 years

Inclusion criteria for CR researchers

- Demonstrated expertise in veteran CR that resulted in the development of a model, instrument, policy, collaboration, and so on, related to veteran CR
- Demonstrates a broad and historical view of veteran CR
- Work aligns with at least one of the primary veteran CR domains of focus: (1) work and other productive activities and (2) social relationships and activities
- Does not have another role in the Enhancing Veteran Community Reintegration Research project
- Willing to participate for 1-2 years

VA CR Program Office Leaders

Expert informant interviews with this group will be used to recruit VA veteran CR program office leaders into the MSP. Interviewees will be asked to participate in the MSP or nominate someone to represent the program office on their behalf.

Representatives From Community-Based VSOs

As the scope of ENCORE was on veteran CR research agenda to target future research and increase the impact of existing research, recruitment focused on national organizations and programs that still have critical contact with veterans who are not enrolled in or using VA services. To build the list of potential non-VA community veteran CR program leaders, members of the research team will search for VSOs using the following resources:

1. The national directory of VSOs assembled by the VA
2. The VA's congressionally chartered National Advisory Committee list of VSOs
3. The VA Office of Community Engagement's current list of VA-partnered community organizations
4. Internet search engines, using combinations of the following terms: "Veteran," "community," "reintegration," "integration," "inclusion," "return," "nonprofit," and "service"

In addition, the ENCORE team will ask for VSO nominations from the James A Haley Research Service VEG.

To refine the database, ENCORE will assess the appropriateness of partnering with each organization with the VA's internal *Non-Profit Organization Due Diligence Worksheet* [63] to ensure that the nonprofit organization serves veterans with transparency and integrity (ie, clear mission, goals, and history; available list of board and staff members; available list of services, products, and clientele; verified in nonprofit integrity databases; and not associated with controversy or lawsuits). Organizations that pass the due diligence assessment will be scored against additional inclusion criteria (Textbox 1).

XSL•FO
RenderX

Veterans, Their Families, and Caregivers

We will use snowball sampling to identify potential veteran and family member participants. We will ask our network of veteran contacts (eg, the James A Haley Research Service VEG) to provide us with the names of other veterans and family members who may be interested in the MSP, using our inclusion criteria as a guide. We conducted outreach with potential veteran candidates through personal conversations with the veteran or family member to ensure a shared understanding of responsibilities, interests, and goals. Veterans and family members can decide on their own whether to participate in the MSP. The goal of recruiting veterans and family members is to establish collaborative relationships through the MSP, whereby veterans are viewed as equal partners to achieve shared goals [30].

Veteran CR Researchers

The ENCORE team will develop a list of researchers who have demonstrated publishing and research record focused on veteran CR. Specifically, we will identify researchers whose work has resulted in the development of CR models, policy, CR measurements, and innovations that align with the goals of ENCORE. CR researchers will be identified through a review of the veteran CR literature, and a database will be created based on the stated inclusion criteria and will include researchers who work in the VA and those from outside the VA.

Recruitment

ENCORE team members will recruit MSP members via email. Invitations will include the targeted language for each of the MSP stakeholder groups. Potential participants will receive a 2-week response deadline within which to respond. Up to 3 reminders will be sent within the 2-week response time frame, and the last reminder will include discrete response options: (1) yes and (2) no, not at this time.

Phase 2 (Engage): Conduct Expert Interviews and Engage the MSP

Expert Informant Interviews

Sampling

Expert informant interviews will be conducted with representatives from VA program offices to learn about the VA's efforts to address and provide services related to veteran CR. The goals of the interviews will be to learn how VA program offices define veteran CR, what direct or indirect services they provide to veterans, how they set priorities around veteran CR, how their VA program aligns with other VA program offices to address veteran CR, and what studies are needed to improve veteran CR services at the VA (Multimedia Appendix 1). The same inclusion criteria described in Textbox 1 for the MSP members will be used to determine which VA program offices should be contacted for interviews. For VA program offices that meet the inclusion criteria, participants for expert informant interviews will be identified by reviewing public-facing program office websites and VA intranet sites. This activity is focused on the breadth of services and programs used by the VA to support veteran CR and how research can support organizational and program priorities for great impact.

Recruitment

Potential expert informant interview participants will be emailed directly with an invitation to participate in a 30-minute virtual interview. Up to 3 recruitment emails will be sent. The email invitation will include the request for the person to designate another appropriate contact in their office or program if they are unable to participate.

Data Collection Procedures

All expert informant interviews will be conducted virtually using Microsoft Teams. Each participant will receive a short demographic questionnaire to complete and an audiovisual consent form, giving permission for the interview to be recorded. Interviews will be led by 2 experienced qualitative researchers, with one person conducting the interview using a semistructured interview guide (Multimedia Appendix 1) and the other person taking notes using a structured note-taking template. In addition, each expert informant interview participant will be asked for referrals to other VA program personnel who would have expertise relevant to the project.

Data Analysis

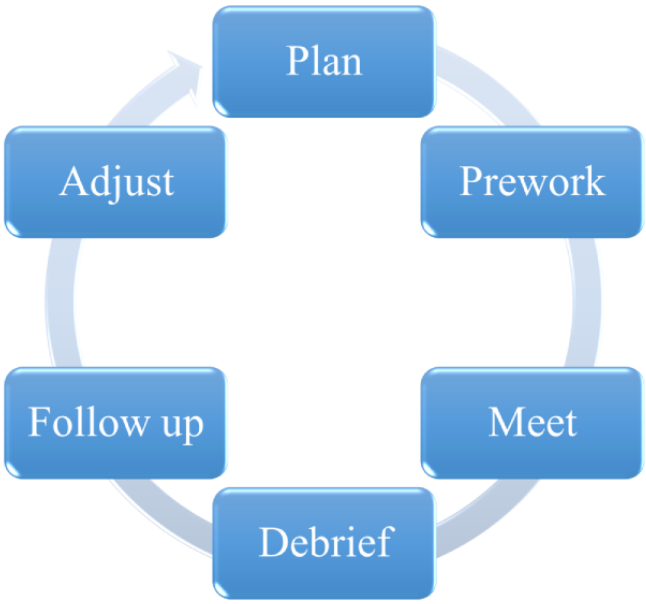
A rapid assessment process and qualitative matrix [64] will be used to analyze key informant interviews with VA program office staff. The rapid assessment process is an iterative team-based technique in which data management and analysis can occur concurrently [65]. Transcript notes will be created, which will represent the interview discussion. As a first level of analysis, notetakers will summarize these interview notes by question.

Next, a qualitative matrix will be developed using Microsoft Excel spreadsheet to organize and visualize the interview data. Transcript note summaries will be entered into the matrix according to case (rows) and questions and quotes (columns), so that in each cell, the source information is summarized as it relates to each case and question. Overall, 2 experienced qualitative team members will code the transcript note summaries using Microsoft Excel columns. Codes are words or short phrases that describe the essential meaning of textual data [66]. Qualitative consensus on the transcript note summaries and thematic descriptions will be achieved through several team meetings.

Engage the MSP

Meeting Facilitation

MSP meetings will be conducted using group facilitation techniques commonly used in organizational development and qualitative research to help groups make decisions or guide them to reach consensus [67,68]. Such techniques offer structure and leadership in group meetings without assuming authority over or responsibility for group outcomes [67,69]. Techniques include flip-charting [67,69,70], asking open-ended and probing questions, and checking in with the group to ensure that everyone is comfortable with group dynamics and processes [69]. ENCORE will collaborate with a facilitator from the Veterans Integrated Service Network 8 Organizational Development Team who is external to the project team. This facilitator will help the MSP to determine and enforce ground



XSL•FO
RenderX

rules and achieve their overall and individual meeting goals and objectives.

Owing to the ongoing COVID-19 pandemic, meetings will be conducted virtually, and facilitation techniques will be modified for the virtual environment. Best practices for conducting virtual group facilitation will be identified by reviewing the literature on virtual qualitative data collection methods. Qualitative researchers have long described this approach, and increasingly, since the beginning of the COVID-19 pandemic, this approach has become more common [71-75].

ENCORE will develop and use a 6-step process for conducting virtual meetings (Figure 2). This process will be developed in conjunction with a VA facilitation expert external to the team. *Step 1* is to plan. The goal of this step is to set tangible outcomes for the meeting. Here, the ENCORE team will set meeting objectives, develop an agenda, determine staff and technology needs for the meeting, identify the meeting structure (eg, Will all work be accomplished as a single large group, or will small breakout groups be required to facilitate discussion?), and gather any materials that the MSP will need to review ahead of the meeting.

Figure 2. The 6-step Enhancing Veteran Community Reintegration Research Multistakeholder Partnership group facilitation process.

Step 2 is prework. The goal of this step will be to ensure that everyone comes to the meeting with the baseline knowledge or information that they need to accomplish the meeting goals. In this step, the ENCORE team will develop and send materials to the MSP for review; gather baseline information from the MSP by sending opinion polls and surveys to the group, if applicable; develop any presentation and breakout group materials for the meeting; and assign staff roles for the meeting. Roles will include the following: (1) facilitator, in charge of leading the meeting; (2) producer, responsible for ensuring the smooth flow of the meeting from activity to activity and troubleshooting any technology issues; (3) notetaker, in charge of observing and documenting group processes and discussions; (4) chat monitor, responsible for monitoring the chat feature of the virtual platform, responding to chats, and bringing important points to the attention of the group verbally; and (5) breakout group facilitators, in charge of facilitating small group sessions.

Step 3 is to meet. ENCORE team members will convene half an hour before each scheduled meeting to check whether their audiovisual technology works and troubleshoot any issues. Next, a technology check will be conducted for MSP members, so that they can verify their audiovisual connections for the meeting. The group facilitator will present the goals and objectives of the meeting, review the group's ground rules, and ensure that the group is on track to meet their goals. In some sessions, breakout groups (small groups of 4-6 MSP members and an ENCORE group facilitator and notetaker) will be needed to encourage rich discussion of a topic. After the large group reconvenes, MSP members from breakout groups will report the results of their discussion.

Step 4 is to debrief. This critical step will directly follow the meeting during which the ENCORE team and the external facilitator will discuss what worked, what did not work, and what needs to change before the next meeting. After debriefing, *step 5* is to follow-up. During this step, the MSP will receive an *engagement and satisfaction survey* (Multimedia Appendix 2); notes from the meeting; and occasionally, a request for feedback and approval of a product developed during the meeting. This will provide the ENCORE team with an opportunity to extend engagement with the MSP. Finally, *step 6* is to adjust. The adjustment step will allow the team to synthesize information from the MSP meetings (step 3), impressions from the team debriefing (step 4), and results from the *engagement and satisfaction survey* (step 5; follow-up) to determine if and how the approach or processes need to be modified.

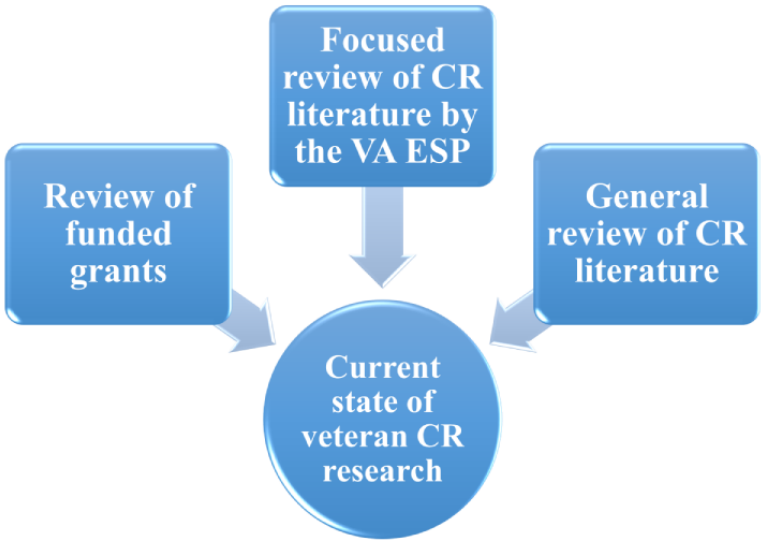
Surveys

Qualtrics [76], a web-based survey platform, will be used to survey MSP members throughout the project. Before their first meeting, MSP members will receive a *welcome survey* (Multimedia Appendix 2), which asks how they or their organization defines veteran CR, what is needed to improve

XSL•FO
RenderX

veteran CR research, and demographic information. Refer to phase 5 for further information about evaluation activities.

Meeting Notes and Breakout Activities



A dedicated notetaker will monitor and record group processes, discussion topics, consensus, and outcomes during each meeting. Notes will be reviewed by the ENCORE team members directly following each meeting and amended, if necessary. Chat box conversations will also be included in these notes and contextualized to document every form of participation that occurs. Notes will be shared with the MSP and analyzed using rapid content analysis [77-79] to refine products, determine areas for improvement in meeting processes, and earmark items for follow-up.

Phase 3 (Mobilize): Gap Analysis and Technical Assistance for Researchers

Gap analysis is a tool or process used to identify and define current issues within a department or field of study. Gap analysis of the relevant literature and funded veteran CR–related studies that have been published over the past 10 years will be conducted to gain a more comprehensive understanding of the state of veteran CR research. Furthermore, the areas of research on veteran CR that have received the most and least attention will be identified to highlight areas of focus that may require additional research in the future.

Gap analysis of the state of veteran CR research will be framed by ENCORE's two key veteran CR domains of focus and will use a three-step process (Figure 3): (1) review veteran CR research that was funded by VA and non-VA grants in the past 10 years; (2) collaborate with the VA ESP to compile an evidence compendium of veteran CR research focusing on interventions that promoted veteran CR among veterans with PTSD, TBI, SCI, or polytrauma; and finally, (3) review the veteran CR literature not included in the other 2 searches. Findings from research portfolio reviews, ESP requests, and literature reviews will be aligned with the 2010 RR&D SOTA goals to evaluate progress and critical gaps. This activity will form the evidence base for the research agenda–setting activities.

Figure 3. Sources contributing to the Enhancing Veteran Community Reintegration Research gap analysis. CR: community reintegration; ESP: Evidence Synthesis Program; VA: Department of Veterans Affairs.

In years 4 and 5, ENCORE will also offer technical assistance services to researchers, VA program offices, and community organizations seeking to conduct research that is related to veteran CR. Activities and services will focus on (1) consultations that provide insight and assistance on leveraging the elements of the ENCORE veteran CR research agenda, (2) providing feedback about grant solicitations and grant proposals through the MSP meetings, and (3) connecting with experts in the field for additional support.

Phase 4 (Promote): Communication Plan

In the *promote* phase, the ENCORE team will connect with the VA Health Services Research and Development Center for Information Dissemination and Education and consult with experts in dissemination and implementation (D&I) and KT. The primary target audiences for D&I and KT activities will be veteran CR researchers both within and outside VHA. The goal of this phase will be to communicate veteran CR research needs for great impact of research on policies and services. Through continued MSP engagement in the format of regular meetings and email communications (as described previously), a stakeholder-driven and prioritized D&I plan will be developed for ENCORE project deliverables and ENCORE-informed research, policies, and practices. Secondary audiences (eg, policy makers, service providers, and VA patients) will be targeted based on stakeholder input. In partnership with MSP stakeholders, public-facing dissemination products and resources will be developed and refined with the help of an ENCORE VEG to ensure that the products are meaningful to and tailored to meet the needs of multiple audiences. In addition, a public-facing website that contains links to selected products will be created and hosted through the Center for Information Dissemination and Education. Dissemination activities beginning in this phase, including the development of publications, are estimated to continue for at least 1 year after completing the project.

XSL•FO
RenderX

Phase 5 (Evaluate): MSP Surveys

Following each MSP meeting, participants will receive a *meeting satisfaction and feedback survey* (Multimedia Appendix 2), asking for comments on their experiences and seeking feedback about ways to improve. Occasionally, surveys will be sent to MSP members, asking them to finalize products, make decisions, and prioritize the next steps for upcoming meetings and products. Close-ended survey items will be analyzed using descriptive statistics. Open-ended survey responses will be analyzed using a matrix analysis process [64,80]. Given the iterative nature of the project, ENCORE will review the evaluation needs regularly.

Ethical Considerations

The local VA Research and Development Committee at the James A Haley Veterans' Hospital has determined this evaluation to be a quality improvement project with nonresearch status. Therefore, it is not subject to human participants research ethical reviews, and written informed consent will not be required before data collection [81]. However, owing to local facility policies, written consent for audio-recording the interviews will be required for data collection.

Privacy and Security

Interviews will be recorded using Microsoft Teams, and audio files and notes will be saved in a secured network folder. The secured folder is accessible to the members of the evaluation team. When reporting the results of the interviews, all efforts to preserve confidentiality will be made, and data will be reported in the aggregate when appropriate.

Ensuring Inclusion and Accessibility

All recruitment and data collection materials will be drafted between eighth and tenth grade level using *plain language* principles for clear communication [82]. Technology checks and one-on-one technical assistance will be offered to ensure that all participants can fully participate in virtual meetings regardless of visual, hearing, or cognitive impairments.

Results

As of December 2022, data collection for ENCORE is ongoing. So far, 20 representatives from 16 VA program offices providing veteran CR–related services participated in a 30-minute telephone interview. Notably, through these interviews, veteran CR was understood to occur at any time after separation, not just immediately after military separation or retirement. Furthermore, veteran CR is cyclical and extends across the veteran's lifetime as opposed to a single point in time. ENCORE developed and assembled the MSP, reviewed the VA funding portfolio and veteran CR research literature, and conducted a scientific gap analysis. The MSP comprises VA program directors (10/25, 40%), veterans and caregivers (5/25, 20%), established veteran CR researchers (5/25, 20%), and representatives of community-based VSOs (5/25, 20%). The MSP developed a veteran CR research agenda that included 3 research priorities [22]. In addition, the MSP is currently working with the ENCORE team to prepare materials for dissemination. The ENCORE project is funded till June 2024.

Discussion

Significance

ENCORE's 5-year road map contains 5 phases of activities that are essential to achieve the overall impact goal of ENCORE, which is to improve VA policies, programs, and services related to veteran CR. The ENCORE protocol engages the MSP as full partners throughout the process, including in the formation of research questions and in shaping the design, funding, conduct, and dissemination of studies [29]. Therefore, the ENCORE protocol is uniquely situated to not only identify gaps in the veteran CR research literature but also to determine a ranking of the priority of those gaps. An engaged stakeholder-driven process to generate and prioritize a research agenda is known to increase the relevance and utility of sustainable interventions and services [29,34]. Owing to the stakeholder engagement activities that ground this project and the overlapping timelines for all phases, detailed planning of each activity is critical to avoid delays and ensure that all stakeholder activities run smoothly.

Engagement is becoming understood to be central to the development, implementation, and dissemination of research activities [83]. The use of an MSP for engaging stakeholders to identify research priorities and develop a research agenda is a novel approach for mobilizing veteran CR research [84]. It differs from traditional methods for reaching consensus across sectors as a means of engagement. For example, the more traditionally used Delphi method aims to reach consensus through indirect methods such as questionnaires and typically relies on experts instead of those directly affected [85,86]. In contrast, ENCORE uses an MSP to engage stakeholders, allowing for their direct input. The MSP's feedback will help to ensure that veteran CR research will have a lasting impact by addressing research questions identified as relevant by the veteran community [83].

Strengths and Limitations

Strengths of this project include stakeholder engagement activities that were deliberately and thoughtfully planned to achieve project goals. A rigorous process is being used to select candidates for the MSP, and additional efforts are being made, such as using an external facilitator for well-planned and executed meetings. Given the diversity of perspectives, MSP products are more likely to be relevant and responsive. Limitations include the resources (eg, staff and time) available, which affected the project's scope and narrowed the focus to veterans (not active duty service members); VA programs; and other governmental and nongovernmental organizations discussed by VA stakeholders, which did not include the Department of Defense. Similarly, limited resources also affected the team's ability to plan and conduct projects that prioritize stakeholder engagement. The veteran and family member group did not constitute a representative sample of veteran viewpoints but rather a collaborative partnership where their shared voices and experiences were valued in the process of shared decision-making. In addition, owing to COVID-19, some MSP members had additional responsibilities that precluded them from attending all meetings.

Conclusions and Implications

The goal of ENCORE is to improve the impact of veteran CR research on policies and programs. This protocol describes methods that can be used by researchers and other professionals for engaging multiple stakeholders to prioritize research, program, and policy needs of specific populations. By grounding activities in authentic stakeholder engagement to accomplish project objectives, ENCORE can work toward achieving its goal. Using a stakeholder-engaged process is more likely to result in a relevant and responsive veteran CR research program.

Acknowledgments

The views expressed in this paper are those of the authors and do not necessarily reflect the position or policy of the Department of Veterans Affairs or the US government. This material is based on work supported by the Department of Veterans Affairs, Veterans Health Administration, Office of Research and Development, Health Services Research and Development (IVI 19-487). The authors would like to acknowledge every member of the Multistakeholder Partnership and their Enhancing Veteran Community Reintegration Research consultants for their hard work and contributions to this project. The authors would also like to acknowledge the expertise and influence of Thuy Boardman and thank her for all of her help.

Abstract

Background: Commercialized since 2019, emicizumab (Hemlibra) was available only in French hospital pharmacies for prophylaxis of hemophilia A with or without inhibitors. Since June 15, 2021, patients can choose between a hospital and community pharmacy. These changes in the care pathway have important organizational consequences for patients, their relatives, and health professionals. Two training programs are available for community pharmacists: the "HEMOPHAR" training program proposed by the national reference center for hemophilia and the Roche training program proposed by the laboratory that markets the product.

Objective: The PASODOBLEDEMI study aims to evaluate the direct impact of the training programs provided to community pharmacists in the context of the dispensing of emicizumab, and to evaluate patients' satisfaction with their treatment whether they choose dispensation from a community pharmacy or retained dispensation from the hospital pharmacy.

Methods: We designed a cross-sectional study based on the 4-level Kirkpatrick evaluation model: the immediate reaction of community pharmacists following training (*Reaction*), the knowledge acquired during the training (*Learning*), the professional practice of community pharmacists during dispensing of the product (*Behavior*), and patients' satisfaction related to the treatment whether it is dispensed from a hospital or from a community pharmacy (*Results*).

Results: Considering that single outcome measures cannot adequately reflect the complexity of this new organization, the Kirkpatrick evaluation model provides 4 distinct outcomes: the immediate reaction after the HEMOPHAR training program, the level of knowledge acquired after the HEMOPHAR training program, the impact of training on professional practice, and patient satisfaction with access to emicizumab. We developed specialized questionnaires for each of the 4 levels of the Kirkpatrick evaluation model. All community pharmacists involved in dispensing emicizumab, whether they have followed the HEMOPHAR or the Roche training program or neither, were eligible for inclusion. All patients with severe hemophilia A were eligible, irrespective of inhibitor use, age, treatment with emicizumab, and whether they chose dispensation from a community pharmacy or retained dispensation from a hospital pharmacy.

Conclusions: The new organization for dispensing emicizumab to patients with hemophilia A in French community pharmacies must be accompanied by optimal safety and quality conditions due to the risk of serious and urgent bleeding situations in the

XSL•FO
RenderX

management of rare bleeding diseases. The elaboration of the PASODOBLEDEMI protocol has already a positive impact with the commitment of all health professionals, physicians, hospital and community pharmacists, and the patient community. The results will be disseminated among the French authorities and will enable, if necessary, proposing this access model to other rare diseases.

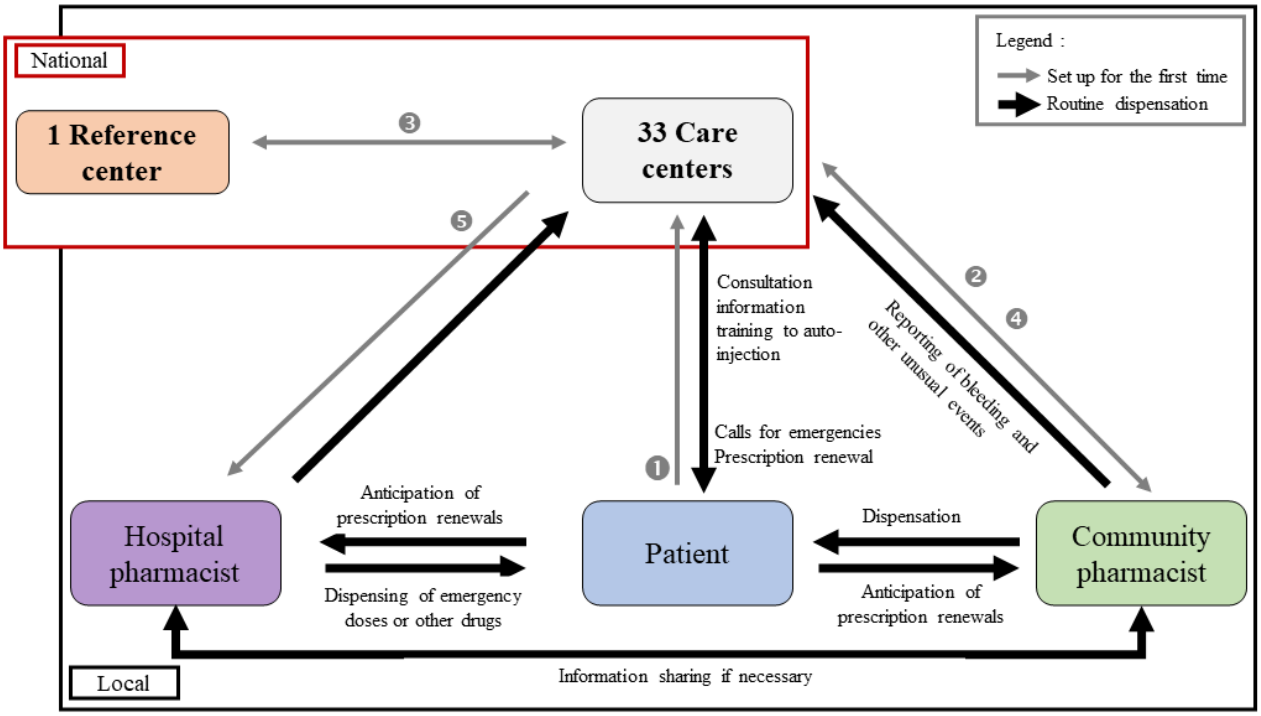
Introduction

Background

Severe hemophilia A is an inherited bleeding disorder due to the deficiency of clotting factor VIII (FVIII), which causes bleeds occurring internally into joints and muscles, or external bleeding from minor cuts, surgical procedures, or injuries. The frequency and intensity of bleeding depends on the level of FVIII deficiency. In high-income countries, the life expectancy of patients with severe hemophilia A is decreased by 37%, the prevalence is estimated to be approximately 6 per 100,000 males, and prevalence at birth is to be approximately 9.5 cases per 100,000 males [1]. In France, the prevalence of severe hemophilia A has been estimated to be approximately 2095 patients in September 2022 [2]. Conventional management consists of FVIII replacement therapy. To maintain a sufficient level of clotting factor in the bloodstream to prevent bleeds, patients with severe hemophilia A are typically prescribed prophylactic treatment that consists of regular administration of FVIII, for example, every day, week, or month, according to how long the factor lasts in the body. Although effective, this treatment can only be administered intravenously, and in France, as well as in other countries [3-6], dispensation FVIII is only available from hospital pharmacies; they both contribute to organizational and geographical constraints [7] as well as a significant mental burden for patients and their caregivers, particularly for the parents of children with hemophilia [8].



Dispensing Circuit of Emicizumab in France

Emicizumab (Hemlibra) is a laboratory-engineered protein that works by performing a key function in the clotting cascade that is normally carried out by the FVIII protein [9-12]. It can be prescribed for routine prophylaxis to prevent or reduce the frequency of bleeding episodes in adults and children of all ages, newborn and older, with hemophilia A, with or without treatment with an FVIII inhibitor [13-15].

In 2019, emicizumab received marketing authorization for severe hemophilia A with or without an inhibitor in Europe [16]. This drug was initially available only from French hospital pharmacies, but from June 15, 2021, it has also been available in community pharmacies. The availability of emicizumab in community pharmacies was accompanied by the implementation of a rigorous new organization of the care pathway (Figure 1), ensuring that all professionals involved in the management of patients were identified by community pharmacists for an optimized exchange of information with the hospital pharmacy and the national reference center for hemophilia. Community pharmacists have the possibility to follow the training program by making a request to the reference center for hemophilia. The e-learning course called “HEMOPHAR” is based on the disease and its issues, and was designed by a multidisciplinary team of health care professionals from the reference center for hemophilia, as well as the platform for exchange and research on blood-derived medicines and their recombinant analogues (Plateforme d'Echange et de Recherche sur les Médicaments DErivés du Sang et leurs analogues recombinants) of the French society of clinical pharmacy (Société Française de Pharmacie Clinique). Also, a short training session organized by Roche, which that markets the drug, validated by the French medicines agency (Agence nationale de sécurité du médicament et des produits de santé) is proposed to pharmacists who order the drug; this is dispensed by telephone and aims to review the key points on the proper use of this medicinal product (including storage methods and ordering).

XSL•FO
RenderX

Figure 1. New organization of the dispensation circuit of emicizumab since June 15, 2021, in France. The black arrows indicate the routine dispensing organization, including emergency management of bleeding episodes. The gray arrows represent the setting up of the organization for the first time initiated by the patient, whose steps are numbered in the order of implementation. The patient indicates his/her chosen community pharmacy to one of the 33 care centers. The care center requests the connexion codes for the e-learning course "HEMOPHAR" from the reference center for hemophilia, and the community pharmacist is invited to follow the training. To facilitate the relationships between hospital and community pharmacists, practical information sheets are shared, including a contact sheet, checklist for dispensing emicizumab, and liaison sheet between the community pharmacist and the care center. The hospital pharmacy is informed by the care center about the transition of dispensing emicizumab in community pharmacy.

Objectives of the PASODOBLEDEMI Study

These changes in the dispensing circuit have important organizational consequences for community pharmacists, becoming both new stakeholders and contacts in the patient care pathway [17]. The effectiveness of this new organization, and in particular the training, therefore needs to be evaluated. To address this, we designed a national study that aims to evaluate the direct impact of the training programs provided to community pharmacists in the context of the dispensing of emicizumab, and to evaluate patient satisfaction with their treatment whether they choose dispensation from a community pharmacy or retained dispensation from the hospital pharmacy.

Methods

Evaluation Strategy: the Kirkpatrick Model

Overview

The Kirkpatrick model (KM) represents a reference for the evaluation of training programs. Studies of various designs and purposes were addressed using the KM; for example, to evaluate a nutritional education program provided by health care professionals [18], to evaluate a train-the-trainer program for health care providers [19], to assess the training of cardiopulmonary resuscitation for nurses [20], to evaluate educational programs for undergraduate dental students regarding appropriate prescribing behavior during their early educational years [21], or to determine the effectiveness of a course for community health workers [22].

The popularity of the KM can be traced to several factors [23]. First, it addressed the need for training professionals to understand training evaluation in a systematic way by providing a straightforward language for communicating about training outcomes. Second, the KM provides trainers with a way to measure the results of what they do in terms of economic impacts and outcomes, which also measures the success of the organization. In addition, to simplify the complex process of training evaluation, a guide to the type of questions and the criteria that may be appropriate to focus on at different temporalities and information levels is provided.

Level 1: Reaction

The first level of evaluation consists of collecting immediate feedback from participants after completing the training. This information can be used to determine which elements of the training are working well or appreciated, and which ones need to be improved. Indicators such as participation rate, completion rate, or time spent on training are typically collected to supplement participant feedback.

Level 2: Learning

The second level is to accurately measure what participants did or did not learn during the training. Usually, the KM suggests a pre- and posttraining evaluation to quantify progress, for example, through knowledge tests or competency interviews. In contrast to immediate reactions to training, this level allows

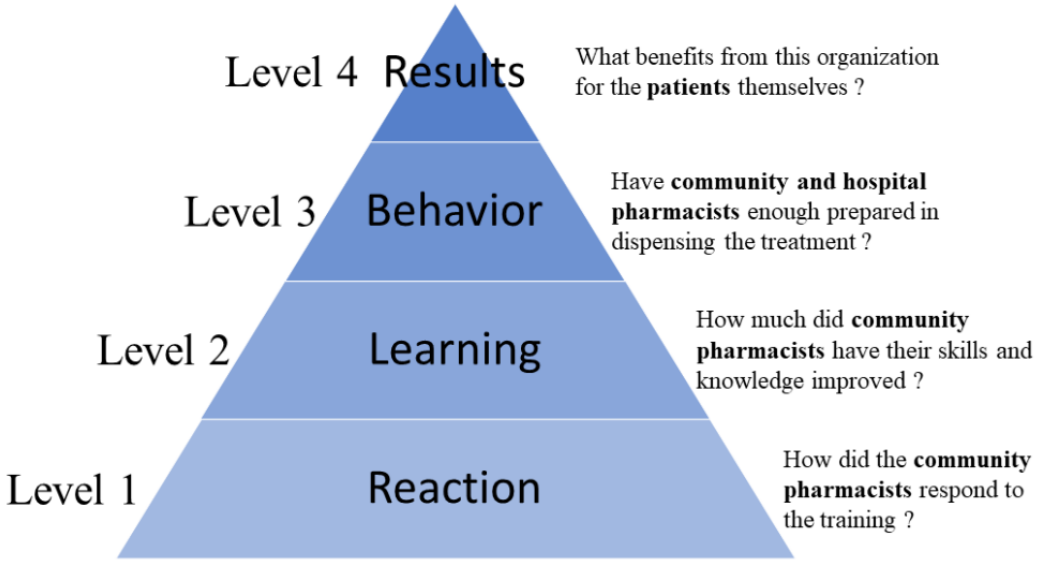
XSL•FO
RenderX

for the measurement of specific outcomes by identifying *Learning* objectives or targeting expected effects of training. When pretraining data are missing, the knowledge acquired post training is evaluated in accordance with the expected knowledge.

Level 3: Behavior

The third level is to determine if the training had a direct impact on the participants' behaviors. This level of evaluation is the most time-consuming because it takes several weeks or months for participants to build confidence and apply their knowledge in their professional practice. To measure *Behavior*, data collection and feedback experience are needed to give participants the opportunity to apply the skills they learned during training; for example, by exposing them to a simulated situation. It is important to mention that a lack of behavioral change does not necessarily mean that the training was ineffective.

Level 4: Results



The fourth level consists of assessing the impact of behavioral changes of the participants on the systemic organization, and in determining if the training reached the expected impact or improved the organization.

Methodology

Study Design

We designed a cross-sectional study based on the KM. The first 3 levels are based on the data directly collected from the pharmacists. Level 1 refers to the evaluation of the immediate reaction of community pharmacists who followed the HEMOPHAR e-learning program and level 2 to their knowledge acquisition. Level 3 consists of evaluating the professional practice of both hospital and community pharmacists in the dispensation of emicizumab. The fourth level of the KM refers to the patients' satisfaction related to treatment, whether dispensed from a hospital or a community pharmacy (Figure 2).

Figure 2. The Kirkpatrick model adapted to the PASODOBLEDEMI study.

Study Populations

The Community Pharmacists Dispensing Emicizumab

Community pharmacists who received personalized login codes for the HEMOPHAR e-learning program from the national reference center for hemophilia were eligible for inclusion in this study for the evaluation of *Reaction* and *Learning*. All community pharmacists involved in the dispensing of emicizumab since June 15, 2021, whether they have followed the HEMOPHAR training program or the Roche training program or neither, were eligible for the evaluation of *Behavior*. Retired community pharmacists are excluded, as are those who have changed practice locations and are no longer practicing in a community pharmacy dispensing emicizumab.

Patients With Severe Hemophilia A With or Without an Inhibitor

All patients with severe hemophilia A, with or without an inhibitor, regardless of age, treatment with emicizumab, and whether they chose dispensation from a community pharmacy or retained dispensation from a hospital pharmacy, were eligible for the evaluation of the results. For those younger than 18 years, a legal representative fills out the questionnaire, and for those aged 18 years or older who need assistance in completing the questionnaire, this may be provided by caregivers or relatives.

Time Frames

A clinical research associate (CRA) is specifically dedicated to contact community pharmacists, informing them of the study modalities and outcomes, and inviting them to complete the e-questionnaires at the appropriate time (Table 1). Immediately after training is completed, the community pharmacists are invited to complete a questionnaire; this will be used to evaluate *Reaction*. The CRA is also able to incite community pharmacists—who have received their connexion codes but who have not yet started the HEMOPHAR learning program—to finalize the HEMOPHAR training program. During the HEMOPHAR training program, community pharmacists also

XSL•FO
RenderX

complete 4 quizzes related to the following sections: presentation of the disease, therapeutic management, organization of care, and practice in the community pharmacy. The responses to the quizzes will be used to evaluate *Learning*. All community pharmacists are invited to complete the e-questionnaire related to *Behavior* at least 3 months after the implementation of the organization. Patients treated with emicizumab are invited to complete the appropriate questionnaire related to *Results*, an e-questionnaire specific to dispensation from hospital pharmacies, and a second e-questionnaire specific to dispensation from community pharmacies.

Table 1. Objectives, the eligible population, time frames, and measurement tool per levels of evaluation.

Levels	Objectives	Eligible population	Time frame	Measurement tool
Level 1: Reaction	To evaluate immediate reactions after the HEMOPHAR training program	Community pharmacists who followed the HEMOPHAR training program	Immediately after the HEMOPHAR training program	Short e-questionnaire and invitations sent by email
Level 2: Learning	To evaluate the level of knowledge acquired after the HEMOPHAR training program	Community pharmacists who followed the HEMOPHAR training program	During the HEMOPHAR training program	Responses to quizzes
Level 3: Behavior	To evaluate the impact of training on professional practice	All community pharmacists	At least 3 months after the implementation of the organization	e-Questionnaire and invitations sent by email
Level 4: Results	To evaluate the patients' satisfaction regarding access to emicizumab	All patients treated with emicizumab	At least 3 months after the implementation of the organization	e-Questionnaire available with a QR code or specific URL

Development of the Questionnaires

The e-questionnaire related to *Reaction* was intentionally short and composed of 8 questions, including 5 questions based on the 4-item Likert-scale (not at all satisfied, not very satisfied, somewhat satisfied, and very satisfied) and 3 closed-ended questions (yes/no; Multimedia Appendix 1). The estimated time to complete this e-questionnaire is estimated to be approximately 1 minute.

The e-questionnaire related to *Behavior* was composed of 13 multiple-choice questions (Multimedia Appendix 2). The estimated time to complete this questionnaire is estimated to be approximately 8 minutes.

The e-questionnaires related to *Results* were adapted to the dispensing choice of the patient (Multimedia Appendices 3 and 4). They were composed of 33 questions. The estimated time to complete this questionnaire is estimated to be approximately 6 minutes.

The content of the questionnaires was initially defined by a multidisciplinary team composed of hospital and community pharmacists and research scientists specialized in methodology and care accessibility. A scientific committee was specifically constituted for the PASODOBLEDEMI study in order to challenge and validate the purposes, methodology, questionnaires, and expected outcomes. This committee was coordinated by the reference center for hemophilia and composed of hospital and community pharmacists, physicians, and the French association of patients with hemophilia (Association Française des Hémophiles). Following the recommendations of the scientific committee, the content of the e-questionnaires has evolved by integrating operational and organizational aspects and optimizing literacy. The e-questionnaires were finally tested in real-life conditions on a sample of eligible populations. The content of the questionnaires was finally validated by the scientific committee in July 2022.

Ethical Considerations

The study complies with the reference methodology for studies and evaluations in the health field [24]; therefore, it did not require written consent to participate. The ethics committee of the Hospices Civils de Lyon approved the study (n°2022-06-01 obtained on June 14, 2022). The PASODOBLEDEMI study was registered in ClinicalTrials.gov (NCT05449197 related to the evaluation of *Reaction*, *Learning*, and *Behavior*, and NCT05450640 related to the evaluation of *Results*).

Results

Administration

All e-questionnaires may be filled out using a PC or mobile device. The hospital and community pharmacists are invited by email to complete the e-questionnaires accessible using a login and password sent by the CRA for the evaluation of *Reaction* and *Behavior*; this also allowed the linking of data between evaluation levels. The e-questionnaire related to *Results* is accessible to eligible patients via a QR code or a specific URL presented on a paper information note, hand-delivered by the community pharmacist or hospital pharmacist when the patient comes for treatment or consultation.

Data Collection

Data collection for the first 3 levels started on July 1, 2022, and for the fourth level, the questionnaires for patients were available since September 12, 2022. The study ended on December 31, 2022.

XSL•FO
RenderX

Discussion

Anticipated Findings

The availability of emicizumab in community pharmacies represents a significant advancement of the care pathway for patients with hemophilia A. The direct expected benefit concerns the improvement of the patients' satisfaction by reducing the mental burden due to the geographical and organizational constraints to hospital pharmacies [8]. As observed in the management of other diseases, distance to the pharmacy may play a role in pharmaceutical management, leading, for example, to inappropriate and inadequate medication and management of asthma for patients living further from their preferred pharmacy [25]. Also, the dispensing by community pharmacies may provide better access and satisfaction to the patients [26]. For example, it is reported that the dispensing in community pharmacies of medicines previously only available from hospital pharmacies during the first wave of the COVID-19 pandemic in Portugal led to a significant increase in satisfaction levels in all evaluated domains: pharmacist's availability, opening hours, waiting time, privacy conditions, and overall experience [27]. In the United States, satisfaction of patients with schizophrenia was improved by dispensing a long-acting injectable medication in community pharmacies during the COVID-19 pandemic [28]. In addition, a collaboration between opioid treatment programs and community pharmacists supported the feasibility and acceptability of physician prescribing and community pharmacy for access to methadone [29].

The new organization for dispensing emicizumab to patients with hemophilia A in French community pharmacies must be accompanied by optimal safety and quality conditions due to the risk of serious and urgent bleeding situations in the management of rare bleeding diseases. Based on the KM, the PASODOBLEDEMI study focuses on the evaluation of the training program and patient satisfaction 1 year after the implementation of the community-based dispensing of emicizumab. Widely used in the literature [30], the KM presents advantages, including ease of implementation and provision of evaluation of the systemic impacts on the organization. Considering that single outcome measures cannot adequately reflect the complexity of the organization, the KM provides 4 distinct outcomes.

The KM presents limitations [23] because the 4-level implementation can be time-consuming and requires an expensive investment to collect data and analyze learning outcomes. It is also difficult to establish a direct link between outcomes and training.

Other methodologies have been developed and used for evaluation of training programs, but which were not adapted to the PASODOBLEDEMI study. For instance, the Context-Inputs-Process-Product model (or the Stufflebeam model) [31,32] is based on the comparison of pre- and posttraining program evaluation to assess the gain in knowledge and confidence of participants; the Levels of Learning model (or the Kaufman model) is based on the use of specific evaluation scales (Kaufman Test of Educational Achievement) as an individually administered battery that provides in-depth assessment and evaluation of skills [33], but the design of this model is too rigid for the objectives of this study; and the Success Case Method (or the Brinkerhoff model) that is closer to an economically oriented performance scale with a study design based on a survey and semistructured interviews [34].

Conclusions

The elaboration of the PASODOBLEDEMI protocol has already had a positive impact with the commitment of all health professionals, physicians, hospital and community pharmacists, as well as the patient community. The results will be disseminated to the French authorities and will enable, if necessary, proposing this access model to other rare diseases.

Acknowledgments

The PASODOBLEDEMI study received institutional support from Roche-Chugai Laboratories. The authors thank the scientific committee of the PASODOBLEDEMI study; Béatrice Clairaz (community pharmacist, copresident of the French society of pharmaceutical sciences [Société Francophone des Sciences Pharmaceutiques Officinales]), Yesim Dargaud (national reference center for hemophilia, Lyon), Félicia Ferrera (cochair of the Provence-Alpes-Cote-d'Azur Unions for health professionals (Société Française de Pharmacie Clinique, Marseille), Nicolas Giraud (president of the French hemophilia association [Association Française des Hémophiles]), Rémi Varin (hospital pharmacist, Rouen), and Fabienne Volot (expert center coordinator, Dijon). The authors thank the team from Roche for their follow-up on the project (Loïc Bergougnoux, Aurélie de Lehvenfehlt, Hélène Baudesson, and Chloé David). The authors also thank Pr Claude Négrier for his involvement in the development of the study and Philip Robinson (health research department of the Hospices Civils de Lyon) for proofreading our manuscript.

Data Availability

The data sets generated during and/or analyzed during the current study are not publicly available due to their confidentiality but aggregated results are available from the corresponding author on reasonable request.

Abstract

Background: Preventive care helps patients identify and address medical issues early when they are easy to treat. The internet offers vast information about preventive measures, but the sheer volume of data can be overwhelming for individuals to process. To help individuals navigate this information, recommender systems filter and recommend relevant information to specific users. Despite their popularity in other fields, such as e-commerce, recommender systems have yet to be extensively studied as tools to support the implementation of prevention strategies in health care. This underexplored area presents an opportunity for recommender systems to serve as a complementary tool for medical professionals to enhance patient-centered decision-making and for patients to access health information. Thus, these systems can potentially improve the delivery of preventive care.

Objective: This study proposes practical, evidence-based propositions. It aims to identify the key factors influencing patients' use of recommender systems and outlines a study design, methods for creating a survey, and techniques for conducting an analysis.

Methods: This study proposes a 6-stage approach to examine user perceptions of the factors that may influence the use of recommender systems for preventive care. First, we formulate 6 research propositions that can be developed later into hypotheses for empirical testing. Second, we will create a survey instrument by collecting items from extant literature and then verify their relevance using expert analysis. This stage will continue with content and face validity testing to ensure the robustness of the selected items. Using Qualtrics (Qualtrics), the survey can be customized and prepared for deployment on Amazon Mechanical Turk. Third, we will obtain institutional review board approval because this is a human subject study. In the fourth stage, we propose using the survey to collect data from approximately 600 participants on Amazon Mechanical Turk and then using R to analyze the research model. This platform will serve as a recruitment tool and the method of obtaining informed consent. In our fifth stage, we will perform principal component analysis, Harman Single Factor test, exploratory factor analysis, and correlational analysis; examine the reliability and convergent validity of individual items; test if multicollinearity exists; and complete a confirmatory factor analysis.

Results: Data collection and analysis will begin after institutional review board approval is obtained.

Conclusions: In pursuit of better health outcomes, low costs, and improved patient and provider experiences, the integration of recommender systems with health care services can extend the reach and scale of preventive care. Examining recommender systems for preventive care can be vital in achieving the quadruple aims by advancing the steps toward precision medicine and applying best practices.

Introduction

Current State of Recommender Systems in Health Care

The integration of recommender systems into eHealth or e-medicine is an underexplored area in research [1]. With the abundance of medical information available on the web, expertise and context-specific knowledge are needed to analyze it effectively [2]. Implementing technology such as recommender systems in health care services can bring about several benefits. First, it can enable aging population groups such as baby boomers, Generation X, and millennials to effectively process and filter the information they find on the web or receive from medical professionals [3]. Second, it can assist insurers and health care providers to shift toward a merit-based payment system, in which providers are compensated based on their patients' outcomes and the ability to lower costs while keeping patients healthy [4]. To facilitate this transition, recommender systems will act as part of the patient-centered team-based workflow, by supporting patient compliance with the treatment protocol. This shift can encourage providers to adopt a preventive approach, rather than just treating secondary and tertiary medical conditions.

Objectives

This study examines the extant literature and formulates quantitative propositions to explore the factors influencing patient use of recommender systems for preventive health decision-making. A proposition is a statement formulated for empirical testing that may be true or false based on some observable phenomena. It also proposes a study design and methods for developing a survey and conducting an analysis. Preventive care helps patients to identify diseases that can cause medical problems before they become serious. Many Americans are unaware of simple tests that could save their lives or prevent years of costly treatment [5,6]. For example, the US Preventive Services Task Force recommends initiating low-dose aspirin use for the primary prevention of cardiovascular disease. In 2019, the Centers for Disease Control and Prevention reported that stroke (cerebrovascular disease) was the fifth leading cause of death in the United States. Patient use of recommender systems can predict and enhance the treatment protocol for diseases such as stroke [7] and could reduce the number of deaths.

The existing literature lacks information about the factors motivating patients to use recommender systems for preventive care. The propositions developed in the study are intended to assist patients in deciding whether to use the available recommender systems for preventive care. We also aim to provide a starting point for future researchers interested in using recommender systems for preventive care. We begin this inquiry into the eHealth recommender system by describing the types of recommender systems. We develop practice-based empirical propositions and further the applied research angle by identifying salient issues with recommender systems. Finally, we discuss general issues with recommender systems and provide strategies to address them to improve the use of recommender systems.

Recommender System Types and Applications

Overview

Traditional recommender systems can be classified as collaborative, content based, and hybrid [8]. Recommender systems also use the following algorithmic approaches to recommend items: group and knowledge-based recommendations [9] and demographic filtering [10]. Finally, there is a context-aware filtering classification.

Collaborative Filtering

Collaborative filtering is the most used type of recommender system built on a collaborative algorithm that uses 1 user's choice to predict subsequent user preferences [11]. Correlation among users plays an essential role in this type of recommender system. Collaborative filtering applications are heavily used in e-tourism, where the preferences of previous visitors are used to predict activities that new travelers may engage in [10]. In addition to traditional collaborative filtering methods, *matrix factorization* improves the algorithm by using a baseline [12]. Other proposed enhancements to the collaborative filtering method include using trust as a replacement for the evaluation performed by a user. Results from studies indicate that using trust as a filler for rating preserves the accuracy and coverage of the predictions provided by the recommender systems [13]. To improve customer resource management, researchers modified the collaborative filtering method to include a multifactor for a bipartite network—that is, an affiliation network. The proposed model improved the recommendations' accuracy and diversity [14].

Researchers have proposed a hybrid method to address the limitations of the traditional collaborative filtering approach. By incorporating the Big 5 personality dimensions, the collaborative filtering algorithm's active learning capabilities are enhanced, allowing for the use of personality type to overcome the problem of sparsity, resulting in improved accuracy and a great number of recommendations [15]. Other modifications include developing new systems that can learn and adapt to user feedback to elicit changes in health behaviors. For example, researchers have proposed a collaborative filtering-based computer-tailored health communications system that delivers personalized messages to individual patients based on explicit feedback (ratings) about past messages. These studies suggest that most users have positive opinions about smoking cessation support messages recommended based on their past ratings [16]. Another example of adapting to user feedback is creating an algorithm to recommend treatment based on patients' pretreatment preferences and posttreatment satisfaction. This study demonstrates the feasibility of using a collaborative filtering recommender system to provide accurate recommendations and guide shared decision-making [17].

Furthermore, collaborative filtering and clustering can be used to develop a drug recommendation system that suggests medications for patients with diabetes by comparing a specific patient profile with those of patients with similar characteristics [18]. Similarly, collaborative filtering and clustering can be used to develop a recommender system for patients with cardiovascular diseases [19]. Although the number of studies

XSL•FO
RenderX

on collaborative filtering systems is increasing, their application in the health care domain remains limited. The use of this type of recommender system for computer-tailored interventions and health recommendations is still in its early stages. However, there is potential for these systems to determine appropriate drugs and treatments for patients and deliver personalized messages that motivate behavior change.

Content-Based Filtering

Content-based recommender systems (CBRSs) rely primarily on item descriptions [20]. They evaluate options and recommend a product, person, or service based on a user's previous acquisitions or suggested preferences [21]. The process of a CBRS is divided into 3 steps. First, the content is represented in a processable format. Then, the algorithm learns about the user. Finally, a recommendation is made for that specific user. The advantage of a content-based system is that it offers personalized recommendations and does not require a rating or previous documentation of an item, thus making the recommendation process more efficient [22]. However, the complexity of the current e-service and e-product landscape requires CBRS users to integrate it with other recommender algorithms.

CBRSs have a range of applications in health care, such as promoting data set reusability, refining the research process, and recommending health education. They accomplish this by streamlining the process of identifying relevant data sets. For example, by deducing researchers' academic interests from their list of publications, the system can make data set recommendations that users may find useful or interesting [23]. In addition, the process of conducting clinical research studies is refined by calculating the similarity between annotated publications and the research query and recommending the most relevant literature. This enhanced recommender system can be integrated into research platforms to support future medical studies by helping researchers refine their research questions [24]. Furthermore, CBRS can be used to develop a content-based system that recommends health educational websites to users based on the metadata of the videos they have watched. The system suggests relevant websites for a given health video and facilitates the search for additional related content [25]. Although existing studies propose novel approaches, they have yet to be implemented in the broader health care context, and their limitations warrant further exploration. However, as the volume of health-related information increases, solutions that assist users in selecting relevant information become increasingly important. This recommender system can support health information retrieval by reducing the burden of searching for relevant information.

Hybrid Filtering

The hybrid filtering recommender system aims to compensate for the shortcomings of a classification model or enhance others with the advantages of an algorithm [21]. Hybrid recommender systems are a special type that combines ≥2 recommendation strategies. For example, researchers combine collaborative and knowledge-based filtering systems to create hybrids in the restaurant industry. When using hybrid systems, rich data, such as how a particular food helped reduce weight [26], can act as a filtering mechanism for group members. Results show that semantic knowledge-based ratings improve the collaborative filtering model [27]. Subsequent studies build upon previous findings by including an additional contextual modification that improves the performance of the recommender system [27]. Traditional methods of accessing videos, audio, and television have changed; a technological development is IP television, which streams content over proprietary IP-based networks. The recommender systems proposed by researchers suggest videos to users, which they would not have selected otherwise. Results show that recommender systems provide valuable recommendations despite high demand [28]. Most models today are developed as hybrids because they are more robust.

An example of hybrid collaborative filtering is a system that recommends search terms for a given patient to clinicians. The proposed hybrid model outperforms top-N recommendations by improving the efficiency and effectiveness of retrieving relevant patient information [29]. Another example is a Drug Development Recommendation model that supports pharmaceutical companies in determining which drug groups to develop. The Drug Development Recommendation model supports decision-making before companies initiate new drug development and improves the success rate by making recommendations tailored to a specific company and its unique business conditions. Another hybrid recommender system was developed to generate peer and content recommendations for patients with diabetes based on their profile, health status, and ratings of personalized content. This development offers a glimpse into the potential of recommender systems to promote a positive, healthy lifestyle via the implementation of a personalized, mobile peer support system [30]. The applications of hybrid recommender systems in health care are emerging; however, they are not used extensively in the health domain. The number of published studies on the use of hybrid models in health care is minimal so far. However, the limitations of content-based and collaborative recommender systems suggest that new studies will likely explore applications of the hybrid approach further.

Group Recommendation

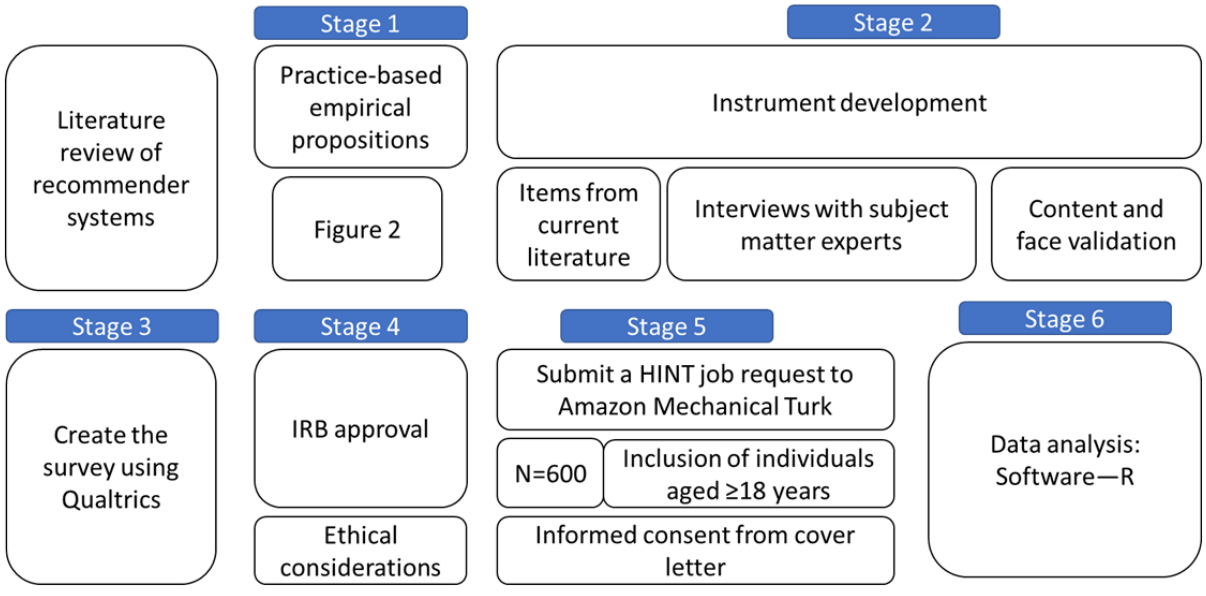
Group recommendations are based on the collaboration of an entire group [9,31]. Alternatively, some refer to this recommendation type as community based [32]. An individual's community may include colleagues, friends, and family; members typically have a common outlook. Expansions in this area include travel and location-based services, where the trust walker algorithm enhances users' perception of the reliability of location recommendations given [32]. Another study concentrated on folk recommendations with a tripartite composition, suggesting that this type of filtering connects users with the same interests via social tagging; a well-known example of this recommender system is Flickr [33]. The group recommender system matrix is sparse, and users' preferences are unknown. Sparsity is a problem in a group recommender system matrix, and researchers developed a memory-based technique to resolve the sparsity issue. The results indicated that the proposed method performs better than existing approaches in generating group recommendations [34].

XSL•FO
RenderX

Group recommender systems support decision-making by integrating the preferences or attributes of members. There is an increase in the number of studies that evaluate group recommender systems; however, their exploration remains low in the eHealth and e-medicine categories. Previous studies have assessed the composition of a group and ways to optimize the accuracy of recommendations. A study found that personality could improve the accuracy of predictions [35]. Another network-based recommender algorithm in an Italian health care organization computed similarities among patients. It generated a ranked list of physicians and hospitals suitable for a given patient profile using health data shared by the community [36]. It will be challenging to generate a real group consensus in the health care domain; however, studies show that there are ways for group recommender systems to achieve a high level of agreement among their members [37].

Context-Aware Recommender Systems

The context-aware recommendation system (CARS) category is relatively new; it modifies the content-based or collaborative filtering classes. This category is noteworthy owing to its potential for expanding research on recommender systems. Certain factors define CARSs, some of which include purchase purpose, location, and time. The e–health care, e-music, and e-travel domains successfully use the CARS algorithm. Change over time is an assessment of contextual factors that points to change over time to determine static or dynamic elements. Factors are assessed based on what is known about the facet and whether it is unobservable, partially observable, or fully observable. There are 3 forms of context-aware recommendations (prefiltering, postfiltering, and context modeling), which include the context as part of the rating process [38]. Adding context and trust enhances the collaborative filtering algorithm to combat the sparsity problem. The results from studies including these modifications indicate better recommendations [39]. A prefilling contextual technique referred to as item splitting is used to separate the characteristics of an item into a minimum of 2 distinct contextual factors; this is another method of improving the sparsity problem [40]. Hybreed is a tool developed to integrate context in the recommender system design [41]. Using accuracy and diversity as performance measures, a comparison of the 3 forms of contextual recommendation models indicates that the task affected both performance measures. Therefore, further studies in this area are needed, as no attempts have been made to reproduce the 3780 experiments conducted in this study [42].



A detailed review of context awareness and health awareness in eHealth revealed that both factors are essential for developing user-personalized recommender systems [43]. Considerable amounts of data have accumulated in clinical databases. Recommender systems can supply patients with basic descriptions of information in health records to facilitate the comprehension of their health status. A study hypothesized whether the retrieval precision of an advanced health recommender system was higher than that of a naive system. The results indicated that advanced health recommender systems enhanced patient understanding of health records more than a naive system [44]. Researchers from a separate study proposed a cloud-based hybrid predictive model for a personalized health information service. Experiment results discovered that participants have a positive response toward usability measurement dimensions [45-47] of the system, such as perceived usefulness, expectation confirmation, perceived value, satisfaction, and perceived trust [48].

Methods

Overview and Workflow

This study will use a multistage qualitative methodology to explore patient perceptions about using recommender systems for preventive care decisions. Stage 1 of the framework focuses on developing practice-based empirical propositions. Stage 2 includes the development of survey instrument. Then, we will obtain institutional review board (IRB) approval for the study in stage 3, before data collection and analysis can be conducted in stages 4 and 5, respectively (Figure 1).

Stage 1—Practice-Based Empirical Propositions

Overview

Although recommender systems are seen as valuable in health care, no studies synthesize the factors leading patients to use this technology. The following sections present the propositions developed from constructs in previous studies that may influence patient recommender systems. Examining factors influencing the use of this technology is vital because it will support achieving the quadruple health aims—improving the patient population, reducing the cost of care, enhancing the patient experience, and improving provider satisfaction [49].

Privacy

Privacy is an issue within the literature on recommender systems [50]. Privacy concerns stem from the need for users to disseminate personalized information to allow for the best recommendation [51]. Researchers have developed methods to combat privacy challenges; however, this factor may still affect the patient's perception of usability. Strategies to protect privacy include the secure processing architecture and the anonymous contributions architecture [52]. Another attempt to reduce privacy concerns in recommender systems is justification messages to improve the experience with a recommender system [53]. A recommender system can also assist individuals in making decisions regarding their privacy by providing them recommendations and warnings based on their privacy preferences [54].

Privacy concerns present unique challenges when adopting technology in health care. For example, users of wearable medical devices are vulnerable to data security and privacy protection issues [55]. Wearable technology data security can be classified into technical security, data management, or laws and regulations. Privacy concerns challenge mental health care providers with each advancement in technology used to deliver psychotherapy services [56]. Although using email, SMS text messaging, telehealth, electronic medical records, and mobile apps aid mental health providers, such technologies simultaneously increase the risks of unintended breaches of confidentiality. As privacy and confidentiality are regarded as essential considerations in mental health care, telepsychology is limited by concerns around privacy. To address these concerns, several researchers develop a risk assessment tool to assess whether health ITs (HITs) comply with privacy policy standards [57]. They find that users of HITs emphasize the need for transparency and policies that define the type of data collected and used. Thus, as privacy risks emerge as a common concern for health care professionals and patients, privacy issues undermine users' confidence and willingness to use HITs. Privacy concerns affect the adoption of technology in health care. Therefore, maintaining the security and privacy of protected health information will be crucial for the future of health care.

Proposition 1—Privacy concerns may negatively affect the use of health care recommender systems for preventive care.

Trust

A social network of interlinked nodes connected by their confidence relations is a trust network [58,59]. Trust-based models help resolve sparsity problems [60]. Modifying existing recommender system classifications with trust improves ratings' accuracy [61]. An early study on peer production services revealed that trust-based recommender systems can substantially enhance services and overcome the issue of information overload [62]. Trust can be aggregated into ontology and used to update user profiles to improve the recommendation process [63]. In scenarios where patients or individuals face conflicting recommendations, trust can help the user to make a better choice regarding the accuracy of the results [64]. Trust represents a vital antecedent of the acceptance and use of technology in health care. A recent study identifies perceived usefulness, usability, training, and technical support as trust facilitators. In contrast, the lack of privacy, perceived risks, and cost and security issues represent the main barriers [49]. Similarly, another study analyzes the enablers and impediments of trust in digital health. These trust factors indicate whether to place trust in digital health technologies [65]. Asan et al [66] focus on clinicians as primary users of artificial intelligence (AI) systems and how trust shapes their use and adoption of AI. In this context, trust refers to applying AI-based systems to support clinical decision-making. The lack of trust in AI deters users' adoption of this technology in health care. As trust is the most notable factor influencing the adoption of wearable health devices [67], understanding how users define trust in the health care technology context provides insight into the use of technologies.

Proposition 2—Trust may positively affect the use of health care recommender systems for preventive care.

Effectiveness

An effective recommendation will help a customer make a better choice or choose a product that they would otherwise not have selected. Studies have shown that a combination of rating and content can increase effectiveness [68]. Systems can provide less effective measures by overestimating or underestimating a recommendation for a particular patient [69]. Variations in predictions should be carefully considered during the development of a health system. For preventive care measures, overestimation may cause the most ripple effects. For example, a test ordered very frequently could increase costs, or inaccurate preventive measures could have considerable medical consequences. The lack of effectiveness is an issue when adopting technology in health care. For example, technological tools, including telehealth, mobile app, and SMS text messaging, can address the mental health crisis during the pandemic. Each tool helps provide the needed psychological support; for instance, the effectiveness of telehealth is comparable with that of in-person counseling services [70]. A similar study assesses the effectiveness of mobile health (mHealth) technology in suicide prevention. The results suggest that these mHealth technology tools effectively reduce suicide-specific outcomes [71]. In addition, digital health technology effectively monitors and treats asthma [72]. Ineffectiveness is a considerable adoption

XSL•FO
RenderX

barrier because it indicates the future utility of a given technology in health care.

Proposition 3—Effective recommendations positively affect the use of health care recommender systems for preventive care.

Accuracy

Accuracy is one of the most frequently used measures for evaluating a recommender system; however, these often include complex calculations that average customers are not privileged to access. The patient's perception of whether the system is making correct predictions may influence use [69]. Service providers use accuracy measures to help customers make better product and service selections. Will the patient's perception that the recommendations are correct affect their opinion and usability of preventive health recommendations? Accuracy is also an issue when adopting technology in health care because the low accuracy of these technologies raises concerns regarding the threat posed to patient safety [73]. The adoption of these technologies should be carefully considered, especially if their performance is inferior to that of current practices. A recent study examines the quality of information provided by web-based symptom checkers, where physicians outperform symptom checkers regarding the accuracy of diagnostic data [73]. This accuracy concern highlights the need for further studies on symptom checkers. Users cannot solely depend on the technology; for example, the Apple Watch overestimates the value for energy expenditure of patients with cardiovascular disease but accurately measures their heart rate [74]. These accuracy issues imply that it is premature to use the Apple Watch for cardiac rehabilitation. Therefore, caution should be exercised when adopting technology with accuracy issues in health care.

Proposition 4—Perceived accuracy positively affects the use of health care recommender systems for preventive care.

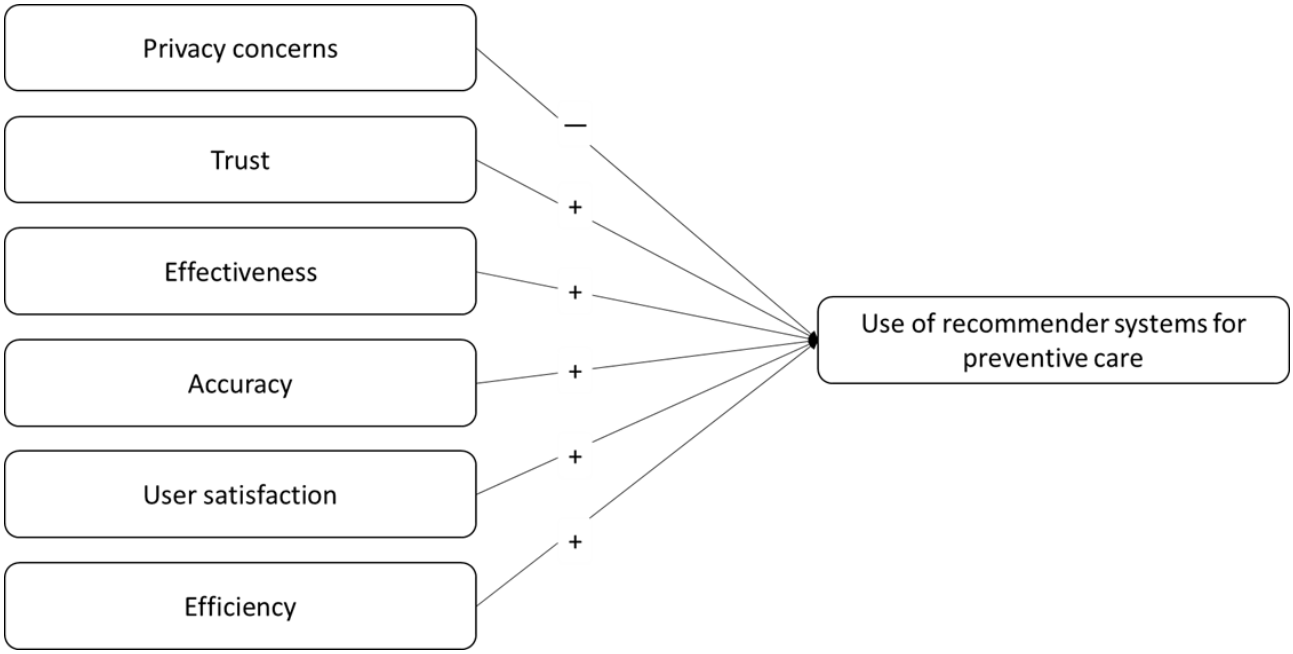
User Satisfaction

User satisfaction refers to the perception of the system services after personally experiencing the system [75]. The level of satisfaction that patients receive from using community-based health care recommender systems may vary across individuals. If customers are more satisfied, they tend to implement the recommendations; the opposite is true if they are dissatisfied [48]. HIT literature reports high user satisfaction leading to increased adoption of technology in health care in various health care settings. For example, patients' acceptance of the health technology program increased with high patient satisfaction with the digital tools incorporated into the program [76]. Patient satisfaction with telemedicine determines its long-term viability beyond the pandemic [77]. Patients experienced higher satisfaction with web-based visits than with in-person visits, which is not surprising considering that health care professionals can still address patients' questions and concerns without compromising quality. High user satisfaction leads to great acceptability for lifestyle apps in mHealth [78]. User satisfaction indicates that a specific technology sufficiently satisfies patients; however, low satisfaction rates suggest that the barrier to adopting that technology in health care is important.

Proposition 5—User satisfaction positively affects the use of health care recommender systems for preventive care.

Efficiency

A fundamental business system requirement is efficiency. For example, one of the largest recommender systems, Google, searches in seconds. Similarly, more specialized recommender systems are expected to perform tasks quickly or reduce the time it takes to make choices [79]. Efficiency is the user's perception that the recommendation improved decision-making [47]. When adopting HIT such as recommender systems, efficiency is important. HIT refers to technology that assists in preventing, diagnosing, and treating diseases. HITs, such as electronic health records and health information exchanges (HIEs), facilitate care coordination by making information available and providing real-time decision support to physicians [80]. HIEs enable the sharing of patient health information electronically among providers, patients, and payers across different health care settings [81,82]. Researchers have assessed the impact of HIT's efficiency. The findings demonstrated that HIT improves efficiency by decreasing use rates [83]. A similar study found that adopting HIT enhances hospital efficiency. However, adopting HIT and increasing the employment of physicians nullifies the positive impact on hospital efficiency [84]. Finally, another study aimed to determine whether participating in HIE networks improves hospital efficiency. The author concludes that participating in HIEs improves hospital efficiency but calls for more research [85]. Similar to the implementation of other large-scale HIT, recommender systems may affect patient efficiency.



Proposition 6—Perceived efficiency positively affects the use of health care recommender systems for preventive care.

Stages 2 and 3—Instrument Development and Operationalization of Variables

Researchers can develop an instrument after literature reviews and interviews with subject matter experts, including information systems professionals, physicians, and patients. An expert in survey design will be consulted to ensure that the questions are phrased appropriately to elicit proper responses for the measured factors. The review team can consist of 3 to 5 individuals to represent the abovementioned expertise, including the principal investigator. Before the final items are selected for the survey, we will assess content and face validity using a short questionnaire that includes the items and construct definitions [86,87]. IRB approval may not be required for this process; 25 to 30 professionals or students can be used to elicit the validation results. Items will be rated on a 7-point scale from 1 (not at all) to 7 (completely), aligned with the construct's definition. Items that do not match precisely with the construct definitions—responses below the mean—should be refined or removed from the final instrument. Discarded questions can be replaced with new ones, and the validation process can be repeated. Figure 2 depicts the plausible measurement model for the likelihood of using recommender systems for preventive care with several reflective indicators. Table 1 presents the constructs and references.

Table 1. Recommender system constructs and references.

Constructs and items	Studies
Privacy concerns	Xu et al [88,89]
I am concerned that the recommender system will collect large amount of personal information from me.	—[a]
I am concerned that the recommender system will use my personal information for unauthorized purposes.	—
I am concerned that unauthorized people will have access to my personal information.	—
Trust	Liu and Tao [90] and Kim et al [91]
The recommender system is trustworthy.	—
The content of the recommender system is reliable.	—
Overall, I trust the recommender system.	—
Competency-related trust	Esmaeilzadeh [92], Mpinganjira [93], and McKnight et al [94]
The recommender system is competent.	—
The recommender system performs its role very well.	—
Effectiveness	Liu and Tao [90]
The recommender system provides personalized recommendations that are based on my information.	—
The recommender system personalizes my health care experience by acquiring my personal preferences.	—
The recommender system delivers personalized health care services.	—
Accuracy	Yang et al [95]
The recommender system offers consistent results over time.	—
I feel confident that the recommender system offers error-free results.	—
User satisfaction	Park et al [96]
Overall, I am satisfied with the recommender system.	—
The recommender system meets my expectations.	—
I recommend the recommender system to others in health care.	—
Efficiency	Garg et al [97]
The recommender system will help in providing health care services.	—
The recommender system will increase the speed of services.	—
The recommender system will increase efficiency.	—

[a]Not applicable.

The dependent variable—the use of recommender systems—can be modeled based on the theory of planned behavior using a binary item [98-100]. This theory contends that behavioral, normative, and control beliefs affect a person's intentions to perform a particular behavior; the strength of these intentions influences an individual's actual behavior [101,102]. This proposed study design adopts the theory of planned behavior as a fundamental behavior theory to represent patient behavior, especially in terms of their use of recommender systems. Researchers can examine patients' adoption of recommender systems by extending the theory of planned behavior to the health care context. Individual attitudes, subjective norms, and perceived control influence patients' intention to use recommender systems. Therefore, individual perception and social influences are antecedents of their intention to use recommender systems; the greater this intention, the more likely that the adoption behavior will be realized. The use variable can be dichotomous (yes or no).

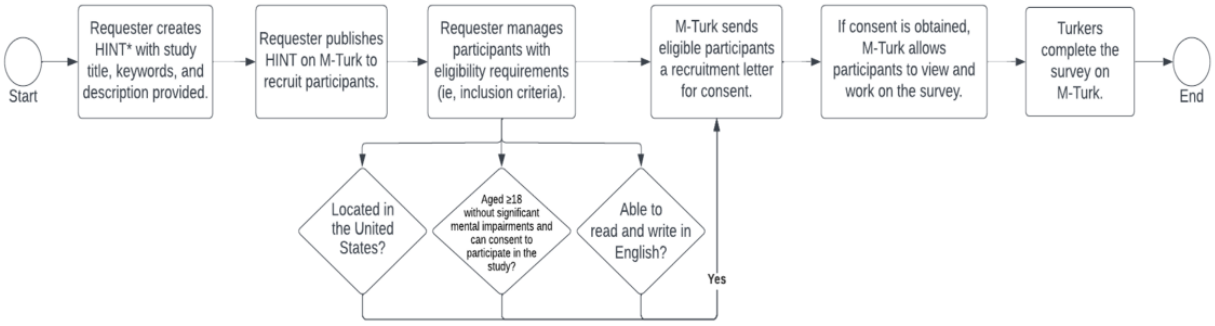
Privacy concerns can include 3 items [88,89]. When formulating trust items, researchers can combine two trust constructs: (1) general trust [90,91] and (2) competency-related trust [92-94]. The effectiveness construct can use 3 reflective items [90]. The accuracy construct can be measured using 2 items [95]. Short-form measures have limitations; however, they are as effective at capturing a construct as extended scales when adequately designed [103]. Possible robustness checks are discussed in the *Stage 6—Data Analysis* section. Overall, 3 reflective items can be used to measure user satisfaction [96] and efficiency [97]. Scale scores can be computed as the averages of individual items and anchored to strongly agree,

XSL•FO
RenderX

agree, somewhat agree, strongly disagree, disagree, and somewhat disagree.

Stage 4—Ethics Approval

This study has been submitted for ethics approval to the California State University Institutional Review Board (reference number: 2038900-1) through a secure web portal. Approval may take 4 to 6 weeks, depending on whether revisions are required and the frequency with which the board meets. It will be approved if the board finds that this study involves minimal risk to the participants. Participants are informed that they can skip questions they do not feel comfortable answering or choose not to participate. The survey is anonymous, and participants cannot be identified.



Stage 5—Initial Data Collection: Amazon Mechanical Turk

Overview

This study will be conducted via the web; this aligns with the study's aims to examine the perceptions of adults in need of preventive care. Data will be collected using Qualtrics (Qualtrics) via an anonymous survey link. Qualtrics is a web-based data collection tool; its functionality allows users to create a customized survey.

Amazon Mechanical Turk is a hosted platform that allows researchers access to a wide range of participants [104]. Participants are called *turkers* or *crowdworkers*. They browse their profile for Human Intelligence Tasks (HINT), which includes a brief description of the responsibilities. Posting the survey on the HINT list will initiate participant recruitment for the study. Amazon Mechanical Turk allows requesters to select worker requirements to enforce the inclusion and exclusion criteria. To be included, participants should be aged ≥18 years without serious mental impairments and consent to participate in the study. Participants must be in the United States and be able to read and write in English. The procedure for recruiting individuals and how participants access and complete the survey is depicted in Figure 3.

Figure 3. Amazon Mechanical Turk (M-Turk) workflow. HINT: Human Intelligence Tasks.

The survey cover page will be used to distribute the recruitment letter and obtain informed consent. The letter will also provide an overview of the study, participation criteria, and any benefits or risks to the participant. Completed survey data are automatically stored if Qualtrics is used. It is reasonable to assume that the time needed to complete the survey will be approximately 10 to 15 minutes. Before beginning the survey, all participants will receive a vignette [105] describing what a recommender system is and an example of how it will be used in their care.

Sample Vignette

Recommender systems are the systems that are designed to suggest things to the user based on many different factors. They are used by companies such as Google, Instagram, Spotify, Amazon, Reddit, and Netflix, to entice users with relevant content. A health recommender system may propose preventive measures to patients based on their clinical history and demographic characteristics. For example, based on available data, it may recommend talking to a primary care provider about the decision to initiate low-dose aspirin use for the primary prevention of cardiovascular disease.

Participants will answer 19 to 20 reflective questions to measure each construct, as outlined in Table 1. They will answer demographic questions on ethnicity, race, sex, income, education, employment, and the number of chronic conditions. No compensation will be provided for participating in the study. A sample size of approximately 600 participants may result in a medium effect size where the *r* value varies from 0.3 to 0.4. Effect size is a quantitative measure of the magnitude of the experimental effect [106].

Stage 6—Data Analysis

Researchers can use R to analyze the research model; it is stage 5 of the proposed study design. The following robustness check can be used to evaluate the measurement instrument. Principal component analysis will be performed; only factors with eigenvalues >1 will be selected; and then, a visual assessment will be conducted using a scree plot. A parallel analysis will be completed to review the eigenvalues for the 6 factors in the conceptual model. A Harman Single Factor test can be performed to test the effect of common bias to ensure that a single factor does not emerge. To assess discriminant validity, exploratory factor analysis will be performed. Then, any factor loading <0.70 will be examined; a loading value of 0.55 is considered as good and 0.45 is considered as fair [107]. Reliability and validity will be examined using Cronbach α; a value >0.7 is satisfactory. Multicollinearity should be examined as part of the analysis; correlation should fall below the conventional threshold value of 0.6 [108,109].

To establish the reliability and convergent validity of individual items, the average variance extracted for each construct will be

XSL•FO
RenderX

calculated. Composite reliability measures the overall reliability of a collection of heterogeneous but similar items. Composite reliability >0.70 threshold and extracted variance >0.50 threshold are recommended [110]. The analysis of *variance inflation factors* will determine whether multicollinearity exists among the tested variables. Variance inflation factors are a scaled version of the multiple correlation coefficients between 1 variable and the remaining independent variables. Variance inflation factors below the cutoff value of 10 indicate that multicollinearity among the variables is not supported [111]. Researchers should perform confirmatory factor analysis. The goodness-of-fit indices [112-114], adjusted goodness of fit, comparative fit index, Normed Fit Index by Bentler and Bonett [115], root mean square error approximation, and root mean square residual will be examined.

Results

Data collection and analysis will begin after institutional review board approval is obtained.

Discussion

This study proposes practice-based empirical propositions for developing recommender systems in health care, focusing on identifying the factors influencing patients' use of these systems. We also provide a study design and methods for creating a survey and conducting an analysis. Our study highlights the potential of recommender systems to improve population health by educating patients about disease prevention and motivating them to use preventive services. This study aims to guide future research in the health care domain by exploring the application of recommender systems in preventive care.

Clinical quality measures such as preventive metrics are essential for monitoring health care quality. Often, patients are unaware of the many preventive quality metrics that can help improve their health care outcomes. Improved patient awareness of preventive measures helps not only them but also physicians and insurers to meet the metrics of clinical quality initiatives from advanced payment models such as primary care first, accountable care organization, merit-based incentive payment system, and Healthcare Effectiveness Data and Information Set. Hybrid recommender systems can help patients filter and use data about preventive quality metrics, making the information more accessible. Using the propositions mentioned in this paper, health care professionals and researchers can examine the factors that will lead patients to use recommender systems for preventive care.

There are advantages to implementing recommender systems and general issues that may influence patient use of the systems. As discussed in the propositions, patient privacy concerns may affect patients' likelihood of using recommender systems. Issues stemming from privacy concerns may lead patients to not share their medical records, resulting in the cold start problem. The cold start problem affects recommender systems because new users do not have a profile, thereby limiting the ability of the recommendation systems to provide meaningful information. Another privacy concern is the intrusive nature of recommender systems [69]. Algorithms require direct feedback that is linkable to a particular user; this may engender privacy concerns. Patients may be less likely to seek recommendations if their searches or history can be linked to them by administrators.

To improve patient use of recommender systems, developers must be able to improve the trust in the systems they use or the administrators governing the data collection, processing, and dissemination processes. An issue with recommender systems is overspecification, which could result in duplicate preventive testing. Patients who receive duplicated recommendations may reduce their trust in the system's capabilities. Duplicate testing may result in 2 issues: patient fatigue may reduce trust or overuse may increase costs. To reduce the influence of overspecification on preventive recommendations, developers may consider integrating current structured data from the patient's medical records to train and test recommender systems.

Perceptions about the effectiveness and accuracy of recommender systems also reduce the likelihood of patients using them. A factor that could cause efficiency or accuracy issues with algorithms is the sparsity problem, in which some services have many ratings and others do not. Data accumulation is a method to rectify the sparsity problem to facilitate accurate predictions [8]. Efforts to address this data sparsity issue should include developers working closely with insurers, providers, and patients to limit the factors affecting their likelihood of sharing data. Data blocking on the physician's side may also lead to sparsity; in response, the Cures Act should limit this practice by 2023. Furthermore, a patient may choose to share the data; however, it may not be exportable or interoperable with data from the internet or other sources. Unfortunately, data from multiple inoperable sources can lead to low efficiency. Health care organization professionals can tackle this challenge by implementing systematic data standards such as Systematized Nomenclature of Medicine, Logical Observation Identifiers Names and Codes, Current Procedural Terminology, and International Classification of Diseases and the fast health care interoperable resource standards.

This study does not address all the psychological aspects of recommender systems. Further studies are needed to better understand the physiological effects of these systems on users [69]. The trust construct developed in this study does not relate to the patient-physician trust. However, when addressing concerns about privacy and sensitive patient data, it is crucial to consider the patient-physician relationship in the design of web-based recommender systems. Developers should include features for effective communication and collaboration between patients and qualified health professionals.

Providing access to IT support services and mobile options for accessing preventive recommendations can improve patient satisfaction. Efficiency and scalability also play key roles in determining the success of recommender systems. As the amount of data available on the web continues to grow, algorithms must be able to handle the increased computational demands. Studies have shown that accuracy does not necessarily increase with large amounts of data, but computation time may [116]. Health care professionals may consider partnering with large IT companies that offer cloud computing resources to address

XSL•FO
RenderX

scalability issues. Federal insurers such as Medicaid may also consider using a portion of cost savings from tracking preventive care to fund cloud computing hubs.

Additional studies are necessary on the physiological aspects of recommender systems [69]. In doing so, developers may improve user satisfaction and, therefore, the likelihood of use. Health care records can contain some of the most sensitive data about a person's life. Addressing the intrusive nature of recommender systems and the sensitivity of patient data leveraging the patient-physician relationship is paramount. Developers of web-based recommender systems should include features for effective communication and collaboration between patients and qualified health professionals. It may not be feasible to grant patients access to their private physicians; however, allowing access to a professional may improve patient satisfaction. Recommender systems should provide, at minimum, some IT support services and offer a mobile way to access preventive recommendations [117]. Many large IT companies such as Amazon, Microsoft, and IBM have entered the health care arena; it may be opportunistic for health care professionals to partner with them to access cloud computing resources.

Abstract

Background: Users' feedback is a key asset for organizations that want to improve their services. Studying how organizations are enabling their users to participate in evaluation activities is particularly important, especially when there are vulnerable or disadvantaged people, and the services to be evaluated can be life-changing. This is the case in the coassessment by pediatric patients experiencing hospital stay. The international literature reports a few attempts and several challenges in systematically collecting and using the pediatric patient experience with respect to hospitalization, to undertake quality improvement actions.

Objective: This paper describes the research protocol of a European project intended to develop and implement a systematic pediatric patient-reported experience measures (PREMs) observatory that will be shared by 4 European children's hospitals in Finland, Italy, Latvia, and the Netherlands.

Methods: The VoiCEs (Value of including the Children's Experience for improving their rightS during hospitalization) project uses a participatory action research approach, based on a mixture of qualitative and quantitative methods. It consists of 6 different phases, including a literature review, an analysis of the previous experiences of pediatric PREMs reported by project partners, a Delphi process, a cycle of focus groups or in-depth interviews with children and their caregivers, a series of workshops with interactive working groups, and a cross-sectional observational survey. The project guarantees the direct participation of children and adolescents in the development and implementation phases of the project.

Results: The expected results are (1) a deeper knowledge of published methodologies and tools on collecting and reporting pediatric patients' voice; (2) lessons learnt from the analysis of previous experiences of pediatric PREMs; a consensus reached through a participatory process (3) among experts, (4) pediatric patients and caregivers about a standard set of measures for the evaluation of hospitalization by patients; (5) the implementation of a European observatory on pediatric PREMs; and (6) the collection and comparative reporting of the pediatric patients' voice. In addition, the project is aimed at studying and proposing innovative methodologies and tools for capturing the pediatric patients' feedback directly, avoiding the intermediation of parents/guardians.

Conclusions: Over the last decade, the collection and use of PREMs have gained importance as a research field. Children and adolescents' perspectives have also been increasingly taken into consideration. However, to date, there are limited experiences regarding the continuous and systematic collection and use of pediatric PREMs data for implementing timely improvement actions. In this perspective, the VoiCEs project provides room for innovation, by contributing to the creation of an international,

XSL•FO
RenderX

continuous, and systematic pediatric PREMs observatory that can be joined by other children's hospitals or hospitals with pediatric patients, and foresees the return of usable and actionable data in benchmarking.

Introduction

Context

Children are one of the most fragile segments of the population and they might be disadvantaged in expressing their opinions, experiences, or preferences. As stated by the Manual for Human Rights Education with Young People, "the child has the right to express freely views on all matters affecting him/her, and the child's views should be given due weight." Great efforts have been made in Europe to strengthen "the right of the child to be heard" [1]. Recently, the European Union (EU) and the UNICEF (United Nations International Children's Emergency Fund/United Nations Children's Fund) promoted #TheRealChallenge campaign to raise attention on this right and make children express their views [2]. The European Youth and Information Counselling Agency (ERYICA) aims to uphold the right of young people to be empowered, make informed choices, and be active in society [3]. The project GIOCONDA financed under the LIFE+ program involves young people as protagonists of an action of participative democracy, with special attention to environment and health policies [4]. The Council of Europe "Guidelines on Child-Friendly Health Care" has promoted the design of health care services centered on children's rights and needs, considering their opinion and easing their participation. The World Health Organization (WHO) has also promoted a tool to assess the quality of hospital care provided to children in a systematic and participatory way, as well as children's rights in a hospital [5,6].

Literature and practice are demonstrating the centrality of listening to children and young people's voices on health care, both to increase the awareness of how this vulnerable population experiences care and to improve health care policy and practice [7]. Coproduction is among the most promising forms of participation with young people [8].

Current Knowledge and Previous Experiences

Evaluation of health care services is a coassessment process including comonitoring and coevaluating activities of lay people [9]. The most used definition of coproduction in the public sector defines coassessment as being focused "on monitoring and evaluating public services where state and lay actors work together to assess service quality, problems, and/or areas for improvement" [10, p. 772]. Consequently, coassessment usually happens retrospectively, when the service has been already experienced, but with the possibility of prospectively affecting the future design or delivery of the services [10]. The use of coassessment results can inform co-design and coinnovation processes aimed at improving or innovating services [11].

The participation of lay actors in coassessment processes remains rare in several sectors [12-14]. Strokosch and Osborne [12] described the negative experiences of assessment processes involving people with disability in the United Kingdom, by either public social and health care organizations or for-profit organizations. Loeffler and Timm-Arnold [13] reported a low or bad level of public involvement in coassessment initiatives concerning public safety and social services not only for young people, but also for elderly people, both using digital channels and traditional methods. Indeed, the level of participation depends also on the successful design and implementation of these coassessment initiatives. Among the most important antecedents of public participation in the evaluation of services, the so-called opportunities are those more closely linked to the service organization's activities. Organizations create opportunity of public participation by facilitating the citizens' engagement in the processes; by increasing the people's ability to effectively coproduce; by reducing the difficulties of participation [15,16]; or by setting motivational incentives, nudges, and other levers of participation [17,18]. Pestoff [19] referred to the "ease of involvement," which encompasses the cost of the involvement, the professional support including capacity building and direct mobilization of coproducers, and the definition of motivational incentives and nudges. Working on people's ability encompasses investigating these factors, which include human capital and socioeconomic conditions [20], individual characteristics (ie, age, sex, educational level), and being a user of the service to be evaluated as a factor affecting the internal efficacy of people, namely, how much they feel able to participate in certain activities, as well as their engagement [21].

From this perspective, studying how health care organizations can facilitate public participation in coassessment of services is extremely relevant. This is particularly important when the application of such research activities concerns the participation of vulnerable or disadvantaged people, and the services to be evaluated can be life changing. This is the case of the coassessment by pediatric patients experiencing hospitalization. As hospitalization represents a very delicate moment, it is especially important to focus on health-related vulnerable children and adolescents. This research project focuses on raising children's and adolescents' voices on their experience with hospital care, by studying and implementing opportunities for them to coassess and, consequently, contribute to the improvement of hospitalization services.

There are several experimental or cross-sectional studies aimed at investigating children's perceptions during hospitalization [22-25]. Using the Hospital Consumer Assessment of Healthcare

XSL•FO
RenderX

Providers and Systems Survey (HCAHPS) [26] and the Picker Institute [27] questionnaires, health care organizations or systems periodically collect measures of experience with services, as perceived by samples of patients. At the EU level, only sporadic international attempts were found in the literature on children's experience of hospitalization, which aimed at detecting their voices on a census-like, continuous, and systematic basis [28,29]. Nevertheless, previous experiences were mainly time-constrained and did not include systematic data collection. Moreover, they were mainly sample based, not involving potentially all children, without a systematized cross-border perspective and impact.

Although children are one of the most fragile segments of the population and the hospitalization experience can per se make them more vulnerable, usually hospitalized children do not have a chance to express an opinion about the care they received. Conversely, practitioners should make decisions considering children's preferences and opinions. To this end, it is necessary to develop a tool able to give pediatric patients the opportunity to make their voices heard about such delicate moments. Developing a common and scalable observatory that continuously collects data on children's and parent's experiences with hospital care across the EU is an ambitious goal that allows the children's right of expression to be guaranteed. To the best of our knowledge, there is no European standard on patient-reported experience measures (PREMs) for children, nor an example of pediatric PREMs observatory that can be joined by European and non-European countries in the future, for collecting and benchmarking the pediatric patient voice.

This protocol presents the VoiCEs (Value of including the Children's Experience for improving their rightS during hospitalization) project, which represents a fundamental step toward the improvement of children's rights of coassessing and coinnovating health care services, as well as of practitioners' attention on their young patients' rights. This paper presents the (1) settings, (2) aims, (3) methods and analysis, and (4) ethical aspects of the VoiCEs project.

Setting

The project will be conducted by a public university in Italy, which is the principal investigator (PI) and works with a dedicated research team.

A total of 4 children's clinical university hospitals from different European countries will be directly involved as project partners:

- Meyer Children's University Hospital, Florence, Italy (AOU Meyer)
- Children's Clinical University Hospital, Riga, Latvia (CCUH)
- HUS New Children's Hospital, Helsinki, Finland (HUS)
- Erasmus University Medical Center, Sophia Children's Hospital, Rotterdam, The Netherlands (EMC)

The 4 countries cover the European south-north-east-west areas, which will ease the development of a scalable model at the European level. The 4 hospitals involved have already worked on the collection of hospitalized children's voices. In the Finnish project LAPSUS, digital methods have been piloted to capture experiences from children and teenagers [30]. The children's hospitals in Florence (Italy) and Riga (Latvia), and several university children's hospitals in the Netherlands as well, adopted PREMs for children's hospital care [28,29,31,32], reporting results on web platforms to support children-driven improvements [28,29,33,34]. These valuable experiences achieved good results in terms of child participation, and they will be the starting point to design a new European tool.

To this end, the participation within the consortium of the UNICEF, with its international and local experience on the promotion of children's rights, will ensure the focus on the priority, synergies with other European projects concerning children's rights, and a wider impact of the project.

This positive impact at the European level will be also enhanced by the support to the project from other organizations, such as:

- The European Children's Hospitals Organisation (ECHO), which supports cross-border collaborative actions and learning processes for promoting children's rights in European hospitals and improving health and care for pediatric patients;
- The Italian Association of Children's Hospitals (AOPI), which will help further promote the results among the children's hospitals in Italy;
- The Picker Institute, whose competence and interest on patient experience will contribute to increase the strength of the scientific approach adopted in the project and support a wider dissemination of its results.

Aims

The aim of the VoiCEs project is to design and implement a system ensuring that hospitalized children can continuously be involved and heard. This would help identify which aspects of care in pediatric hospitals should be improved from their point of view. The long-term objective is to make inpatient care more child-friendly in children's hospitals.

The specific objectives to be reached within the duration of the project are as follows:

- To develop a common list of measures and questions to collect the experience of pediatric patients and their parents, by directly involving experts among researchers, hospital staff and stakeholders, and children from the 4 European countries of the participating children's hospitals;
- To implement and to provide hospitalized children a mechanism to express their feelings and perceptions about their hospitalization experience in a continuous way;
- To enhance the attention of children's hospital professionals on the relevance of hearing and taking into consideration the voices of their pediatric patients in evaluating and improving services;
- To provide hospital professionals with guidelines for defining information material and organizing training programs, with the aim of promoting children's rights to make their voices heard on the experience of hospitalization; and using children's feedback for supporting improvement actions.

The project will contribute to enhancing children's participation in the evaluation and improvement of health care services during

XSL•FO
RenderX

hospitalization. This will be done with the implementation of a common PREMs tool and benchmarking system in the 4 children's hospitals and with the planning of quality improvement activities. At the local level, one of the expected results is the increased awareness among hospital staff, as well as external stakeholders, of the relevance of listening to the voices of children as patients. This makes it possible to ensure high-quality health care services and a better experience during hospitalization. Another important outcome that can be expanded to a national level will be the benefits of child-friendly care developed using the results of the PREMs observatory. The middle-term impact will be the improvement of children's rights in the setting of the 4 children's hospitals involved in the project. At the European level, the project will make a common tool available to collect the children's experience of hospitalization, such as the validated PREMs questionnaire, and technical protocols to implement the systematic data collection. These tools will be available for other children's hospitals at the European level within the ECHO network and beyond, who can easily join the children PREMs observatory in the future.

Methods

Overview

The project will use an integrated mix of qualitative and quantitative methods that "seeks convergence, corroboration, correspondence of results from the different methods" [35, p. 259]. It provides a more complete picture, seen from different perspectives, so supporting a more in-depth understanding of the phenomenon. Within a mixed methods strategy, the adoption of different methods of data collection will be used as a means of advancing the analysis, with the results of one method at an earlier stage of research being used to inform the following one, introduced sequentially [35]. Indeed, for each phase of the project, a specific approach, as described below, will be used for producing evidence to be used in the following phases: (1) literature review; (2) analysis of the previous experiences of pediatric PREMs; (3) Delphi process; (4) focus groups (FGs) or in-depth interviews (IDIs) with children and their parents; (5) workshops with interactive working groups; and (6) cross-sectional observational survey.

The project will be based on the participatory action research approach [36,37]. Practitioners and scholars will promote the direct patient participation in research activities [38]. The children's involvement in all project steps, from the definition of the tool to collect their experience to the definition of information materials and training programs, will allow them to express their views.

The collaboration between university and children's hospitals will ensure the integration of the scientific approach and interest in new knowledge with the push toward action and engagement to improve the real life of children during their experience of hospitalization. The partnership of the consortium members with key research players, such as the Picker Institute, will support the rigor of the adopted methods. Researchers, hospital managers, and professionals with clinical competences will work together to understand general and context-specific opportunities and challenges, and to support the organizations to make changes in their services to improve the children's experience. In addition, the direct target of the project, such as children and adolescents, will be engaged directly thanks to the involvement activities carried out by the children's hospitals.

The project will be inspired by the human rights–based approach to health care [6], aiming to ensure availability, accessibility, acceptability, and quality of health services, specifically hospitalization services for pediatric patients. The principles the project will refer to are nondiscrimination, accountability for health services, as well as enhancing patient-centered health care addressing inequalities. Accordingly, the project will focus not only on outcomes, but also on processes, in particular, assessment and analysis, priority setting, program planning and design, implementation, and monitoring, facilitated by the support of the PREMs that will be implemented. In this way, the project will strengthen the capacities, on the one hand, of the pediatric patients as rights holders to make their claims and, on the other one, of the children's hospitals as duty bearers to meet their obligations and ensure health care of good quality, using the domains of patient-centered care as a basis [39] and catering for the specific needs of children.

The 2 aforementioned approaches will pervade the methods used in each project phase to achieve their objectives, as will be described in the following sections.

Literature Review

A systematic scoping review, based on peer-reviewed articles, gray literature, and project reports, will be conducted with the aim of drawing from the literature evidence on the collection of children's and adolescents' reported experience of hospitalization. Inclusion criteria, guiding the definition of the search algorithm, will be (1) as specific setting, the hospital stay; (2) as specific target, children and adolescents; (3) PREMs, thus excluding satisfaction and patient-reported outcome measures; (4) tools to collect data on children's experience, by identifying mechanisms that are aimed at giving children the right to express their voices; (5) use of children's feedback for quality improvement, in particular at a micro level within a health care organization, namely, PREMs data reporting at the ward level. The results of the literature review will inform the following collaborative process, including the Delphi process, as well as the FGs and IDIs.

Analysis of the Previous PREMs Experiences in Children's Hospitals

The project encompasses the analysis of the previous experiences of children PREMs implementation and data collection in the children's hospitals where a children's involvement initiative has been already implemented. This activity will aim at identifying and sharing lessons learnt by the children's hospitals, by analyzing their current or previous experiences in terms of pros and cons, strengths, and weaknesses, as well as good practices concerning PREMs implementation. The experiences will be described by each hospital using a common grid of analysis and shared during a workshop for comparing findings. Field notes will be taken by the participants and used together with the analytical documents

XSL•FO
RenderX

on the previous PREMs experiences as complementary data to be analyzed. The analysis will be performed starting from an exchange of knowledge and practices among the children's hospitals, particularly on tools and mechanisms they used/are using for listening to children's voices, and on how to include children's voices in the hospital's processes of decision making (ie, health care quality improvement actions, hospitalization services' co-design processes). Also in this case, the results of the previous PREMs experiences' analysis will inform the collaborative process, namely, the Delphi process, and the FGs and IDIs.

The Delphi Process

A collaborative, consensus-building process involving children and their families as well as experts and professionals will ensure the development of the PREMs questionnaire as a common tool among the children's hospitals. This collaborative process based on a Delphi methodology will be implemented for achieving a multidisciplinary consensus on target populations, experience domains and subdomains, specific questions, and administration tools for gathering children's voices during their hospital stay. The members of the panel will express their opinions on techniques, mechanisms, and tool for engaging with children and adolescents in a systematic, continuous, and structured way, bringing the perspective of their domain of expertise.

The panel will include at least fifty participants, with different professional backgrounds and profiles, such as researchers, hospital staff, and stakeholders, from the various countries and the supporting bodies involved.

Panel members will be contacted and enrolled by the research team, the 4 children's hospitals, and other supporting institutions, also involving experts from organizations not directly involved in the project, to ensure a wide participation.

Upon acceptance, the members of the panel will receive a detailed informative pack, based on the results of the literature review, on the analysis of the previous PREM experiences and attend a preparatory event. After the latter phase, the panel members will be emailed an invitation to participate in a survey consisting of structured questions for evaluating the PREMs questionnaire for pediatric patients. Two or three rounds are expected, to define a questionnaire for collecting the pediatric patients' experience. The Delphi process will also include topics for defining the most appropriate tool to directly engage children and adolescents. A final consensus conference will be organized to finalize the process and release the questionnaire as the key final output.

The output of the Delphi process will represent the baseline of the following action research phases.

FGs and IDIs

For directly involving pediatric patients and their caregivers, each children's hospital will organize and conduct at least one FG or IDI with children and parents' representatives. Because of the COVID-19 pandemic, some partners could not adopt this in-dept methodology or will conduct only IDIs. IDIs provide rich qualitative information, although interactions among children or parents cannot be monitored directly.

The objectives of FGs and IDIs will be (1) to explore dimensions and subdimensions of experience with hospitalization that are relevant from the point of view of pediatric patients and parents; (2) to discuss the most appropriate way to involve children and adolescents in providing direct feedback on their experience of hospitalization; and (3) to validate the questions that will be used for PREMs data collection.

Detailed guidelines will be defined by the PI, to guide the hospital partners in the enrollment of pediatric patients and their caregivers, conducting FGs or IDIs or both, and in the data collection and analysis phases. The target population will be:

- Pediatric patients (4-17 years); younger children can be involved for testing dimensions and questions, according to the guidelines.
- Their parents or caregivers (≥18 years).

The enrollment technique and procedure will consider the complexity and specificity of each hospital population, practices, and context. Each hospital will enroll convenience samples, determined by the availability of patients and caregivers, as allowed by the COVID-19 pandemic.

IDI transcripts, field notes, and documents will be kept in text files.

Workshops With Interactive Group Activities

The project's most important tool for meeting the objective of the PREMs observatory implementation will be based on the organization of well-prepared workshops. The workshops will focus progressively on the operative design and implementation of PREMs data collection and sharing, the promotion of the awareness among pediatric patients and their caregivers/guardians as well as among professionals about the relevance of PREMs data collection, the mechanisms for benchmarking the PREMs data and their visualization, and, finally, the strategies for using PREMs results for the children's hospital quality improvement.

Professionals in different areas (ie, technical, communication, data protection, and management) from each partner of the project will work together under the supervision of the Steering Committee and of the Board responsible for the action to produce practical protocols or guidelines that will guide the activities of the projects. Each partner will identify professionals with expertise in the area that is the object of the action to work together: at least one expert for each partner will be selected because of their professional proficiency on the topic.

The Technical and Data Protection Committee of the project will hold a series of videoconferences and workshops. For each topic, a draft protocol will be prepared and discussed during the workshops, with the aim of incorporating the amendments into the documents and distributing them among partners and projects' boards. This process will allow the committees to define common protocols to design a web system to collect and report survey data. Moreover, collaborative webinars and workshops will be used to define models and guidelines of information materials and training programs for improvement

XSL•FO
RenderX

actions based on the PREMs results. Field notes will be taken during the workshops.

The PREMs Observatory

The outcome of all the previous research activities will be the implementation of a system for digitally and continuously collecting, reporting, and benchmarking data on pediatric experience with hospitalization. Moreover, the project will contribute to identifying and experimenting an innovative tool for the direct involvement of children and adolescents in the PREMs data collection.

It is expected to collect data on children and their caregivers' experience during a hospital stay in a systematic way and involve all patients and caregivers like a census [28,29,34,40]. Each hospital will systematically engage pediatric patients (0-17 years old) to request their participation in the PREMs data collection.

During the implementation phase of the survey, for administering and collecting the PREMs questionnaire, the hospitals will be free to adopt the organizational and operational processes they prefer to enroll and engage children in participating in the survey. In any case, each hospital will adhere to all the requirements established and agreed to in the previous phases of the project, to perform the PREMs collection on a continuous basis, that is, the participating hospitals will use a minimum standard set of common questions defined throughout the Delphi process and FGs or IDIs, and the same output in terms of data collection, registration, and management. The shared questionnaire might be integrated with other questions relevant for each children's hospital context. Data will feed a common data reporting web platform for benchmarking children patient–reported experience indicators among hospitals.

It is expected to accompany the survey implementation process with information and communication activities, to make both children and adults aware of the possibility to report about their experience in the hospital. Health care professionals will be also engaged in the training processes. To this end, the project partners will collaboratively design and produce information and communication materials to inform children and caregivers of the PREMs existence. All materials will be designed to be child friendly. While the design will be collaborative, the executive elaboration will be done directly by each hospital, by translating materials and adapting them to the specific context, also deciding what kind of materials to produce.

The PREMs observatory will also allow the design and test of an innovative tool addressing children and adolescents, appropriate for different age groups and enabling them to participate actively in providing their evaluation of the hospitalization experience.

Ethical Considerations

As the project will directly or indirectly encompass the interaction with humans, specifically with minors, the ethical aspect will be carefully considered. As mentioned in the "Ethical Approval" section, the general protocol of the VoiCEs project has been submitted to an ethics committee by the PI. In addition, all participating hospitals, which will have direct contact with pediatric patients and caregivers and manage individual-level data, will submit the protocol to their Ethics Committee for the research activities directly involving them. This activity will imply ethics review, exemptions, and approvals, with the definition by each hospital of the informed consent process and documents, and of data confidentiality, ownership, use and purposes, treatments, security measures, and appointments for external privacy officers. One of the outputs of the research is a unique data protection and sharing protocol focused on ethics and privacy issues, based on the EU and national laws, including privacy laws, General Data Protection Regulation (GDPR), and the Convention of the Rights of the Child. This document will be used by each hospital for internally defining the detailed and context-specific ethical aspects of the VoiCEs project.

Ethical Approval

The protocol of the VoiCEs project has been submitted to the approval of the Ethics Committee of the Sant'Anna School of Advanced Studies and Scuola Normale Superiore of Pisa. The approval was obtained on March 25, 2022 (protocol number 07/2022). All participating hospitals submitted the protocol to their Ethics Committee for the research activities involving them directly.

Data Management and Oversight

Data collection, processing, and sharing processes will be different for each research activity.

The literature review will encompass the search of evidence using literature databases and sources. Data obtained from the search and the consequent analysis will use digital documents and tables with cells organized into rows and columns, such as Excel (Microsoft Inc), Stata (StataCorp), or SAS files (SAS Institute).

For FGs and IDIs, data will be collected through observations, notes, recordings, transcripts, and reports that the hospitals responsible for the activity will prepare. Data will be collected and elaborated by the PI in a final report that will be provided to Delphi panelists, shared with other partners, and submitted to a qualitative comparative analysis.

The Delphi process will encompass an online form to collect the point of view of the panelists. The panelists will give their point of view by accessing a platform using personal identification credentials that will be provided to them via email. Data from each round will be assembled and sent back anonymously to all panel members. Additional rounds will be organized, as the first one, until consensus is reached.

During the workshops, data will be collected through notes, reports, and minutes. Data will be elaborated in a final document (either a protocol or a set of guidelines).

The PREMs survey will gather data with an online questionnaire, or with specific innovative tools or both, according to the outputs of the previous research activities of VoiCEs. The details concerning the content and the process of administration as well as those on data processing and management procedures will be established using the technical and data-sharing protocols that will be developed collectively

XSL•FO
RenderX

by the partner under the supervision of the Technical Board and the Data Protection Board:

- A data-sharing protocol focused on privacy issues, setting out the basis on which patient experience data will be collected and used for subsequent actions. The partners will consider the EU and national laws, including privacy laws, GDPR, and the Convention of the Rights of the Child, to ensure the experience data of children are reported in a legal and ethical manner. This protocol will ensure ownership and buy-in of data collection and sharing processes, and will describe all potential and permitted uses of collected patient data for subsequent actions (eg, performance measurement and evaluation, research activity).
- A technical protocol allowing for the creation of a solid web platform to share data. The technical creation of the web platform will be entrusted to a company under the supervision of the Technical Board. It will be a tool to visualize the data.

The main features of the data reporting platform will be the presentation and visualization of quantitative and, if possible, qualitative data collected using tables and graphics, besides assuring the benchmarking activity between hospitals (or single wards) using specific indicators based on the data collected from each hospital.

After sufficient data have been collected, they will be made available to each hospital, and to each ward of the hospitals, whenever data are enough to guarantee the anonymity of respondents. The web platform functionalities will be shared and approved during a specific web workshop.

The data will be conserved for the duration of the project and for the time necessary to complete the reports and the scientific publications envisaged in the project.

Data from the children PREMs observatory will be conserved permanently, and will be stored on servers located in Europe.

The collection and storage systems (eg, web, platforms, servers) will follow the information and communication technology policies of the PI, and additional details and conditions will be established on the data protection protocol that will be collectively elaborated under the supervision of the Data Protection Board.

Results

Literature Review

The main objective of the literature review is to map existing evidence on measuring children's and adolescents' experience of hospitalization. The research group has analyzed and organized the results by identifying themes and patterns emerging from existing research. The analysis of peer-reviewed papers, reports, and gray literature has explored the following aspects: type of dimensions and subdimensions of children patients' experience of hospitalization; list of sources (question banks) and previously used questionnaires; type of methodology of the paper; administration and data collection methods; type of population targets to be engaged, such as children of different age groups or with specific health conditions and needs; countries and languages of the study; and use of data for quality improvement actions.

Analysis of the Previous PREMs Experiences of Children's Hospitals

The analysis of the previous experiences in PREMs data collection of the children's hospitals involved in the project will allow to identify the key aspects of these experiences (ie, start date, duration, method of implementation) and the list of questions already used. A comparison of the dimensions and subdimensions covered by these questionnaires will be made, to identify the diverse questions used to investigate the same area. A SWOT analysis will be finally conducted to synthetize the strengths, weaknesses, opportunities, and threats of the process implementation of the PREMs data collection within the children's hospitals. Results will be checked with data from other sources of information on the topic (ie, websites, reports, articles) to corroborate the findings [35]. Computer software, possibly SAS or Stata, will be used for qualitative data analysis that will follow the approaches suggested by Bailey [41] and Gioia [42].

Delphi Process

The feedback and evaluations provided by panelists in each round of the Delphi process through closed- and open-ended questions about the content and form will be analyzed by the research team in a descriptive statistical process with measures of central tendency and variability, and qualitatively to synthesize the key emerging themes. The report of each round will be sent back anonymously to all panel members to share answers and discussions, thereby enabling the participants to reflect on different views and modify their own, until the consensus is reached.

Variables of analysis are expected to be related to the relevance of the following areas, disaggregated for characteristics of panelists:

- target groups' populations in terms of type, age, disease, access to care;
- phases of the hospitalization journey to be investigated;
- type of data collection tool to be administered;
- time of data collection tool administration;
- dimensions and subdimensions of children patients' experience of hospitalization;
- preferences in terms of the most appropriate way (ie, an eventual innovative tool) to directly engage children and adolescents in collecting their voices.

The results of the Delphi process will be analyzed by performing descriptive statistics, using software such as Stata. If possible, statistical tests will be performed to provide an estimate of the probability that any association among variables is genuine. For instance, additional t tests or χ^2 tests could be performed for investigating any differences in the preferences and opinions of different groups of panelists (ie, different stakeholders, different ages, different countries).

The output of the Delphi process, and of the FGs and IDIs, will inform the following phase with the interactive working group realized during online and in-person workshops.

XSL•FO
RenderX

FGs and IDIs

The results of the FGs and IDIs will be analyzed and presented by focusing on the following contents: type and relevance of dimensions and subdimensions of pediatric patients' experience of hospitalization; type of data collection tools more appropriate to engage an active participation of children and adolescents (ie, an innovative tool); and validity of questions in cognitive, psychometric, cultural, and linguistic terms. The primary data will be collected directly by the children's hospitals realizing the FGs or IDIs. Qualitative data will be analyzed using computer software packages by a group of at least two individuals for each hospital. Before the analysis, the research group will define the relevant categories of analysis and the key issues and concerns, also in the form of keywords associated with the themes [35]. In a first phase, the analysis of the qualitative data will be aimed at identifying key aspects for each aforementioned category by target population. Extracts from IDIs and FGs will also be reported in each hospital reports. Each hospital will be responsible for this first analysis of the results and for sharing them with the other partners in a brief report in English. In a second phase, researchers will look for relationships and connections in data from different hospitals, trying also to report the results in diagrams showing the link between concepts and adding some transparency to the process of qualitative data analysis [35]. Finally, the results of the FGs or IDIs will be merged with those of the Delphi process, to ensure the centrality of the children's and adolescents' perspectives in the consensus building process on the identification of PREMs data collection tools. This second phase will involve the PI who will conduct a comparative analysis among the results of the 4 hospitals to value the contribution of children's and caregivers' involvement.

Workshops With the Interactive Working Groups

The process of action research implemented during the workshops is based on discussion, comparison, evaluation, and critical analysis of practices by experts to produce an improvement in the field of experience. Before each workshop, the researchers will define the most important contents to be registered and eventually coded (ie, the type of event, participants, shades of opinion, use of a particular word or expression, references provided by participants) [35]. The analysis of these qualitative data could also be conducted using software such as NVivo (QSR International) for facilitating both organization, storage, coding, and analysis of data. The results of this research work will allow the definition of shared documents containing an analysis and interpretation of the contents shared during the workshop, which will act as a base for shared protocols and structured rules of the project.

In addition, quantitative variables will be used to measure the results of the interactive group activities, which will allow to compute process indicators related to (1) the number of people involved and variability of their profile, (2) time spent versus time expected for producing the outputs, and (3) the number of protocols and guidelines finalized.

The PREMs Observatory

The PREMs observatory will include a questionnaire measuring the experience. This latter questionnaire will be designed according to what emerged during the collaborative process. Each children's hospital is responsible for the data collection and will send aggregated data to the PI, who will realize comparative analyses and benchmarking on secondary data.

The variables used will measure both process and outcomes [43]. The results of the activity in terms of process will be measured by considering the hospitalization rates and the expected response percentage in each of the children's hospitals involved in the project. The outcome will be measured in terms of PREMs, distribution among hospitals, and their trend over time in accordance with the improvement actions that will be implemented in each hospital.

The innovative tool will be considered as an additional result, and the feedback from children and adolescents during its experimental use will be analyzed.

Discussion

Expected Findings

The VoiCEs project will provide room for innovation, by contributing to the creation of an international and systematic, pediatric PREMs observatory that can be joined by other children's hospitals or hospitals with pediatric patients, foreseeing the return of usable and actionable data in benchmarking.

Among the expected results, the project will allow:

- the implementation of a European observatory on pediatric PREMs;
- the collection and benchmarking of the pediatric patients' voices;
- the design and test of innovative methodologies and tools for capturing the pediatric patients' feedback directly, avoiding caregivers' intermediation; and
- for a more children- and adolescent-driven health care services' design.

The VoiCEs project will contribute to enhancing direct participation of children and adolescents in the evaluation and improvement of health care services during hospitalization, considering the scarcity of systematic processes of coassessment [12,13,44]. The project will directly involve young individuals, in addition to adults with various expertise, knowledge, and skills, in a circular process of coassessment for co-design and coinnovation. Indeed, coproduction processes have the most potential in terms of meaningful, effective, and sustainable participation of young people [8]. The final aim is to put in place a system for improving service quality, improving the experience of young people with services, and enhancing the adherence to the principles of public governance with young populations, for which feasibility is not easily or always possible [45].

This project is contributed by the study of the most effective methodologies for collecting the perspectives of children and adolescents, with caution exercised for the customization of

XSL•FO
RenderX

tools, techniques, and processes considering their abilities and preferences. Studies have shown that the ability to participate and the opportunity for participation are key antecedents that organizations should consider when designing these processes of direct engagement [15-18]. Moreover, a recent review of the literature showed that the lack of time availability seems to constrain coproduction [44]. Thus, directly involving children and adolescents, who usually have lower limitations in time availability, could be an opportunity to increase the participation of individuals in assessing and designing services better.

The first evidence collected on this topic shows that previous experiences are experimental or single shot [22-25], or struggled in really involving children and adolescents, mainly engaging with parents, particularly mothers [28]. This project will reach its goals by also developing a common standard to be adopted by pediatric hospitals, or hospitals with pediatric patients, for collecting comparable data and activating learning processes among providers.

This use of the results of pediatric patients' and caregivers' coassessment can activate a positive circle, by comparatively emphasizing problems or areas for improvement and good practices to learn [10, p. 772]. This implies a prospective use of these data for the future co-design, coinnovation, or codelivery of services [11,12,46]. Benchmarking of these data provides suitable feedback for professionals to enable improvement and reputational mechanisms [47,48], as well as identifying the good performers and the good practices to be disseminated [49].

Another key additional step will be sharing the impact that these data had on the practice. While there is conflicting evidence on the effect of public disclosure on citizen behavior [50]; thus, future research should study people's preferences with and reaction to the exposure to different forms of information based on patient data.

From this perspective, providing organizations with evidence on how to really ensure participation of young people in coassessment of services is extremely relevant for allowing a concrete engagement of the most fragile segments of the population who might be disadvantaged in expressing their opinions, experiences, or preferences. In this sense, this project will contribute to strengthening "the right of the child to be heard" [1].

Limitations

The project encompasses a coordinated and integrated use of different research methodologies. Their coordination over time is a critical aspect. The research group and the partners from each hospital will identify and minimize issues related to each research approach and methodology.

For the FGs, IDIs, and Delphi process, a principal bias that can be anticipated using relatively small explorative samples is the lack of compliance with the selection criteria, due to the availability of different profiles and the critical circumstances resulting from the pandemic. Concerning the FGs and IDIs, the heterogeneity of feedback, preferences, and needs can be achieved by ensuring the presence of subgroups among the participants, based on relevant characteristics such as age, sex, citizenship, socioeconomic level, and health problems.

In the case of Delphi panelists, special attention will be focused on the representation of different countries, at least on those from which the participating institutions originated (ie, Italy, Latvia, Finland, and the Netherlands); further, owing to the participation of the ECHO network, we will be able to focus on other European countries. Moreover, we will consider different professions and profiles to ensure heterogeneity of opinions and a variety of perspectives. An oversampling of panelists will be performed for minimizing the eventuality of a low response rate.

The PREMs observatory implementation will have to face the obstacles and constraints resulting from the specific contexts and practices already in use, as well as from different policies of data protection and sharing.

Conclusions

Coassessment may contribute to cocreating public value at different levels [51]. However, it is essential to put in place adequate opportunities to assure people the rights of participating in evaluation initiatives. This is particularly important for vulnerable people in delicate moments. This protocol presents the VoiCEs project, its methodology, and expected results. It aims at studying, identifying, and sharing cocreated methodologies and tools for facilitating the participation of young people in the evaluation and improvement of health care services.

The VoiCEs project will lead to the development of a European observatory on children's and adolescents' voices, especially regarding their experience of hospitalization, which would represent a fundamental step in facilitating pediatric patients' and their caregivers' participation in coassessment and, lastly, coinnovation processes in health care.

Acknowledgments

The VoiCES (Value of including the Children Experience for improving their rightS during hospitalization) project was cofunded by the European Union's Rights, Equality and Citizenship Programme (2014-2020) under grant agreement REC-RCHI-PROF-AG-2020. The authors want to thank the supporting bodies of VoiCES that participated in the design phase of the project, namely, the Picker Institute, in particular Phillip Stylianides (Chief Operations Officer of the Picker Institute); ECHO (European Children's Hospitals Organisation), in particular Ruben Diaz Naderi; AOPI (Italian Association of Children's Hospitals), in particular Mauro Ricca. A particular acknowledgment goes to the researchers of the Management and Healthcare

XSL•FO
RenderX

Laboratory (MeS) of Sant'Anna School for their continued support, and to Professor Sabina Nuti for her vision and scientific contribution.

Data Availability

Data generated or analyzed during this study will be included in future published articles. Moreover, data collected and compared among providers will be published on a public section of the project website [52] as an output of the project itself.

Authors' Contributions

MB contributed to methodology, supervision, validation, formal analysis, writing—reviewing and editing, project administration, and funding acquisition. EC contributed to project administration. IC was responsible for formal analysis, methodology, writing—reviewing and editing, data curation, visualization, and investigation. SDR took care of methodology, supervision, validation, formal analysis, writing—original draft preparation, writing—reviewing and editing, project administration, and funding acquisition. VS performed formal analysis, methodology, data curation, visualization, and investigation. MV was responsible for conceptualization, supervision, writing-reviewing, and editing. All authors reviewed, edited, and approved the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: The unequal distribution of academic and professional outcomes between different minority groups is a pervasive issue in many fields, including surgery. The implications of differential attainment remain significant, not only for the individuals affected but also for the wider health care system. An inclusive health care system is crucial in meeting the needs of an increasingly diverse patient population, thereby leading to better outcomes. One barrier to diversifying the workforce is the differential attainment in educational outcomes between Black and Minority Ethnic (BME) and White medical students and doctors in the United Kingdom. BME trainees are known to have lower performance rates in medical examinations, including undergraduate and postgraduate exams, Annual Review of Competence Progression, as well as training and consultant job applications. Studies

XSL•FO
RenderX

have shown that BME candidates have a higher likelihood of failing both parts of the Membership of the Royal Colleges of Surgeons exams and are 10% less likely to be considered suitable for core surgical training. Several contributing factors have been identified; however, there has been limited evidence investigating surgical training experiences and their relationship to differential attainment. To understand the nature of differential attainment in surgery and to develop effective strategies to address it, it is essential to examine the underlying causes and contributing factors. The Variation in Experiences and Attainment in Surgery Between Ethnicities of UK Medical Students and Doctors (ATTAIN) study aims to describe and compare the factors and outcomes of attainment between different ethnicities of doctors and medical students.

Objective: The primary aim will be to compare the effect of experiences and perceptions of surgical education of students and doctors of different ethnicities.

Methods: This protocol describes a nationwide cross-sectional study of medical students and nonconsultant grade doctors in the United Kingdom. Participants will complete a web-based questionnaire collecting data on experiences and perceptions of surgical placements as well as self-reported academic attainment data. A comprehensive data collection strategy will be used to collect a representative sample of the population. A set of surrogate markers relevant to surgical training will be used to establish a primary outcome to determine variations in attainment. Regression analyses will be used to identify potential causes for the variation in attainment.

Results: Data collected between February 2022 and September 2022 yielded 1603 respondents. Data analysis is yet to be competed. The protocol was approved by the University College London Research Ethics Committee on September 16, 2021 (ethics approval reference 19071/004). The findings will be disseminated through peer-reviewed publications and conference presentations.

Conclusions: Drawing upon the conclusions of this study, we aim to make recommendations on educational policy reforms. Additionally, the creation of a large, comprehensive data set can be used for further research.

Introduction

Overview

Diversity and inclusion in the health care workforce is fundamentally important to the delivery of health care. There is strong evidence to suggest that an inclusive workforce is able to better meet the needs of a diverse patient population and leads to better patient outcomes [1,2]. According to the latest available data from National Health Service Digital, as of September 2021, the share of Black and Minority Ethnic (BME) staff in the National Health Service workforce in England was 24.2%, which is higher than the proportion of BME people in the general population (18%) [3].

One of the current barriers to a diverse workforce is differential attainment. This is defined as “an unexplained variation in results in assessment, training, and recruitment outcomes seen in candidates based on factors other than academic ability when compared to their peers” [4] and is presently observed across several important demographic characteristics, including gender, age, socioeconomic status, and ethnicity. It is well recognized that Asian and BME trainees are more likely to perform poorly in undergraduate and postgraduate medical examinations [5,6], Annual Review of Competence Progression, and applications for training and consultant posts [7,8]. A BME candidate is independently more likely to fail both part A and Part B of the Membership of the Royal Colleges of Surgeons (MRCS) examinations and 10% less likely to be deemed appointable for core surgical training [9,10]. Additionally, only 20% of leadership roles across the surgical colleges are held by BME surgeons [11] despite BME staff making up 46% of the medical workforce [12]. Furthermore, BME surgeons are disproportionately more likely to be referred to the General Medical Council (22% BME vs 17% White) [10].

The current understanding of causes of differential attainment is derived from thematic analyses on the barriers and issues facing BME doctors. There are several recognized factors, including curriculum and examination biases; relationships between BME trainees and trainers; a lack of support and mentorship; differences in social and cultural capital; and feelings of workplace exclusion due to microaggressions, harassment, and discrimination [13-17]. The Royal College of Surgeons of England’s Kennedy Report specifically attributes these factors as potential barriers to the progression of equality and diversity in surgery [10]. This is significant as surgical training has a unique reliance on the “apprenticeship” between the trainee and the trainer, leading to potentially unique differences in the relative effect of the aforementioned factors associated with differential attainment in surgery.

Rationale for This Study

The evidence base for determining differential attainment is generated by smaller scale, qualitative studies, which have demonstrated that the experience of BME students and trainees

XSL•FO
RenderX

is a factor contributing to differential attainment. However, smaller-scale studies may only capture a limited insight of the experiences of BME trainees and provide limited appreciation of the heterogeneous mix of different trainees of different ethnicities with a variety of experiences under the BME umbrella. Additionally, there is little published evidence that focuses on assessing the unique elements of the "surgical" experiences of surgical trainees, junior doctors, and medical students. This observational, multicenter study aims to compare both the experiences of surgical training between different ethnicities and the level of attainment reached. This study will ultimately aim to evaluate the relationship between educational and training experiences in surgery and attainment and analyze the role of ethnicity in this relationship.

Aims and Objectives

The ATTAIN (Variation in Experiences and Attainment in Surgery Between Ethnicities of UK Medical Students and Doctors) study aims to answer the following questions:

- Are the experiences and perceptions of surgical education different between BME and non-BME medical students and junior doctors? If so, how and where are these differences seen?
- In what ways are measures of attainment in surgery linked to experiences and perceptions of surgical education?

Primary Objective

The primary objective of this study is as follows:

- To compare the effect of experiences and perceptions of surgical education of students and doctors of different ethnicities.

Secondary Objectives

The secondary objectives of this study are the following:

- To measure potential differences in both the experiences and perceptions of surgical education of students and doctors of different ethnicities on attainment.
- To identify potential factors associated with potential differences in educational experience and attainment between the aforementioned cohorts as areas of further study.

Methods

This study will consist of a 15-minute questionnaire (Multimedia Appendix 1), which will be administered over a 28- to 32-week period. This will be distributed to every medical school and Higher Education England region.

Our population of interest consists of all medical students and nonconsultant grade doctors, including doctors in training and nontraining roles in foundation year, core or specialty trainee, as well as fellowship or staff and associate specialist (SAS) grade equivalents, with any experience of surgical training in the United Kingdom. This will be defined as any substantial period of time (being more than a total of 4 weeks) when the primary place of work or learning was (or is) in a surgical department or specialty, including but not limited to medical school rotations, assistantships, and clinical roles.

Inclusion Criteria

The following will be included in the study:

- Medical students at UK medical schools, identified by the Medical Schools Council, who have self-identified as having experience of surgical training as defined above.
- Anyone who has worked as a nonconsultant grade doctor (including doctors in training and nontraining roles in foundation year, core or specialty trainee, as well as fellowship or staff and SAS grade equivalents) in the United Kingdom, regardless of the country of graduation with experience of surgical training as defined above, either during medical school (if graduated in the United Kingdom) or when working as a doctor in the United Kingdom.

Exclusion Criteria

The following are excluded from the study:

- Doctors or medical students who have not had either a surgical placement during medical school or experience of surgical training in the United Kingdom as defined above.
- Doctors or medical students who have not either attended medical school in the United Kingdom or worked in the United Kingdom in a clinical role as a doctor.
- Consultant doctors who have completed their surgical training, attained their certificate of completion of training, and are employed as a temporary or permanent consultant.

Survey Development

The survey was developed using the guidance set out in "Developing questionnaires for educational research: AMEE Guide No. 87" [18]. An initial literature review was conducted based on the General Medical Council's "Evaluating the impact of interventions aimed at addressing variation in progression associated with protected characteristics known as Differential Attainment" [19]. Expert opinion was sought from academic surgeons and medical educationalists (Katherine Woolf, PAB, SF, EI, and SV) to increase content validity. Questions were integrated from previously validated questionnaires, such as the Everyday Discrimination Scale [20] and Maslach Burnout Inventory [21], to increase the construct validity of our survey. A further focus group was conducted to ensure the conceptualization of our constructs matched how respondents thought of them, to increase the face validity of our questionnaire. A pilot questionnaire (N=78) was conducted to ensure reliability and to determine construct validity. This is a first of its kind cross-sectional survey; therefore, we will be using the preliminary survey with results as a comparator to assess reliability of the study. In addition, questions were based on literature and evidence-based theories that underwent peer review from established experts in this field. Our questionnaire will collect demographic data, including questions on protected characteristics such as self-defined ethnicity, socioeconomic status, gender, and grade. Data on academic attainment will consist of questions detailing a participant's achievements, including medical school decile, prizes, publications, Annual Review of Competence Progression outcomes, MRCS examination results, and specialty training application outcomes. Surgical experiences will consist of questions around the working relationships participants have with colleagues,

XSL•FO
RenderX

experiences of discrimination due to ethnicity, and feelings of burnout.

Patient and Public Involvement Statement

This study will involve input of medical students and doctors of different grades. An initial survey was distributed at a national medical conference, which yielded information on topics of interest. The preliminary questionnaire was piloted among medical students and junior doctors, who gave qualitative feedback on the design of the study. The finalized questionnaire was distributed to collaborators who gave additional feedback.

Data Collection

Eligible participants will be invited to participate via web-based and in-person recruitment, including but not limited to medical school societies, medical school mailing lists, organizations focused on medical education, social media, surgical colleges, Higher Education England deaneries, and independent professional surgical bodies.

Additionally, snowball sampling will be incorporated, as eligible participants will be invited to collaborate as regional leads prior to the study period, with one collaborator per medical school or deanery. The collaborators will ensure that their medical school or training deanery is engaged with the study; they will be responsible for dissemination of the questionnaire and are recruited specifically to ensure participants are representative of their local population to prevent bias. Eligible regional leads will be acknowledged as collaborative authors under the "ATTAIN Study Group" in future publications. Participants will also be asked to share the questionnaire with other eligible colleagues.

Data Protection, Consent, and Confidentiality

The questionnaire will be hosted and stored in Jisc [22], which is compliant with regulations including General Data Protection Regulation and good clinical practice guidelines (ICH E6). The research team will have access to data determined by the study lead. Audit logs are also available to provide an overview of data access and modifications. Participants will receive a participant information sheet before starting the questionnaire. Participants will give consent for publication on completion of the questionnaire; consent can be rescinded up until completion of the questionnaire for any or no reason. On completion and submission of the questionnaire, consent cannot be withdrawn, as no identifiable data are collected. If the questionnaire is not completed, data will not be collected or stored. The only personal data collected from participants is ethnicity, participants' names or email addresses will not be collected. Any data collected will only be accessed by the members of the research team at any time. Upon the completion of each questionnaire, all documentation will be stored on a secure server that will be only accessible to the chief investigator, study leads, and statistics team.

Data Analysis

Statistical Analysis

The Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) [23] guidelines for cross sectional studies will be followed. Participants will be stratified by level of training prior to analysis, and results will be presented separately. Methods of data imputation will not be used. Descriptive statistics will be presented by ethnicity. Demographic characteristics and questionnaire responses will be described by the following statistics: mean (SD), median (IQR), and frequency with proportion. All hypotheses will be tested at a 5% significance level. Differences in participant characteristics and questionnaire responses between ethnicities will be assessed using parametric and nonparametric tests, including chi-square tests, ANOVA, and Kruskal-Wallis H tests, which will be followed by multiple appropriate post hoc pairwise comparisons with Bonferroni correction. An explanatory model will be created by hierarchical multiple linear regression, with the dependent variable attainment and the following covariates: ethnicity, perceptions of surgical training, surgical experience, sex, socioeconomic status, and age. A correlation matrix will test for the presence of multicollinearity. Another possible confounding variable will be geographical location; the data will be stratified by region and examined for such an effect for those regions with a sufficient number of respondents. SPSS (version 28; IBM Corp) [24] will be used for analysis. Post hoc analyses may be undertaken in the future as part of follow-up studies.

Sample Size Calculation

A priori sample size calculation was performed for a 2-tailed test of 2 independent proportions using G*Power (version 3.1.9.7; Heinrich-Heine-Universität Düsseldorf) [25], based on a comparison of MRCS A pass rates between White and BME candidates. Our predicted effect size was estimated based on historical data sourced by Scrimgeour et al [9] from the Intercollegiate MRCS database held by the Royal College of Surgeons of England. With α and β error probability set to .05 and .2 respectively, a minimum of 318 participants per group will be required. Broadly stratifying by level of training (eg, medical student, foundation or core trainee, and registrar or SAS grade) and dividing into BME versus non-BME, this means that 1908 participants will be required ($318 \times 6 = 1908$).

Ethics Approval

The protocol was approved by the University College London Research Ethics Committee on September 16, 2021 (19071/004). Participants gave informed consent for their anonymized responses to be used for research purposes, including for analysis, presentation, and publication of data. There will be no compensation type for participation in the study.

Results

Data collected between February 2022 and September 2022 yielded 1603 respondents. Data analysis is yet to be competed. The findings will be disseminated through peer-reviewed publications and conference presentations.

Discussion

Overview

Impact

Understanding the combined effect of individual experiences of surgical training is important in breaking barriers and promoting change within the medical workforce, leading to a more diverse and inclusive profession. To our knowledge, this is the first study to evaluate the relationship between educational and training experiences in surgery and attainment and analyze the role of ethnicity in this relationship. Although both the presence of [7-17] and possible causative factors for differential attainment based on gender, ethnicity, and socioeconomic status have been demonstrated [26-28], a comprehensive, high-powered data set linking experience and attainment is not currently present.

Expected Impact

The ATTAIN study's findings will add value to the current body of work in differential attainment by providing further insight and context to the interaction between different causative factors. We also hope to highlight areas of excellence and areas of improvement in surgical education, directing suggestions for evidence-based changes to undergraduate and postgraduate surgical education. Our findings offer policy makers evidence-informed recommendations to improve undergraduate and postgraduate surgical education, which will guide the creation and expansion of resources that can efficiently mitigate differential attainment. As society moves to tackle systemic inequalities, we hope our study will demonstrate a commitment to achieve this within medicine and surgery.

We also hope to remind the workforce of the principles of respect that are pivotal to our duties as health care professionals. Mental well-being and burnout are key performance indicators and should be protected to drive excellence in an individual's career progression.

Limitations

One of the potential limitations of this study is the lack of prior validated questionnaires on differential attainment. It could be argued that the topic of "differential attainment" is so large that a single questionnaire would not be an appropriate method able to collect valid or reliable data. We have tried to improve the quality and rigor of our questionnaire by using a well-established methodology for questionnaire construction and incorporating elements from previously validated questionnaires that are valid for our research question. However, bias cannot be eliminated from the study. Sampling bias may occur if recruitment is limited to streams disproportionately used by one group (eg, overusing social media may attract more medical students and junior trainees). This will be minimized by using multiple communication channels, including professional bodies and trainee-led organizations. Additionally, recall bias is unavoidable in sections of the questionnaire where past achievements are recounted.

We also recognize that our research question is heavily focused on ethnicity; however, there are several different factors that are known to be independently associated with differential attainment, including gender and socioeconomic status.

Although these factors may be controlled for in the study, it may be difficult to completely account for nonlinear intersectional relationships between factors. Future research should be considered to explore the relationships between these different factors in more detail.

Conclusions

We envisage that the results of the study will provide us with an advancement in knowledge on factors that correlate to attainment and provide us with greater depth in understanding the link between attainment in surgery and experiences of surgical training. Following the results, we aim to create national guidance for independent surgical bodies to incorporate into the current strategies used to tackle the inequalities and injustices in health care.

Acknowledgments

We would like to thank and acknowledge Professor Katherine Woolf for her input into the design of the questionnaire.

This research received no specific grant from any funding agency in the public, commercial, or nonprofit sectors.

Data Availability

The data sets generated during and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

IO and SB conceived the study and have contributed equally as first authors. All authors have made significant contributions to the design of the questionnaire and the protocol paper and fulfill the ICMJE (Recommendations for the Conduct, Reporting, Editing, and Publication of Scholarly Work in Medical Journals) criteria for authorship.

Conflicts of Interest

None declared.

Abstract

Background: Psychological counseling is perceived as a treatment that could significantly improve older individuals' psychological and behavioral functioning. There is a dearth of information on the impact of psychological counseling on preserving dignity and facilitating good aging among older people in Singapore.

Objective: The objectives of this study are as follows: (1) to assess advance care planning among older people and their perception of life and health, end of life, and end-of-life care; (2) to explore older people's accessibility and receptiveness toward counseling; (3) elucidate older people's perspectives on counseling and its impact on emotional management and decision-making; (4) to assess older people's competencies in emotional management; and (5) to propose an intervention model for enhancing older people's well-being and dignity through psychological counseling in Singapore.

Methods: A mixed method study design involving quantitative and qualitative methods will be used. Older individuals receiving some form of preventive, primary, or long-term care in the community through voluntary welfare organizations from the senior activity centers located in eastern Singapore participated in the qualitative phase. Six older individuals from each senior activity center have been enrolled for the interview phase to explore 6 components: the Advanced Care Planning (ACP) booklet, Trait Meta Mood Scale (TMMS), accessibility and receptiveness toward counseling, and emotional management and decision-making. The ACP, an instrument designed to assess advanced care planning among older individuals, and the TMMS, an instrument developed to measure meta-mood experience and emotional management, were used in the quantitative phase among 100 participants. The data will be analyzed thematically using NVivo version 12, whereas descriptive statistics and a 2-tailed, 1-sample *t* test will be conducted in SPSS (version 25; IBM Corp) for empirical data analyses.

Results: The qualitative phase, which involves a semistructured interview, has been completed among 20 older individuals aged 66-86 years. Thematic analysis of the data is still ongoing. Meanwhile, the quantitative phase commenced on March 22, 2022, with 100 participants providing signed informed consent to participate in the study. The study is expected to be completed by March 2023.

Conclusions: The mixed methods study will document the current awareness of ACP, accessibility and receptiveness toward counseling, and the potential use of psychological counseling in enhancing well-being and dignity among older people in Singapore. The research findings will benefit policy makers in their decision-making when attempting to mitigate the potential barriers to seeking counseling assistance among older people.

Introduction

Overview

The current rising older population in Singapore reflects that one-fourth and half of the population will be older than 65 years by 2030 and 2050, respectively [1]. Previous studies have demonstrated that older people experience diverse aging-related complexities that require counseling intervention: depression, anxiety, grieving, loss of functional health abilities, financial dependence following retirement, social isolation, intergenerational and marital conflicts, and mental and emotional challenges [2,3]. These issues have been increasingly reported among older parents filing for financial maintenance with the tribunal court [4]. Hence, the prevalence of depressed older adults is expected to rise from 19,000 to 50,000 by 2020 [3].

Depression among older people is one of the main causes of suicide in comparison to other age groups globally. Despite implementing relevant policies and high awareness of mental health issues in Singapore to reduce recent suicide rates, the numbers among older adults remain relatively high [5]. For instance, individuals aged 60 years and older accounted for 25%-30% of suicide cases reported in Singapore in 2016, rising to 35.7% in 2017 [5]. Chan [6] also reported that older individuals with extensive depressive symptoms are among the main focus of the Singaporean government.

Recent studies have disclosed the need to accommodate the impacts of demographic shifts on Singapore's health care eldercare initiatives [7]. The Singapore Ministry of Health provides intermediate and long-term services to address these concerns about the country's aging population. These policies come in the form of community and residential health care services. While community clinics include hospitals for the chronically ill and nursing homes that are responsible for the provision of residential health care services, center-based health care services are provided by rehabilitation, day care, and psychiatric centers [8].

The Singaporean government has taken diverse approaches to provide better care for older people. For instance, the government is on the verge of increasing the number of nursing home beds to 14,000, accounting for a 50% increase from the report in 2010 [9]. These measures were based on the expected increase in demand for beds as the aging population continues a rising trend [6]. The Ministry of Health has also used smart technologies to facilitate cost-effective eldercare services [10]. Kong and Woods [10] recommended collaborative and contextually sensitive strategies to design and develop smart solutions for older people. Likewise, Ansah et al [11] suggested that resource planners and policy makers proactively review health needs and improve the dignity of the aging population in Singapore.

Despite the availability of previous treatment plans for psychiatric care, counseling is a current treatment approach, especially in recent cases of depression among older people [12]. Psychological counseling is presently perceived as a treatment that could significantly optimize individuals' psychological and behavioral functioning [12,13]. As most older people spend the remainder of their lives within the community, insights into how residents uphold their sense of dignity within the community are valuable to managing aging stressors. An aging population creates both opportunities and pressures for Singapore's welfare and health sectors. More importantly, the risk of dignity loss is high among older people during acute hospital care [14].

Dignity is vital to older individuals and their caregivers. However, it remains unclear how older people define dignity or dignified care and how it is influenced by psychological counseling [15]. Past research investigated how older people's dignity could be safeguarded or enhanced by facilitating individual autonomy [16], providing personalized care, reinstating control, portraying respect, and conducting advocacy and sensitive listening [13]. Identifying older people as individuals and the aspects and values important to them are also fundamentals of care that could potentially conserve their dignity before death [13].

Why Is It Important to Conduct This Study?

Approximately 30% of the 400 suicide cases reported in Singapore in 2019 involved individuals aged 60 years or older [7]. The number of Singaporeans older than 65 years who lived alone increased from 47,000 (9.7%) in 2016 to 67,600 (11.6%) in 2019 [7]. Previous studies also revealed that older adults with ailments and disabilities are exposed to cumulative suicide risks [17] and depression symptoms [3]. As the implications of aging reflect mental health complexities, aging is affected by several losses that require constant adjustments. Aging-oriented losses involve potential stress factors, specifically for older adults with compromised health conditions. Past studies have also highlighted how ailments and disabilities pose risks to older people and how mitigating factors could substantially reduce diseases and mortality rates among older adults [18].

Given the rising aging population, Singapore's government health care is unable to accommodate all older people in hospitals and nursing homes. Hence, the Ministry for Social and Family Development developed a policy for older adults to "age in place," in which they could independently live in their homes and communities. The policy encourages good health by increasing preventive, primary, and long-term care [19]. Additionally, these various types of care offer health and social care needs to support the families of older adults and can be successfully implemented with effective psychological counseling. As physical and cognitive activities represent essential and modifiable protective factors for cognitive decline and dementia, counseling interventions could assist in preventing these issues in older people [3,11].

There is a dearth of information on the effectiveness of counseling older adults in the Singaporean context. However, certain issues have been reported in the literature to impact accessibility and receptivity toward counseling services among the aging population. For instance, the cultural stigmatization associated with psychological counseling services specifically among older people [20,21] makes individuals believe seeking professional counseling is socially unacceptable [22].

XSL•FO
RenderX

Thus, older adults are less inclined and receptive to counselling, even when such assistance is necessary, based on their low awareness of the benefits. Likewise, older adults tend to be deterred by health and disability issues during counseling sessions due to accessibility and receptiveness. These concerns could adversely affect older individuals' daily functioning and dignity preservation levels.

Counseling could be advantageous for older adults with emotional and psychological issues as a form of antidepressant and for ameliorating various mental disorders for behavioral shifts [23]. Counseling can also assist older adults' emotional management and decision-making processes by addressing psychological issues. Hence, counseling in emotional management and decision-making processes would enhance the individuals' sense of dignity in life and aging-oriented transitions. Apart from establishing government-funded counseling services under the family service centers [20], Singapore has also developed social welfare agencies, religious institutions, educational schools, and other governmental institutions that offer counseling services to the general public. Counseling services are also provided by multiple social service agencies and public and private hospitals [21].

Nevertheless, these various counseling services have not been elucidated in the context of Singapore as the impact of psychological counseling in preserving dignity and facilitating good aging among older people remains unknown. In other words, the experience and benefits of the counseling services provided to older citizens are underreported. To fill this research gap, this study aims to propose an intervention model for enhancing older people's well-being through counseling.

Research Objectives

The objectives of this study are as follows: (1) to explore older people's accessibility and receptiveness toward counselling; (2) to assess the improvement of older people's dignity in emotional management and decision-making processes following psychological counseling; and (3) to propose an intervention model for enhancing older people's well-being through psychological counseling.

Research Questions

Due to the paucity of data regarding the impact of counseling services on older adults' dignity and the aging process, this study aims to answer the following questions:

- Do older people in Singapore have counseling access and receptiveness?
- Do counseling services improve emotional management among older people?
- Do counseling services improve dignity among older people?
- Do counseling services affect decision-making processes among older people in Singapore?

Methods

Study Design and Study Area

This study uses a mixed method research design by combining quantitative and qualitative approaches to explore the life experiences of Singaporeans older than 60 years and interpret their lived experiences, such as interactions with qualified counselors accredited by the Singapore Association of Counseling and Singapore Association of Social Workers or social workers. Data are gathered using an exploratory sequential mixed methods design, thereby broadening the scope and dimension of the study. Both qualitative and quantitative approaches offer exceptional strengths that will facilitate robust findings in this study [24-26].

The 5 Singaporean estates with a high number of individuals aged 60 years and older [27] were identified. Bedok and Tampines in the eastern part of Singapore have the largest older populations, with 62,750 and 43,700 people, respectively, followed by Hougang in the northeastern part of Singapore with 41,920 older residents and Ang Mo Kio in the northern part of Singapore with 41,390 older residents. Given the high population of older individuals in Bedok and Tampines, older individuals receiving some form of preventive, primary, or long-term care in the community through voluntary welfare organizations (VWOs) have been recruited for this study. Furthermore, a total of 78 senior activity centers (SAC) in Singapore (a VWO with 10 SACs is located in eastern Singapore) were selected for this study.

Study Population

The study population comprises individuals aged 65 years and older from various parts of Singapore.

Inclusion and Exclusion Criteria

Textbox 1 shows the inclusion and exclusion criteria for selecting the study participants.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Participants must be 65 years of age or older on the first day of selection.
- Participants must be living in the community.
- Participants must be interested in the study and receive some form of preventive, primary, or long-term care services.
- Participants must be willing to attend counseling sessions in emotional management and decision-making processes.

Exclusion criteria

- Older individuals who are currently admitted to a nursing home.
- Older individuals who are mentally incapacitated based on a history of confirmed mental disorder or unable to understand the research protocol when briefed by the researcher.

RenderX

Sample Size Calculation and Sampling Technique

The sample size for the quantitative phase was estimated based on the total population of older people in the study locations, the 95% CI, a precision error of 5%, and estimates from previous related studies on the proportions of participants with satisfactory accessibility and receptiveness levels toward counseling [28]. Specifically, the sample size was estimated by using the formula for analytical and cohort studies presented below:

Where

n = sample size

$z_{1-\alpha/2}$ = z statistic for 95% CI = 1.96

$z_{1-\beta}$ = z statistic for 90% power = 1.28

P_1 = Proportion of participants with satisfactory accessibility and receptiveness levels toward counseling in 1 group and

P_2 = Proportion of participants with satisfactory accessibility and receptiveness levels toward counseling in 1 group

P_1 and P_2 were obtained from previous studies reporting the proportions of participants with satisfactory accessibility and receptiveness levels toward counseling [15,28]. The obtained values were substituted into the equation to calculate the required sample size (n). The computed sample size was adjusted for eligibility by assuming that approximately 30% of the participants have access to and are receptive to counseling. Furthermore, a nonresponse rate of 20% was also considered before deciding on the final sample size.

The probability proportionate to size method was used to allocate sample size for each region and part of Singapore to facilitate proportionate distribution of older individuals receiving some form of preventive, primary, or long-term care in the community through VWOs. Thereafter, a simple random sampling technique was used to obtain the required number of participants from each region. Meanwhile, purposive sampling was used in selecting the SACs.

Qualitative Phase: Study Instrument and Interview Session

A small sample of participants was invited to participate in the qualitative phase, with an equal number of samples from each SAC. As described by previous scholars, 10% of the computed sample size for the quantitative phase was recruited for the interview session. However, an equal number of older individuals were selected from each SAC in various parts of Singapore to participate in the study. The interview session was performed using a semistructured questionnaire. The instrument enables participants to share their views and experiences of counseling services, while some of the responses can be measured numerically.

Six components were explored during the interview session, including the use of the Advanced Care Planning (ACP) booklet among older people, the Trait Meta Mood Scale (TMMS), older people's accessibility and receptiveness toward counseling, and the improvement of older people's dignity in emotional management and decision-making. The interview guide was reviewed in subsequent sessions to explore any new emerging themes.

Quantitative Phase: Instrument Development and Administration

This study uses the ACP and the TMMS instruments. The ACP is a booklet that was designed by the Agency for Integrated Care for recording and planning health and personal care. It comprises 5 main sections that focus on important lifestyle activities, concerns about current health status, views toward life and health, end of life, and preferred end-of-life care. The items are presented as either multichoice options or on a 5-point Likert scale ranging from 1 to 5, depending on the section. For the section on lifestyle activities (4 items), 1="there is little point in being alive without the quality of life," while 5="I would like to be able to live for as long as possible." For the section on participants' views toward end of life (4 items), 1="strongly disagree" and 5="strongly agree." On the other hand, the section on preferred end-of-life care is presented as multichoice options with 9 items.

Meanwhile, the TMMS is a 24-item instrument that was developed to measure meta-mood experience [29]. The TMMS is considered suitable for this study as it is the most used self-administered measurement for individuals' emotional management [29]. The instrument comprises 3 subscales (Attention to Feelings, Clarity of Feelings, and Mood Repair) with 8 items each that evaluate the 3 meta-mood experience components with a 5-point Likert scale ranging from 1="strongly disagree" to 5="strongly agree." The Attention to Feelings Subscale measures attention to personal and external moods and emotions; the Clarity of Feelings Subscale assesses personal abilities to discriminate feelings among one another; and the Mood Repair Subscale evaluates older individuals' ability to perform self and external regulations [30].

A structured questionnaire was also developed to assess participants' views regarding counseling and its impact on their dignity and decision-making process. This was based on the themes identified in the qualitative study and an in-depth review of several studies in the literature. Operational definitions were also developed based on the themes obtained. Three experts assessed the questionnaire for content validity. Thereafter, the instrument was distributed to 10 social workers or counselors for face validity assessment. The comments received were reviewed and necessary modifications were made. The final questionnaire was presented in English, and no translation into local languages was conducted. Pretesting was performed on 20 older individuals from selected SACs for internal consistency and reliability. Findings from the experts' opinions and pilot testing were used to prevent potential ceiling and floor effects from the questionnaire items that may affect accurate data interpretation. The developed questionnaire was distributed to randomly selected older individuals at all selected SACs. The data obtained from the quantitative and qualitative approaches were combined to provide a more robust assessment of the study. Table 1 depicts the research matrix.

To assess older people's competencies in emotional management	✓	
To propose an intervention model for enhancing older people's well-being and dignity through psychological counseling	✓	✓

Ethical Considerations

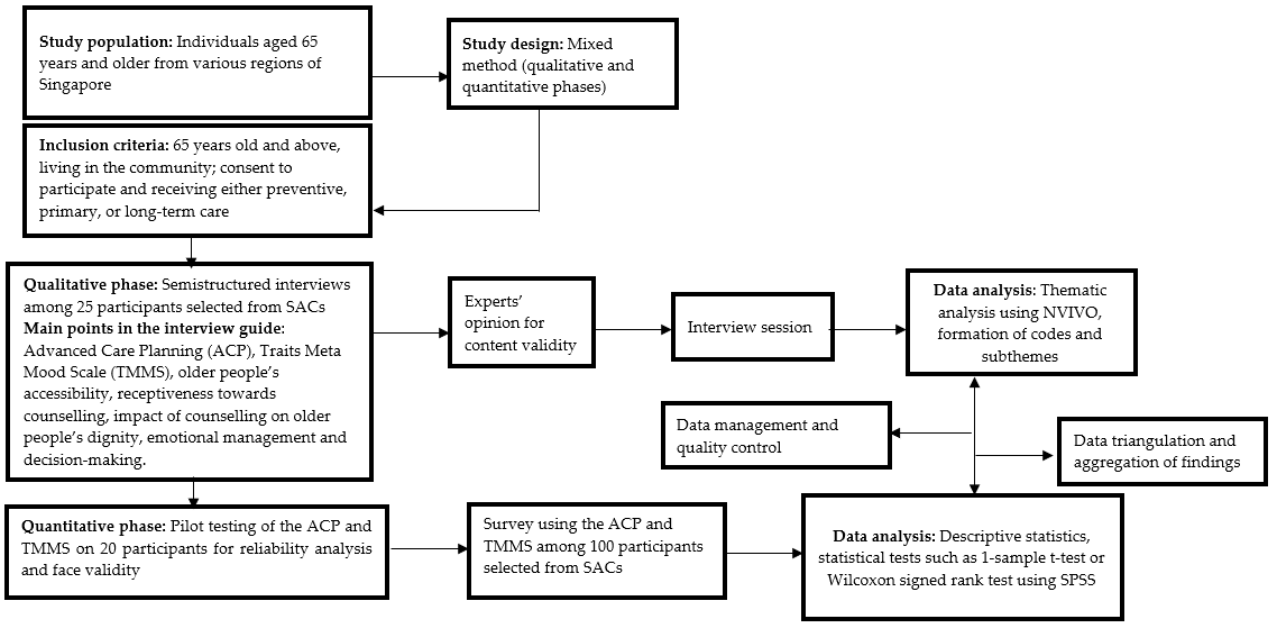
Ethical considerations in this study entail 2 key ethical principles: honesty and respect for human rights [27,31-33]. Certain ethical questions need to be addressed, since older individuals are research participants. The privacy, safety, and confidentiality of participants' data are guaranteed. Hence, both informed and signed consent were obtained before the interview and questionnaire administration. A cover letter with vital information on the research objectives was attached to the questionnaire and interview guide. This study protocol has been approved by the Universiti Sains Malaysia Human Research Ethics Committee (USM/JEPeM/21110760).

Management

Participants' anonymity will be protected in this study [34-36]. Data will be kept confidential to ensure that the identities of older individuals are protected [37-39]. Research instruments and clinical records containing participants' data will be represented in a coding system. Thus, participants' private information will not be revealed when submitting the data and findings to regulatory institutions or sponsors [40,41]. Only the researchers will be able to access the participants' records and the coding system. Two copies of consent forms were provided to be signed by the researcher and each participant. All the files will be stored in a single folder in a secured location.

This research poses no risk to the participants. No personal expenses will be incurred by the participants during the study. Furthermore, no incentives or financial compensation will be given for participation. The research budget will be used for any further expenses. This study is based on voluntary participation and has no implications for the participants' counseling if they decide not to participate. Older individuals can decide to withdraw from the research regardless of time, if desired, without any consequences to their counseling or care at the SACs. The expected research findings might be published in a journal article or presented at conferences or meetings; however, participants' identities will remain confidential.

Quality Control Measures



A number of methodological resources, such as mixed method study design, inclusion criteria, and random sampling, were used in this study to minimize bias and ensure quality data collection. The interview session was performed by the principal researcher, while trained enumerators assisted in the quantitative phase of data collection. The enumerators were trained during the pilot test to familiarize them with the research instrument. To further ensure quality control, the principal researcher assessed the enumerators periodically to see if they were following the survey protocol. If necessary, the enumerators also assisted the participants while they completed the questionnaire to minimize missing data. Quality control was assessed in the retrieved questionnaires based on the quality and completeness of the data.

Data Analysis

Findings from the qualitative study will be transcribed and coded. Interview transcripts will be analyzed using NVivo (version 12; QSR International). The identification, coding, and categorization of meaningful patterns into themes and subthemes will be performed to facilitate the construction of a structured questionnaire for the quantitative study. For the quantitative phase, the internal consistency of the questionnaire items will be evaluated using a reliability test based on Cronbach α values. Items will be considered acceptable and reliable if the Cronbach α value is equal to or greater than .7. Participants' background information and other sections in the questionnaire will be analyzed using descriptive statistics. Continuous variables will be subjected to normality tests using the Smirnov-Kolmogorov test and presented as means (SD) or medians (IQR) accordingly. Statistical tests such as a 2-tailed, 1-sample *t* test or Wilcoxon signed rank test will be applied. A *P* value of .05 will be considered statistically significant, and all empirical analyses will be performed using SPSS (version 25; IBM Corp). The flow of the research process, including the vital concepts, is presented in Figure 1.

XSL•FO
RenderX

Figure 1. Sequential explanatory approach of the research. ACP: Advanced Care Planning; SAC: senior activity center; TMMS: Trait Meta Mood Scale.

Timeline

Older individuals for the quantitative study have been recruited, and the phase was completed in February 2022. Participant recruitment for the quantitative phase commenced immediately upon executing the qualitative phase. The quantitative phase began on March 22, 2022, and was completed in May 2022. Data analysis was performed in September 2022, and the research was completed in March 2023.

Results

We have obtained ethical approval to conduct this study from the Universiti Sains Malaysia Human Research Ethics Committee (USM/JEPeM/21110760). The qualitative phase, which involved a semistructured interview, was conducted from January 14, 2022, to February 16, 2022, among 25 individuals aged 66-86 years. Thematic analysis of the data is still ongoing. Meanwhile, the quantitative phase commenced on March 22, 2022, with 100 participants providing signed and informed consent to participate in the study. The face-to-face administration of the ACP and TMMS instruments and data collection closed on May 10, 2022. Data analysis and manuscript writing was performed in March 2023.

Discussion

Expected Findings

Old age comes with various losses of functions and roles, thereby leading to an increased reliance or dependency on others. Thus, the first objective of this study is to use mixed methodology in assessing older people's perspectives on ACP, life and health, end of life, and end-of-life care. The ACP instrument is a booklet designed by the Agency for Integrated Care for recording and planning health and personal care, and the main sections comprise important lifestyle activities, concerns about current health status, views toward life and health, end of life, and preferred end-of-life care. Findings from this study will elucidate participants' views of these pertinent aspects of ACP.

Policymakers in Singapore have recently highlighted the need to provide a conducive environment for older people to age effectively and to be independent for as long as possible [20]. For instance, it is estimated that by 2030, due to the nation's ultralow fertility rate, those older than 65 years will be supported by only 2.1 million Singaporeans of working age [27]. Hence, the results will assist to understand if participants' views align with the government's position to ensure improved independence among the nation's aging population.

In addition, information about perceived social support, the connection between health and exercise, and current health status or comorbidity will be gleaned from the ACP instrument. Perceived social support is an important predictor of quality of life and satisfaction with life among adults aged 65 years and older [42]. Understanding how older people define physical activity has also been associated with the perceived benefits of healthy aging [43,44]. In terms of health status, a recent study on the epidemiologic characteristics of multimorbidity in Singapore's aging population found that hypertension and lipid disorders were among the most prevalent disease combinations [45]. Singapore was also reported to have a higher prevalence of multimorbidity compared to several countries worldwide [46], with more than 19% of the population having multimorbidity. Thus, participants' concerns regarding their health status and present comorbidity will add to the current knowledge pool.

The second objective focuses on qualitative analyses of participants' perspectives on counseling, awareness and receptiveness toward counseling services, and potential barriers to seeking counseling assistance. Counseling and psychotherapy are confidential conversations between a counselor and a client that are performed to provide solutions to problems [47,48].

XSL•FO
RenderX

Factors such as perception and attitude toward counseling, affordability, financial status, and accessibility are some of the consistent factors influencing receptiveness toward counseling among older individuals [49-51]. Given the limited information on the aforementioned aspects in the Singaporean context, findings from this study will provide opportunities for relevant bodies to ascertain the factors to focus on in enhancing the receptiveness toward counseling among older people.

Our third objective was to understand older people's perspectives on dignity and how their emotional management and decision-making are influenced by counseling. End-of-life patients' dignity is a vital theme in the context of palliative care, and health care professionals are expected to address complicated decisions on specific aspects of patients with terminal illnesses [52,53]. Given that older people tend to be more vulnerable to loss of dignity following advanced age and deteriorating health, dignified care is a significant health care goal that ought to be preserved during counseling interventions, especially for older people [54]. Previous studies conducted elsewhere found that terms such as *self-worth*, *self-recognition*, and *self-expression* were used by older participants in describing dignity [55,56]. We expect the participants in this study to use similar terms but tailored to the nation's context given the different cultural backgrounds compared to Western perspectives.

In terms of the impact of counseling on emotional management and decision-making, diverse views ranging from positive to negative effects may be conveyed by participants since they might have faced challenges in seeking counseling assistance. For instance, a previous study conducted in Tehran, Iran, found that psychological counseling on mental well-being had a positive impact on emotion and self-management ability among older women [57]. Dai et al [58] also performed a meta-analysis of studies conducted among Chinese populations and found that psychologically based therapies were effective in ameliorating depression symptoms among older people. The contents of the ACP instrument used in this study entailed pertinent topics on mental health, the selection of treatment goals (comfort-focused vs full treatment), available care options in the community, and available care options during end of life, which might have a positive effect on emotional management and decision-making. However, difficulties in assessing counseling services or challenges are faced during the counseling process.
