This is a multicenter, 3-parallel-arm, randomized controlled trial of 18 months duration designed to assess whether cigarette smokers switching to C-F NA will undergo measurable improvements in oral health parameters and dental esthetics as a consequence of avoiding exposure to cigarette smoke. This study aims to assess differences in study end points of oral health parameters and dental esthetics at multiple study time points between smokers switching to C-F NA and smokers who continue to smoke.

Study Population

Eligible participants will be healthy adult regular cigarette smokers (self-reported daily smoking of >10 cigarettes per day for at least 5 consecutive years) and never smokers without clinical signs of periodontitis.

Smokers will be offered access to free smoking cessation programs. Only those who refuse to participate in the smoking cessation program and express willingness to switch to C-F NA will be eligible for randomization.

Never smokers (those who have smoked <100 tobacco cigarettes in their lifetime) will also be included as a reference group.

Participants will be required to satisfy all the inclusion criteria as presented in Textbox 1.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria for smokers (study arms A and B)

- Adults (aged 18-50 years)
- Cigarette smokers of ≥10 cigarettes per day
- Smoked for at least 5 consecutive years before screening
- Verified smoking status by exhaled breath carbon monoxide (CO) ≥7 ppm at screening
- Willingness to switch to a combustion-free nicotine alternatives, if required by the randomization
- Refusal to participate in smoking cessation programs
- Presence of at least 10 natural anterior teeth in total (cuspid to cuspid and lower and upper jaw)
- Healthy participants, not taking regular medications for chronic medical conditions
- Accepting to comply with the requirements of the study, including installing an app on their smartphone

Inclusion criteria for never smokers (study arm C)

- Adults (aged 18-50 years)
- Have not smoked >100 tobacco cigarettes in their lifetime
- Verified nonsmoking status by exhaled breath CO <7 ppm at screening
- Presence of at least 10 natural anterior teeth in total (cuspid to cuspid and lower and upper jaw)
- Healthy participants, not taking regular medications for chronic medical conditions
- Accepting to comply with the requirements of the study, including installing an app on their smartphone

Exclusion criteria for smokers (study arms A and B) and never smokers (study arm C)

- Significant oral soft tissue pathology or any type of gingival overgrowth other than plaque-induced gingivitis
- Periodontitis based on the 2017 World Workshop on the Classification of Periodontal and Peri-Implant Diseases and Conditions [28], which requires the following:
  - Detectable interdental clinical attachment loss ≥3 mm at ≥2 nonadjacent teeth
  - Buccal or oral clinical attachment loss ≥3 mm with pocketing ≥3 mm detectable at ≥2 teeth
  - Only participants with mild to moderate gingivitis will be recruited
- Fixed and removable orthodontic appliances or removable dentures
- Any other medical condition that, in the opinion of the principal investigator, would jeopardize the participant's safety or diminish the validity of the study results
- A course of treatment with any medications that
  - interfere with the cyclooxygenase pathway (eg, anti-inflammatory drugs including aspirin and ibuprofen) within 3 days before each visit
  - are known to have antibacterial activity (eg, antibiotics) within 7 days before each visit
- Significant history of alcohol or drug abuse within 24 months before screening, as determined by the investigator
- For smokers, planning to quit smoking within the next 6 months
- For smokers, regular use of nicotine (eg, e-cigarettes, nicotine replacement therapy, nicotine pouches) or tobacco products (eg, heated tobacco products, oral smokeless) other than their cigarettes within 14 days of screening
- Pregnant or breastfeeding or intention to become pregnant during the study
- Active participation in another clinical trial

Study Design

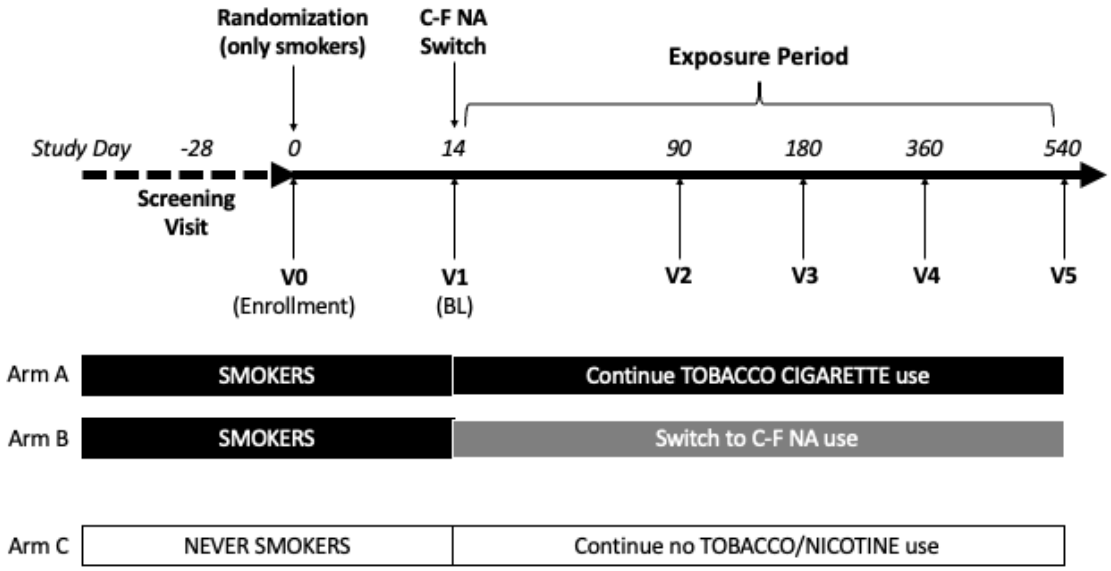
This is an 18-month, prospective, multicenter, open-label study with 3 parallel arms, using randomization and control to assess a range of oral health and dental esthetic metrics (Figure 1). The primary objective is to compare these metrics between cigarette smokers transitioning to C-F NA and those who continue smoking.

Eligible smokers will be allocated randomly to either the control group (arm A), which will receive standard care inclusive of cessation counseling (ie, very brief advice [VBA]) or the intervention group (arm B), which will be given a C-F NA of their choice and will also receive VBA. Individuals who have

never smoked will form a reference group (arm C). Throughout the study, participants from all 3 groups will undergo regular assessments of their oral health and dental esthetic. The study will be conducted in 4 dental clinics across 4 different countries (Italy, Poland, Moldova, and Indonesia).

The study protocol adheres to the guidelines stipulated by the Standard Protocol Items: Recommendations for Interventional Trials (SPIRIT) guidelines.

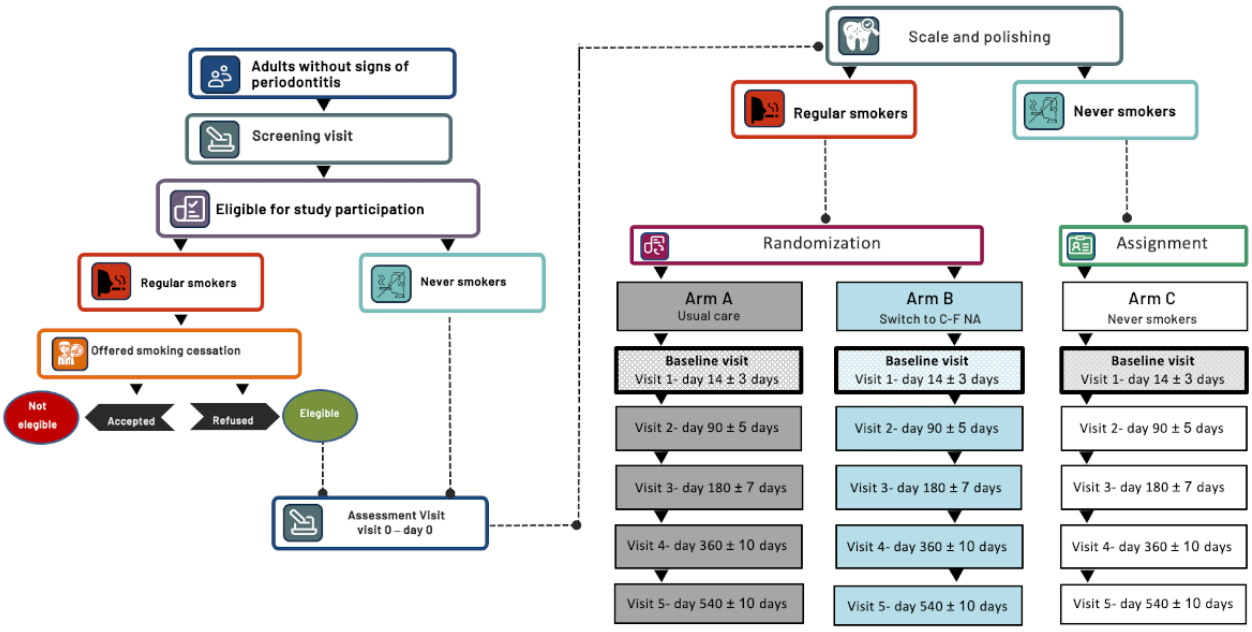
Figure 1. Study design. Smokers not intending to quit and without clinical signs of periodontitis were randomized to either standard care (arm A) or combustion-free nicotine alternatives (C-F NA; arm B). A reference group of never smokers will also be included but not randomized (arm C). Participants were prospectively reviewed at 4 dental clinics for cigarette consumption and C-F NA use, oral health and dental esthetic measurements, vital signs, and adverse events for up to 18 months.



The study flow is illustrated in Figure 2.

All participants will attend a total of 7 clinic visits: day −28 to day −1—screening; day 0—enrollment and randomization (visit 0); day 14—baseline visit (visit 1); day 90—week 12 (visit 2); day 180—week 24 (visit 3); day 360—week 52 (visit 4); day 540—week 76 (visit 5).

Figure 2. Study flow diagram of study participants. C-F NA: combustion-free nicotine alternatives.



Screening visits will be performed within 28 days before enrollment to verify the eligibility criteria (visit 0; Figure 2). During the screening visit, sociodemographic data, medical and oral health history, detailed information about nicotine and tobacco consumption, and interest in trying C-F NA will be recorded. Screening for periodontal disease will be performed to exclude periodontitis, as per the definition of the guidelines of the 2017 Classification of Periodontal and Peri-implant Diseases and Conditions [28]. Smokers will be offered a smoking cessation program as per local guidelines. Any smokers who express the intention of booking for the cessation program or to quit smoking in the next 6 months will be urged to do so and will not be recruited in the study. Participants taking part in the study will be informed that they are free to quit smoking and withdraw from the study at any time. Moreover, smokers will be encouraged to quit smoking at every contact throughout the study.

Within 28 days of the screening visit, eligible participants will be invited to attend an enrollment visit (visit 0). Inclusion and exclusion criteria will be verified again. Smokers will be reminded of the risks associated with smoking before enrollment in the study and that they are free to voluntarily quit smoking and nicotine or withdraw from the study at any time. All participants will undergo a series of measurements (Tables 1-3) followed by dental scaling and polishing procedures to remove calculus, plaque, and stain.

Smokers not intending to quit will then be randomly assigned to either the control (arm A) or the intervention (arm B) group. The randomization sequence will be generated by a computer, with an allocation ratio of 1:4 (arm A: arm B) to accommodate for the estimated 25% proportion of participants achieving a sustained reduction in cigarette consumption of at least 90% in arm B (as detailed in the Statistical Considerations section). Smokers in the control group (arm A) will receive standard care, inclusive of cessation counseling (ie, VBA) at each study visit. Smokers in the intervention group (arm B) will have the option to try and choose a preferred C-F NA (ECs and HTPs) from a given pool of popular options present in the respective markets and will also receive VBA.

Individuals who have never smoked will be allocated to the reference group (arm C). Never smokers in the reference group will serve as comparators for assessing any background changes in the primary study end point (ie, Modified Gingival Index [MGI]) that may occur over time. Although never smokers will not undergo randomization, efforts will be made to achieve a comparable distribution of sex and age across all study arms.

The trial is designed as an unblinded trial because of the nature of the intervention, where participants and trial staff cannot be blinded to the specific intervention being provided. However, data analyses will be conducted blind to study arms allocation. All other trial staff who have access to outcome data will remain blinded until prespecified data analyses will be completed.

Baseline measurements will be performed at visit 1 (baseline visit) and 14 days after scaling and polishing procedures at enrollment (visit 0). Study measurements will include MGI assessment, plaque imaging, dental shade quantitation, tooth stain scores, and oral health–related quality of life questionnaires (Tables 1-3).

Smokers in arm B will be provided with a C-F NA of their choice. They will receive training and counseling on how to use the chosen C-F NA and will be provided with a full 2-week supply of the required consumables (cartridges or pods or e-liquid refill bottles for ECs and tobacco sticks for HTPs). Participants wishing to use an HTP will receive one kit and a supply of tobacco sticks of their choice. They will receive the number of tobacco sticks per day corresponding to the number of cigarettes smoked per day at baseline. Participants wishing to use a vaping product will receive one vaping kit and a supply of e-liquids of their choice. Products will be supplied at each subsequent visit throughout the study according to the study product supply schedule in Table 4.

After the baseline visit, participants will be invited to attend 4 more clinical visits (visits 2-5) to repeat study measurements (Tables 1-3).

Throughout the study, monitoring of cigarette consumption, daily C-F NA use, and oral hygiene routine will be carried out regularly using the tracker app and personal diaries. Monitoring of cigarette consumption and daily C-F NA use will also be achieved by asking participants in arm B to return all empty, partly used, and unused consumables (tobacco sticks, EC cartridges, and e-liquid refill bottles) at each study visit. The tracker app will also identify any protocol violations, collect adverse events (AEs), and send reminders (eg, next scheduled appointment, study restrictions, and instructions) throughout the study duration. The use of a dedicated tracker app adds an innovative element to continuously collect data and enhances adherence to the study protocol.

Before each study visit (visits 1-5), all participants will be required to refrain from scaling and polishing procedures, avoid modifying their habitual oral hygiene (eg, mouthwash, mouth rinse, and interdental floss), refrain from flossing for at least 72 hours before each study visit, refrain from mouth rinsing for at least 24 hours before each study visit, refrain from tooth brushing for at least 2 hours before each study visit, refrain from eating and drinking (except water) for at least 2 hours before each visit, and abstain from smoking for 2 hours before each visit. This is to minimize any potential interference with study outcomes and to maintain consistency in data collection. Throughout the study, any modifications in the oral hygiene routine of participants will be recorded using the tracker app.

A detailed description of the measurements that will be specifically performed at each trial visit is provided in Multimedia Appendix 1.

[a]Participants wishing to use a heated tobacco product will receive one kit and supply of tobacco sticks of their choice; they will receive the number of tobacco sticks per day corresponding to the number of cigarettes smoked per day at baseline. Participants wishing to use a vaping product will receive one vaping kit and supply of e-liquids of their choice.

Study End Points

Primary End Points

The primary objective of the study is to compare changes in MGI by Lobene et al [29] between baseline and end of the study (ie, 18 months' time point) among participants who continue to smoke tobacco cigarettes (arm A) and participants who switch to C-F NA (arm B).

Secondary End Points

In addition, the study will analyze the number of secondary objectives, including within- and between-group variations at each study time point from baseline for MGI assessment, plaque imaging, dental shade quantitation, tooth stain scores, and oral health–related quality of life questionnaires.

Study Measurements and Calibration

A detailed description of the study measurements that will be specifically carried out at the dental clinic is provided in Multimedia Appendix 2.

All assessors will be trained on MGI scoring, tooth stain assessment, and the correct use of technologies and software used to quantify dental plaque, tooth discoloration, exhaled carbon monoxide monitoring, and electronic case report form (eCRF) use. Assessors will be periodically calibrated on MGI scoring and tooth stain assessment. To ensure consistency in the measurements, the same assessor will collect all study end points in the same participant over the entire study period.

Data Monitoring and Study Safety

A trial monitoring plan will be developed based on the trial risk assessment and includes on-site monitoring. The clinical research organization will arrange an independent monitor, separate from the investigators and the sponsor, to ensure compliance with trial protocols and policies, participant protection, and accurate data collection.

AEs and serious AEs (SAEs; eg, those related to oral conditions, tobacco cigarette smoking, C-F NA use, nicotine withdrawal symptoms, or nicotine overdosing) will be recorded on the AE page of the eCRF throughout the study. Participants will be interviewed at each visit to investigate signs or symptoms. Signs or symptoms will be elicited at each visit by open questioning, such as "How have you been feeling since your last visit?" "How have you been feeling regarding your oral cavity?" Participants will also be encouraged to spontaneously report AEs occurring at any other time during the study via the dedicated mobile app or the communication channels provided for the study. The investigator must gather sufficient information to determine the outcome and causality of AEs and SAEs and promptly notify the competent authority, if necessary.

Study Withdrawal

Participants may be withdrawn from the study prematurely for the following reasons: (1) experience an SAE, (2) develop a

concurrent disease which at the discretion of the investigator no longer justifies the participant's participation in this study, (3) sustain any uncorrectable protocol deviations during the study, (4) decide to stop their participation, (5) become pregnant, and (6) exhibit uncooperative behavior or nonattendance. After consultation with the clinical research organization, the investigator will notify participants' discontinuation from the study.

Data Collection and Protection

For data collection, each participant will be allocated an eCRF. Anonymized data from each study visit will be entered directly into the eCRF, which will then serve as a source document for the trial. This data entry process ensures that data are collected accurately and consistently at all study sites.

Each participant will be assigned a unique study identification number (participant ID). Participant's personal data will not be linked to the research results, and only a limited number of members of the research team will have access to the decoding list that links participant IDs to their personal information. All information obtained during the study procedures, including participant data and personal details, will be treated as private and confidential in accordance with ethical and privacy regulations.

The trial will reach its formal conclusion on the date of the final visit of the last participant in the last country involved in the study.

Ethical Considerations

The study will be conducted in accordance with the Principles of Good Clinical Practice and the Declaration of Helsinki. All 4 local ethics review boards reviewed and approved the study and, where appropriate, translated the relevant documentation (eg, informed consent form, participant's information sheet). The trial is registered with ClinicalTrials.gov (NCT04649645). The study was approved by the ethics review board of the coordinating center, the Azienda Ospedaliera di Rilievo Nazionale e di Alta Specializzazione "Garibaldi" (697/CE; dated November 11, 2020). Informed consent was obtained from all the participants.

The intention is to disseminate the study results through articles in peer-reviewed journals and conference presentations. A summary of the results will be available on the study website for public access. The anonymized data will be available to researchers upon reasonable request.

Statistical Considerations

Sample Size Calculation

For a valid sample size calculation, literature research was performed for the primary end point of the study (ie, MGI). Unfortunately, no data were available for such a study. However, data from studies with mouth rinse were available, and based on these studies [30,31], a mean MGI change of 0.08 with an SD of 0.18 of the MGI seemed relevant.

However, in these studies, higher mean MGI changes were observed because active treatment was administered, which was not the case in this study. Thus, several scenarios with different mean MGI changes and SDs will be applied.

The following hypotheses will be tested with a 1-sided independent *t* test:

H0: $\mu A \leq \mu B$ versus H1: $\mu A > \mu B$

where μA denotes the mean change MGI from baseline to after 18 months of regular smoking and μB denotes the mean MGI from baseline to after 18 months of C-F NA use.

For sample size calculation, SAS software (version 9.4; SAS Institute) was used and several scenarios were applied, assuming that the data are normally distributed. The results are summarized in Table 5, which presents the calculated sample sizes for the comparison of μA versus μB by a 1-sided independent *t* test, a significance level of 5%, and a power of 90%, depending on the expected MGI change and SD.

As no active treatment is given in this study, a lower effect than the observed values needs to be assumed. Therefore, a mean MGI change of 0.1 with an SD of 0.21 was chosen. Hence, a sample size of 77 patients per treatment group is required. Considering a dropout rate of 20% over 2 years' observation phase [32,33], a sample size of at least 92 per treatment group is required. In addition, it is estimated that approximately 25% of those switching to C-F NA use will abstain or substantially (≥90%) reduce smoking [34], and only these participants deliver valid results. Therefore, 4 times more participants should be recruited in the C-F NA group (4 × 92 = 368). This results in a total sample size of 460 (92 in arm A+368 in arm B).

In arm C, we have determined a sample size of 40, empirically with no formal statistical analysis, as this cohort's primary study end point (ie, MGI) is expected to be stable throughout the study.

Table 5. Summary table including the sample size for each arm of the study depending on the mean Modified Gingival Index (MGI) change and SD.

Nominal power	Mean MGI change	SD[a]				
		0.20	0.21	0.22	0.23	0.24
0.9	0.10	70	77	84	92	100
0.9	0.15	32	35	38	41	45
0.9	0.20	18	20	22	24	26

[a]Expected sample size is the same per each group and it is indicated by the rows (ie, 70-100, 32-45, and 18-26) according to the SD and MGI combinations.

Statistical Analyses

Statistical methods used in the analysis of this study will include descriptive statistics with the descriptive presentation of the total sample value, mean, SD, median, minimum, maximum, and 95% CIs for (pseudo) continuous data and categorical data. Further evaluations will be summarized in tables by counts and percentage of scores.

Statistical methods for primary study end points will include the following: the Shapiro-Wilk test of normality on calculated values (in case of normal distribution, a 2-sided independent *t* test and in case of nonnormal distribution: a 2-sided Mann-Whitney *U* test) and a linear mixed model with the random factors "center" and "study arms by center."

Designated as study arm C, the never-smoker group will establish a baseline reference for the oral health parameters. This group is anticipated to provide insights into the underlying changes in the primary study end point (MGI) that may emerge over time in individuals who have never smoked.

Statistical methods for secondary study end points will include the following: for comparisons of each study arm for parameters such as MGI assessment, plaque imaging, dental shade quantitation, tooth stains scores, and oral health–related quality of life questionnaires, the Shapiro-Wilk test of normality on calculated values (in case of normal distribution, a 2-sided independent *t* test and in case of nonnormal distribution: a 2-sided Mann-Whitney *U* test); for comparisons of each assessment time for parameters such as MGI assessment, plaque imaging, dental shade quantitation, tooth stains scores, and oral health–related quality of life questionnaires, the Shapiro-Wilk test of normality on calculated values (in case of normal distribution, a 2-sided independent *t* test and in case of nonnormal distribution: a 2-sided Mann-Whitney *U* test); accounting for missing, unused, and spurious data.

If only one value of the parameter MGI is missing after day 1, the last available observation will be carried forward. The analysis will be performed on the substituted data. For secondary parameters, no replacement of missing values will be applied.

A generalized linear regression model will be used to adjust for all identified confounders. To identify possible predictors of primary and secondary study end points, a regression model will be estimated in which each study end point will be entered as the dependent variable. Possible predictors will be entered into the model as independent variables (including study group; age; gender; cigarette consumption; combustion-free nicotine delivery systems use; and frequency of personal oral hygiene, eg, tooth brushing, mouth washing, and dental flossing frequency) to assess the interactions. Following the results obtained from each regression model, comparisons between and within study groups will be performed using analysis of covariance adjusted for age, gender, and frequency of personal oral hygiene followed by the Tukey post hoc comparison test.

The goal of our study is to help smokers abstain from cigarette smoking to assess changes in oral health regardless of the product used. This study is not designed to compare the efficacy between HTPs and ECs in terms of smoking cessation. Nonetheless, we will consider a secondary analysis that takes into account the potential different impact of HTPs versus ECs in terms of oral health outcomes.

Results

Participant recruitment began in October 2021, and enrollment has been completed in June 2023. Results will be reported in 2025.

Discussion

Overview

Although the negative effects of cigarette smoking on oral health and tooth discoloration are well known [35,36], there are only limited data about the impact of C-F NA such as ECs and HTPs. In particular, there are no long-term studies assessing the impact on oral health and teeth appearance when substituting conventional cigarettes for these combustion-free alternatives. This study was specifically designed to address these research questions. In particular, this study tests the hypothesis that avoiding exposure to cigarette smoke toxicants may translate into measurable amelioration in gingival response, dental plaque build-up, enamel discoloration, and tooth staining in participants with mild to moderate gingivitis by comparing participants who smoke tobacco cigarette with those who switch to using C-F NA or participants who never smoked.

In addition to its obvious relevance to health and esthetic concerns, this study seeks to expand on regulatory science. Regulatory authorities (eg, the US Food and Drug Administration) recommend investigating the oral health effects of novel tobacco and nicotine products to better understand their impact at individual and population levels as well as exploring additional study end points for the assessment of their short- and long-term effects in oral health studies [37]. Our study is designed to provide improved design knowledge for oral health switching studies and, most importantly, to streamline new innovative cutting-edge technologies that can be used for future studies on existing and emerging tobacco and nicotine products (including oral smokeless products).

The study design incorporates several significant and groundbreaking characteristics. First, we aim to enhance adherence to C-F NA and optimize overall compliance with the study's instructions through the provision of a diverse range of products, encompassing the most popular options available in the market. This approach allows participants to tailor their own gratifying "nicotine experience" by selecting the C-F NA that aligns with their preferences. By doing so, we anticipate not only fostering a transition to the latest technology but also facilitating the reduction of cigarette smoking and bolstering long-term prevention of relapse [38-42]. It is worth highlighting that this aspect of personal choice is notably absent in studies of harm reduction. Furthermore, it is important to emphasize that the outcomes of this research will not be product specific, thereby minimizing constraints on generalizability.

Second, the study is being run in many different locations across the globe and so the challenge was to find a primary end point that could be measured by different operators in different sites, using a standardized measurement system that has been used

previously and so has provenance. The index to be used had to be simple, reproducible, and relatively easy to compare between different sites and different operators. Ideally, the assessors should be able to calibrate the index to be used and compare the calibration results. The MGI is a widely used industry-standard index to determine changes in the gingival health of volunteers in clinical studies [29,43,44]. This index is simple, noninvasive, and reproducible, and it is hoped that it will be possible to train different examiners in different locations to align their assessments, thus making the results comparable. As the MGI is noninvasive, there is no gingival probing, and it is thought to be easier to calibrate examiners and compare kappa scores. Although subjective in nature, the lack of probing removes one of the variables present in using pressure to probe the gingivae. It is also thought to afford greater sensitivity in determining therapeutic efficacy [45]. This study will be the first to investigate the long-term impact of smoking or C-F NA intervention on MGI.

Third, the selection of secondary study end points is strategic because it considers what drives smokers to turn to cleaner nicotine and tobacco products. This is particularly persuasive for young adults, for whom a cardiovascular-cancer-respiratory risk–based narrative is either ineffective or even counterproductive, and for whom concern about bad breath and poor dental esthetic (because of enamel discoloration and “tar” stains) may be a much more significant reason to refrain from smoking. Although experimental work comparing the effects of C-F NA on tooth staining and discoloration has been published [46-48], this study is the first to consider this powerful narrative of oral health in a clinical trial; therefore, we have included innovative 21st century technologies for objective and consistent quantitation of dental shade discoloration (by calibrated spectrophotometry) and dental plaque changes (by digital imaging technology; quantitative light-induced fluorescence) among the study end points to investigate whether switching completely from cigarettes to C-F NA can improve gum health, reduce bad breath, and restore teeth appearance. Small-scale clinical trials have been recently conducted at the Center of Excellence for the Acceleration of Harm Reduction of the Catania University to confirm the validity and reproducibility of dental shade assessment by digital spectrophotometry and dental plaque quantitation by light-induced fluorescence technology in current, former, and never smokers [49,50].

Fourth, maximizing the magnitude of observable changes at the study end points is critically important. Given that several factors (including duration of smoking exposure, variations in oral hygiene practices, type of diet, and level of alcohol consumption) can significantly affect assessments of gum health and dental esthetics, we reduced baseline variability by using data obtained after the visit during which scaling and polishing was carried out. By removing dental plaque, calculus, and stains, we provide all study participants with the best possible oral health status (gum health and teeth appearance) at the beginning of the study. Considering that a 14-day interval is generally required to allow gingival restoration from tissue trauma caused by scaling and polishing [51], measurements that will be considered for this normalized baseline will be obtained 14 days after scaling and polishing. Any progressive change in gum health or tooth appearance will be compared with the reference data of this baseline. In addition to the inclusion of a full scale and polish at the beginning of the study in an attempt to maximize the magnitude of observable changes of study end points, it is also important to consider that the length of the study is adequate and that the study population will have to be one that allows the possibility of measuring such a change. Although the long-term impact of smoking and smoking cessation on gingival health and tooth appearance has never been investigated in a prospective trial, the planned 18 months duration of the study is deemed to be adequate for the detection of significant changes in study end points. Chronic periodontal disease is common in smokers and is an irreversible condition that may stabilize with active treatment [52]; however, it is unlikely to improve with the simple measure of smoking cessation alone. Therefore, participants with periodontitis will be excluded and only participants with mild to moderate gingivitis will be recruited, as they are more likely to show measurable changes in study end points with continuing to smoke, smoking cessation, or the use of C-F NA.

Fifth, personal oral hygiene and dietary patterns can significantly influence both primary and secondary study end points. To mitigate this impact, a standardized approach to oral hygiene will be implemented within the study parameters. Participants will be explicitly advised against altering their established oral hygiene practices for the duration of the study. Furthermore, adherence to specific restriction criteria before each scheduled study visit will be emphasized, aiming to prevent any confounding of the collected data. Recognizing the variable effects stemming from individual oral hygiene and dietary habits, we incorporated a cohort of never smokers as a reference group. This inclusion serves to establish a benchmark for comparison and analysis. To address the inherent challenge of ensuring consistent measurement of study end points, especially in cases involving diverse operators across multiple sites, we will provide comprehensive training and implement meticulous calibration procedures.

Finally, compliance with the research protocol is important because it would decrease or nullify the anticipated improvements in study end points if cigarettes were not fully or largely replaced with C-F NA. Participants will be reminded of the importance of adhering to their randomized product allocation and of abstaining from or substantially reducing the daily consumption of cigarettes (by at least 90% of their regular cigarette smoking at baseline) at every study visit. A significant feature of switching studies is close reporting of cigarette consumption and (or) C-F NA use; participants will record the consumption of cigarettes and use of C-F NA on each visit in their study diary. In addition, participants will be asked to return all empty, partly used, and unused consumables. Throughout the study, smoking and C-F NA use will be monitored via an app. The SMILE Tracker app is an integral component of the Smile study designed to monitor participants’ behaviors and lifestyle choices. Through daily prompts, the app assists in tracking cigarette consumption, use of combustion-free nicotine delivery systems, and regular oral hygiene practices such as brushing, flossing, and mouthwash use. In addition, it functions

as a personal diary for participants to log any changes in their oral care routine. Moreover, the SMILE Tracker app features a system to monitor protocol adherence, identify deviations, and gather data on potential AEs and SAEs. It sends automated reminders to participants for their upcoming appointments and study restrictions and provides instructions to ensure adherence and accurate data collection during the study. Furthermore, it includes a step counter to encourage physical activity among users. Of note, noncompliance with the study items is an interesting outcome in itself (particularly in consideration of the wide selection of different products offered in the study). Although compliance with this study is not expected to be significantly different compared with other comparable studies, our power calculations are overestimated to account for a 75% noncompliance rate. The C-F NA population would therefore be overrepresented by recruiting4 times the number of participants in the C-F NA category (ie, for every participant randomized in the control population, 4 will be randomized in the C-F NA population).

The acknowledgment of the impact of COVID-19 pandemic restrictions on recruitment is duly noted. However, it is deemed unlikely that these restrictions will exert a significant impact. This assertion is based on the fact that recruitment proceedings were initiated in October 2021, a period during which well-defined guidelines had already been established at the dental clinic across all 4 participating sites.

Conclusions

This study represents a pioneering effort in assessing the long-term effects of smoking and smoking abstinence on oral health. Through a prospective approach, it aims to provide novel insights into the relationship between smoking habits and oral well-being. The data derived from this study will significantly enhance our existing understanding of the impact of smoking on oral health. Moreover, the study outcomes hold the potential to shed light on the role of C-F NA as a potentially cleaner nicotine alternative to tobacco smoking. This is particularly relevant for individuals who prioritize concerns such as bad breath and dental esthetics. This study's emphasis on oral health aligns with a broader objective of alleviating the burden of smoking. Several parameters measured in this study (including MGI and dental plaque build-up) are linked to the development of periodontal disease. It is noteworthy that the progression from chronic gingivitis to periodontitis raises the risk of cardiovascular disease [4,5], thereby underscoring the broader health implications of the study's results.

Acknowledgments

Funding for this study was provided by ECLAT Srl, a spinoff of the University of Catania, through a grant from the Foundation for a Smoke-Free World. The Foundation for a Smoke-Free World is a US-based nonprofit 501(c)(3) private foundation dedicated to ending smoking in the current generation. The authors are solely responsible for the content, selection, and presentation of facts as well as any opinions expressed in this study. These views should not be interpreted as reflecting the positions of the Foundation for a Smoke-Free World, Inc. ECLAT, a spinoff company of the University of Catania, focuses on delivering solutions to global health issues with a particular emphasis on harm reduction and technological innovation.

Data Availability

The data sets used during or analyzed during this study will be available from the corresponding author upon reasonable request.

Authors' Contributions

GC, DG, PC, RM, and RP conceived and designed the study. GC, DG, and RM formalized the statistical analysis plan. GC, DG, SU, and RP drafted the manuscript. SU designed the figures and tables. All authors have provided critical revisions to the working draft and have read and approved the submitted manuscript.

Conflicts of Interest

RP is a full-time professor of internal medicine at the University of Catania (Italy) and medical director of the Institute for Internal Medicine and Clinical Immunology at the same university. He has received grants from U-BIOPRED (Unbiased Biomarkers for the Prediction of Respiratory Disease Outcomes) and AIRPROM (Airway Disease Predicting Outcomes through Patient Specific Computational Modelling); Integral Rheumatology & Immunology Specialists Network; Foundation for a Smoke-Free World; Pfizer; GlaxoSmithKline; CV Therapeutics; NeuroSearch A/S; Sandoz; Merk Sharp & Dohme; Boehringer Ingelheim; Novartis; Arbi Group Srl; Duska Therapeutics; Forest Laboratories; Ministero dell Universita' e della Ricerca (MUR) Bando PNRR 3277/2021 (CUP E63C22000900006) and 341/2022 (CUP E63C22002080006), funded by NextGenerationEU of the European Union; and the ministerial grant PON REACT-EU 2021 GREEN-Bando 3411/2021 by MUR—PNRR EU Community. He is the founder of the Center for Tobacco Prevention and Treatment at the University of Catania and of the Center of Excellence for the Acceleration of Harm Reduction at the same university. He receives consultancy fees from Pfizer, Boehringer Ingelheim, Duska Therapeutics, Forest Laboratories, CV Therapeutics, Sermo Inc, GRG Health, Clarivate Analytics, Guidepoint Expert Network, and the GLG Group. He receives textbook royalties from Elsevier and is also involved in a patent application for ECLAT Srl. He is a pro bono scientific advisor for Lega Italiana Anti Fumo and the International Network of Nicotine Consumer Organizations), and he is chair of the European Technical Committee for Standardization on "Requirements and test methods for emissions of

electronic cigarettes" (CEN/TC 437; WG4). SAP is a professional dentist and the chairman of the Board of Directors of ECLAT Srl, the spinoff of the University of Catania that sponsors this study through a grant from the Foundation for a Smoke-Free World Inc, a US nonprofit 501(c)(3) private foundation. PC has been affiliated with the Center of Excellence for the Acceleration of Harm Reduction since December 2019 in a pro bono role. He is the coauthor of a protocol paper supported by the Investigator-Initiated Study award program established by Philip Morris International in 2017.

Abstract

Background: Diabetic foot ulcers (DFUs) present a formidable challenge to both patients and health care systems. DFUs significantly reduce the quality of life for patients, prolong hospital stays, and are the cause of approximately 70,000 lower limb amputations across the globe annually. Prevention of DFUs primarily involves the optimization of blood sugar levels and the effective management of complications, particularly peripheral neuropathy. Golden Rice has been proven to lower blood sugar levels due to its beta-carotene content, and Piper crocatum (*P. crocatum*) has been found to be effective in reducing the risk factors of DFUs through biomolecular regulation because of its polyphenol content.

Objective: The principal objective of this study is to identify the efficacy of *P. crocatum*–enriched cookies, with Golden Rice as their primary ingredient, in preventing DFUs. The evaluation will center on their impact on the expression of matrix metalloproteinase-9 (MMP-9), a pivotal factor in the development of DFUs.

Methods: This study is an experimental clinical research that follows the randomized controlled trial method and uses a single-blind design. The participants in the study are outpatients from primary health centers in Makassar, Indonesia, who have been diagnosed with diabetes mellitus. The sample for the study will be randomly selected and subsequently categorized into 2 groups: the intervention group and the control group. The intervention group consumes *P. crocatum*–enriched Golden Rice cookies, while the control group receives cookies without these additives. The participants from both groups will consume their respective cookies (packaged identically) twice a day for 14 days. The cookies will be prepared according to a modified recipe with an emphasis on low glucose content, resulting in 51 calories per cookie, comprising 1% carbohydrates, 6% fat, 4% cholesterol, and 4% fiber, excluding gluten, sugar, and salt. They will be baked at 158°C for 20 minutes. The process involves the addition of 20% Golden Rice and 10% *P. crocatum* ethanol extract, both prepared via maceration with 96% ethanol. The dependent

variable in this study is the expression of gelatinases matrix metalloproteinase, to be assessed at 2 distinct time points—preintervention (pretest) and postintervention (posttest)—with the evaluation conducted through the western blotting method.

Results: The recruitment and testing phase started in January 2024. The study is scheduled to be completed by the end of March 2024. Data analysis will commence in April 2024, and the publication of the results is anticipated in the same year (2024). The study will report on the changes in primary data, encompassing gelatinases matrix metalloproteinase, as well as secondary data, including the ankle-brachial index, neuropathy score, and random blood glucose level.

Conclusions: The findings of this trial are expected to significantly impact the selection of strategies by health care practitioners to enhance diabetes self-management, particularly in the domain of therapeutic snacking, for patients diagnosed with diabetes mellitus.

KEYWORDS

diabetic foot ulcer; prevention; diabetic neuropathy; cookies; food supplement; study protocol

Introduction

Diabetic foot ulcer (DFU) is a major problem in patients with diabetes, affecting 15% of the diabetic population. DFUs significantly reduce the quality of life for patients, prolong hospital stays, and are the cause of approximately 70,000 lower limb amputations across the globe each year [1]. Diabetic foot disease is among the top 10 medical conditions in terms of burden, and it is estimated that up to 34% of individuals with diabetes will experience DFU at some point in their lives [2]. Preventing DFUs and amputations is of utmost importance to alleviate this significant burden on patients, health care systems, and society as a whole [3].

Peripheral neuropathy, the most prevalent type of diabetic neuropathy, primarily affects the nerves in the extremities, especially the feet. It accounts for 6.4% of all complications related to diabetes [4]. This condition predominantly disrupts sensory function, leading to gradual numbness, which increases the susceptibility to developing ulcers due to external injuries. It is crucial to identify these risk factors to enhance the effectiveness of preventive measures for DFUs [5]. Treating diabetic neuropathy presents a significant clinical hurdle. According to some studies, the gelatinase matrix metalloproteinase 9 (MMP-9) has been found to play a vital role in the demyelination of axons and the development of diabetic neuropathy in rodents [6,7]. As gelatinase MMP-9 plays a pivotal role in the initial onset of neuropathy, it is considered crucial in the progression of diabetic neuropathy and could potentially be targeted for treatment purposes [6,7].

Elevated levels of blood sugar and insulin resistance in patients with type 2 diabetes further contribute to the generation of reactive oxygen species (ROS), which intensifies the complications associated with this disease [8]. The activity of vascular MMP-9 is heightened in individuals with diabetes mellitus, partly due to increased production by vascular endothelial cells. Additionally, the activity of ROS plays a significant role in this process [9]. The high levels of ROS and MMP-9 have been found to be associated with glycemic index and diabetes complications [10].

Different types of diabetic-friendly cookies and breads are already in circulation, such as cassava bread, flax meal powder, and grape seed oil bread. However, their purpose is solely to limit glucose intake rather than directly affecting insulin levels. In contrast, noncookie products made with Golden Rice as the main ingredient contain beta-carotene, which can stimulate insulin production in the body by boosting the beta pancreas and decreasing the glycemic index [11]. However, the reduction in glycemic index needs to be supported by the biomolecular environment as an effort to prevent DFUs. The suitable herbal ingredient for combination in these cookies is *Piper crocatum (P. crocatum*). The oral consumption of *P. crocatum*, belonging to the Piperaceae family, has been proven safe among the population in Indonesia [12].

The use of *P. crocatum* has been documented to exhibit numerous therapeutic activities, such as anti-inflammatory effects. It has shown to reduce the expression of tumor necrosis factor alpha, nitric oxide, and interleukin-1β in a liver injury model using rats [13]. In addition, *P. crocatum* also exhibits wound healing activities by increasing the expression of superoxide dismutase 1, alpha-smooth muscle actin, and E-cadherin, and reducing p53 in hyperglycemic fibroblasts [14]. It has antibacterial properties when used topically [15]. *P. crocatum* acts as an antioxidant by reducing the expression of ROS and increasing glutathione peroxidase and cytochrome P450 2E1 [16]. It also demonstrates antihyperglycemic effects when administered orally [17].

Based on relevant studies on *P. crocatum* and its various mechanisms, *P. crocatum* can be used as a base ingredient for cookie-based therapies for the prevention of DFU. If the reduction of MMP-9 is recognized as a beneficial therapeutic target for DFU treatment [18], MMP-9 would also be a favorable target for DFU prevention. This is because the activity and expression of vascular MMP-9 in patients with diabetes mellitus are inherently elevated [19]. Furthermore, the gelatinase MMP-9 plays a crucial role in the pathogenesis of diabetic neuropathy through axonal demyelination, which is one of the risk factors for DFU [6]. Therefore, this study aims to identify the effectiveness of *P. crocatum* cookies with Golden Rice as the

main ingredient for preventing DFUs through the regulation mechanism of MMP-9.

Methods

Study Design

This randomized controlled trial will be conducted at a public health center in Makassar, Indonesia, following a 2-arm, parallel-group, randomized, double-blind, placebo-controlled design. The study protocol was developed in accordance with the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) 2013 checklist (Multimedia Appendix 1). Figure 1 shows the flowchart detailing participant enrollment, allocation, intervention, and assessment, and Table 1 presents the participant timeline.

Outcomes

The main focus of this study, or the primary outcome, is determining the level of MMP-9. The secondary outcomes include examining neuropathy scores and ankle-brachial index (ABI) as well as assessing random blood glucose.

Randomization and Blinding

After obtaining informed consent and discussing the research objectives, a total of 60 eligible participants will be divided into 2 equal groups. Block randomization with a 1:1 allocation ratio will be used. An assistant will conduct the block randomization, ensuring that both the investigators and participants remain blinded to the intervention allocation. The sequence of the blocks will be generated using a random numbers table. All participants will be randomly assigned to either the intervention group or the placebo group. The manufacturer responsible for preparing the supplements will be requested to label the cans containing either therapeutic cookies or placebos with a unique code.

Sample Size Calculation

With a significance level (type 1 error) of 5% and a statistical power of 90%, the sample size for each study group will be calculated to be 25, using a 2-sided *t* test, taking into account the changes in MMP-9 values as one of the primary outcomes [20]. We will clarify that the block lengths in our randomization process will be constant. To account for an estimated attrition rate of approximately 20% during the study, the final sample size will be increased to 30 participants in each group. The estimation of the sample size is calculated using the following formula:

In this formula, α=5%, 1-β=90%, SD1=2.7, SD2=2.7, *d*=2.5.

Cookies Production

Cookies will be created by following the formula provided by Olawoye et al [21], with some modifications. They will be made with a low glucose ingredient composition, resulting in each cookie containing 51 calories, with a composition of 1% carbohydrates, 6% fat, 4% cholesterol, and 4% fiber, free from gluten, sugar, and salt. Following the optimal conditions for producing gluten-free cookies for patients with diabetes, the cookies are baked at a temperature of 158°C for 20 minutes. The procedure is modified by incorporating 20% Golden Rice extract and 10% *P. crocatum* ethanol extract. Each extract will be prepared using the maceration method with 96% ethanol, and its yield will be calculated. The specific details of the *P. crocatum* extraction procedure are mentioned in a previous study [14].

Intervention

A total of 60 eligible participants diagnosed with type 2 diabetes will be assigned randomly to either the therapeutic cookies group (n=30) or the placebo group (n=30). Over 14 weeks, participants in the intervention group will take therapeutic cookies (20 g) twice daily, while participants in the control group will take identical placebo cookies. The therapeutic cookies will be provided by Evelyn Food Supplement company,

chosen for their reputation for providing high-quality, standardized ingredients, which is essential for the integrity of the study. Both therapeutic and placebo cookies will be indistinguishable in terms of weight, size, shape, taste, color, and odor. The placebo cookies are also produced by Evelyn Food Supplement company. The choice of company was made to maintain the highest research standards and to ensure that there are no conflicts of interest, financial support, or other compensation for the researchers.

The trial will consist of 3 study visits: before the intervention, 1 week after the intervention, and at the end of the intervention period. Study participants will receive instructions on how to use their supplements and will be followed up with phone calls every 3 days throughout the study. Compliance will be assessed by evaluating the number of unused supplements returned by each individual, with the remaining cookies counted to determine total supplement intake. Additionally, participants will be asked to maintain a reporting diary to document any adverse events experienced following the consumption of therapeutic cookies. If any adverse events are attributed to the consumption of therapeutic cookies, participants will be instructed to discontinue taking the supplements and will be promptly referred to a specialist for appropriate treatment. The study participants will not receive any specific dietary recommendations or dietary regimens.

Blood Sample Collection

Blood samples for the identification of MMP-9 will be collected from each participant at a specific time point in the morning, following an overnight fast. The samples will be drawn at approximately 8 AM to ensure consistency and minimize potential variations in MMP-9 levels due to diurnal rhythms. This fasting state collection will aim to provide a baseline measurement of MMP-9 levels. Additionally, blood samples will be collected both before and after the intervention involving the administration of cookies to assess potential changes in MMP-9 levels in response to the intervention.

Measures and Measurements

Demographic Questions

Participants will be requested to provide information about their gender, age, marital status, the medication and herbs currently being consumed, profession, educational level, distance from the place of residence to the nearest health care service, residence in a city or rural area, duration of having diabetes, and any other diseases or illnesses experienced.

Primary Outcome

A blood sample of 5 mL will be collected, and the samples will be centrifuged at 3000 rpm for 5 minutes to separate the serum samples before and after the intervention. The levels of MMP-9 will be determined using western blotting in triplicate. Proteins will be extracted using M-PER Mammalian Protein Extraction Reagent (Thermo; catalog number 87785) according to the manufacturer's instructions. Protein quantification will be performed using Pierce 660 nm protein assay reagent (Thermo; catalog number 22660). The proteins will be separated on a 10% sodium dodecyl sulfate-polyacrylamide gel electrophoresis and transferred to a polyvinylidene fluoride membrane (Immun-Blot, Bio-Rad). Then, the membrane will be incubated with specific primary antibodies, including anti–MMP-9 (catalog number EP1254; anti-rabbit; 1:500 dilution) and anti–β-actin (catalog number ab8227; anti-rabbit; 1:1000 dilution). Blocking will be performed using 5% skim milk in Tris-Buffered Saline with Tween 20, followed by incubation with the appropriate secondary antibody. The protein bands will be visualized using enhanced chemiluminescence Prime Western Blotting Detection Reagents (GE Health Care; catalog number RPN2232), and the blots will be captured using a Gel Doc machine (Geldoc Syngene Gbox Seri Chemi xrq) [22].

Secondary Outcomes

The secondary outcomes include examining neuropathy score, ABI, and random blood glucose. The neuropathy score will be assessed following a previous study [23], using a 10-g Semmes-Weinstein Monofilament. During the monofilament testing, the participants will be instructed to lie flat on the examination table. To ensure that they could not see their feet, a standard monofilament (5.07/10-gram Semmes-Weinstein nylon monofilament) will be used to lightly apply pressure to three specific areas of the participants' feet: (1) the underside of the first metatarsal head, (2) the underside of the fifth metatarsal head, and (3) the top surface between the first and second metatarsals. The monofilament will be positioned on the foot's surface, forming a perpendicular angle with the skin. The pressure will be gradually intensified until the filament is bent, indicating the application of a predetermined level of pressure. The sites will be examined in a random order, rather than following a specific sequence. If the examinee provided the correct response at any site during the test, further testing at that site was not necessary. However, if the examinee could not correctly identify the interval in which the stimulus was applied, the test would be repeated at that site up to 2 times, aiming to obtain 2 similar correct responses. A site will be considered sensate if either the first response is correct or 2 out of 3 tests yield a correct response. On the other hand, a site will be classified as insensate if there are 2 incorrect responses and 2 "unable to determine" responses or 1 incorrect response and 1 "unable to determine" response. The presence of an insensate area at any of the 3 sites indicates a positive result for peripheral neuropathy in the monofilament test [24,25].

The ABI will be determined by measuring the systolic blood pressure in the arm and leg after a 10-minute rest in a supine position, with both arms and legs straight and relaxed [26]. Manual cuffs will be used for all blood pressure measurements, and the appropriate cuff size will be selected based on the arm circumference determined during screening. The same cuff size will be used for the lower leg, and a straight wrapping technique will be employed. The arm blood pressure will be measured using a sphygmomanometer along with an 8 MHz Doppler device to detect pulses. A single measurement will be taken at each of the 6 sites in the following sequence: left arm, left ankle (dorsalis pedis and posterior tibialis), right arm, and right ankle. The right ABI will be calculated by dividing the higher-pressure measurement from the right ankle (dorsalis pedis or posterior tibialis) by the higher brachial pressure (right or left side). The left ABI will be calculated using a similar method. The lower

ratio from either side will be considered as the participant's ABI [27].

To evaluate the random blood glucose levels, blood samples will be obtained from the capillary of the index finger for each patient. Subsequently, the Accu-Chek Active glucometer, a device manufactured in Germany, will be used to measure the samples, and the recorded values will be documented [28].

Statistical Analyses

The demographic characteristics of all participants will be summarized using descriptive statistics, such as means (SDs), frequencies, and ranges, which will be presented in a tabular form. Statistical analysis of the data will be performed using the SPSS statistical software (version 2, SPSS Inc). $P<.05$ will be considered statistically significant. The normality of the data will be assessed using the Kolmogorov-Smirnov test. Numerical variables will be presented as mean (SD) or median (IQR) values, while categorical variables will be presented as frequency (percentages). To determine differences in numerical variables between the therapeutic cookies and placebo groups, independent sample *t* tests or Mann-Whitney *U* tests will be used. The same tests will also be used to compare alterations in outcome variables between the 2 groups. For within-group comparisons, paired-sample *t* tests or the nonparametric Wilcoxon test will be used. To account for the effects of confounding factors, a general linear model will be applied. In addition, analysis of covariance will be used to account for the effects of confounding factors when appropriate.

Ethical Considerations

Prior to the commencement of this study, ethical review and approval were obtained from the local ethical committee of the Public Health Faculty of Universitas Hasanuddin, Makassar, Indonesia (approval number 10973/UN4.14.1/TP.01.02/2023). This study adheres to all applicable ethical guidelines and regulations governing research involving human subjects.

Informed consent was obtained orally from all participants involved in the primary and data collection. In the case of secondary analyses of research data, the original informed consent, as approved by the institutional review board, explicitly allowed for secondary analyses without the need for additional consent. Participants were informed that their data would be used for research purposes beyond the initial study.

The privacy and confidentiality of participants in this research were rigorously protected. All data collected were anonymized or deidentified to ensure the confidentiality of participants. Any personal identifying information was removed, and data were stored securely to prevent unauthorized access.

Participants received compensation in the form of monetary compensation for their time and participation. The compensation amount was set at IDR 100,000/week (US $7-8/week) and was disclosed to participants during the informed consent process.

The study has been registered on the Thai Clinical Trials Registry website (TCTR20230502001). Any changes to the study protocol will be communicated to the Trials journal.

Results

The recruitment and testing phase started in January 2024. The study is scheduled to be completed by the end of March 2024. Data analysis will commence in April 2024, and the publication of the results is anticipated in the same year (2024).

Discussion

Expected Outcomes

This study focuses on the significant issue of DFUs in patients with diabetes and the importance of preventing DFUs and associated amputations. DFUs affect approximately 6.4% of the global diabetic population [29], reduce quality of life, prolong hospital stays, and lead to a considerable number of lower limb amputations globally each year [30]. Notably, peripheral neuropathy, the most prevalent type of diabetic neuropathy, plays a critical role in the development of DFUs due to its impact on sensory function and increased susceptibility to ulcers [31].

In the realm of diabetic neuropathy, MMP-9 is considered crucial in its progression and holds a potential target for treatment purposes [32]. Furthermore, it is important to acknowledge that elevated blood sugar levels and insulin resistance in diabetes contribute to the generation of ROS, intensifying the complications associated with the disease [33]. The activity of MMP-9 is heightened in individuals with diabetes, partially due to increased production by vascular endothelial cells and the influence of ROS [33].

MMP-9 plays a role in increasing tissue inflammation, which is one of the contributing factors to diabetic neuropathy [32]. By reducing MMP-9 activity, we can decrease inflammation that harms peripheral nerves. MMP-9 can damage blood vessel walls, leading to impaired blood circulation to nerves [34]. Reducing vascular damage can enhance blood flow to nerves, aiding in the prevention of neuropathy. Additionally, MMP-9 can harm the extracellular matrix surrounding nerve cells. If MMP-9 is reduced, the extracellular matrix may be better preserved, offering improved protection against nerve damage. Excessive MMP-9 activity has been linked to apoptosis or nerve cell death [35]. By reducing MMP-9 activity, we can help safeguard nerve cells from death, which contributes to neuropathy. Furthermore, MMP-9 can contribute to nerve degeneration and loss of nerve function. Lowering MMP-9 can assist in slowing down or halting this degenerative process [36].

The main interest of this study is the concept of diabetic-friendly cookies, which can stimulate insulin production in the body by boosting the beta pancreas and decreasing the glycemic index through the mechanism of MMP-9 reduction. To further support the reduction in glycemic index and prevent DFU, the suitable herbal ingredients for combination in these cookies are Golden Rice and *P. crocatum*. They are known for their safety and therapeutic activities, such as anti-inflammatory effects, wound healing activities, antibacterial properties, antioxidant effects, and antihyperglycemic effects. The oral consumption of *P. crocatum* and Golden Rice extracts has been proven to be safe in humans. A functional beverage containing *P. crocatum* was

developed, demonstrating significant antioxidant and antidiabetic properties, and it was acceptable by consumers [37]. A recent study has also identified the use of *P. crocatum* as a healthy food and drink option for reducing blood sugar levels in patients with diabetes mellitus [38].

The reduction of MMP-9 as the study objective may not be sufficient to completely prevent diabetic neuropathy, as this disease is highly complex and involves numerous factors. However, reducing MMP-9 can be a potentially helpful step in mitigating the risk and impact of diabetic neuropathy, particularly when combined with other appropriate treatment approaches.

This study explores the biological mechanisms underlying diabetic neuropathy and the potential role of MMP-9, providing valuable insights into the pathophysiology of DFUs and potential therapeutic targets. The safety and acceptance of *P. crocatum* and Golden Rice extracts in humans, as demonstrated in previous studies, support the feasibility of incorporating these ingredients into dietary interventions to prevent DFUs.

Although this study delves into biological mechanisms and potential therapeutic interventions, the translation of these laboratory findings into clinical applications may require further research and clinical trials. The study may have limitations regarding the generalizability of its findings. It is essential to acknowledge that dietary interventions may have varying effects on individuals with different demographics, comorbidities, and genetic factors. The study duration is also considered a limitation, as it does not cover a long-term assessment of the effects of cookies and herbal ingredients.

Conclusions

In conclusion, the findings of this study hold the potential to significantly influence the strategies used by health care practitioners in enhancing diabetes self-management, particularly in the domain of therapeutic snacking, for patients diagnosed with diabetes mellitus. Considering the substantial burden of DFUs on patients, health care systems, and society, it is crucial to focus on preventing DFUs and amputations. Exploring potential therapeutic targets like MMP-9 and using natural ingredients like *P. crocatum* in combination with other diabetes-friendly products may provide promising avenues for preventing DFUs and improving the outcomes for patients with diabetes. Further research and clinical trials would be necessary to validate the efficacy and safety of such interventions. These insights can inform the selection of strategies for health care practitioners to enhance diabetes self-management, thereby benefiting patients with diabetes mellitus.

Acknowledgments

This research was funded by the Research and Community Service Institute of Hasanuddin University. However, the institution had no role in the study design; collection, management, analysis, and interpretation of data; writing of the report; and the decision to submit the report for publication.

The authors would like to express their gratitude to all participants for their valuable contributions.

Data Availability

The data sets generated and analyzed during this study are not publicly available due to patient confidentiality concerns but are available from the corresponding author upon reasonable request. All requests will be subject to review and approval on a case-by-case basis. We are dedicated to making the data available, where possible, while ensuring the protection of participants' confidentiality and privacy.

Abstract

Background: The optimal educational approach for preparing health professionals with the knowledge and skills to effectively recognize and respond to family violence, including child maltreatment and intimate partner violence, remains unclear. The Violence, Evidence, Guidance, and Action (VEGA) Family Violence Education Resources is a novel intervention that can be completed via self-directed learning or in a workshop format; both approaches focus on improving health professional preparedness to address family violence.

Objective: Our studies aim to determine the acceptability and feasibility of conducting a randomized controlled trial to evaluate the effectiveness of the self-directed (experimental intervention) and workshop (active control) modalities of VEGA, as an adjunct to standard education, to improve learner (*Researching the Impact of Service provider Education [RISE] with Residents*) and independent practice (*RISE with Veterans*) health professional preparedness, knowledge, and skills related to recognizing family violence in their health care encounters.

Methods: The *RISE with Residents* and *RISE with Veterans* research studies use embedded experimental mixed methods research designs. The quantitative strand for each study follows the principles of a pilot randomized controlled trial. For *RISE with Residents*, we aimed to recruit 80 postgraduate medical trainees; for *RISE with Veterans*, we intended to recruit 80 health professionals who work or have worked with Veterans (or their family members) of the Canadian military or the Royal Canadian Mounted Police in a direct service capacity. Participants complete quantitative assessments at baseline, after intervention, and at 3-month follow-up. A subset of participants from each arm also undergoes a qualitative semistructured interview with the aim of describing participants' perceptions of the value and impact of each VEGA modality, as well as research burden. Scores on potential outcome measures will be mapped to excerpts of qualitative data via a mixed methods joint display to aid in the interpretation of findings.

Results: We consented 71 individuals to participate in the *RISE with Residents* study. Data collection was completed on August 31, 2023, and data are currently being cleaned and prepared for analysis. As of January 15, 2024, we consented 34 individuals in the *RISE with Veterans* study; data collection will be completed in March 2024. For both studies, no data analysis had taken place at the time of manuscript submission. Results will be disseminated through peer-reviewed publications; academic conferences; and posting and sharing of study summaries and infographics on social media, the project website, and via professional network listserves.

Conclusions: Reducing the impacts of family violence remains a pressing public health challenge. Both research studies will provide a valuable methodological contribution about the feasibility of trial methods in health professions education focused on family violence. They will also contribute to education science about the differences in the effectiveness of self-directed versus facilitator-led learning strategies.

Introduction

Background

The prevention of family violence, which includes intimate partner violence (IPV) and child maltreatment, remains a global public health priority. IPV encompasses a range of behaviors by a current or former romantic or sexual partner that causes or can cause physical, psychological, or sexual harm, including physical assault or violence, sexual coercion or assault, threats of harm, stalking or surveillance, and verbal degradation or humiliation [1]. Child maltreatment refers to adverse caregiver or parent behavior, including physical, sexual, or emotional abuse; physical or emotional neglect; coercive control; and exposure to IPV between adult caregivers, which result in actual or potential physical or emotional harm to the child. Globally, up to 1 in 3 children are exposed to at least 1 form of maltreatment before the age of 18 years [2-4]. Similarly, 27% of ever-partnered women between the ages of 15 and 29 years will experience IPV in their lifetime, with 24% of women aged 15-19 years and 26% of women aged 19-24 years having experienced IPV before the age of 15 years [5]. The literature details a significant and positive association between exposure to child maltreatment and increased vulnerability to IPV victimization over the life course [6,7]. In addition, a fulsome and consistent body of evidence demonstrates that exposure to child maltreatment or IPV is associated with a range of health-risk behaviors and negative health outcomes, including significantly elevated risk for early-onset smoking and alcohol use, teen pregnancy, underimmunization, obesity, heart disease, chronic pain conditions, substance abuse, suicide attempts, posttraumatic stress disorder, eating disorders, depression, anxiety, among others [1,8-10]. Importantly, the prevalence of child maltreatment and IPV in families of Active Duty and Veteran service members is even higher. For example, nearly 63% of Active Duty and Veteran members of the Canadian Armed Forces (CAF) report exposure to maltreatment in childhood [11], and upward of 25% of Active Duty or Veteran members of the CAF (or whose partner is a member or a Veteran of the CAF) self-report IPV victimization or perpetration in their lifetime [12-14]. Among this subgroup of the population, a history of child maltreatment or IPV exposure is also associated with a range of physical and mental health disorders, which can be exacerbated by deployment-related traumatic experiences, including military sexual trauma; receipt of incoming artillery, rocket, or mortar fire; or knowing someone seriously injured or killed while deployed [11,15].

Critically, a growing compilation of clinical guidance and guidelines indicates that the probability for negative health outcomes related to family violence exposure, including child maltreatment and IPV, can be attenuated via early interaction with a health care professional that is considerate and who prioritizes not only physical and emotional safety in the health care encounter but also the broader social, psychological, and physical health needs of an exposed patient [4,16-20]. For this reason, health professionals have been identified as having an essential role in family violence prevention via recognizing and responding to this exposure and its associated sequelae in their health care practice. Unfortunately, several studies detail uniform challenges to family violence recognition and response across the health professions, including limited formal curriculum during preservice training, discomfort and a lack of confidence related to asking about and responding to family violence disclosures, and the perception that there is insufficient time to adequately address family violence disclosures in health care practice [21]. Paralleling these barriers is a dearth of evidence regarding how to best prepare health professionals with the knowledge and skills to effectively recognize and respond to suspected or disclosed family violence exposures in health care contexts [21,22]. It is also unclear whether family violence education efforts should be optimally targeted to preservice versus in-service health professionals, nor is it clear the extent to which repeated exposure to family violence curriculum is necessary to achieve and maintain professional competencies in this area.

Broadly, educational interventions focusing on family violence, which have been evaluated in undergraduate, postgraduate, and continuing education contexts, vary in their instructional approaches and often fail to consider active controls in their research designs [22-27]. In addition, there has been limited emphasis on developing and evaluating interventions that address the complex overlap between IPV, children's exposure to IPV, and other forms of child maltreatment [28,29]. Given the prevalence, overlap, and health-related burdens of child maltreatment, IPV, and children's exposure to IPV, there is an urgent need to identify empirically supported educational interventions that adequately prepare the health professionals to care for individuals and families impacted by all forms of family violence. Additionally, the field of health professions

education stands to benefit from research studies that provide evidence for the optimal educational approach (eg, self-directed learning vs facilitator-based approaches) to improve health professionals' knowledge and skills in complex areas, such as family violence. This methodological contribution can also offer guidance on whether the optimal educational approach varies according to the health professional's status as a learner or an independent practitioner.

Aims

The objective of our 2 complementary studies are to determine the acceptability and feasibility of conducting a randomized controlled trial (RCT) to evaluate the effectiveness of the self-directed (experimental intervention) and workshop (active control) modalities of the Violence, Evidence, Guidance, and Action (VEGA) Family Violence Education Resources [30], as an adjunct to standard education, to improve learner (*Researching the Impact of Service provider Education [RISE] with Residents*) and independent practice (*RISE with Veterans*) health professional preparedness, knowledge, and skills related to recognizing family violence in their health care encounters. Detailed information about the VEGA Family Violence Education Resources (hereafter referred to as "VEGA") is available on the web [31] and in the *Methods* section. Briefly, VEGA was developed based on systematic reviews and consultations with members of 22 national health care and social service organizations in Canada [30]. VEGA is a web-based suite of resources that uses a participatory, encounter-focused curriculum across 4 learning modules that focus on the following areas of family violence: (1) the epidemiology of child maltreatment, IPV, and children's exposure to IPV in Canada; (2) evidence-informed strategies for safely recognizing and responding to (a) child maltreatment and (b) IPV (including children's exposure to IPV) in health care encounters; and (3) principles for ensuring physical and emotionally safe health care encounters for family violence discussions [30]. VEGA can be completed as a self-directed educational activity (ie, self-directed VEGA) via completion of the web-based modules at the learner's own pace, or as a remote or face-to-face workshop (ie, workshop VEGA). VEGA workshops are delivered by trained facilitators who are also regulated and practicing health care professionals; both self-directed VEGA and workshop VEGA take approximately 3 hours to complete [21,30].

Methods

Study Design

The *RISE with Residents* and *RISE with Veterans* research studies use quantitatively dominant, embedded experimental mixed methods research design ("QUAN(qual)") [32]. The use of this design allows for the measurement of important acceptability and feasibility metrics related to enrollment, retention, attrition, and data completeness and the generation of exploratory estimates of the education effect for both VEGA modalities. This design also allows for the systematic collection of qualitative data to provide important contextual information regarding the tenability of a full RCT, as well as a description of how VEGA modalities influence any measured changes in health professional preparedness, knowledge, and skills related to recognizing and responding to family violence. Given the cost and complexity of implementing RCTs, as well as well-documented challenges related to recruiting and retaining health professionals in clinical and education research [33-35], pilot randomized studies that allow for responsive amendments to recruitment, retention, and data collection are an imperative proviso to reduce the possibility of failed or incomplete phase-3 RCTs [36-38].

Quantitative Strand of Data Collection

Quantitative Design and Participants

The quantitative research design for both studies follows the principles of a 2-armed pilot RCT [37,38]. Figures 1 and 2 detail the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) flow diagrams for *RISE with Residents* and *RISE with Veterans*, respectively [39,40]. For *RISE with Residents*, we aimed to recruit a voluntary sample of 80 participants from postgraduate medical residency programs in psychiatry or pediatrics in Ontario, Canada. Directors of each program were asked to circulate recruitment-related materials to their respective program residents, requesting that interested individuals contact the research team to determine eligibility and complete consenting procedures. For *RISE with Veterans*, we aimed to recruit a voluntary sample of 80 health professionals who currently work or have worked in a direct service capacity with Veterans of the Canadian military or the Royal Canadian Mounted Police (RCMP), or their family members, to participate. Directors of Veteran-serving programs, agencies, and organizations had the opportunity to meet with members of the research team to discuss the components of the study and were asked to distribute recruitment materials to potentially eligible staff. Recruitment materials requested that those who were interested in participating contact the research team.

Figure 1. RISE with Residents SPIRIT flow diagram. RISE: Researching the Impact of Service provider Education; SPIRIT: Standard Protocol Items: Recommendations for Interventional Trials; VEGA: Violence, Evidence, Guidance, and Action.

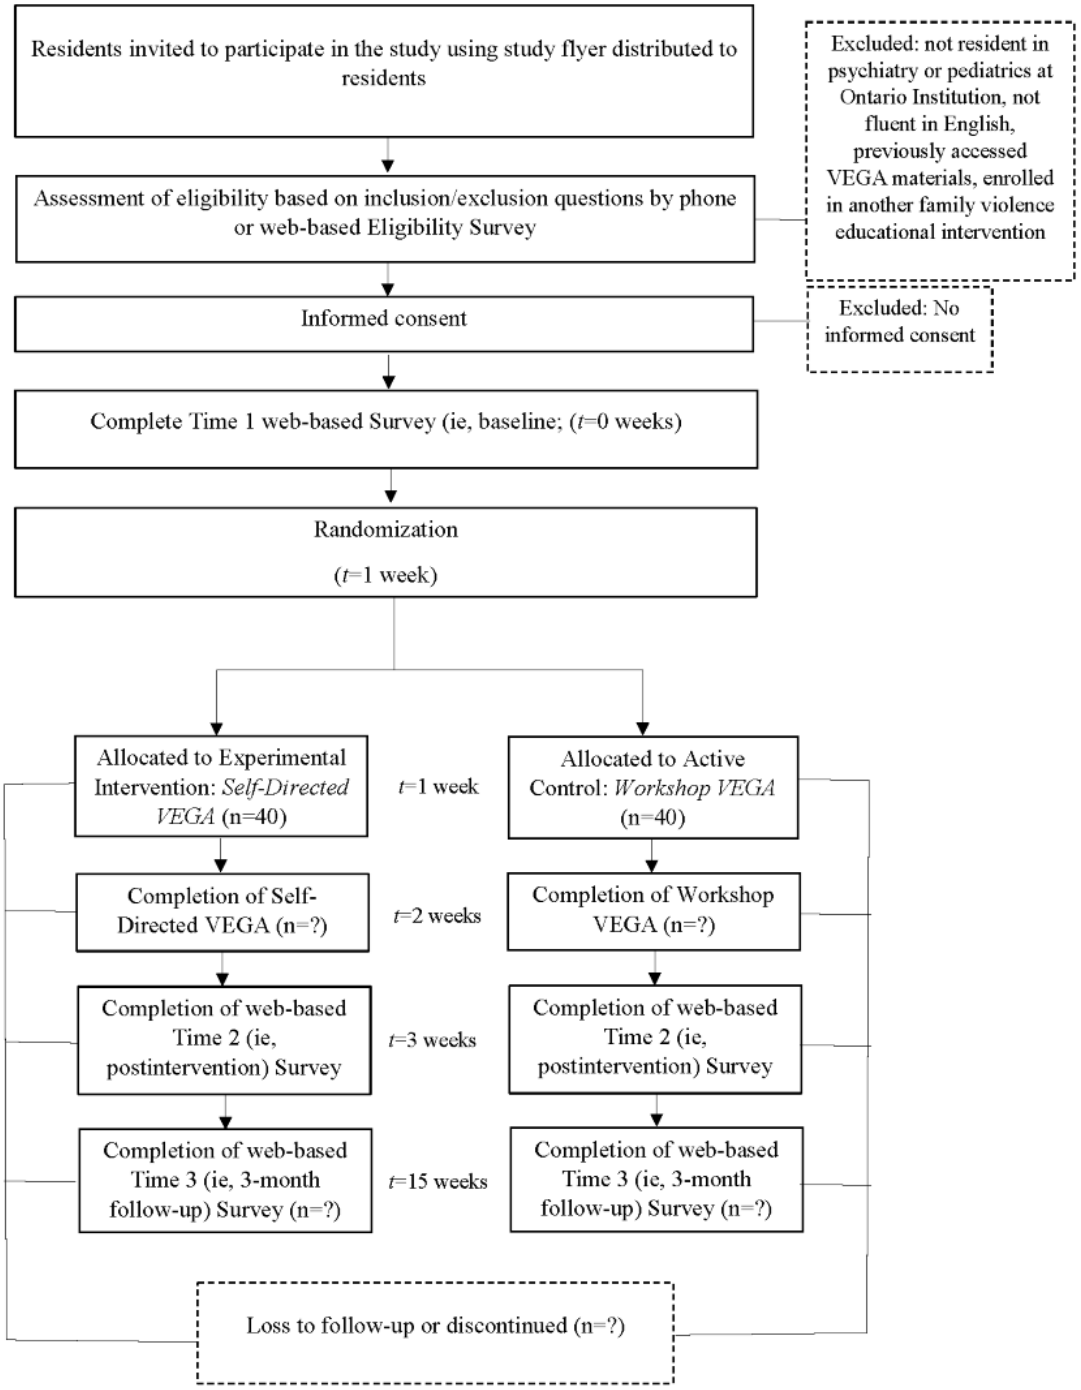

Figure 2. RISE with Veterans SPIRIT flow diagram. RISE: Researching the Impact of Service provider Education; SPIRIT: Standard Protocol Items: Recommendations for Interventional Trials; VEGA: Violence, Evidence, Guidance, Action.

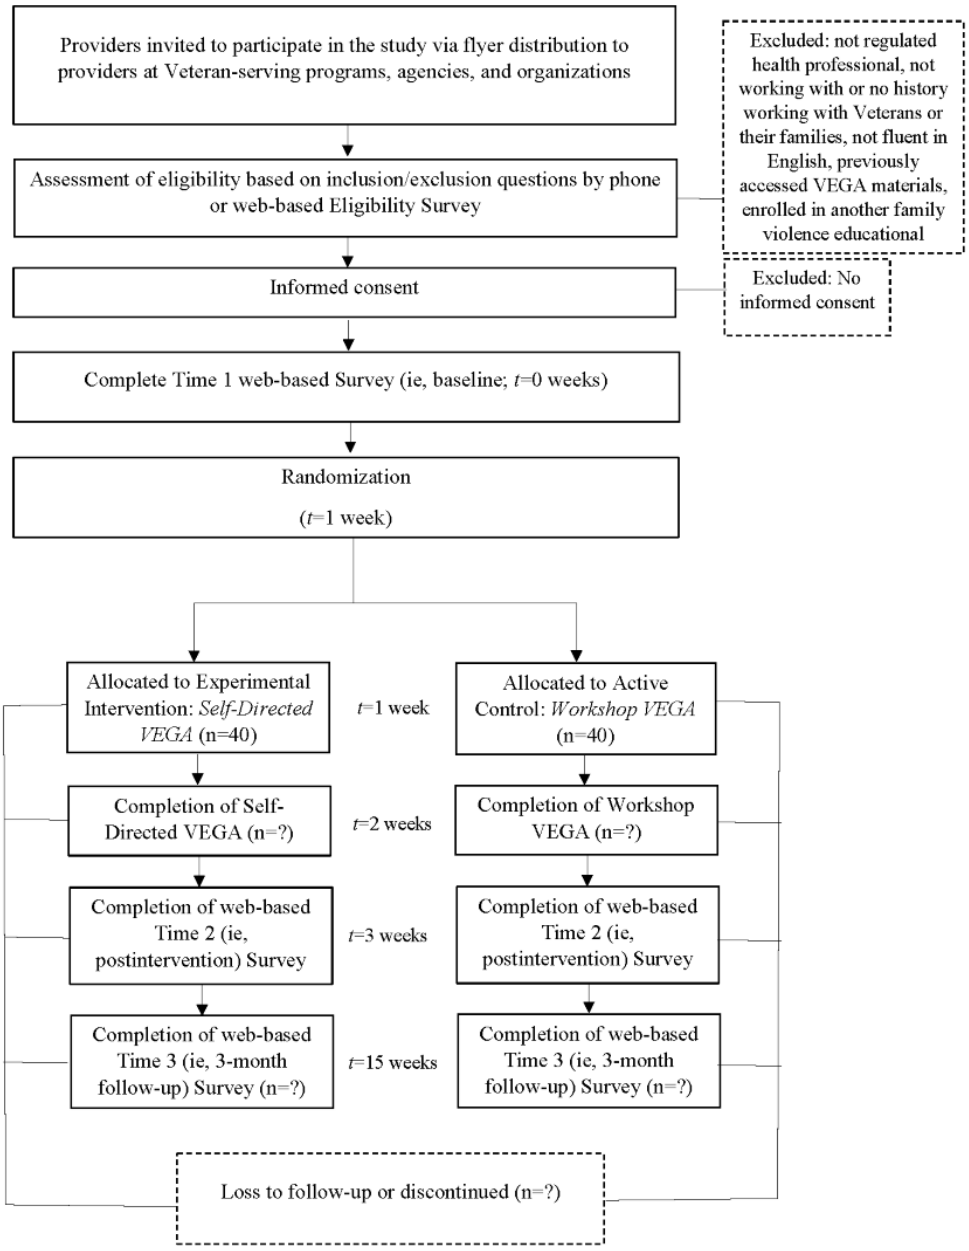

Eligibility Criteria

Eligibility screening was completed over the phone with the study research coordinator (RC) or electronically via REDCap (Research Electronic Data Capture; Vanderbilt University) using the eligibility criteria outlined in Textbox 1. At this time, we also collected sociodemographic characteristics of participants, including age, sex at birth, and self-identified gender. For *RISE with Residents*, we also included information about their residency program; *RISE with Veterans* additionally asked questions about the organization the participants work for, whether they work directly with Veterans of the military or the RCMP, or their family members, and if the latter, whether consent is required by the Veteran for the participant to provide services to the Veteran's family member. We obtained consent from potential participants to keep their responses to the screening measures in cases they were ineligible or did not end up participating in the study. This was for the purpose of comparing those who end up participating with those who do not end up participating to understand if our criteria are systematically excluding any groups. After completing screening, individuals were informed of their eligibility to participate and underwent an electronic informed consent process to participate in the remainder of research activities. Potential participants were provided the option to speak with a member of the research team to review any questions about the consent procedures and research process.

Textbox 1. Eligibility criteria.

Inclusion criteria

- *Researching the Impact of Service provider Education (RISE) with Residents*
  - Physician resident enrolled in a postgraduate medical residency program in psychiatry or pediatrics within Ontario, Canada
  - Willing and able to provide informed written consent and complete all project activities in English
- *RISE with Veterans*
  - 18 years of age or older
  - Regulated health care or social service professional
  - Working with military or Royal Canadian Mounted Police (RCMP) Veterans, or military or RCMP Veteran's family members in a direct service capacity at least 1 day per week

    OR

    Have 2 years of experience working with military or RCMP Veterans, or their family members, in a direct service capacity

    OR

    Have worked with 15 or more clients or patients who were either military or RCMP Veterans, or their family members, in a direct service capacity
  - Willing and able to provide informed written consent and complete all project activities in English

Exclusion criteria

- *RISE with Residents*
  - Have previously accessed the Violence, Evidence, Guidance, and Action (VEGA) web-based or workshop materials
  - Are currently enrolled in or expected to enroll in any other educational intervention focused on family violence (intimate partner violence [IPV], child maltreatment, childhood exposure to IPV) within the study time period
- *RISE with Veterans*
  - Have previously accessed the VEGA materials
  - Are currently enrolled in or expected to enroll in any other educational intervention focused on family violence (IPV, child maltreatment, or childhood exposure to IPV) within the study time period

Randomization and Concealment

Randomization occurred after consent has been obtained and the web-based baseline survey (ie, time 1 survey, see below) is complete. To reduce the possibility of "availability bias," we required the accumulation of 20 consenting participants who indicated their availability to attend a VEGA workshop before randomization, as each VEGA workshop requires a minimum of 10 participants. The cohort of 20 consenting participants were then randomly assigned to the experimental (ie, self-directed VEGA) or active control (ie, workshop VEGA) condition using stratified block randomization [41] with a block size of 4 (blocking factor of 2), using a third-party, internet-based randomization service, Randomize.net. For *RISE with Residents*, randomization was stratified based on two variables: (1) sex at birth (female, male, intersex, or prefer not to answer) and (2) discipline (pediatrics vs psychiatry). For *RISE with Veterans*, randomization was stratified based on sex at birth only. Sex at birth, as opposed to gender identity, was selected as the stratification variable because of a limited number of categories needed to achieve balance across trial arms. The analysis section outlines our proposed approach to disaggregate sex- and gender-based data after the conclusion of both studies.

Masking

Given the nature of experimental and control arms, it is impossible to conceal allocation status from participants, as well as the facilitators of the active control arm (ie, workshop VEGA). Participants were informed of their allocation status by the RC. The RC did not reveal participant allocation status to the study research assistant, the latter of whom was responsible for ensuring quantitative data collection. Participants were also encouraged not to inform the research assistant of their allocation status.

Intervention

VEGA Family Violence Education Resources

Time for completion of self-directed VEGA or workshop VEGA is approximately 3 hours, and pedagogical elements for both approaches have been informed by education scholarship (see Table 1) [42-51]. Participants had or have the option of completing self-directed VEGA in either English or French as the VEGA website offers the content in both languages. Workshop VEGA is delivered in English only in a remote or in-person workshop format by trained facilitators who are regulated health professionals. VEGA workshops are

recommended to have a 10:1 participant-to-facilitator ratio and are standardized via the use of a flexibly structured facilitator guide [30].

Table 1. Pedagogical elements of self-directed VEGA (ie, experimental arm) and workshop VEGA (ie, active control arm) educational approaches.

Pedagogical elements	Self-directed VEGA[a] (experimental arm)	Workshop VEGA (active control arm)
Didactic material [48]	Asynchronous reading	Synchronous lecturing with 2 facilitators
Deliberate practice [49,50]	Case-based animated simulations	Case-based role play
Enabling learning tools [51]	Remote patients, clinical handbook, clinical scripts	Remote patients, clinical handbook, clinical scripts
Test-enhanced learning [46]	Individual multiple-choice questions with response feedback	Group-based polling (ie, multiple-choice) and feedback

[a]VEGA: Violence, Evidence, Guidance, and Action.

Experimental Arm (Self-Directed VEGA)

If a participant is randomized to the experimental arm, they will be or were asked to complete self-directed VEGA at their convenience, within 1 week of being informed of their allocation status. To complete the intervention, individuals are asked to register their access to the VEGA Resources and review and complete all module activities at their own pace during the weeklong intervention period [30].

Active Control Arm (Workshop VEGA)

If a participant is randomized to the active control arm, they will be or were informed that they need to attend a remote VEGA workshop. Because of COVID-19 restrictions in place at the outset of both studies, VEGA workshops take place via Zoom and are delivered by 2 trained facilitators. Workshops include 10 to 20 participants, keeping the recommended 10:1 participant-to-facilitator ratio, and last 3 hours [30].

Intervention Adherence

Intervention adherence is monitored by the RC. The RC has received or will receive attendance reports for participants allocated to VEGA workshops from the VEGA project team, who will also provide the research team confirmation of whether self-directed participants completed the “Self-Declaration of Module Completion Form” embedded within the self-directed VEGA website. Self-directed VEGA participants receive email reminders from the RC every 2 days to complete the modules within the intervention window [30].

Data Collection

The primary outcomes for the *RISE with Residents* and *RISE with Veterans* research studies are related to the acceptability and feasibility of RCT implementation. To this end, the RC tracked or is tracking the number of individuals for each study who (1) agreed to be screened, (2) are eligible for participation, and (3) enroll. We are also recording the number of (4) emails or phone calls needed to arrange all research assessments and the number of participants who (5) drop out, (6) could not be reached for follow-up, (7) complete the interventions, and (8) partially complete versus fully complete secondary outcome research assessments. As an indicator of feasibility, we are also recording the total time to complete all secondary outcome research assessments and track the number of protocol amendments (if any) and their rationale. Acceptability and feasibility metrics will be matrixed alongside sociodemographic characteristics (sex at birth, gender, age, etc) of screened and consented participants.

Table 2 details the list the measures that are being used to assess the secondary (ie, education-related) outcomes and their correlates in the *RISE with Residents* and *RISE with Veterans* research projects and their respective overlap. The research assistant is administering research assessments of family violence knowledge and skills via REDCap to participants in both studies at 3 time points: the week before they begin their VEGA intervention (time 1), posteducation (ie, postintervention; time 2), and 3 months after the time 1 survey is completed (time 3). Participants are being asked to complete the surveys within 1 week, from the date they are initially sent, on their own time. Each assessment takes approximately 30 minutes to complete.

Table 2. Quantitative research assessments for *RISE with Residents* and *RISE with Veterans*.

Measure	*RISE*[a] *with Residents*			*RISE with Veterans*		
	Baseline	Postedu-cation	3-month follow-up	Baseline	Postedu-cation	3-month follow-up
Adapted Brief Individual Readiness to Change Scale (BIRCS) [52]: The original BIRCS was developed by Goldman [52] to assess health professional readiness to learn and implement new evidence-based practices in the field of addictions; respondents were asked to indicate on a 5-point Likert scale the extent to which they disagreed (0=strongly disagree) or agreed (4=strongly agree) with 5 statements about their use of "direct service techniques that are based on research" (eg, I believe I have the skills to use them; I believe I have the flexibility to use them). For the purposes of our research, we adapted the items to be specific to child maltreatment, added 2 items (eg, "I believe I have the knowledge to recognize and respond to all forms of child maltreatment in my practice"; "I am motivated to learn about child maltreatment"), and replicated the set of items for intimate partner violence (IPV) (ie, BIRCS—Child Maltreatment; BIRCS—IPV). After reverse scoring 1 item, the mean score of the responses for each scale is used to interpret the results, with a higher mean score indicative of a greater readiness to make practice changes related to child maltreatment or IPV.	✓	—[b]	—	✓	—	—
Adapted Child Maltreatment Vignette Scale (CMVS) [53,54]: For the original CMVS, respondents are prompted to review 14 distinct analog vignettes that depict a range of signs and symptoms of child maltreatment exposure. On completing their review of each vignette, participants are asked to indicate their responses to four items: (1) "is this child being maltreated" (yes/no); (2) "please indicate how confident you are in your response (50%-100%, your answer must be between 50% and 100%)"; (3) "would you report this case to children's services?" (yes/no); and (4) "please indicate how confident you are in your response (50%-100%, your answer must be between 50% and 100%)." With permission from the original authors, the measure was adapted to the Canadian context via removing 1 scenario from the measure (due to concerns about multiple maltreated children), amending physician-focused language to "health professional" and changing (1) for each vignette to "for any child/youth in this scenario, do you have a reason to suspect child maltreatment?" (yes/no) and changing (3) for each vignette to "would you report this case to Child Welfare Services?" (yes/no). Adaptations were made in consultation with clinical experts in child maltreatment impact assessment at a tertiary care center in Ontario, Canada. Responses to (1) and (3) for each vignette will be scored as either correct ("1") or incorrect ("0") as predetermined, a priori; a mean "knowledge and skill accuracy" score is generated for analysis, with higher scores indicative of greater knowledge and skill accuracy related to child maltreatment.	✓	✓	✓	✓	✓	✓
Mandatory Reporting Self-Efficacy Scale (MRSES) [55]: The MRSES is a 7-item measure that asks respondents to indicate the extent to which they perceive their ability to implement a series of behaviors related to mandatory reporting of child maltreatment. Response options for each item are anchored on a scale from 0 to a 100, with statements at 0, 50, and 100 indicating "cannot do at all (0)," "moderately can do (50)," and "highly certain can do (100)." A total score is generated by summing items across the scale for each participant, with higher scores indicative of greater self-efficacy related to recognizing and reporting suspected child maltreatment.	✓	✓	✓	✓	✓	✓

Measure	*RISE*[a] *with Residents*			*RISE with Veterans*		
	Baseline	Postedu-cation	3-month follow-up	Baseline	Postedu-cation	3-month follow-up
Adapted Preparedness Subscale of the Physician Readiness to Manage Intimate Partner Violence Survey (PREMIS) [56,57]: The PREMIS is a 67-item self-report tool that was developed to assess physician management of IPV across 10 subscales. The Preparedness Subscale asks respondents to indicate the extent to which they feel prepared to address various aspects of IPV recognition and response when working with their clients across 11 items; these aspects include the conduct of safety assessments, asking appropriate questions about IPV, responding to IPV disclosures, among others. Response options are on a 7-point Likert scale ranging from "not prepared" (1) to "quite well prepared" (7), and items are averaged to generate a mean score for practitioner preparedness, with higher scores indicative of generally greater preparedness to recognize and respond to IPV. Preparedness items were adapted to focus on child maltreatment, allowing our team to determine participant preparedness to recognize and respond to both IPV and child maltreatment in their practice encounters.	✓	—	✓	✓	✓	✓
Adapted Knowledge Subscale of the Physician Readiness to Manage Intimate Partner Violence Survey (PREMIS) [56,57]: The knowledge subscale of the PREMIS assesses the accuracy of participants actual knowledge about IPV against a set of multiple-choice, matching, and true-or-false questions capturing information about IPV signs and symptoms and risk factors that are informed by the current literature. A total score of correct items is used to represent actual IPV knowledge, with higher scores indicative of greater knowledge.	—[b]	—	—	✓	✓	✓
Adapted Opinions and Self-Efficacy Subscale of the Physician Readiness to Manage Intimate Partner Violence Survey (PREMIS) [56,57]. The opinions (24 items) and self-efficacy (3 items) subscale of the PREMIS assesses participants' agreement with statements capturing thoughts and beliefs related to recognizing and managing IPV in clinical practice. Response options are on a 7-point Likert scale ranging from "strongly disagree" (1) to "strongly agree" (7); items are averaged to generate a mean score for opinions and self-efficacy, with higher scores indicative of generally positive opinions and self-efficacy to recognize and manage IPV in practice. Developed in the United States, the original scale contained an item related to state-specific reporting of "IPV, elder abuse, and child abuse"; this item was removed for our studies to reduce redundancy with other measures and to reduce measurement burden. Self-efficacy items were asked at all time points in the study, with opinions items asked at baseline and 3-month follow-up.	—	—	—	✓	✓[c]	✓
Thoughts and Beliefs about Role Responsibility to Recognize and Respond to Family Violence (TBR-FV) [21]. The TBR-FV is a measure created by our research team that captures participants' perceived professional responsibility related to recognizing and responding to IPV and child maltreatment in their health professional encounters. The generation of this measure was informed by a mixed methods program of research evaluating health professions education in family violence [21].	✓	—	—	✓	—	—
Healthcare Provider Attitudes toward Child Maltreatment Reporting Scale (HPA-CMRS) [58,59]: The HPA-CMRS is a 26-item psychometrically validated scale that asks respondents to indicate the extent to which they agree with statements that capture attitudes and beliefs regarding the reporting of child maltreatment to child protective services. Items are rated on a 5-point Likert scale ranging from "0" (strongly disagree) to "4" (strongly agree) and summed to produce a total score, with higher total scores indicative of more positive attitudes and beliefs toward the reporting of child maltreatment.	✓	—	✓	—	—	—
Adapted Version of the Achievement Goals for Work Domain (AGWD) [60,61]: The AGWD is a 23-item, psychometrically validated measure of work-related achievement goals that map onto the 4 goal orientations described by Achievement Goal Theory. Respondents are asked to indicate their agreement with 22 statements that follow the stem of "In residency, my goal is..." Response options range from "1" (strongly disagree) to "7" (strongly agree), and responses are summed to generate a total score for each subscale corresponding to each type of goal orientation; higher scores are more indicative of the respondent's affinity to that goal orientation.	✓	—	—	—	—	—

[a]RISE: Researching the Impact of Service provider Education.

[b]Not applicable.

[c]Only the self-efficacy items will be administered at this time point.

Sample Size

A sample size of 80 participants (40 per arm) for each study was selected based on the recommendations of Whitehead et al [62] and Norman et al [63]. Based on these guidelines, a sample of 40 participants randomly allocated to each intervention arm would provide, at minimum, 80% power to detect a moderate (0.5 SD to 0.6 SD) effect size, which is indicative of a clinically significant change. In following this algorithm, our team will be able to consider the needed recruitment and retention rates to successfully implement a definitive education trial.

Qualitative Strand of Data Collection

Qualitative Design and Participants

The qualitative portion of both studies is guided by the principles of qualitative description, which is a flexible yet rigorous approach to conducting qualitative health research that has clinical and practical relevance [64]. Qualitative description is being used to expand and extend what we learn about acceptability and feasibility of implementing the experimental and active control interventions and associated research activities, as well as capture the perceived value and impact of VEGA's educational modalities, using the language of participants. Given that the qualitative data will complement the quantitative strand of data collection, we used purposive criterion sampling [65] to select a subsample of the participants from the active control and experimental arms of each study (n=60; 15 per arm, per study) to participate in a one-on-one semistructured interview with an unmasked member of the research team. For *RISE with Residents*, recruitment of qualitative participants is stratified by resident discipline and residency year, whereas for *RISE with Veterans*, qualitative recruitment is stratified by participants' sex at birth (male vs female).

Data Collection

Individual semistructured interviews take place after intervention completion. Interviews are up to 60 minutes in length and conducted via Zoom using the audio function only (or by phone, if the participant prefers). Interviews are being audio-recorded and transcribed verbatim to ensure data integrity. A semistructured interview guide of 5 to 7 key questions and probes is used to guide interview experiences. Field notes completed by the interviewer document interview observations that may be relevant to analysis.

Quantitative and Qualitative Data Analysis and Integration

On the completion of data cleaning, descriptive statistics (means, SDs, relevant quantiles, and proportions) will be used to compare VEGA modalities with respect to measures taken at baseline to ensure that groups do not significantly differ on sociodemographic characteristics [66]. The proportion of participants who met eligibility requirements, who enrolled, who were lost to follow-up, and who completed all quantitative secondary outcome assessments will be calculated. Assuming a normal distribution, standardized effect estimates for each of our educational outcomes in the form of Cohen *d* will be calculated for postintervention and 3-month follow-up time points. These data will be analyzed using intention-to-treat analysis. Depending on acceptability and feasibility outcomes, sample size calculations for a proposed RCT will be generated using the effect size and variance estimates from the posteducation change data for the selected outcome measures. Although forced-choice frameworks in REDCap reduce the proportion of missing data at the item level, missing follow-up data will be addressed using imputation procedures, where appropriate [67].

Transcripts of qualitative interviews, as well as associated field notes, are being exported into and managed in NVivo (Lumivero). On completion of both studies, transcripts will be analyzed using reflexive thematic analysis [68] and the constant comparison technique, which will allow for the identification codes, categories, and themes related to implementing and evaluating both VEGA modalities among health professionals in a postgraduate training (ie, learner) and independent practice setting. After conducting separate quantitative and qualitative analyses, quantitative and qualitative data will be integrated for interpretation via a mixed methods joint display [69]. Quantitative acceptability and feasibility metrics will be mapped to excerpts of qualitative data on perceived acceptability or educational burden; this joint display will support a comprehensive interpretation of the extent to which definitive trials examining VEGA in our sample populations are tenable. A separate joint display will cross-tabulate scores on secondary outcome measures with qualitative excerpts of VEGA's perceived value and impact for improving health professional knowledge and skills in family violence.

Ethical Considerations, Protocol Deviations and Amendments

Risks associated with the *RISE with Residents* and *RISE with Veterans* studies are minimal. All de-identified data are being stored on a secure server at McMaster University, as approved

by the Hamilton Integrated Research Ethics Board (HiREB). Any identifying data will be destroyed on completion of both studies. Only the research team has access to study-related data; anyone outside of the research team who wishes to analyze the data can request to do so via formal secondary data analysis approval procedures administered via the HiREB. Anticipated adverse events that are relevant to this study include those related to participant safety and well-being and include (1) participants' own experiences with IPV or child maltreatment, which may raise or contribute to distress during the educational intervention or during research activities, and (2) participants' experiences with providing care to patients who have experienced IPV or child maltreatment, which may be distressing. Anticipated adverse events that are not serious are discussed, as needed by research staff, with the principal investigator if the nature of the adverse event is considered to signal unresolved risk to the participant. VEGA workshop facilitators are regulated health professionals with significant training and expertise in distress protocols. As per our protocols, emergency medical services are alerted as required if there is concern about imminent risk to life of an adult or safety of a child. The principal investigator, who is a registered social worker and psychotherapist, continues to follow regulated reporting requirements as necessary and determine whether other steps are needed to mitigate any risks to participants. Given that the purposes of both studies are to determine acceptability and feasibility of RCT implementation, a detailed accounting of any adverse events, research protocol deviations, and amendments continues to be tracked and documented by the RC, in collaboration with the principal investigator. Given the emphasis of both studies on the acceptability and feasibility of proposed RCT procedures, a data monitoring committee has not been established; however, findings from the present studies will inform the development of a data monitoring committee should results indicate that pursuit of a full RCT is acceptable and feasible.

Ethics Review

The *RISE with Residents* and *RISE with Veterans* research projects have been approved for human research by the HiREB, affiliated with McMaster University in Ontario, Canada. The associated project approvals are HiREB #14381 (*RISE with Residents*) and HiREB #14243 (*RISE with Veterans*), respectively. All research procedures will be performed in accordance with the relevant guidelines and regulations of the HiREB and Tri Council Policy Statement on the Ethical Conduct for Research Involving Humans. In both studies, informed consent for study participation is obtained from all participants.

Results

Study Timeline

The *RISE with Residents* and *RISE with Veterans* studies were registered and posted to ClinicalTrials.gov on August 5, 2022. As of January 15, 2024, we consented 71 individuals to participate in the *RISE with Residents* study and data are currently being cleaned and prepared for analysis. A total of 6 amendments were submitted to the HiREB throughout the duration of the *RISE with Residents* data collection period; no adverse events were reported by research participants. For the *RISE with Veterans* study, as of January 15, 2024, we have consented 34 individuals to participate in the study and data collection will be completed in March 2024. At the time of writing (January 2024), 7 amendments were submitted to the HiREB and no adverse events have been reported by research participants.

Dissemination Plan

In addition to the open-access publication of our research protocol, our team has identified several strategies that will accelerate the translation of our findings into education guidelines, practice, and scholarship. First, we will publish study findings for both the *RISE with Residents* and *RISE with Veterans* studies in open-access, peer-reviewed journals according to reporting guidelines for mixed methods [70], pilot trial [71], and education studies [72]. Second, end-of-grant knowledge translation will involve the preparation of 1-page infographics and curriculum recommendations for project funders at the Royal College of Physicians and Surgeons of Canada, the Atlas Institute for Veterans and their Families, and our network of health professions associations; representatives from each association generously disseminate our knowledge translation products via posts to their website, social media channels, and listserve platforms. Finally, we will present our findings at national and international conferences focused on health professions education and education scholarship.

Discussion

Key Findings

The *RISE with Residents* and *RISE with Veterans* research studies aim to determine the acceptability and feasibility of conducting an RCT to evaluate the effectiveness of the self-directed (experimental intervention) and workshop (active control) modalities of the VEGA Family Violence Education Resources [30], as an adjunct to standard education, to improve learner (*RISE with Residents*) and independent practice (*RISE with Veterans*) health professional preparedness, knowledge, and skills related to recognizing family violence in their health care encounters. We compare these 2 educational modalities for 2 key reasons. First, evidence indicates that self-directed education may be as effective as traditional education methods for improving knowledge and skills among health professionals, especially when self-directed methods incorporate active learning strategies [73,74]. Given that VEGA is a free, online, and brief intervention, determining the extent to which self-directed education yields improved preparedness, knowledge, and skills among learner and independently practicing health professionals, as an adjunct to formal curriculum, could (1) widely (and rapidly) shift the preparation of Canadian health professionals to effectively recognize and respond to family violence without requiring formal curricular changes and (2) meaningfully contribute to our understanding about effective postgraduate and continuing education strategies, which has education implications beyond family violence and the VEGA intervention.

Second, the comparison of educational modalities in our respective studies minimizes the variability that could not be

accounted for if VEGA were compared with a non-VEGA control; this includes variability related to intervention content and emphasis, student enthusiasm, among others. RCTs in education scholarship have been controversial because they typically average too many variables to yield any real insights [75,76]. This is particularly true when an intervention is compared with a passive control or an active control that is focused on a separate subject. By keeping the content standard, varying only the educational modality, and placing emphasis on evaluating the acceptability and feasibility of an RCT, both studies address each of these important issues [77-79].

Strengths and Limitations

A particular strength of the *RISE with Residents* and *RISE with Veterans* research studies lies in their emphasis on postgraduate and continuing education contexts. It is possible that family violence education may be especially impactful in the postgraduate training period given the need to (1) understand that children, youths, and adults can present with signs and symptoms of all types of family violence in every health professional subspecialty and (2) demonstrate competencies related to the scope of one's professional responsibilities (eg, mandatory reporting) and the purview of one's clinical practice, including when and how to make appropriate treatment referrals to prevent or reduce mental or physical health impairment. To this end, the results of the *RISE with Residents* and *RISE with Veterans* studies provide a valuable methodological contribution about the feasibility and acceptability of trial methods in postgraduate and continuing education focused on family violence in the Canadian context; it will also contribute new knowledge to education science about the differences between the effectiveness of self-directed versus facilitator-led learning strategies at different stages of the learning trajectory, more broadly.

The limitations of the *RISE with Residents* and *RISE with Veterans* research studies are influenced by the scope of the available literature on effective interventions for preventing family violence and mitigating associated harms, more generally. For example, it is important to note that IPV occurs in all countries, cultures, religions, and socioeconomic groups in the world. However, generally speaking, IPV is a gendered phenomenon; cisgender and transgender women and girls are disproportionately affected by IPV. Yet, increasing evidence indicates that IPV may be perpetrated by men toward women and by women toward men and occur in same-sex, gender, and sexually diverse relationships [10]. IPV may materialize in marital relationships, common-law relationships, cohabitation, or any intimate relationship including dating and casual sexual relationships across the age spectrum [10]. Yet, most epidemiological and intervention data related to IPV and its prevention have been collected in the context of cisgender, heterosexual adult relationships; thus, the information contained in VEGA is largely informed by that lens. Similarly, information regarding evidence-based approaches, practices, and programs for individuals who use violence (ie, perpetrators of IPV or child maltreatment) is limited. This limitation is also reflected in the evidence reviews and available guidance for working with perpetrators contained within the VEGA education modalities [10,80-82]. Finally, and methodologically, our quantitative measures rely on learner and independent practitioner self-report, which can be prone to bias. However, our selected measures have undergone psychometric scrutiny and heavily rely on a behavioral intention framework, which is consistent with the concept of self-efficacy (ie, beliefs about capabilities)—a construct with moderate-to-strong associations with provider behavior change [83,84].

Conclusions

We expect that the *RISE with Residents* and *RISE with Veterans* research studies will provide critical evidence related to the acceptability and tenability of evaluating VEGA in postgraduate and continuing education settings. Both studies will also provide foundational estimates of intervention impact among 2 distinct populations. To this end, the findings have broader implications for the possibility of improving the preparation of health professionals to be able to recognize and respond to family violence in their care encounters safely and effectively. The generated effect estimates will serve as benchmarks for replication and, more specifically, the design of adequately powered and methodologically robust evaluations of the VEGA and other family-violence focused educational interventions over the long term.

Acknowledgments

For *RISE with Residents* and *RISE with Veterans*, a Letter of Permission from McMaster University was provided to evaluate the Violence, Evidence, Guidance, Action (VEGA) Family Violence Education Resources. We acknowledge the support of Dr Harriet MacMillan, who is the lead of the VEGA Project, to undertake this work and appreciate Dr MacMillan acting as the VEGA Advisor for the *RISE with Residents* and *RISE with Veterans* research projects. We would also like to acknowledge the input of Fardous Hosseiny, MaryAnn Notarianni, Ashlee Mulligan, and Catherine Virelli of the Atlas Institute for Veterans and Families on the *RISE with Veterans* recruitment procedures. *RISE with Residents* is funded by a 2021 Medical Education Research Grant from the Royal College of Physicians and Surgeons of Canada (award reference number: 21/MERG-05). *RISE with Veterans* is funded by the Atlas Institute for Veterans and Families (formerly the Centre for Excellence for PTSD and Related Mental Health Conditions; agreement number: 2021-0630). The views expressed in this paper do not necessarily represent the views of the Royal College of Physicians and Surgeons of Canada, nor the Atlas Institute for Veterans and Families. The Royal College of Physicians and Surgeons of Canada and the Atlas Institute for Veterans and Families were not involved in the design of these studies, nor were they involved in the writing of this manuscript.

Data Availability

To protect human privacy, data are not publicly available. Should researchers wish to complete secondary analysis of the *RISE with Residents* and *RISE with Veterans* research data, they may formally apply with a request to do so via the Hamilton Integrated Research Ethics Board (HiREB).

Authors' Contributions

MK, EBS, DES, and MV were all involved in the development of this protocol. MK drafted this manuscript. All authors were involved in the critical revision of the paper for intellectual content and its final approval before submission. All authors read and approved the final manuscript. Generative AI was not used for writing any portion of this manuscript.

Abstract

Background: Knee osteoarthritis (KOA) is one of most prevalent and fastest-growing causes of pain, impaired mobility, and poor quality of life in the rapidly aging population worldwide. There is a lack of high-quality evidence on the efficacy of traditional Chinese medicine (TCM), particularly acupuncture, and a lack of KOA practice guidelines that are tailored to unique population demographics and tropical climates.

Objective: Our HARMOKnee (Heat and Acupuncture to Manage Osteoarthritis of the Knee) trial aims to address these gaps by evaluating the short- and medium-term clinical and cost-effectiveness of acupuncture with heat therapy in addition to standard care, compared to standard care alone. Through a robust process and economic evaluation, we aim to inform evidence-based practice for patients with KOA to facilitate the large-scale implementation of a comprehensive and holistic model of care that harmonizes elements of Western medicine and TCM. We hypothesize that acupuncture with heat therapy as an adjunct to standard care is clinically more effective than standard care alone.

Methods: A multicenter, pragmatic, parallel-arm, single-blinded, effectiveness-implementation hybrid randomized controlled trial will be conducted. We intend to recruit 100 patients with KOA randomized to either the control arm (standard care only) or intervention arm (acupuncture with heat therapy, in addition to standard care). The inclusion criteria are being a community ambulator and having primary KOA, excluding patients with secondary arthritis or previous knee replacements. The primary outcome measure is the Knee Osteoarthritis Outcome Score at 6 weeks. Secondary outcome measures include psychological, physical, quality of life, satisfaction, and global outcome measures at 6, 12, and 26 weeks. A mixed method approach through an embedded process evaluation will facilitate large-scale implementation. An economic evaluation will be performed to assess financial sustainability.

Results: Patient enrollment has been ongoing since August 2022. The recruitment process is anticipated to conclude by July 2024, and the findings will be analyzed and publicized as they are obtained. As of November 6, 2023, our patient enrollment stands at 65 individuals.

Conclusions: The findings of our HARMOKnee study will contribute substantial evidence to the current body of literature regarding the effectiveness of acupuncture treatment for KOA. Additionally, we aim to facilitate the creation of standardized national guidelines for evidence-based practice that are specifically tailored to our unique population demographics. Furthermore, we seek to promote the adoption and integration of acupuncture and heat therapy into existing treatment models.

Introduction

Knee osteoarthritis (KOA) is an age-related degeneration representing “wear and tear” of the knee joint, and it is one of the most prevalent and fast-growing causes of pain, impaired mobility, and poor quality of life (QOL) in the rapidly aging population worldwide [1]. The 2019 Global Burden of Disease Study reported that the knee is the joint most frequently affected by osteoarthritis, with a prevalence of approximately 365 million, followed by the hand and the hip [2].

Acupuncture is the most prevalent form of traditional medicine practice, with 183 of 202 (90.5%) surveyed countries recognizing its use, as reported by the World Federation of Acupuncture-Moxibustion Societies [3]. A bibliometric analysis reported that of 2189 positive recommendations for the use of acupuncture, about 68% were associated with 107 pain indications [4].

A review of 10 randomized controlled trials (RCTs) concluded that acupuncture is an effective treatment for KOA-related pain and physical dysfunction [5]. However, major updated clinical guidelines from the American Academy of Orthopaedic Surgeons, Joint Surgery Branch of the Chinese Orthopaedic Association, American College of Rheumatology/Arthritis Foundation, and others still consider acupuncture treatment to be insufficient, limited, conditional, or unrecommended for KOA [6]. A review highlighted the lack of evidence supporting the efficacy and cost-effectiveness of acupuncture in osteoarthritis due to poor methodological quality, significant heterogeneity, inadequate reporting of acupuncture treatment details, small sample sizes, and high placebo responses in studies [7].

The primary aim of our study is to evaluate the short- and medium-term clinical effectiveness of acupuncture, part of traditional Chinese medicine (TCM), with far-infrared heat therapy in addition to standard care, compared to standard care alone. The secondary aims include (1) performing a process evaluation to understand the context and identify mechanisms of impact that will inform large-scale implementation of the intervention and (2) performing an economic evaluation to assess the cost-effectiveness of the intervention. We hypothesize that acupuncture with heat therapy as an adjunct to standard care is clinically more effective than standard care alone.

Methods

Design

The study is an effectiveness-implementation hybrid trial, which combines effectiveness and implementation components [8,9]. This will be a type 1 hybrid trial where the emphasis and primary aim is to evaluate the effectiveness of acupuncture with far-infrared heat therapy as an adjunct to standard care through a pragmatic RCT under real-world conditions, and its secondary aim is to understand the context of implementation through a mixed-method, process-oriented approach. The pragmatic nature of the study was guided by the Pragmatic Explanatory Continuum Indicator Summary (PRECIS-2) tool [10].

The study will be conducted as a multicenter, pragmatic, parallel-arm, single-blinded RCT using a mixed method approach comparing the clinical effectiveness of acupuncture with far-infrared heat therapy as an adjunct to standard care and standard care alone. The Standard Protocol Items: Recommendations for Interventional Trials (SPIRIT) [11] and the Osteoarthritis Research Society International (OARSI) clinical trial recommendation on the design and conduct of clinical trials for KOA [12] guided the development of the trial protocol. To ensure clear reporting of acupuncture treatment details, Standards for Reporting Interventions in Clinical Trials of Acupuncture (STRICTA) reporting guidelines [13] will also be followed. The findings of the trial will be reported according to the Consolidated Standards of Reporting Trials (CONSORT) 2010 [14] guidelines for reporting parallel-group randomized trials. The study will use an explanatory sequential mixed method design where the qualitative data from interviews will be used to interpret and provide context for the quantitative results.

Participants

We will recruit patients based on the eligibility criteria outlined in Textbox 1.

Textbox 1. Eligibility criteria.

Inclusion criteria

- National Institute of Health and Care Excellence (NICE) clinical criteria for knee osteoarthritis (KOA) [5]:
  - Being aged 45 years or older
  - Having activity-related joint pain
  - Having either no morning joint-related stiffness or morning stiffness that lasts no longer than 30 minutes
- Being a community ambulator with or without walking aid

Exclusion criteria

- Alternative diagnosis to KOA, such as referred pain from the spine or hip
- Other forms of arthritis, such as inflammatory arthritis
- Inability to comply with study protocol (eg, due to dementia)
- Previous knee arthroplasty
- Being a wheelchair user
- Medical conditions that would medically interfere with study involvement, such as decompensated heart failure, stroke, and end-stage renal failure
- Allergies to metal (needles)

Components of the Study

The Heat and Acupuncture to Manage Osteoarthritis of the Knee (HARMOKnee) study will have three components: (1) an RCT, (2) an economic evaluation, and (3) a process evaluation.

Component 1: RCT

This RCT will be administered in accordance with the STRICTA guidelines, an extension of the CONSORT statement designed to enhance the quality of clinical trials of acupuncture [13].

Trial Procedure and Recruitment

By using the hospital's electronic medical records and appointment system, patients who are referred to the orthopedic surgery outpatient clinic at a tertiary hospital in Singapore will be screened based on the eligibility criteria prior to their actual consultation visit. During the clinic visit, potential patients will be invited to participate in the study if they meet all the inclusion and exclusion criteria. A research assistant will share details of the study with patients who are interested. Written informed consent will be obtained for those who subsequently agree to join the trial. The reasons for rejection to participate will be recorded. Each consenting participant will be asked to complete the baseline measures. Patients will then be randomized into the control arm or the intervention arm. Considering previous studies [15,16], patients who have received TCM treatment within 1 week prior to the trial will be subject to a 2-week washout period, counting from their last TCM treatment date. They will be requested to stop any form of acupuncture before beginning the trial. For this group of patients, randomization and baseline measures will be performed after the wash-out period. Participants are allowed to take any analgesics as needed throughout the study duration, and this will be recorded. All medications (prescription and over the counter), vitamin and mineral supplements, and herbs taken by the participant will be documented. Data collection will be done at baseline and weeks 6, 12, and 26. The research assistant will follow up with the participants regularly to ensure study completion. Figures 1 and 2 illustrate the study schedule of enrollment, interventions, and outcome measurements according to the SPIRIT guidelines and the CONSORT flowchart, respectively.

Randomization and Concealment of Allocation

Patients who consent to participate will be randomized in a 1:1 allocation ratio to intervention or standard care using a stratified, permuted, block randomization method (block sizes of 4, 6, and 8). Stratification is based on gender with a female to male ratio of 2:1. The unbalance ratio was based on the World Health Organization's estimate of the prevalence of symptomatic osteoarthritis for people aged 60 years or older, among whom the prevalence of women is almost double that of men (male vs female: 9.6% vs 18%) [17]. The allocation sequence is generated by an independent statistician a priori using Stata (version 16.1; StataCorp) and will be kept concealed from the study team. Randomization will be done using the REDCap (Research Electronic Data Capture; Vanderbilt University) randomization module based on the allocation sequence; allocation will be locked once assigned. Randomization and intervention allocation will only be performed by the study team after the patient is counselled fully about the study and provides informed consent.

Intervention: Acupuncture Plus Heat Therapy and Standard Care

After reviewing international literature and engaging with local TCM experts, this clinical intervention was designed in accordance with local practice. The intervention involves acupuncture with far-infrared heat therapy in addition to standard care, which will be administered by qualified TCM practitioners from Tan Tock Seng Hospital's Complementary Integrative Medicine Clinic (CIMC) and Singapore Chung Hwa Medical Institution (SCHMI), who have full registration with the Traditional Chinese Medicine Practitioners' Board and a minimum of 3 years of acupuncture practice. Before the commencement of the trial, all the acupuncturists from the participating institutions will undergo training on acupoint locations and needling methods to ensure standardization of acupuncture techniques in accordance to the acupuncture protocol that was developed by consensus among all the senior acupuncturists participating in this trial. The treatment protocol and rationale are elaborated below.

Our study aims to evaluate the therapeutic effectiveness of acupuncture combined with far-infrared heat therapy in addition to standard care, compared to standard care alone. To achieve this purpose, we have not included sham acupuncture as an inactive control in our study design. There are controversies about the validity of sham acupuncture. A study found that sham acupuncture may produce comparable effects on biomarkers as *verum* acupuncture, which suggests that sham acupuncture, being an inactive intervention akin to a placebo, should be reevaluated [18]. Additionally, heat therapy will yield beneficial

outcomes in the treatment, regardless of whether *verum* or sham acupuncture is used.

Acupuncture Intervention Rationale

Although the 2007 Singapore Ministry of Health clinical guidelines for KOA recommend electroacupuncture as an adjunct therapy, anecdotal input from our local subject matter experts suggests that some patients are afraid of electrical stimulation and that it is generally less well tolerated due to the pain of electrical stimulation. Studies have also shown that even though electroacupuncture has advantages compared to standard care, acupuncture with heat therapy, a more tolerable option, possesses similar efficacy as electroacupuncture when combined with the usual pharmacotherapies [19]. Therefore, we chose to evaluate acupuncture with heat therapy to establish its clinical effectiveness as an adjunctive therapy in the management of KOA, with long-term implementability a key consideration.

Upon careful review of the evidence-based Guidelines of Clinical Practice with Acupuncture and Moxibustion for KOA [20] and the intervention protocols of several acupuncture RCTs that examined patients with KOA (Multimedia Appendix 1, Figure S1 [10, 21-29]), acupoints that were previously reported to be effective in pain relief and improving knee flexibility were identified.

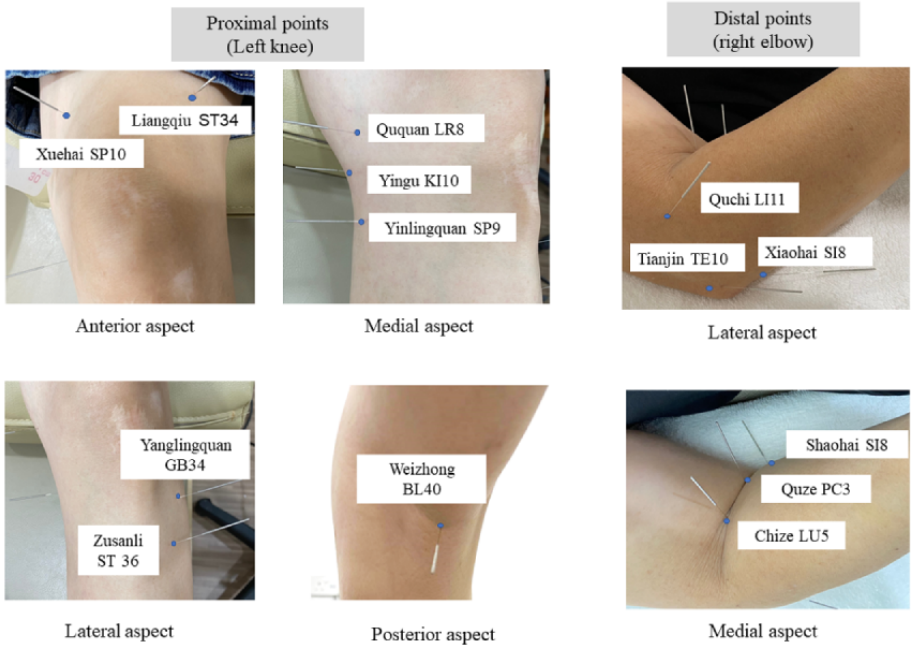
Guided by international evidence in consultation with the local TCM collaborators, a consensus on a set of proximal and distal acupoints based on TCM meridian differentiation was reached (Multimedia Appendix 1, Figure S2 [30,31]).

Acupoint Selection

In total, 14 needle insertions will be made on a fixed set of proximal and distal acupoints for each patient per session (Figure 3).

Distal acupoints will be applied on the opposite elbow [32] to increase the analgesic efficacy according to contralateral collateral needling (缪刺) from *Huang Di Nei Jing* (*Yellow Emperor's Inner Classic* in English). It is a therapy where the right side is acupunctured if the left side is diseased and vice versa; the upper side is acupunctured if the below is diseased and vice versa. Studies have shown that contralateral collateral needling unblocks collaterals and is potentially more effective than conventional acupuncture for some conditions, including hemiplegia following acute ischemic stroke, cervical shoulder pain, insomnia, and KOA [33-35]. From a pragmatic perspective, patients with bilateral knee pain will only receive acupuncture on the most painful knee and the opposite elbow. This practice is supported with evidence that suggests unilateral acupuncture is equally as effective as bilateral acupuncture in increasing function and reducing the pain associated with KOA [36].

Figure 3. Proximal and distal acupoints.



Treatment Regimen

The patient will be treated in a supine position with pillows under both knees. After a standard disinfection procedure, a 30 × 40–mm disposable stainless steel acupuncture needle (YangTzeKing Impex S Pte Ltd) will be inserted according to the location defined; the direction of insertion and the safe depth range are specified in Multimedia Appendix 1, Figure S2 [21, 30,31]. Basic manipulations such as lifting and thrusting, twirling, and rotating are applied until the needling sensation (*de-qi*) is obtained. After *de-qi* is obtained, uniform reinforcing-reducing (平补平泻) manipulations are applied. The needles will be retained for 30 minutes (except for weizhong [BL40], where the needle is removed immediately after the needling sensation is obtained), whereupon 2 manipulations will be applied at 10-minute intervals before needle removal. During needle retention, far-infrared heat therapy will be applied at the lateral, medial, and anterior sides of the knee for 10 minutes each for a total of 30 minutes while maintaining a 30-cm safety distance (Figure 4). The treated region will be observed

and checked for redness at 10-minute intervals to prevent burn injury. A total of 12 acupuncture sessions will be administered twice a week for 6 weeks in addition to standard care. A minimum of 50% attendance (6 of 12 sessions) is required to qualify as completing the study treatment. There are no make-up sessions should the patient miss the scheduled appointment. Total numbers and dates of attended and missed sessions will be recorded for analysis purposes. The study intervention will be conducted at TTSH, CIMC, or SCHMI. The patients are allowed to indicate their preference for the treatment location at the start of the intervention and must attend at the selected location throughout the 6-week intervention. Each TCM session takes approximately 40 minutes, involving acupuncture and heat therapy. Safety precautions will also be exercised to ensure the safety of the patients. Generally, acupuncture is safe and has a low risk of adverse events [37]. However, since the most common adverse events are subcutaneous hematomas and hemorrhages at the site of needling [37], the TCM practitioner will take extra precaution if patients indicate during informed consent that they are taking antiplatelets or anticoagulants. All adverse events that occur during the treatment will be documented.

Figure 4. Heat therapy applied during acupuncture.

Standard Care

Standard care generally constitutes simple lifestyle advice, analgesia, and a referral to the outpatient physiotherapist. The physiotherapist conducts an assessment and recommends a variety of lifestyle modifications and exercise therapy. Any other treatment or the involvement of allied health professionals, such as dieticians, will take place at the discretion of the managing physician. The patients in the standard care group will be discouraged from seeking acupuncture treatment for 6 to 8 weeks after randomization. However, if they do so, it will be noted and accounted for in the analysis.

Withdrawal Criteria

The study intervention may be discontinued under the following circumstances: (1) a serious adverse event arises from the intervention, (2) a participant opts for total knee replacement, (3) a participant is unable to continue the study (eg, because of the sudden onset of any medical condition that prohibits continuing the study), and (4) a collaborator withdraws due to unforeseen circumstances. The participants may also withdraw voluntarily from the study intervention for any reason.

Outcome Measures

The choice of outcome measures is based on the OARSI guidelines for lifestyle diet and exercise clinical trials in osteoarthritis [38]. The recommended core outcomes include pain, physical function, and global patient assessment. Additional outcomes include health-related QOL and global physician assessment. Outcome measures will be collected at baseline (pretreatment), week 6, week 12, and week 26. The primary end point in this study is the Knee Osteoarthritis Outcome Score (KOOS-12) at week 6. KOOS-12 is a specialized tool designed to evaluate patients' knee condition, and it assesses the short- and long-term effects of knee injuries [39]. It reduces respondent burden by 70% from the original KOOS while providing scale scores for knee-specific pain, function, and QOL, along with a summary measure of overall knee impact [40]. The KOOS score has been validated in Singapore [39,41].

Baseline measures such as demographics, socioeconomic status, medical comorbidities, knee symptoms, radiographic severity, height, and weight will be collected.

Additionally, after considering the progression and severity of KOA as defined in TCM clinical guidelines published in China (Multimedia Appendix 1, Figure S3), 2 evaluation forms have been designed. The Knee Osteoarthritis TCM Evaluation Form (Multimedia Appendix 1, Figure S4) was specifically created to integrate the KOOS-12 knee survey with questions based on TCM syndrome differentiation for KOA. This will enable the investigators to assess the efficacy of the treatment by analyzing syndrome differentiation. This form will be administered at week 1 (start of treatment, before the first acupuncture session), week 4 (midtreatment, before the seventh acupuncture session) and week 6 (end of treatment, after the 12th or last acupuncture session). The Knee Osteoarthritis Visual Analog Scale and Range of Motion Evaluation Form (Multimedia Appendix 1, Figure S5) will be administered before and after each of the 12 biweekly acupuncture sessions over 6 weeks.

Clinical data (glycated hemoglobin, blood pressure, and other chronic disease parameters) and operational and cost data (health care use) will also be obtained through the health care administrative databases for economic evaluation.

Outcome Assessment and Blinding

Except for the TCM evaluation forms (Multimedia Appendix 1, Figures S4 and S5), the remaining outcome measures will be measured by blinded outcome assessors. All outcome assessors will receive training prior to study initiation to ensure good inter- and intraobserver reliability, particularly for the functional performance testing. Patients will be instructed not to reveal their allocation to the outcome assessors. Outcome assessment will be conducted at the TTSH physiotherapy clinic. Unblinding will be carefully considered and justified in each case of medical emergency or clinical treatment decisions that require the intervention to be known, following the study protocol and ethical guidelines.

Sample Size Calculation

The sample size needed to find a 10-point difference for KOOS-12 (the primary outcome) between the intervention and control arms with a power of 90%, a *P* value of .05 (2-sided) and an SD of 14 is n=42. The 10-point difference is based on the minimal clinical important difference for KOOS [42]. The anticipated baseline and SD are based on studies done in similar populations. Accounting for a 20% drop-out rate, a total of 100 patients will be needed for the study.

Data Analysis Plan

Results will be analyzed by the intention-to-treat principle. However, data will also be analyzed by a per-protocol approach to account for protocol violations, such as patients who were deemed not compliant to treatment or patients who underwent a surgical procedure of the knee due to treatment failure during the study. Descriptive frequency analysis will be used for baseline characteristics. For continuous variables, the mean and SD will be reported and for categorical variables, the frequencies and percentages will be reported. Between-group comparisons of change from baseline to the 26-week follow-up in the primary and secondary continuous outcomes will be analyzed using a generalized linear mixed model (GLMM). Testing for normality of distributions of outcomes will be based both on the Shapiro-Wilks test and a visual analysis of the histogram plot. Categorical secondary outcomes will be analyzed using the ordinal logistic regression function under the GLMM. A 2-sided *P* value less than .05 will be considered statistically significant. An analysis will be done on the nature of the missing data to determine if the data are missing at random or a systemic bias is present resulting from the missing data.

Data Management

All data will be monitored by the principal investigator and the study team independently of the study sponsor. Data quality measures include queries to identify outliers and missing data. A unique identifier will be assigned to each patient after enrollment to ensure patient confidentiality. Data will be collected and stored on the REDCap system, which is a widely used and secure web application for clinical data management in research. REDCap is password protected, and access rights to the study database are only granted to authorized people. Physical study files will be stored under lock and key.

Safety Monitoring Plan

A safety monitoring review will be done quarterly. Data monitored include serious adverse events and research-related events such as pain, burn, or any other adverse events that may arise due to the conduct of study activities. Safety monitoring reviews will be done by the principal investigator and the co–principal investigator of the study team. The study may be stopped by the principal investigator if serious safety concerns emerge. In the event that a critical adverse event occurs and a decision must be made to terminate the study, interim analyses will be conducted by an independent statistician.

Adverse events and other unanticipated effects of the intervention will be spontaneously reported by the acupuncturists. All reporting will be collected and assessed by the study team. Unanticipated problems involving risk to participants or other events will be reported to the institutional review board.

Confidentiality of Data and Patient Records

Only authorized study personnel will have access to the secured cabinet(s) or room(s) where hard-copy data will be stored. The electronic data will be stored on a password-protected desktop computer, laptop, and external HDD. The databases will not include subject identifiers, and the data relating subject identifiers to subject identification codes will be stored separately.The research data will only be accessible to the study team (including principal investigators, co-investigators, research coordinators, and statisticians). The anonymized and password-protected sharing of research data will be allowed with external institutions.

Ancillary and Posttrial Care

Enrolled participants are covered by indemnity for unexpected negligent harm due to the trial procedure.

Dissemination Plan

We anticipate that it will take between 3 and 4 months to compile the final results for the appropriate journal. The study results will be made available to the participating physicians

and the medical and TCM practitioner community via academic publication.

Component 2: Economic Evaluation

An economic evaluation will be conducted in tandem. The Panel on Cost-Effectiveness in Health and Medicine recommends the use of a societal perspective to ensure that potentially important indirect costs, such as productivity and caregiver cost, are not omitted [43]. The study will be conducted from a societal perspective to determine the cost-effectiveness of the intervention [43].

The cost data will be collected via hospital administrative databases and patient-reported questionnaires to estimate direct medical, direct nonmedical, and indirect costs based on the validated OA Cost and Consequences Questionnaire (OCC-Q), which has been adapted to the Singapore context. The OCC-Q will be administered at baseline, 12 weeks, and 26 weeks.

The primary measure of health benefit will be quality of life years measured using the EQ-5D [44]. The incremental cost-effectiveness ratio over the trial period of acupuncture with heat therapy in conjunction with standard care compared to standard care only will be determined.

Results from the economic evaluation will be reported based on the Consolidated Health Economic Evaluation Reporting Standards (CHEERS) statement [45].

Component 3: Process Evaluation

The process evaluation will be embedded within the trial. The process evaluation is crucial in understanding the functioning of an intervention by examining its implementation, mechanisms of impact and contextual factors, and use of evaluation to understand how interventions work in practice. This is vital in building an evidence base that informs policy and practice. The Medical Research Council guidelines for the conduct of process evaluations [45] will be used to design the process evaluation.

The focus will be on fidelity of actual delivery, context, and mechanisms of impact with the goal of eventual large-scale implementation. Context includes anything external to the intervention that may act as a barrier or facilitator to its implementation. The examination of mechanisms of impact seeks to identify the potential causal pathways that resulted in the changes seen.

Ethical Considerations

Ethics approvals were obtained from the National Healthcare Group Domain Specific Review Board (2021/01106) and Parkway Independent Ethics Committee (PIEC/2022/022), which oversee human research studies in the participating centers. This study will be conducted in accordance with the ethical principles in the Declaration of Helsinki, International Council for Harmonisation Good Clinical Practice guidelines, and it is consistent with the applicable regulatory requirements of the Human Biomedical Research Act in Singapore. Written informed consent will be obtained from all participants who agree to join the study after screening. A translator and an impartial witness will be present throughout the consent process if a participant is unable to understand English. All study documents were deidentified and research data will be anonymized and password-protected to ensure privacy and confidentiality. This trial is covered under the National Clinical Trials Insurance.

Results

Patient enrollment has been ongoing since August 2022. The recruitment process is anticipated to conclude by July 2024, and the findings will be analyzed and publicized as they are obtained. As of November 6, 2023, our patient enrollment stands at 65 individuals.

Discussion

Overview

TCM has been growing in popularity as a viable treatment option for KOA in recent times. Systematic reviews have suggested that TCM has potential effectiveness in terms of pain relief and functional improvement and leads to few adverse events [46]. However, there have been significant concerns raised about the quality of evidence, with significant methodological flaws in many of the studies and a high risk of bias. Acupuncture in particular has had a fairly large base of evidence, but an overview of the various systematic reviews on the effectiveness and safety of acupuncture in KOA suggested while it has advantages in KOA, there is a significant risk of bias and reporting deficiencies that needs to be addressed [47].

In addition, there is little evidence for TCM treatment of KOA that is tailored to the unique demographics of populations in tropical climates. Many local practitioners often refer to China's Clinical Guidelines of Acupuncture and Moxibustion for KOA, published in 2015 [20]. The guidelines include treatment options based on various TCM syndrome classifications, such as liver and kidney yin deficiency with blood stasis in tendons, spleen and kidney deficiency with dampness in the joint, and kidney yang deficiency with phlegm and blood stasis syndromes. Each syndrome delineates a distinct pattern of symptoms. A local study highlighted a significant difference in the syndrome differentiation for KOA (Multimedia Appendix 1, Figure S6 [48]), with a very high proportion (51%) of patients with KOA in Singapore experiencing the spleen and kidney deficiency with dampness in joint syndrome type, as compared to a mere 4.2% of patients with KOA in China [48,49]. The guidelines from China therefore may not be suited to Singapore's unique patient demographics.

Our HARMOKnee study aims to (1) add high-quality evidence for acupuncture treatment for KOA to the existing literature on a broader scale; (2) support the development of locally standardized national evidence-based practice guidelines tailored to our unique population demographics; (3) support the implementation and integration of acupuncture and heat therapy into current treatment models supported by process and economic evaluations; and (4) establish a foundation for the development of an integrated model of care that harmonizes both Western and Eastern care components.

Strengths and Limitations

One of the major strengths of our HARMOKnee study is that it follows the gold standard for research design: an RCT. The RCT design guarantees that the research uses a rigorous methodology and controls for potential confounding variables. The likelihood of bias can be reduced through allowing more precise assessment of the intervention's efficacy. This study also adheres to the STRICTA guidelines, which provide a standardized framework for reporting acupuncture trials. All relevant data will be reported, thereby enhancing the study's transparency and reproducibility. Moreover, this effectiveness-implementation hybrid study has incorporated an implementation component with the clinical effectiveness assessment. Its benefits include allowing the researchers to maximize the efficiency of their research while collecting data on both effectiveness and implementation, thereby identifying gaps in implementation and increasing the likelihood that the interventions will be effectively implemented and disseminated in real-world settings.

Limitations include the use of a pragmatic study design to mimic real-world conditions as closely as possible. This has an impact in terms of what treatment the control arm receives and how the intervention is delivered. Considerations to ensure intervention delivery fidelity have been incorporated, including standardization and training among acupuncturists. In addition, the treatment that the control arm receives will be meticulously recorded as part of the cost questionnaire and will be included in the analysis. Second, due to logistical and funding limitations, we are only able to include a follow-up period of up to 26 weeks. This will not allow us to establish the long-term effectiveness of this intervention.

Conclusions

The findings of our HARMOKnee study will contribute substantial evidence to the current body of literature regarding the effectiveness of acupuncture treatment for KOA. Additionally, we aim to facilitate the creation of standardized national guidelines for evidence-based practice that are specifically tailored to our unique population demographics. Furthermore, we seek to promote the adoption and integration of acupuncture and heat therapy into existing treatment models.

Acknowledgments

The authors would like to thank the Singapore Ministry of Health for support through the TCM Research Grant (TCMRG-5-NHG-01). The funders played no role in the study's design, data collection and analysis, publication decision, or manuscript preparation.

Abstract

Background: Hand hygiene is crucial in health care centers and schools to avoid disease transmission. Currently, little is known about hand hygiene in such facilities in protracted conflict settings.

Objective: This protocol aims to assess the effectiveness of a multicomponent hand hygiene intervention on handwashing behavior, underlying behavioral factors, and the well-being of health care workers and students. Moreover, we report our methodology and statistical analysis plan transparently.

Methods: This is a cluster randomized controlled trial with 2 parallel arms taking place in 4 countries for 1 year. In Burkina Faso and Mali, we worked in 24 primary health care centers per country, whereas in Nigeria and Palestine, we focused on 26 primary schools per country. Facilities were eligible if they were not connected to a functioning water source but were deemed accessible to the implementation partners. Moreover, health care centers were eligible if they had a maternity ward and ≥5 employees, and schools if they had ≤7000 students studying in grades 5 to 7. We used covariate-constrained randomization to assign intervention facilities that received a hardware, management and monitoring support, and behavior change. Control facilities will receive the same or improved intervention after endline data collection. To evaluate the intervention, at baseline and endline, we used a self-reported survey, structured handwashing observations, and hand-rinse samples. At follow-up, hand-rinse samples were dropped. Starting from the intervention implementation, we collected longitudinal data on hygiene-related health conditions and absenteeism. We also collected qualitative data with focus group discussions and interviews. Data were analyzed descriptively and with random effect regression models with the random effect at a cluster level. The primary outcome for health centers is the handwashing rate, defined as the number of times health care workers performed good handwashing practice with soap or alcohol-based handrub at one of the World Health Organization 5 moments for hand hygiene, divided by the number of moments

for hand hygiene that presented themselves during the patient interaction within an hour of observation. For schools, the primary outcome is the number of students who washed their hands before eating.

Results: The baseline data collection across all countries lasted from February to June 2023. We collected data from 135 and 174 health care workers in Burkina Faso and Mali, respectively. In Nigeria, we collected data from 1300 students and in Palestine from 1127 students. The endline data collection began in February 2024.

Conclusions: This is one of the first studies investigating hand hygiene in primary health care centers and schools in protracted conflict settings. With our strong study design, we expect to support local policy makers and humanitarian organizations in developing sustainable agendas for hygiene promotion.

Introduction

Background

Globally, approximately 3% of deaths and 5% of disability-adjusted life years are attributable to the effects of a lack of safe water, sanitation, and hygiene (WASH) [1]. More than half of WASH-attributable deaths occur in sub-Saharan Africa [1].

Hand hygiene is crucial to sustaining individual and community health. Pathogens can easily be transmitted from contaminated hands to other people's hands, eyes, and mouths [2]. Inadequate hand hygiene can therefore increase the risk for transmission of diarrheal, respiratory, and skin diseases [3-5].

In 2022, a quarter of people worldwide [6] and three-quarters of people living in sub-Saharan Africa [7] lacked access to basic hygiene, defined as having a functioning handwashing station on the premises with water and soap. Hand hygiene is of particular importance in health care centers and schools (which we collectively refer to here as facilities) because populations considered vulnerable frequent them. In these facilities, pathogens can spread easily over health care workers' or students' hands [8,9]. In health care centers, basic hygiene means additionally that the handwashing station needs to be at the point of care and within 5 m of toilets, while it can be equipped with hand sanitizer instead of soap [10]. Access to basic hygiene in both facility types is low. Only three-fifths of schools worldwide [11] and two-fifths of health care centers at the point of care in low- and middle-income countries [10] are estimated to have access to basic hygiene services. Handwashing stations are half as common in primary health care centers compared to secondary and tertiary health care centers [12].

In fragile and conflict settings, sanitation infrastructure is often overburdened, water quality is poor, and water quantity is insufficient [13,14]. Water is thus primarily used for drinking and cooking, and hygiene and sanitation needs become secondary [15,16]. Basic hygiene access in health care centers and schools is therefore of even greater importance. There are little data on handwashing practices in these facilities, although the United Nations Children's Fund estimates that >50% of children without basic hygiene at school live in fragile or conflict contexts [17]. Such facilities are often excluded from hand hygiene investigations during crises, despite the increased risk of infections [18,19]. Furthermore, collecting baseline data and following monitoring and evaluation activities of hand hygiene usually have a low priority in these facilities [14,18,19].

Objectives

Our study is embedded in the hands4health (h4h) project as an effectiveness evaluation component. The project is funded by the Swiss Agency for Development and Cooperation and led by 10 partners from academia, nongovernmental organizations, and the private sector [20] in close collaboration with the ministries of health (MoHs), ministries of education (MoEs), and other key stakeholders of the project countries, Burkina Faso, Mali, Nigeria, and Palestine (refer to Multimedia Appendix 1 for the project consortium overview). The h4h project has the overarching objective of increasing hygiene in primary health care centers and schools without any functional water supply in the context of protracted conflict settings. The h4h consortium developed a systematic approach with a multicomponent hand hygiene intervention (MCHHI; refer to the Intervention and Control subsection) to improve the health of patients, health care providers, students, and teachers by improving their hand hygiene and water infrastructure. Our study aims to evaluate the effectiveness of the h4h MCHHI on the hand hygiene of health care workers and students by achieving objectives 1 to 4 (Textbox 1). All our objectives will be assessed using a cluster randomized controlled trial (cRCT) design because the MCHHI is implemented at cluster level (ie, health care center or school). By publishing this protocol, we aim to transparently report our study design, methods, and statistical analysis plan. Consequently, we intend to avoid duplicate studies, coordinate research efforts, and demonstrate our accountability to report the results in a timely manner.

Textbox 1. The hands4health (h4h) study aim with the more specific objectives 1 to 4.

Evaluate the effectiveness of the h4h multicomponent hand hygiene intervention (MCHHI) on the hand hygiene of health care workers and students

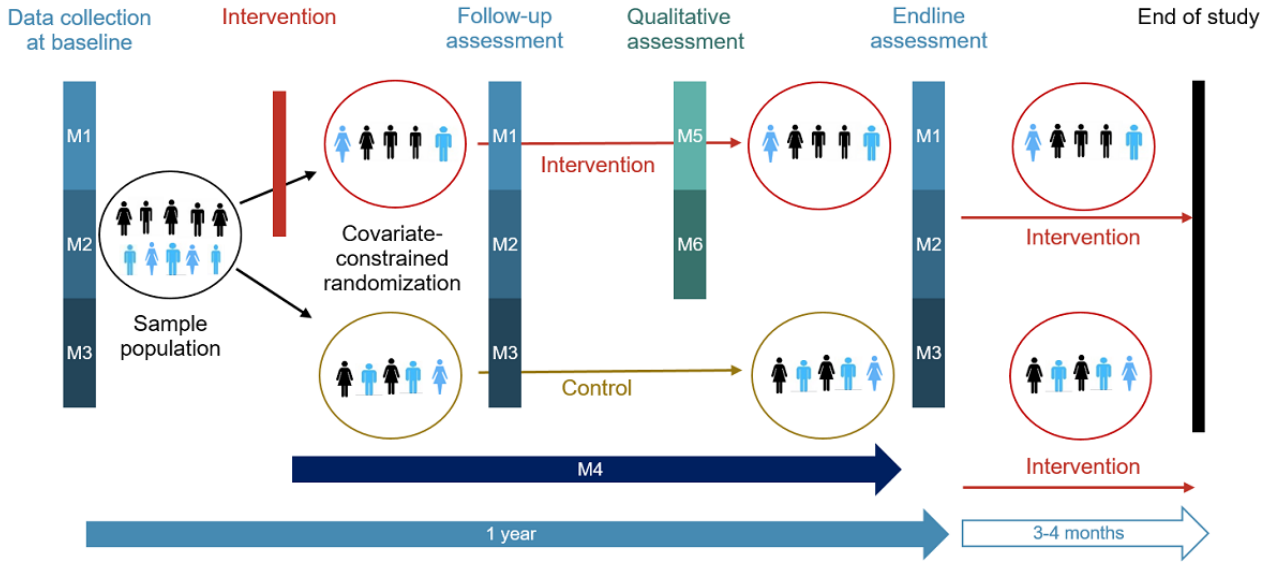
- Objective 1: assess the effectiveness of the h4h MCHHI on the hygiene-related risks, attitudes, norms, abilities, and self-regulation (RANAS) behavioral factors; handwashing behavior; and well-being of health care workers and students.
- Objective 2: assess the hygiene-related RANAS behavioral factors, handwashing practices, and well-being of health care workers and students at baseline.
- Objective 3: assess the perceived effectiveness of the h4h MCHHI on the health and well-being of health care workers and students in the intervention facilities.
- Objective 4 (exploratory): assess the effectiveness of the h4h MCHHI on the predefined health conditions and absenteeism of health care workers and students (objective 4 is exploratory because we did not take it into account during the sample size calculation; therefore, the sample size might be too small to detect a difference in the incidence of hygiene-related health conditions between the 2 study arms; however, as patient information remains anonymous, and the data collection does not add a big burden to the implementation partners, we decided to include this objective).

Methods

Study Design

We are conducting a parallel cRCT in 4 countries (Burkina Faso, Mali, Nigeria, and Palestine) with 2 study arms per country (Figure 1). For the cRCT, we collected baseline data in 24 primary health care centers per country (March to May 2023 in Burkina Faso and Mali) and 26 schools per country (February to June 2023 in Nigeria and Palestine). The data collection included hand hygiene observations; a survey about hand hygiene-related risks, attitudes, norms, abilities, and self-regulation (RANAS) behavioral factors as well as practices and well-being; and microbiological analyses of hand-rinse samples. The project partners implemented the h4h MCHHI in 12 randomly assigned primary health care centers and 13 randomly assigned schools per country. One to 2 months after the implementation of the intervention, we conducted follow-up data collection in both study arms where we repeated the observations and the survey, plus additional qualitative data in the respective intervention arms (November to December 2023 in all 4 countries). One year after baseline, we collect endline data in both study arms, including the same types of quantitative data as in the baseline data collection period (February to April 2024 in Burkina Faso and Mali and May-June 2024 in Nigeria and Palestine).

Figure 1. Overview of the hands4health study design, including the data collection methods M1 to M6. M1: module 1 (risks, attitudes, norms, abilities, and self-regulation and well-being survey); M2: module 2 (structured observation); M3: module 3 (hand-rinse samples); M4: module 4 (diary approach); M5: module 5 (focus group discussions); and M6: module 6 (key informant interviews).



We use a mixed methods design [21,22]. By collecting qualitative data before the start of the cRCT and during the cRCT, we assess WASH-related needs and perceptions about the effectiveness of our intervention on the health and well-being of our study population. By collecting quantitative data about WASH-related health determinants such as the prevalence of handwashing and RANAS behavioral factors, we will assess the effectiveness of the h4h MCHHI on our study population's hand hygiene and well-being.

Our study design is based on previous h4h project activities. First, the project coordination partner commissioned 2 reviews on current tools used for WASH infrastructure in health care centers and schools [23]. Second, the main local implementation partners used a Facility Evaluation Tool for Water, Sanitation, and Hygiene in Institutions (FACET) to assess the WASH

infrastructure of the facilities in the study regions [24]. Third, the project coordination partners led a theory of change approach [25]. The theory of change aims to understand the complexity of the WASH system in the study countries to identify key stakeholders, problems, and starting points for potential solutions. The partners conducted various workshops and interviews with stakeholders and project staff to support this process. Fourth and last, we collected qualitative data with focus group discussions (FGDs) to investigate the local perceptions and needs of hygiene in the pilot facilities. The project consortium then used all this information to develop the h4h MCHHI for each country (refer to Multimedia Appendix 2 [26-37]).

Setting

This study focuses on primary health care centers in rural areas of Burkina Faso and Mali and primary schools in Nigeria and Palestine from 2021 to 2024 (Table 1). All 4 countries involved in this study are subject to protracted conflicts. In the West African countries, jihadists and other radical groups have been terrorizing the population, leading to a rise in internally displaced persons, while Palestine has been under Israeli military occupation for 56 years [38-41]. All targeted facilities in our study regions suffer severe water shortages and a lack of WASH infrastructure and maintenance activities. Moreover, most facilities expect being overcrowded in the near future due to a rise in internally displaced persons. In Maiduguri, Borno State, Nigeria, the schools are already overcrowded, with an average of 101 students per elementary class [42].

Table 1. Description of the country settings of the hands4health project.

	Burkina Faso	Mali	Nigeria	Palestine
Cluster type	Primary health care centers	Primary health care centers	Primary schools	Primary schools
Clusters (n=100), n (%)	24 (24)	24 (24)	26 (26)	26 (26)
Geographic region	West Africa	West Africa	West Africa	Middle East
Country region	Boucle du Mouhon	Ségou and San	Borno State	West Bank

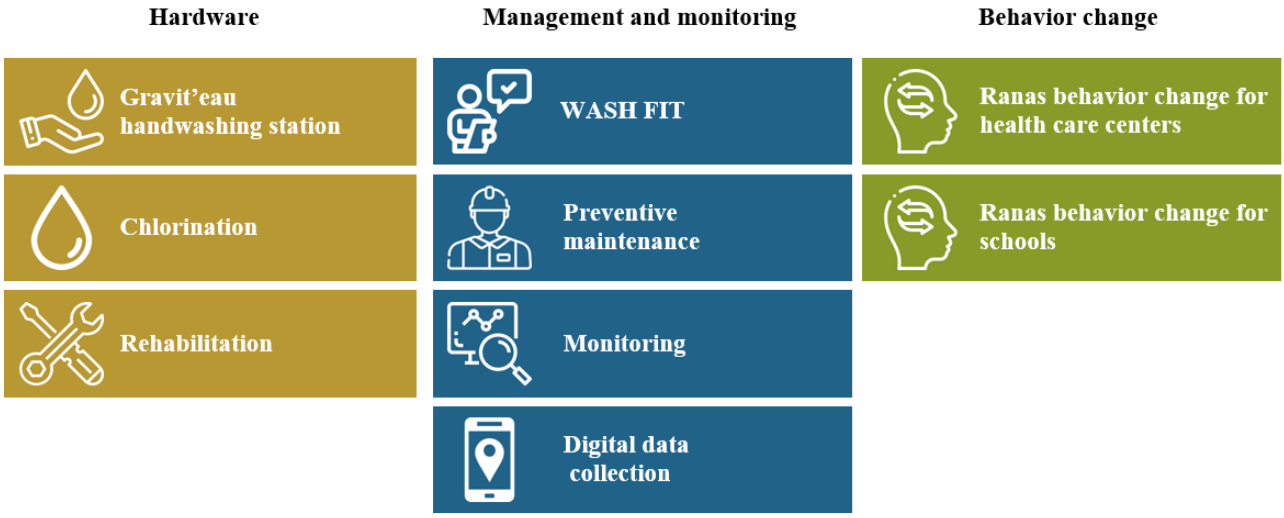
[c]Nigeria: Situation Report (OCHA; July 18, 2023) [45].

[d]N/A: not applicable.

Intervention and Control

The MCHHI varies by study country because it was adapted to each country's needs, local acceptability of intervention components, and tools available for health care centers or schools (refer to Multimedia Appendix 2 for a detailed description). The intervention components, covering hardware, management and monitoring, and behavior change are depicted in Figure 2. In terms of hardware, a handwashing station that recycles water, called Gravit'eau, was locally built and adapted in terms of height and size of basin to the type of institution (ie, health care center or school) in the African countries. Per health care center, 2 individual stations were installed and positioned according to the health care provider's wishes. In Nigeria, 2 stations were placed near 4 to 6 classrooms and toilet areas serving our selected sample of 50 students in each school. In Palestine, recycled water was not culturally accepted. Therefore, instead of receiving a station, we supported the schools with infrastructure rehabilitation work. Facilities in the control arm will receive the intervention once the cRCT is completed. Any viable potential improvements identified during the trial will be implemented.

Figure 2. The hands4health multicomponent hand hygiene intervention components implemented in at least one of the study countries grouped according to hardware (yellow), management and monitoring (blue), and behavior change (green). The icons were sourced from Freepik. RANAS: risks, attitudes, norms, abilities, and self-regulation; WASH FIT: Water and Sanitation for Health Facility Improvement Tool.



Recruitment and Eligibility

Primary Health Care Centers

We selected the primary health care centers with the support of the local implementation partners. They conducted a FACET survey in 179 centers in Burkina Faso and 60 centers in Mali. From these centers, we selected a subset based on the following inclusion criteria: at the time of the FACET survey, the facility (1) did not have any water source directly connected to the building, (2) had a maternity ward, (3) had at least 5 employees, and (4) was impacted by insecurity but was still deemed accessible to the implementation partners. Of the centers meeting these criteria, the implementation partners chose 48 (n=24, in each country) that were most likely to remain accessible for at least 1 year.

As study participants in the health care centers at baseline, we invited all health care workers who met the inclusion criteria and were present at the time of data collection for the quantitative data collection. The inclusion criteria for the quantitative data collection were as follows: health care workers (1) aged at least 18 years and (2) in direct physical contact with patients. The exclusion criteria were as follows: health care workers (1) whose primary occupation does not involve the health care center of the h4h project, (2) who have a skin condition that precludes the use of soap or alcohol-based handrub, and (3) who refuse to participate. All recruited participants received a unique ID. The same eligibility criteria will apply for the follow-up (1-2 months after the intervention) and endline (12 months from the baseline) data collection.

As part of the quantitative data collection in health care centers, we conducted structured observations during patient consultations. The patients needed to fulfill the following inclusion criteria: (1) aged at least 18 years or being accompanied by a legal guardian aged ≥18 years; and (2) visiting the facility for a physical examination, injections or vaccinations, or a blood test. We did not observe sensitive procedures such as giving birth.

Participants for the qualitative data collection at follow-up will be recruited from those who participated in the quantitative baseline data collection. In addition, we will seek to recruit others working in the intervention centers, such as hygiene technicians or people working in administrative positions, as well as stakeholders within the community, state, region, or country of the intervention whose position is related to WASH in health care centers.

Primary Schools

The MoE in Nigeria and Palestine identified 51 and 50 schools, respectively, as being greatly in need of WASH infrastructure. The implementation partners conducted a FACET survey in each of these schools before the start of this study. From these 101 schools, we selected 52 (51.5%; n=26, in each country) based on the following inclusion criteria: at the time of the FACET survey, the school (1) was deemed accessible to the implementation partners, (2) lacked a functional water source, and (3) had ≤7000 students studying in grades 5 to 7.

For the baseline data collection, we selected 50 eligible students aged 10 to 12 years from 1 or 2 classes from each school using random sampling. If a school had a single class consisting of ≥50 students within our target age group, we selected our sample from this class. However, if no class in our target age group had ≥50 students, we randomly selected 2 classes from within the target age group and selected our sample from these classes. For the different data collection modules, we randomly selected subsets from the 50 previously selected students (Figure 1). The inclusion criteria for both quantitative and qualitative data collection were as follows: (1) aged 10 to 12 years and (2) registered at the school for the duration of the study period (1 year). The exclusion criteria included (1) not providing signed consent (for the guardians) and assent form (for the students), (2) having a medical condition that prevents them from washing their hands, (3) having unexplained intermittent attendance in school (school teachers were consulted, and the school's absenteeism records were checked), and (4) not being in the same school for the course of the study (1 year). The same 50 students will be revisited for the follow-up (1-2 months after

the intervention) and endline (12 months from the baseline) data collection.

In addition to the data collected from students, we will collect qualitative data from teachers and key stakeholders at follow-up. The eligibility criteria for teachers are as follows: (1) aged ≥18 years, (2) permanent employee in one of the intervention schools, and (3) teaching one of the classes included in the intervention. The exclusion criterion is refusal to participate. Key stakeholders will be identified through purposeful sampling, primarily through consultation with the local implementation partners. Key stakeholders will be eligible for inclusion in the study based on the following criteria: (1) they occupy a role within the community, state, or region of the study that is associated with WASH in schools (eg, teachers and school principals or people working in any of the organizations that are part of the WASH cluster, such as the MoE or MoH); and (2) they are aged ≥18 years. The exclusion criterion is refusal to participate.

Ethical Considerations

All our study protocols were approved by the Ethikkommission Nordwest- und Zentralschweiz (Ethics Committee for Northwestern and Central Switzerland; AO_2023-00004 and AO_2023-00047) and the ethics boards in each project country: (1) the Comité d'Ethique pour la Recherche en Santé (Ethics Committee for Health Research) in Burkina Faso (2023-02-020), (2) the National Institute of Public Health in Mali (05/2023/CE-INSP), (3) the National Health Research Ethics Committee in Nigeria (21/2023), and (4) the institutional review board of An-Najah National University in Palestine (H Sp. Feb. 2023/18). Study participants in the health care centers and legal guardians of schoolchildren gave written informed consent to participate in this study, whereas schoolchildren gave oral assent. For structured observations, the local implementation partners obtained consent in both facility types before the baseline observations. At the health care center level, consent was obtained from the director of the center for the duration of the study period. In addition, oral consent was obtained from the patients who visited the centers at the time of the observations. Similarly, at the school level, consent was secured from the school administration and from the parents of the participating students. All participants received a unique ID that was coded and will be completely anonymized by the end of this study. Our study protocols for health care centers and schools are registered in ClinicalTrials.gov (NCT05946980 and NCT05964478). We report our study in line with the CONSORT (Consolidated Standards of Reporting Trials) statement: extension to cluster randomized trials [46].

Randomization

We used covariate-constrained randomization to allocate facilities into the control and intervention arms. This methodology, also referred to as restricted randomization, was first suggested by Moulton [47] to minimize the risk of baseline imbalances. These issues are usually more prominent in cRCTs due to the relatively low number of randomized units.

A statistician who was not involved in any h4h field activities performed the covariate-constrained randomization after baseline data collection following these steps: (1) definition of a set of maximum imbalance criteria for several important baseline characteristics, (2) generation of a list of all potential allocation sequences that satisfy these criteria, (3) verification of the independence of units, and (4) random selection of one of the valid sequences as the final allocation.

For health care facilities in Mali and Burkina Faso, we defined the following four constraints: (1) proportions of health care facilities with shortages in water sources should be perfectly balanced, (2) a difference in the proportion of secure facilities of <10 percentage points, (3) a difference in the mean proportions of the population living within 5 km of <10 percentage points, and (4) a difference in the mean proportions of accurate handwashing in each facility of <3 percentage points. In Mali and Burkina Faso, 248,574 and 767,792 potential allocation sequences, respectively, satisfied all 4 criteria.

For schools in Palestine, we first stratified the clusters before applying the restricted randomization. This stratification was based on two key parameters: (1) the directorate in which the school is located; and (2) the school's geographic location, categorized as city, town, or village. After stratification, the allowed allocation sequences had to satisfy the following criteria: (1) balanced administrative areas for schools across both arms, (2) balanced sex, (3) a difference of ≤33% points in the proportions of schools connected to a water network across the arms, (4) a difference of ≤33% percentage points in the proportions of schools with consistent access to water, (5) a difference of <50 in the mean numbers of students across the arms, (6) a difference of <0.2 in the mean grades across the arms, and (7) a difference of <50 in the mean ratios of the number of handwashing stations to the total number of students across the arms. In total, 394 potential allocation sequences satisfied all criteria.

For Nigeria, we defined the following criteria: (1) similar proportions of schools with no currently available water source, (2) similar proportions of schools with <2 days of water availability, (3) similar proportions of schools located in a village as opposed to a city or town, and (4) similar proportions of primary schools in comparison to mixed primary and secondary schools. Other variables allowed a certain degree of imbalance but still required consideration to ensure appropriate balance. These included (1) a difference of ≤200 students in the average student numbers per school between the study arms, (2) a difference of ≤25 percentage points in the proportions of schools with water network connections across the arms, and (3) a difference of ≤25 percentage points in the proportions of schools with water availability for 3 to 5 days a week across the arms. Of all potential allocation sequences, 57,054 satisfied all criteria.

Blinding

To reduce selective counting of colony-forming units (CFUs) of bacteria in the hand-rinse samples collected at baseline, the laboratory workers assessing the number of CFUs were blinded. The data collectors delivered the coded samples to the laboratory workers. From the identification code of the samples, the laboratory workers could not derive whether the sample was collected in an intervention facility or a control facility. The

laboratory workers will be blinded again at endline data collection.

Quantitative Methods

We collected quantitative data with four different modules: (1) module 1 (RANAS and well-being survey), (2) module 2 (structured handwashing observations), (3) module 3 (microbiological analysis of hand-rinse samples), and (4) module 4 (diary approach for predefined health conditions).

Module 1: RANAS and Well-Being Survey

We started the survey by asking participants about sociodemographic information, followed by knowledge questions about hand hygiene and self-reported hand hygiene practices (for detailed descriptions of the variables, refer to Multimedia Appendix 3). The survey proceeded with questions to measure the RANAS behavioral factors, such as perceptions of costs and benefits of consistent hand hygiene, social norms, and ability beliefs, on 5-point Likert scales to measure frequencies, magnitudes, and degrees [27]. Questions about the hygiene infrastructure in the facilities followed this section. In health care centers, there were additional survey items on the quality of care, and in schools, on student well-being. Well-being was assessed with the KINDL tool (Kinder Lebensqualität Fragebogen, Children's Quality of Life Questionnaire), which was developed specifically to measure health-related quality of life in children and adolescents by assessing different domains of well-being [48].

We conducted the survey with all participating primary health care workers and a randomly chosen subset of 25 students per school at baseline and will repeat at follow-up (1-2 months after the intervention) and endline (12 months from the baseline). The survey will be interviewer administered using Open Data Kit Central software (version 2022.3.1) on Android tablets or smartphones.

Module 2: Structured Handwashing Observations

Structured handwashing observations are considered the gold standard method to assess handwashing behavior [12,49]. We conducted the observations with primary health care workers and schoolchildren at baseline and will repeat these observations at follow-up and endline. Due to structural differences in health care centers and schools, we chose 2 different observation approaches for the 2 facility types.

In primary health care centers, staff members from the implementation partner or the regional MoH were trained by the first author (AG) as observers for the baseline data collection. Observers usually worked in the health care centers in a different role, and they visited the facility under the pretext of performing their usual role and did not declare that they were observing handwashing. Hence, the handwashing observations were conducted covertly. The observers were equipped with an observation tool programmed in Open Data Kit Central (version 2022.3.1) on their smartphone. During their visit, they spent 1 hour in each unit to record all hand hygiene actions taken by the health care providers, as well as their handwashing techniques [50]. The same observation process will be repeated at follow-up and endline.

In schools, student handwashing was observed by implementation partners who were trained by the second author (YA). To aid the identification of participating students, all children were given badges, with 1 color for those participating and another for those not participating. The students were told that the color assignment was random. The implementation partners observed each student's handwashing practices across a variety of occasions, including the 2 critical moments: before eating and after using the toilet (among others, eg, after eating and after playing). To observe handwashing before eating, we involved the students in an experiment. We engaged the children in a 30-minute painting activity, after which the children were rewarded with a popcorn snack and granted a 15-minute break to enjoy it together. This created an opportunity to observe whether the children washed their hands before eating the snack. Observers did not reveal their intention of observing handwashing throughout the time of the data collection. In Nigeria, we additionally observed the children for 3 hours. The observation started at 9 AM (60 minutes before the breakfast break) and ended at noon (90 minutes after the break). Four observers were stationed near all available water points and toilets. Using a paper-based observation tool, the observers recorded all participating students who washed their hands and whether they did so before eating, after using the toilet, or at another time point. In addition, any participating student observed using the toilet who did not wash their hands was also recorded.

Observers then cross-checked their results to eliminate instances of duplicate observations for the same students. They merged observations made at different critical times or water points for the same student and confirmed whether those who used the toilet also washed their hands, particularly in scenarios where toilets were situated at a considerable distance from the water points. After this cross-checking process, the data were transferred to Open Data Kit Central (version 2023.3.1) for analysis and storage. These observations yielded a dichotomous measure: whether handwashing occurred at each critical event. However, options such as "not visible" or "soap or water was not available" were included to account for potential complications. If feasible, we observed the handwashing steps of students who washed their hands. Observations will be repeated in schools at follow-up and endline.

Module 3: Microbiological Analysis of Hand-Rinse Samples

We collected hand-rinse samples of all participating health care workers and a randomly selected subset of 12 students at baseline with a modified glove juice method as described by Pickering et al [51]. We asked the participants to insert their hand into a Whirl-Pak bag (Nasco Sampling LLC; sizes 2041 mL and 7120 mL for adults and children, respectively), filled with 350 mL of bottled drinking water without chlorine. The participants were asked to shake their hand in the water and rub their thumb and fingers together for 15 seconds, and then the sample collector massaged the participant's hand through the bag for another 15 seconds [51]. Afterward, we repeated the procedure with the other hand.

We kept the Whirl-Pak bags containing the samples on ice in an isolation box and processed them within 8 hours of sampling [51]. We used membrane filtration to detect CFUs of *Escherichia coli* and total coliforms. In a field laboratory, we passed 100 mL of the bag's content through the filter paper, which we then placed on Nissui Compact Dry EC plates (Shimadzu Diagnostics Europe) to incubate them at 35 °C −0.5 °C to +0.5 °C for a duration of 24 hours [51]. For quality control, we carried out a duplicate filtration of every 10th sample and a negative control, only containing the bottled water, each day.

We calculated the lower detection limit of CFUs by dividing 1 CFU per plate by the filtrate volume and then multiplying it by the total Whirl-Pak volume of 350 mL. We calculated the upper detection limit by dividing 301 CFUs per plate by the filtrate volume and then multiplying it by the Whirl-Pak volume. We normalized and $\log_{10}$-transformed the CFUs per hand for the statistical analysis [51]. We will repeat the same hand-rinse sampling procedure again at follow-up and endline.

Module 4: Diary Approach for Predefined Health Conditions

Using a diary approach, we will ask health care center directors to collect longitudinal data on the hygiene-related health conditions of patients. These conditions include maternal and neonatal mortality, stillbirths, postpartum endometritis, neonatal sepsis, umbilical cord infections, and infections of wounds after treatment. For each relevant health condition among patients, the director will be asked to report the date of diagnosis, and if known, the duration of the condition, the etiology, and ultimate outcome (eg, recovery or death). Detailed descriptions of the health conditions are presented in Multimedia Appendix 4 [52].

Similarly, hygiene-related absences of all participating health care workers and the 50 students will be reported during the period after the intervention until the endline data collection in both study arms. For absenteeism in health care centers or schools, the person responsible will record the event, the number of days absent, and the reason for the absence. We define absenteeism as hygiene related if the facility worker or student experienced diarrheal diseases (including cholera), respiratory tract infections (including tuberculosis, COVID-19, and influenza), bacterial infections of the skin and eyes (including trachoma), and newly diagnosed HIV and hepatitis B or C. The diary will consist of 1 table per month containing all different health conditions and subcategories. No personal information will be recorded in this module.

Outcomes

Primary Outcome

Due to the difference in settings, health care centers and schools have different primary outcomes. In health care centers, the primary outcome is the handwashing rate, defined as the number of times each health care worker performs good handwashing practice with soap or alcohol-based handrub at one of the World Health Organization (WHO) 5 moments for hand hygiene [53], divided by the number of moments for hand hygiene that presented themselves during the patient interaction. The handwashing rate was assessed by structured handwashing observations over 1 hour per unit in a health care center. The 5 moments for hand hygiene are defined by the WHO as follows:

1. Before touching a patient
2. Before clean or aseptic procedures
3. After risk or exposure to body fluids
4. After touching a patient
5. After touching a patient's surroundings

In schools, the primary outcome is the number of participating students who wash their hands before eating. This number was collected using structured handwashing observations after students were given a snack after their participation in a painting activity. We selected this outcome because it allows for an objective assessment across all participating students, given that all were presented with this handwashing opportunity during the course of the experiment.

Secondary Outcomes

The most important secondary outcomes in both settings are as follows:

1. Self-reported handwashing practice on a Likert scale ranging from *almost never* to *almost always* (in health care centers: for each of the 5 moments for hand hygiene; in schools: before eating and after using the toilet)
2. The $\log_{10}$-transformed number of total coliforms and *E. coli* CFUs per hand before handwashing
3. RANAS behavioral factors measured on a 5-point Likert scale
4. Hygiene-related absenteeism and health conditions, which are summarized in Multimedia Appendix 4; the sum of each outcome variable will be used separately per facility (cluster) as a measure for statistical analysis, and health conditions will be reassessed with local experts in the respective countries to ensure feasibility before the start of the intervention

Secondary outcomes only applying to the school setting are as follows:

1. Good handwashing practice defined as the number of students who wash their hands after using the toilet (assessed by structured handwashing observation)
2. Self-reported well-being of students assessed using the KINDL tool [48], with responses given on a Likert scale ranging from *almost never* to *almost always*

Statistical Analysis

Sample Size Calculation

We ran a series of simulations using R software (version 4.1.3; R Foundation for Statistical Computing) to determine the required sample size for health care centers. For the simulations, we assumed 6 staff members per health care center, a mean number of 5 (SD 5) times a person was supposed to wash their hands, and an intracluster correlation coefficient of 0.15; we needed to enroll 10 health care centers in each trial arm to detect a difference of 15 percentage points in the proportions of handwashing during the 5 critical moments for handwashing (30% control vs 45% intervention) with 81% power at a 2-tailed 5% significance level. To account for potential loss to follow-up,

we enrolled 24 health care centers per country in Burkina Faso and Mali.

Within schools, we assessed the number of clusters (schools) and students per school with simulations using R. We aimed for a power of 80% at the 95% CI and anticipated an intraclass correlation coefficient of 0.2. In the simulation, we assumed a prevalence of handwashing before eating of 20% in control schools versus 45% in intervention schools after 1 year from the baseline. On the basis of this assumption, we needed 13 schools per trial arm with 50 students per school. However, the number of students assessed for different modules will differ throughout the study due to capacity limitations of assessing the 50 students included in each school.

Statistical Methods

We summarized baseline characteristics using descriptive statistics (Textbox 2). We will investigate the difference in the observed proportions of always handwashing at the 5 critical moments as defined by the WHO for primary health care centers and of the number of participants who wash their hands before eating for primary school students between the 2 study arms at follow-up using random effect logistic regression models. We will only include the intervention as a predictor in the primary analysis. For the primary analysis, we will use the available case population of health care workers and students, which will be analyzed according to the intent-to-treat principles.

Textbox 2. Statistical methods used for the analysis of the results of the different quantitative modules of the hands4health study.

Modules and statistical methods

- Risks, attitudes, norms, abilities, and self-regulation and well-being survey (module 1)
  - Descriptive statistics
  - Random effect linear regression modeling
  - Random effect logistic regression modeling
- Structured handwashing observations (module 2)
  - Random effect logistic regression modeling
- Microbiological analysis of hand-rinse samples (module 3)
  - Random effect negative binomial regression modeling
- Diary approach for predefined health conditions (module 4)
  - Descriptive analysis with the sum of each outcome variable calculated separately per facility
  - Random effect linear regression modeling

Qualitative Methods and Analysis

Before the baseline data collection and at follow-up, we supplement our quantitative methods with two modules of qualitative methods: (1) module 5 (FGDs) and (2) module 6 (key informant interviews [KIIs]).

Module 5: FGDs

FGDs offer a practical way to gather insights more efficiently than other qualitative methods [54,55]. Before the onset of the study, the local implementation partners with experience in qualitative data collection collected data through FGDs involving health care workers, students, and teachers. These FGDs helped us to gain insight into the hygiene-related needs as well as the acceptability of our intervention among health care workers and students. We let the groups vote for their most urgent hygiene-related needs as well as the potential positive and negative impacts of our intervention. After counting and discussing the votes during the FGD, the project consortium adapted the country-specific interventions, and we identified what we needed to include in the quantitative data collection.

We collect data with FGDs again since January 2024 and will continue this data collection until April 2024 with the same trained implementation partners for health care workers and students to assess the perceived effectiveness and potential improvements of the h4h intervention. In addition, we will conduct FGDs with teachers from the schools in the intervention arm. We will train the team containing at least 1 moderator and 1 observer or notetaker before data collection. If the security situation allows, AG or YA will join the team. We will use a field research journal throughout the study to take structured notes and observations of the FGDs. We will audio record and transcribe the discussions and then translate into French or English for further analysis.

All health care workers in the intervention centers will be invited to participate in FGDs.

In health care centers, we will take into account the structures of hierarchy and gender when building mini groups of 3 to 4 participants to allow participants the greatest possible freedom of speech. We chose to have mini groups because the health care workers who participate are expected to have a high expertise in hand hygiene. Usually, the higher the expertise of participants, the smaller the group can be [54]. Depending on the hierarchical levels, 1 to 4 FGDs will take place per facility. We expect to conduct a maximum of 20 FGDs per country (fewer if we reach saturation beforehand) [55].

In schools, we will select students from each class in the intervention arm, in consultation with the school administration. We will conduct FGDs with 5 to 10 boys and girls separately until saturation is reached (or up to the maximum of 5 FGDs with each sex) and 5 FGDs with teachers [55]. KIIs may be conducted instead of FGDs if we do not have enough participants to form groups in both facility types.

Module 6: KIIs

Aiming to further explore issues arising from the FGDs and to understand perceptions of the intervention, we will conduct KIIs with other stakeholders who influence the project's intervention areas, such as representatives of the MoH and MoE as well as local majors. We have identified some of these key informants through the theory of change approach, while others will be suggested by local partners. Here, we chose individual interviews rather than FGDs so that the stakeholder's status does not influence other participants' freedom of speech [55].

If necessary and appropriate, we may carry out interviews on the web, in French or English. Local project partners with experience in interviewing will conduct stakeholder interviews until saturation is reached [55]. We will apply the same steps of audio recording, transcription, and translation for the KIIs as for the FGDs.

We will analyze FGD and KII transcripts as well as field and observation notes using the framework method [56] with MAXQDA software (VERBI GmbH) with at least 1 local partner per country with qualitative expertise.

Triangulation of Results

We triangulate our results throughout the study. Qualitative data from the pilot phase informed our quantitative data collection at baseline. Moreover, questions identified during the quantitative baseline and follow-up data collection will guide our qualitative FGDs and KIIs, which can then be used to better understand our results from the endline data collection By triangulating the results, we will be able to validate them, find discrepancies, and increase our understanding of why certain quantitative results emerged [21,22]. In addition, we might identify new research gaps and potential solutions to issues that we identified during the study period.

Results

The baseline data collection of this study started in February 2023 and ended in June 2023. In Burkina Faso, we conducted 95 RANAS surveys, observed 82 participants, and collected 99 hand-rinse samples in 24 primary health care centers. In Mali, we conducted 105 RANAS surveys, observed 111 participants, and collected 100 hand-rinse samples in 24 primary health care centers. As of March 2024, the analysis of the baseline results in health care centers is completed and a manuscript will be submitted within the same month for publication. In Nigeria, we conducted 640 RANAS surveys, observed 1300 participants, and collected 369 hand-rinse samples in 26 primary schools. In Palestine, we conducted 646 RANAS surveys and observed 1127 participants in 26 primary schools. We did not collect hand-rinse samples in Palestine because the method was deemed culturally inappropriate by the MoE. As of March 2024, data analysis for schools is ongoing. Follow-up data collection took place from November to December 2023 in 24 health care centers in Burkina Faso and Mali, respectively and in 26 schools in Nigeria. Due to the crisis in Palestine, follow-up activities were suspended. As of March 2024, data analysis remains ongoing. Qualitative data collection started in Burkina Faso in January 2024 and is planned to start in Mali and Nigeria in March 2024. Endline data collection started in Mali in February 2024 and will be completed in all countries by June 2024. We will publish more results investigating data collected during the follow-up, qualitative, and endline data collection in the year 2024. Project funding is guaranteed until December 2024.

Discussion

Summary

By implementing a mixed methods approach within a cRCT study design with multiple stakeholders from academia, the private sector, humanitarian organizations, and MoHs and MoEs, we aim to better understand the complex situations in our 4 project countries. We used mixed methods to generate much-needed quantitative data about the WASH infrastructure and behavior in primary health care centers and schools in regions where such data are usually very scarce. At the same time, the qualitative data help to better understand the reasons behind the effectiveness of our intervention and to capture intricacies missed with quantitative data collection. In our opinion, conducting research across disciplines is crucial in humanitarian crisis contexts to guarantee ethical and beneficial outcomes, which policy makers can then use locally.

Research in Conflict Settings

The demand for research in conflict settings is increasing to support evidence-based interventions and impact evaluations [49]. Unfortunately, this type of research is still rare and the quality of existing studies poor [57]. Apart from obvious challenges such as the researchers' and participants' security as well as political instability, additional difficulties might hinder research in these settings [58]. These difficulties include a lack of data, determining the study population, knowing the baseline health status of the study population, displacement of the study population, and issues with logistics [58]. We tried to respond to these difficulties by involving local actors from humanitarian and governmental organizations and the facilities from the project outset. However, the rapidly changing political and security situations in the project countries make it difficult to plan ahead.

Strengths and Limitations

Our study has some noteworthy strengths: first, with the cRCT, we use the study design with the highest level of evidence [59]. Second, by using mixed methods, we can further strengthen our results by triangulation. Third, the design of the MCHHI is data driven and hence well adapted to promoting sustainability in the contexts in which it was implemented. Fourth, one of the core strengths of this study lies within our inter- and transdisciplinary teams and consortium. By including the humanitarian sector, local authorities, health care personnel, teachers, and students early in the process through regular

meetings, the theory of change workshops, and FGDs, we expect to address real needs with our research. Throughout the process of developing the study protocol, we kept consulting with our partners through regular remote meetings and several in-person workshops in the respective countries. This close exchange throughout the project enabled us to rigorously and continuously evaluate the situation in the unstable settings we worked in. Fifth, by conducting this project in 4 different countries, we can gain valuable insights into how the h4h MCHHI needs to be adapted to different contexts and how it can be made more readily available for future interventions in other regions. Finally, we address big data gaps with this study. In Burkina Faso and Mali, the current MoHs actively want to strengthen hygiene, water, and sanitation in health care. However, they lack data about hand hygiene and WASH infrastructure in primary health care to inform their campaigns. This study can inform them directly about current practices and how they can or cannot be influenced with our proposed MCHHI. In schools, the respective MoEs have expressed a keen interest in this study. The findings, which clarify student hand hygiene, are anticipated to be of considerable value. These insights will not only inform about the intervention's impact but will also guide the MoEs in scaling the intervention across a broader spectrum. By identifying the strengths and weaknesses of the intervention, they can further enhance and replicate the successful aspects while avoiding any identified shortcomings.

Despite the strengths, our study has some limitations. First, we could not choose facilities completely at random. They needed a high probability of remaining accessible to the local partners. Therefore, our results are not fully generalizable and might miss some of the people considered most vulnerable and inaccessible. Second, due to the nature of this study, we could not blind the participants, our implementation partners, or the people conducting the statistical analysis. Therefore, a nonblinding bias cannot be excluded. Third, to maintain a balance between achieving a sample size of institutions for a high enough statistical power and having a sufficient budget to implement hardware interventions in all these institutions, 2 Gravit'eau stations per institution were implemented. In health care centers, we expect an average of 3 health care workers using 1 station and, if accessible to patients, approximately 20 patients per day. In schools, the stations were designed to accommodate up to 100 individuals per hour. Judging from the station's strategic positioning, we estimate that 250 to 300 students will be using 1 station during a school day. Fourth, we expect a high social desirability bias in the self-reported handwashing and hygiene behavior data. We anticipate having a more realistic and objective view of handwashing and hygiene behavior by complementing the survey data with observation and hand-rinse data. Fifth, the structured observations might be subject to a Hawthorne effect [60]. We aim to counteract this effect by conducting the observations covertly before the official beginning of the study. In health care centers, we chose implementation partners and MoH staff who regularly visit the centers for other supervision activities unrelated to handwashing. This might still change the participants' behavior, but we expect they did not focus too much on handwashing. We had to inform the head of health care centers before the observations for ethical reasons. Therefore, the possibility that the participants knew why they were observed remains.

Conclusions

To our knowledge, this is one of the most innovative studies to investigate the effectiveness of an MCHHI on the health determinants of beneficiaries in primary health care centers and schools. With our sound inter- and transdisciplinary methodological approach, we expect to generate results and conclusions that can sustainably impact local policy makers and the humanitarian sector working in the project countries and beyond.

Acknowledgments

The authors want to express their utmost gratitude to the Swiss Agency for Development and Cooperation, which funded and supported the hands4health project (7F-l 0345.03.01), with special thanks to Nathalie Wyzer. The authors would also like to thank Bruno Pascual and Sébastien Mercier, their partners from Terre des hommes, Lausanne, Switzerland, as well as the Terre des hommes country offices in Burkina Faso (Kamboulbé Dah, Ibrahim Simia, Dramane Zongo, Salifou Ouedraogo, Dieudonné Belembaongo, Alimata Tall, Philip Parfait, Julien George, and Paolo Pennati), Mali (Hassane Dembélé, Issa Bagayogo, Modibo Traoré, Saran Samaké, Dramane Keïta, Jean-Paul Elle Sibiri Somboro, and Françis Ntéssani), and Nigeria (Zainab Abdulkarim, Usman Kolo, and Muhammad Shuaibu) for supporting them throughout the development and implementation of this study with their expertise and experience. In the same way, the authors are grateful to their partners from Cesvi (Roberto Turcato, Issa Younan, and Ola Sa'o) and the Palestine Polytechnic University (Hasan Abusalha, Maher Ja'bari, and Safa Sultan). The authors want to express their deep gratitude to the regional and national Ministries of Health in Burkina Faso (Valentin Ouedraogo, Martine Kaboré, Oussény Sankara, Malick Nayété, and Houssen Koanda) and Mali (Mamadou Keïta), the Ministry of Education in Palestine (Ahmad Salah, Amjad Hemaidat, Razan Salah, and Wissam Nakhleh), and Ministry of Education—The Borno State Universal Basic Education Board in Nigeria, which actively support their project. The authors thank all data collectors who worked with Terre des hommes and Cesvi for their great efforts and courage to work in these challenging settings. The authors highly appreciate the support of Marco Verber, formerly from the University of Applied Sciences and Arts Northwestern Switzerland, for his technical and project management knowledge, and Anna Gamma, formerly from Ranas Ltd, for her expertise in behavior change. Finally, the authors would like to thank Skat Foundation for its lead in the theory of change process and support for the qualitative data collection (Matthias Saladin, Bertha Camacho, Rena Salzmann, and Meleesa Naughton) and Fabian Peter, cofounder of Gravit'eau, who supported the implementation teams with the construction of the handwashing stations.

Authors' Contributions

MSW is the principal investigator of all impact evaluation research activities of the hands4health study. AG and YMA are responsible for the study design, ethics approval, trial registration, fieldwork supervision, and data analysis. JH was the main statistical adviser, supported by BNO, and KG was the main adviser for the qualitative study design. AB is a focal point of the implementation partner and advised during the process of developing the study protocol, supported all implementation activities, and leads the Water and Sanitation for Health Facility Improvement Tool intervention. MH, MNDF, and AT developed the risks, attitudes, norms, abilities, and self-regulation survey and led the whole RANAS approach. CB and MP developed all infrastructure-related tools and were involved in the overall project management. AG, YMA, BNO, and MSW drafted the manuscript. CB, AB, MNDF, MH, JH, KG, MP, and AT revised the manuscript.

Conflicts of Interest

AT, MNDF, and MH are cofounders of Ranas Ltd. However, Ranas Ltd has no patents, products in development, or marketed products associated with this research. MP is a cofounder of Gravit'eau. However, Gravit'eau is a nonprofit organization that does not promote the handwashing stations with marketing. All other authors declare no other conflicts of interest.

Abstract

Background: In the global strategy to eliminate leprosy, there remains a need for early case detection to successfully interrupt transmissions. Poor knowledge about leprosy and leprosy-related stigma are key drivers of delayed diagnosis and treatment. Sensitization campaigns to inform and increase awareness among the general population are an integral part of many national neglected tropical disease programs. Despite their importance, the effectiveness of such campaigns has not been rigorously studied in the West African context. A multilingual rural setting with low health literacy in this region presents challenges to the potential impact of sensitization campaigns.

Objective: The primary objective of this study is to assess the causal effect of common practice community sensitization campaigns on leprosy-related knowledge and stigma at the community level and among community health volunteers. Additionally, we will test the potential of novel educational audio tools in the 15 most prominent local languages to overcome literacy and language barriers and amplify sensitization campaigns.

Methods: We will conduct a cluster randomized controlled trial using a sequential mixed methods approach in 60 rural communities across all regions of Togo, West Africa. The study features 2 intervention arms and 1 control arm, with intervention and control assignments made at the community level through randomization. Communities in intervention arm 1 will receive a sensitization campaign in line with the current Togolese national neglected tropical disease program. Communities in intervention arm 2 will receive the same sensitization campaign along with educational audio tools distributed to community households. The control arm will receive no intervention before data collection. Quantitative outcome measures on knowledge and stigma will be collected from a random sample of 1200 individuals. Knowledge will be assessed using the 9-item standardized Knowledge, Attitudes, and Practices Questionnaire. Stigma will be measured using the 7-item Social Distance Scale and the 15-item Explanatory Model Interview Catalogue Community Stigma Scale. We will estimate intention-to-treat effects at the individual level, comparing

the outcomes of the intervention and control arms. In an accompanying qualitative component, we will conduct in-depth interviews with community members, community health volunteers, and health care workers in both treatment arms and the control arm to explore intervention and stigma-related experiences.

Results: This paper describes and discusses the protocol for a mixed methods cluster randomized controlled trial. Data collection is planned to be completed in June 2024, with ongoing data analysis. The first results are expected to be submitted for publication by the end of 2024.

Conclusions: This trial will be among the first to test the causal effectiveness of community-based sensitization campaigns and audio tools to increase knowledge and reduce leprosy-related stigma. As such, the results will inform health policy makers, decision-makers, and public health practitioners designing sensitization campaigns in rural multilingual settings.

Introduction

Overview

Leprosy is a communicable neglected tropical disease (NTD) caused by *Mycobacterium leprae*. In 2022, more than 140,000 cases were reported globally, mainly in Southeast Asia, Africa, and the Americas [1]. Across sub-Saharan African countries, leprosy is found in endemic pockets and is most common among the rural poor [2,3]. Despite effective antibiotic treatment being widely available, new cases of leprosy continue to occur in Togo [4]. In line with experiences in other countries, a significant number of hidden cases is expected [1,5,6]. In its global strategy to eliminate leprosy, the World Health Organization emphasizes the need for early case detection to successfully interrupt transmissions. Additionally, as an independent objective, the need to reduce stigma is emphasized to further alleviate the burden of the disease [7].

Leprosy is a highly stigmatized disease, mainly due to low understanding and knowledge about the disease itself, including misconceptions regarding transmission and treatment [8-10]. While knowledge and stigma are distinct constructs, they often interact. Consequently, a lack of knowledge about the disease can foster false beliefs that may contribute to the stigmatization of patients. However, even with increased understanding of the disease, stigmatizing attitudes can persist [8]. This stigma contributes to patients' hesitation to seek care [10], as well as delayed diagnosis and treatment [11,12]. As a consequence, a delayed or missed diagnosis of leprosy often results in irreversible disabilities causing permanent visible impairments [13], which in turn reinforce stigma and discrimination [14].

Existing sensitization campaigns aim to create awareness and improve understanding of leprosy among the general population and ultimately achieve early case detection and treatment [15]. Common practice leprosy sensitization campaigns include information on the disease itself, transmission, incubation, development, and potential treatment. Group discussions, leaflets, and positive testimonies of people successfully cured are used to overcome potential entrenched misconceptions among the population. Although there is a comprehensive body of literature on conceptualizing the drivers and consequences of health-related stigma [8,16-20], the effectiveness assessment of interventions targeting leprosy-related stigma are rare. A nonrandomized intervention study in India found health posters and focus group discussions to be associated with improved leprosy-related knowledge and reduced stigma [21]. A before-and-after study in Indonesia also showed leprosy sensitization campaigns to be associated with a reduction of stigma [22]. To the best of our knowledge, the effectiveness of leprosy-related stigma interventions has not been studied in the West African context.

Togo has a literacy rate of 67%, and aside from French being the official working language, 49 local languages are widely spoken [23]. Especially in rural communities, local languages are often the predominant mother tongue. Several scholars have shown the impact of language on education outcomes in the multilingual sub-Saharan African context [24-26]. As such, literacy and language barriers are challenging to the potential effectiveness of one-time sensitization campaigns to build comprehensive knowledge and reduce stigma.

In this study, we assess the effectiveness of community-based sensitization campaigns in increasing leprosy-related knowledge and reducing stigma among the target populations in rural Togo. The common practice sensitization campaigns are carried out by the Togolese National NTD program. The campaigns are building on the inclusion of local health care workers (HCWs) and community health volunteers (CHVs) to mobilize community members and convey knowledge. Furthermore, we will establish the effectiveness of novel audio-based tools that provide target populations with information in local languages to overcome language barriers and increase the effectiveness of sensitization campaigns.

We will conduct a mixed methods cluster randomized controlled trial (cRCT) study in 60 rural communities in Togo.

Study Objectives

The main objective of this study is to assess the effectiveness of community-based sensitization campaigns to increase leprosy-related knowledge and reduce stigma. Our results will

inform national policy and decision makers, as well as stakeholders delivering health services and sensitization campaigns.

Specific research objectives are to (1) establish the effectiveness of community-level sensitization campaigns and local language audio tools to increase knowledge and decrease stigma related to leprosy among community members; (2) determine the effects of leprosy training for CHVs (knowledge on diagnosis, treatment, and prevention); and (3) elucidate the mechanisms and experiences of sensitization interventions among community members, HCWs, and CHVs.

Trial Design

We will use a cRCT using a sequential mixed methods design by collecting and analyzing quantitative and qualitative data. The trial will have 2 intervention arms that are randomly assigned across 60 study communities. Intervention arm 1 will receive the sensitization campaign (common practice by the national NTD program). Intervention arm 2 will receive the sensitization campaign (a common practice by the national NTD program) accompanied by audio tools. Control arm will receive no sensitization campaign exposure before endline data collection.

Communities assigned to the control arm will receive intervention arm 1 after data collection to ensure that all communities will receive common practice sensitization campaigns by the end of the study period.

Conceptual Framework

We use the universal health-related stigma and discrimination framework proposed by Stangl et al [27] to guide our understanding of leprosy-related stigma. Stigma is understood as an attribute discrediting the patient, enabling discrimination, and eventually limiting the opportunities of the affected persons [16,18]. The stigma and discrimination framework describes 4 different stages of health-related stigma: the first stage includes drivers and facilitators of stigma, followed by stigma marking to either health conditions or characteristics of affected groups in the second stage. Once stigma marking takes place, the third phase represents the manifestation of stigma, with experience and anticipation of stigma and stigmatizing behavior. Eventually, the manifestation of stigma affects several outcomes in the fourth stage at the individual level for affected persons and at the institutional level, manifesting as discriminating laws and guidelines. Following Stangl et al [27], the first 3 stages are key areas of applied research and interventions aiming at health-related stigma reduction.

In the context of leprosy, potential drivers of stigma are the fear of infection, social exclusion, and devaluation [8]. Misconceptions of leprosy, such as infection being a consequence of committed sins or social misconduct, can also drive stigma [28,29]. Facilitators of stigma are characteristics of affected groups such as low socioeconomic status or low educational background [8,30]. Leprosy-related stigma is commonly expressed by the loss of the social status, reputation, and self-esteem of affected persons. Patients are often socially isolated and face difficulties achieving socially desirable goals such as marriage [31]. Stigma manifestation also includes the anticipation and internalization of stigma [20]. As a consequence of stigma, early symptoms are often concealed, and delays in diagnosis lead to treatment being initiated at a disease stage where permanent, visible impairments and irreversible disabilities already occur.

While we acknowledge that education alone is never as effective as a combination of strategies for stigma reduction [8,32,33], the interventions in this study are designed to primarily target underlying causes and drivers of stigma by addressing knowledge and beliefs about leprosy at the community level. Additionally, the interventions also engage community members in activities aimed directly at reducing stigma. Through the inclusion of audio tools for information dissemination, we aim to acknowledge potential stigma facilitators, such as low literacy rates, in affected groups [30]. Offering learning content in local languages (rather than French), the audio tools could potentially improve campaign effectiveness by increasing self-efficacy through the ability to participate in the intervention as well as being able to understand the content [24-26]. Additionally, our trainings for CHVs and health facility staff in our intervention arms aim to reduce stigma at the organizational and institutional level (for example, avoiding segregation of patients) [15].

Methods

Study Setting and Implementation Partner

This study will be conducted in rural communities in Togo, West Africa. Study communities have been selected from the national NTD database. A community is considered eligible if it is located in a rural area and if at least one leprosy case has been reported in the national register between 2010 and 2020. A community has been classified as rural if its population (aged 18 years and older) did not exceed 1500 individuals based on remote censoring data [34]. Selected study sites span all 6 regions of Togo, yet districts bordering Burkina Faso were excluded due to security concerns. Between 2010 and 2014, 2630 new cases of leprosy were recorded by the Togolese National Leprosy/Buruli Ulcer Control Program. Nonetheless, a high number of undetected cases are expected [5,6]. To increase awareness, promote active case finding, and facilitate access to leprosy treatment, the Togolese National NTD program is working closely with the international nongovernment organization German Leprosy and Tuberculosis Relief Association (DAHW). The main activities of the collaboration include the implementation of skin screening campaigns in particularly vulnerable communities at risk of leprosy. During campaigns, individuals can receive professional skin screenings by dermatologists and appropriate treatment if needed. To increase help-seeking and prevent stigmatization of diagnosed patients, skin screening camps are preceded by a sensitization campaign on general skin diseases and leprosy in particular. Mobilization for sensitization campaigns and skin screenings is typically done by the respective HCWs and CHVs. Where HCWs are trained staff working from health facilities, CHVs received basic training and are voluntarily providing health services within their communities. The sensitization campaigns implemented by the National NTD program and the DAHW form the basis of the intervention to be evaluated in this study,

and study team members include representatives of the Togolese National NTD program and the DAHW to facilitate data collection and implementation.

Intervention Description

The sensitization campaigns in intervention arms 1 and 2 will be carried out in three steps: (1) planning, (2) social mobilization, and (3) implementation. The planning of sensitization and skin screening activities will be done in collaboration with influential forces in the community (eg, traditional chiefs, religious leaders, school principals, CHVs). Choices regarding the date, time, and place of the activity will be made in collaboration with the local opinion leaders. The social mobilization will entail the mobilization of all influential forces in the community to encourage individuals and families to participate in the activity.

On the day of the implementation of the sensitization activities, community members will be invited to educational sessions. The CHVs will give key information on skin-related NTDs, including leprosy. HCWs will support the CHVs to ensure the accuracy of the information and message given out. Topics covered will be clinical signs, symptoms, treatment, environmental aspects conducive to the contraction of the disease, methods of prevention, management, and prevention of disabilities. The knowledge dissimilation will be done with the help of posters, images of leprosy, and the screening of a documentary film on skin-related NTDs, followed by community debates. In addition, community members are actively involved in activities aimed at reducing stigmatizing attitudes and behaviors toward individuals affected by leprosy. Community leaders play a pivotal role in developing strategies to transform community norms that contribute to the stigma surrounding leprosy patients.

After the sensitization stage, consultations will take place for the screening of cutaneous dermatoses. In a private area, health staff will individually assess people who presents with a lesions, sores, or stains on the body. First aid will be offered by health professionals to any person who presents with a skin disorder, and individuals diagnosed with leprosy will be referred to the health facility for treatment initiation and follow-up consultations.

In intervention arm 2, in addition to the activities described above, the CHVs will offer audio tools to households in the study communities. The solar powered tools will contain the learning content of the campaign in audio form [35]. The content will be translated into the 15 most prominent local languages of the communities in intervention arm 2. The tools will remain within the community until endline data collection (approximately 2 months) to allow repetitive learning for all household members.

Implementation

This study is a cRCT, with the randomization unit being the administrative communities. We stratified the random assignment by administrative regions in Togo (Maritime, Plateaux, Central, Kara, and Savanes) to ensure representation of all intervention and control arms across all regions. Since the sensitization campaigns are carried out at the community level and are targeted at the whole community population, cluster randomization was the natural choice of study design. Participation in the sensitization campaign is voluntary, open to all community members, and does not imply participation in the study as such. Survey participants will be recruited from the general community population, irrespective of their participation in the sensitization campaigns.

We used computer-generated random numbers for intervention arm assignment. We set a random seed to 585,506 in Stata (StataCorp) to execute a replicable and random intervention arm assignment. Misfits at the regional level have been balanced at the global level.

Quantitative data have been collected at baseline in all 60 communities and will be complemented with an endline survey 2 months after intervention implementation. Primary outcomes will be collected in all intervention arms before and after intervention.

Baseline data collection took place in March 2023, and endline survey data and qualitative data are planned to be collected in November 2023. Training of health volunteers and professionals and the implementation of campaigns will take place between August and September 2023.

Eligibility Criteria

As described above, intervention participation is voluntary, open to all community members, and does not imply participation in the survey as such. Eligibility criteria for survey participation vary by study component.

Quantitative Study Component

People aged 18 years and older who are resident of the respective community. All CHVs serving a study community and aged 18 years and older will be eligible to participate in the survey.

Qualitative Study Component

People aged 18 years and older and are residents of the respective community. We will also purposefully select some patients with leprosy. CHVs and HCWs serving a target study community and aged 18 years and older will be eligible to participate in the study.

Outcome Measures

Quantitative End Points

Our primary outcomes to assess leprosy-related knowledge among community members will be based on the standardized Knowledge, Attitudes, and Practices Questionnaire adapted to leprosy. We will assess different forms and perceptions of leprosy-related stigma using the Social Distance Scale, asking for individuals own stigmatizing attitudes. Further, we will ask about the perceived attitudes and behaviors in the community using the Explanatory Model Interview Catalogue (EMIC). Individuals not affected by leprosy will receive the Community Stigma Scale. Affected individuals will receive questions related to their experience with stigma. In addition, we will assess a number of secondary outcomes, such as the Participation Scale. The primary and secondary outcomes are shown in Textbox 1.

Textbox 1. Primary and secondary outcomes.

Primary outcomes

- 15-item Knowledge, Attitudes and Practices Questionnaire [36].
- 7-item Social Distance Scale [36].
- 15-item Explanatory Model Interview Catalogue Community Stigma Scale for persons not affected and Explanatory Model Interview Catalogue for persons affected [37].

Secondary outcomes

- 18-item Participation Scale [38].
- 10-item Rosenberg Self-Esteem Scale [39].
- 3-item University of California, Los Angeles Loneliness Scale [40].
- 2-item Patient Health Questionnaire [41].
- 2-item Generalized Anxiety Disorder Scale [42].
- 3-item Alcohol Use Disorders Identification Test for Consumption [43].

Qualitative End Points

We will explore the needs, preferences, and understanding of HCWs and CHVs regarding training on leprosy treatment and care. With in-depth interviews (IDIs) and shared walks, we will build place-based data, examine the practices and perceptions of HCWs and CHVs relating to pathways to treatment and care, and analyze how stigma may mediate these pathways. Additionally, our IDIs with community members will explore cultural norms and beliefs around health seeking and treatment for leprosy and examine perceptions and experiences regarding the sensitization campaign.

Areas of particular interest are (1) understanding the perceptions of HCWs and CHVs regarding the use and appropriateness of the training received on leprosy treatment and care; (2) understanding the perceptions of HCWs and CHVs regarding stigma, diagnosis, treatment, and care of leprosy; and (3) understanding community perceptions regarding the sensitization campaign, the audio tool, and the diagnosis, treatment, and care of leprosy.

Sample Size

Quantitative Sample Size

We conducted a power calculation for our primary end points to determine the required sample size. The power calculation considers the study design of randomized intervention assignment across clusters (communities). To reach a power of 80% in detecting an effect size of 10 percentage points at a significance level of 5% (SD 30, intracluster correlation coefficient=0.05), a sample of a minimum of 15 individuals in each community is given a fixed number of 60 clusters. This leads to an overall required sample size of 900 individuals. To account for potential complications, we targeted a sample size of 1200 individuals. Baseline data collection took place in March 2023, with 1200 individuals successfully interviewed.

Qualitative Sample Size

To determine the qualitative sample size, we follow the principle of achieving data saturation, which ensures that reoccurring themes are exhausted [44]. With a study that uses IDIs and shared walks—with a relatively focused research question—saturation should occur at approximately 20 interviews or with 20 participants. Therefore, we aim to conduct 5-10 IDIs with HCWs in each of the intervention and control arms (15-30 in total) and 10-15 IDIs with community members in each of the intervention and control arms (30-45 in total).

Recruitment and Data Collection

Over the course of the study, we will integrate several rounds of quantitative and qualitative data collection with community members, CHVs, and HCWs. For an overview of all data collection instruments, see Table 1.

Table 1. Data collection instruments of a mixed methods cluster randomized controlled trial to assess the effectiveness of leprosy sensitization campaigns in rural Togo. A summary of study instruments, respondents, and procedures. Data collection and intervention implementation will take place between March 2023 and June 2024.

Data collection type and instrument	Population and recruitment					Sample size	Estimated duration (minutes)	Timing of data collection
	Population	Observation unit	Sampling unit	Sampling method	Eligibility			
Quantitative								
Survey baseline	Community members of all 60 study communities	Individual	Households	Random selection	Adult men and women aged ≥18 years, preferably household head and spouse	1200	20	Before Intervention
Survey endline	Community members of all 60 study communities	Individual	Households	Random selection	Adult men and women aged ≥18 years, preferably household head and spouse	1200	30	After Intervention
Survey CHV[a]	CHVs of all intervention communities	Individual	Community	Census (intervention arm 1 and 2)	CHV of study community	40	20	After Intervention
Qualitative								
In-depth interview cover sheet	HCWs[b], CHVs and community	Individual	Community	Purposive	Adult men and women aged ≥18 years and HCW, CHV or community member in the respective communities that provide written informed consent	45-75	N/A[c]	During intervention
In-depth interview guide	HCWs and CHVs	Individual	Community	Purposive	Adult men and women aged ≥18 years and HCW, CHV or community member in the respective communities that provide written informed consent	15-30	45-60	During intervention
Shared walk guide	HCWs and CHVs	Individual	Community	Purposive	Adult men and women aged ≥18 years and HCW, CHV or community member in the respective communities that provide written informed consent	15-20	N/A	During intervention
In-depth interview guide	Community members	Individual	Community	Purposive	Adult men and women aged ≥18 years that identify as a community member in the respective communities and provide written informed consent	30-45	45-60	During intervention

[a]CHV: community health volunteer.

[b]HCW: health care worker.

[c]N/A: not applicable.

Quantitative Survey Participants

At baseline, before intervention implementation, community members were sampled through a random selection of households in all 60 study communities. In each community, 10 households were selected following a random walk procedure adjusted to the local context of widely spread farmsteads [45]. In each selected household, one female and one male household member were interviewed, preferably the household head and respective spouse or husband. For the endline survey, the same individuals will be interviewed. All CHVs will be selected for a quantitative survey during the endline data collection.

Qualitative Interview and Shared Walk Participants

We will conduct IDIs with 5-10 HCWs and CHVs in each of the intervention and control arms. In this phase, we will also invite selected 15-20 IDI respondents to participate in a "shared walk" to walk through their community and show research assistants (RAs) where their work takes place, what locational influences there are on their work, and how they feel anything influences their work in relation to leprosy. We will also conduct IDIs with community members in each of the intervention and control arms (30-45 members in total) to understand (depending on the intervention assignment) their perceptions of the services being offered, the sensitization campaign, and their feelings and experiences regarding leprosy.

A total of 3 RAs will conduct the IDIs and shared walks using standardized instruments. These include a participant information sheet, a consent form, a cover sheet, and interview guides (Table 1). Cover sheets will capture sociodemographic data, including sex, age, employment status, children, partner status, and religion. Cover sheets also include a section for RAs to make reflexive and observational notes. Written informed consent will be obtained from all study participants before beginning interviews. Depending on the preference of the participants, IDIs will be conducted one-on-one in a local language or French and will be audio-recorded. Participants in the IDIs will be asked broad, open-ended questions regarding topics such as the training, the intervention and audio tool, stigma, and perceptions of leprosy. IDIs will be designed to elicit personal responses and then lead to more in-depth and specific narrative-building questions. RAs will probe themes that seem to be of relevance to the participant or that are identified as important recurring themes through the debriefing process.

The "shared walk" will follow the tenets of the docent method defined by Chang [46] to provide more place-based data. The participants decide the route and duration of the walk. The RA will ask the participant to show them locations on the walk that are of significance to them for any reason, but will also ask the participant to show locations that are of particular relevance for the work they do and where significant events (such as education or outreach) take place. Each participant is considered to be an expert guide. The participant is the educator, while the RA is the person who needs to learn from and follow the lead of the participant. These walks will be audio recorded and can be supported by photos if the participant wishes to take them. Any photographs submitted in which it is possible to identify individuals will be anonymized.

Data Analysis

Quantitative Analysis

Our primary analysis will be based on intention-to-treat at the individual level using linear regression comparing the outcomes of intervention and control arms. We will measure our primary outcomes in terms of absolute scores and as a percentage of the total possible score. We will use adjusted standard errors for clustering at the community level, our unit of randomization [47]. We will control for a number of baseline covariates, including gender, age, and education, among others.

Qualitative Analysis

Analysis will begin in the field with systematic debriefings. Debriefings are daily meetings with RAs and are designed to identify where interview questions are gaining in-depth responses and where questions need to be changed or refined [48]. Debriefings will also allow the research team to gain a superficial understanding of the main topics arising from the interviews and the shared walks, so that an initial codebook can be developed [48]. Once all data have been collected, IDIs will be translated, transcribed, and managed using NVivo (version pro 12; QSR International) [49]. We will follow a reflexive thematic analysis approach using the recursive 6 stages of analysis as defined by Braun and Clarke [50]. Data analysts will independently read and re-read transcripts for data familiarization. Transcripts will then be inductively analyzed in blocks of 5, and codes will be reviewed to identify similarities or divergence of ideas. This process will be followed until the coding is complete. The main codes will be presented to the study team to decide where reoccurring codes could build our core themes. After revising the codebook, we will develop a thematic scheme that will be presented to the study team, refined, named, and finalized for interpretation and writing.

Our mixed methods process will follow a sequential approach where we begin with quantitative data collection and analysis and, upon completion, start the qualitative component [51]. We assume that the quantitative data will allow us to develop more focused qualitative questions and that the qualitative data will help us to address any gaps in information that we cannot explain through the quantitative results. Further mixing of the 2 methods will occur during the data analysis of both data sets, when we will combine the qualitative and quantitative to present our findings to support the interpretation of the results. As such, we envision the shared walk data to allow us to identify potential intervention improvements with respect to the information provided, the dissemination of this information, and, in particular, participant understanding of the audio tool.

Ethical Considerations

This study was approved by the Togolese Bioethics Committee for Health Research (025/2022) and the Ethics Commission of the Medical Faculty Heidelberg (S-670/2022), Germany. Before consent, information about the study will be provided (verbal or written). All participants will give (verbal or written) informed consent to participate in the research. Participants will not receive compensation for their participation. The data will be deidentified before analysis and securely stored in a password-protected file and on a password-protected computer. Any photographs submitted during qualitative data collection, in which it is possible to identify individuals, will be anonymized. The trial is registered at the German Clinical Trials Register (DRKS-ID: DRKS00029355).

Results

Data collection started in March 2023 and is planned to be completed in June 2024, with ongoing data analysis. Analysis of the quantitative baseline data has been initiated, and results are planned to be submitted for peer-reviewed publication in the second quarter of 2024. The first quantitative endline and qualitative results are expected to be submitted for publication by the end of 2024.

Discussion

We will use the mixed methods cRCT to measure the causal effect of community sensitization campaigns and audio tools distributed to households on knowledge and stigma related to leprosy. The setting of this study is rural communities in Togo, West Africa. Our nested qualitative components, involving interviews and shared walks with community members and local stakeholders such as CHVs and HCWs, will explore the implementation of the intervention and contextualize the

quantitative results of the trial, while also helping to further characterize the mechanisms through which sensitization campaigns and audio tools affect leprosy-related knowledge and stigma.

The contribution of this study to the literature will be 3-fold. First, we will provide causal evidence on the effectiveness of sensitization campaigns on community-level leprosy-related knowledge and stigma. The literature on this is limited, especially in the West African context. Second, we will test novel audio tools for information dissemination to amplify potential campaign effects. The tools are designed to overcome literacy and language barriers in a multilingual context. Third, our results will contribute to the general understanding of leprosy-related stigma in the West African context. The qualitative and quantitative findings will inform policy makers and public health agents to effectively tailor and implement sensitization campaigns, particularly in challenging rural settings.

A potential limitation of this study is the fact that quantitative stigma indicators are self-reported by community members; this outcome might be affected by social-desirability bias. We will test intervention effects on the respondent's knowledge of the disease, which is a key driver of stigma and not prone to social desirability bias. Further, qualitative IDIs with unaffected and affected community members will allow us to triangulate quantitative findings on stigma.

This cRCT serves to provide rigorous scientific evidence about the causal effectiveness of 2 particular interventions in the broader field of health-related stigma interventions and multilingual low-literacy settings. The results will be beneficial for policy makers and public health agents to guide sensitization campaigns and inform them about the potential of audio tools to complement common practice.

Acknowledgments

This study has been externally reviewed and funded following a competitive grant application and review process by the Academic (Hospital Partnerships Funding Line Academic) program carried out by the Deutsche Gesellschaft für Internationale Zusammenarbeit GmbH. The funders had no role in the design, data collection, analysis, interpretation of data, or manuscript writing.

Data Availability

The final data set used and analyzed for this study will be available from the corresponding author on reasonable request.

Authors' Contributions

DJ, AWB, KB, NMS, DAYG, CK, and TB were responsible for the overall conceptualization of the study design. DJ led the design of the quantitative study components. KB led the design and writing of the qualitative study components and edited the protocol paper. DJ led the writing of the protocol paper. DAYG and AWB oversaw the Togolese ethics approval process and set up the local study implementation systems. DJ oversaw the German ethics approval process. CK and MV are grant holders. JW advised on the qualitative study design and edited the protocol paper. TWM advised on the qualitative study design. SL advised on the quantitative study design. SP supported the quantitative data collection and survey design. DJ conducted the power calculations. AWB, PPB, BS, PG and DAYG provided technical input and contributed with local context expertise and implementation in Togo. TB advised on the quantitative study design and sample size calculation. All authors have read and approved of the final version of the manuscript.

Conflicts of Interest

Abstract

Background: Rare diseases in Europe are defined as diseases with a prevalence of less than 5 per 10,000 people. Despite their individual rarity, the total number of rare diseases is considerable. Rare diseases are often chronic and complex, affecting physical, mental, and neurological health. People with rare diseases face challenges such as delayed diagnosis, limited medical support, and financial burden. Caregivers, usually family members, bear significant physical and emotional burdens. Understanding the experiences of patients with rare disease and their caregivers is critical to effective care, but this is still underresearched. Better support and understanding of the challenges faced by both patients and caregivers is clearly needed. Our study will explore the experiences and needs of people with rare diseases and caregivers of people with rare diseases in relation to accessing health services.

Objective: This study aims to explore the experiences of patients with rare disease and their caregivers with Slovenian health care providers and to create a theoretical model of needs and experiences.

Methods: This is a qualitative thematic analysis study, using the codebook approach. The study will conduct semi–open-ended interviews to understand the experiences and needs of people with rare diseases and caregivers of people with rare diseases in relation to accessing health services. The interview questions will be based on an extensive literature review. Data from the interviews will be analyzed using thematic analysis to identify patterns and build a thematic map. Data will be analyzed by at least 2 coders. To ensure reliability, respondent validation will be conducted and negative cases investigated. Any discrepancies will be resolved by consulting the entire research team until a consensus is reached.

Results: This study was not specifically funded. However, author TČ is supported by grant number P3-0339 from the Slovenian Agency for Research and Innovation. This study was approved by the Medical Ethics Committee of the Republic of Slovenia (0120-47/2022/3), and recruitment is expected to begin in May 2024, with data analysis results anticipated by the end of 2025.

Conclusions: This study will fill an important research gap in Slovenia by exploring the needs and experiences of people living with rare diseases and their caregivers. The results will contribute to the broader field of rare diseases and add knowledge that can inform future research processes and intervention strategies. It also aims to identify neglected areas that have a significant impact on the lives of people with rare diseases. This study is important not only because it addresses the immediate needs of the Slovenian rare disease community, but also because it contributes to a discussion on patient-centered care, health policy design, and the inclusion of psychosocial components in health care.

KEYWORDS

rare diseases; patients; caregivers; needs; barriers; access to health care

Introduction

Rare Diseases in Europe and Slovenia

In Europe, rare diseases are defined as diseases with a prevalence of less than 5 per 10,000 people in the population [1]. While individual disease incidence is small, the collective number of all types of rare diseases is large [2]. The estimated number of rare diseases is currently between 6000 and 8000 [3]. They are usually chronic and complex and are associated with physical, mental, or neurological disorders. The psychosocial and emotional impact on affected individuals and families is significant and often exacerbated by a lack of adequate community support and services [4].

Health Care Needs of Patients With Rare Disease

Rare diseases, due to their multisystemic nature and associated cognitive and developmental challenges, manifest a wide range of symptoms, resulting in diverse health care needs. Managing these symptoms necessitates the involvement of various health care professionals, the use of medical devices, and "orphan drugs" [5]—specialized medicinal products developed to treat, diagnose, or prevent specific rare diseases [6].

Challenges Faced by Patients With Rare Disease and Caregivers

Rare diseases present numerous challenges, not only for those directly affected but also for their caregivers. These challenges include delayed diagnosis, difficulties accessing health care, and the financial burden of medical treatment [7]. Caregivers of individuals with rare diseases, who are often parents or spouses, shoulder a substantial physical and emotional burden without receiving financial compensation [8]. Their responsibilities encompass providing transportation, running errands, offering emotional support, monitoring symptoms, and performing additional household tasks [9,10]. Many caregivers are forced to reduce or quit their jobs due to these caregiving responsibilities, leading to additional financial strain [11]. The caregivers' physical and mental well-being directly impacts the level of care they can provide to patients with rare diseases [2].

Research Gap in Slovenia

In Slovenia, rare diseases pose a significant public health concern and represent a considerable challenge for the health care system [12]. It is roughly estimated that around 150,000 patients are affected by rare diseases in Slovenia [13], which emphasizes the importance of addressing this issue [14]. Recently, a register of rare, nonmalignant diseases was established in the Republic of Slovenia, which should provide valuable insights into this topic. While some studies have been conducted, such as the one by Halec et al [15] on the impact of rare diseases on an individual's quality of life, and others by Stanimirović et al [12-14] focusing on systems development and strategies to improve care for patients with rare disease, there remains a notable absence of research centered on the experiences and needs of patients with rare disease and their caregivers in Slovenia.

Addressing Research Gap by This Qualitative Study

In Slovenia, there is little research on the experiences of caregivers of people with rare diseases, especially compared with the studies on caregivers worldwide. While studies often focus on specific diseases and their pathophysiology [8], a comprehensive exploration of the experiences of both patients and caregivers is crucial for health care providers. Such insights can aid in developing treatments and support services that align with the unique challenges faced by this population [16].

Preliminary findings of a scoping review [17] and discussions with representatives of various rare disease associations highlight the pressing need for better support and understanding of such issues and that there is a lack of knowledge in the field about the challenges experienced by caregivers and people with rare diseases. The Ministry of Health states in the work plan in the field of rare diseases in the Republic of Slovenia for the period 2021-2030 that it would be useful to research the needs of patients with rare diseases in Slovenia, with special attention to social aspects, palliative care, psychological support, and economic aspects [18]. There is, therefore, a need to identify clear areas for change to help researchers, health care providers, and health policy makers develop, plan, and facilitate better services. The establishment of the rare non-malignant diseases registry of the Republic of Slovenia [19] and the development of a more comprehensive rare disease ecosystem [14] are important steps, but qualitative research focusing on the experiences of people living with rare diseases will complement these efforts and provide valuable insights.

Potential Contributions of This Study

This research study holds the potential to contribute significantly to science and the rare disease community in Slovenia by providing a better understanding of the human dimension, which is essential for developing patient-centered policies that consider the psychosocial, emotional, and practical challenges faced by people with rare diseases and their caregivers; identifying gaps in access to health services and psychosocial support; offering insights into priority areas for action that can guide policy makers; and filling a critical research gap in Slovenia by adding valuable knowledge to the rare disease field.

By addressing these aspects, this study has the potential to make a substantial and unique contribution to both the scientific community and the rare disease community in Slovenia.

Objectives

The primary aim of the study is to explore the needs and experiences of adults with rare diseases and caregivers of people with rare diseases with health care service providers in Slovenia. The secondary aim is to identify gaps in access to health care services and psychosocial support.

The objectives of the research are as follows: (1) to gain insights into the needs and experiences of adults with rare diseases with health care providers in Slovenia; (2) to gain insight into the needs and experiences of caregivers of people with rare diseases

with health care service providers in Slovenia; and (3) based on the obtained data, develop a thematic map of experiences and needs.

Research Questions

Our research questions are as follows: (1) What are the needs and experiences of adults with rare diseases in relation to health care providers in Slovenia? (2) What are the needs and experiences of caregivers of people with rare diseases in relation to health care providers in Slovenia?

Methods

The reporting of this study follows the guidelines of the Consolidated Criteria for Reporting Qualitative Studies in the areas that can be applied to a protocol [20].

Research Team and Reflexivity

In this qualitative research study, the interviews will be conducted by TČ, who has a master degree in psychology and is currently working as a researcher. TČ has previous experience with interviews and has spent over a year researching rare diseases and access to health care. Informal discussions were held with representatives of rare disease associations in Slovenia before the study began. These discussions served to develop an initial understanding of the challenges faced by the rare disease community. The main goal was to create a basic knowledge base and gain deeper insights into the problems faced by people living with rare diseases and their caregivers. Participants were informed that the study was part of a doctoral degree pursuit. Disclosure of this information provided transparency regarding the academic aims of the researcher and the context in which the study was conducted. The motivation for the research is rooted in the identified lack of comprehensive studies in this area and emphasizes a commitment to contribute meaningful knowledge to better support people living with rare diseases.

Study Design—Theoretical Framework

The study uses a conceptual framework based on the biopsychosocial model of health [21], which recognizes the interconnectedness of biological, psychological, and social factors associated with rare diseases [22,23]. The biopsychosocial model requires a multidisciplinary approach [24] and emphasizes the importance of a dynamic and empathetic dyadic relationship between clinicians and patients [25]. This approach includes examining various health-related factors, such as access to psychological support, impact on mental health, social support (family support, self-help groups or networks, and help from caregivers), availability of health care services, and financial resources for health-related needs. By applying the biopsychosocial model, this study aims to provide a comprehensive understanding of the unique experiences of people living with rare diseases and, based on this, make recommendations to improve health care services for people living with rare diseases.

The study follows the approach of qualitative thematic analysis [20]. Given the larger scope of our study and the expected high number of participants, we deliberately chose a “codebook” thematic analysis approach [26]. This structured approach aligns with the pragmatic demands of applied research offering a systematic and organized framework for handling a large volume of qualitative data [26]. We will use a structured coding framework to develop and document the analysis [27]. The codebook developed inductively after (some) data familiarization and coding will serve as a tool to guide data coding and a way of mapping or charting the coded data [26]. Themes that will be developed at an early stage after familiarization, will later be refined or new themes developed based on the subsequent inductive data engagement and analytical process [27].

In the final phase of the analysis, the identified themes generated from the coded data will be used to create a thematic map, and the results will be compared with the existing and new data to assess their relevance and reliability [26].

Participant Selection

Participants will be selected through purposive and snowball sampling. Participants will be invited by the research team by email or telephone. Email invitations will be sent by the research team using contact details from a public database of the National Contact Point for Rare Diseases, to which individuals have previously given consent to be contacted. We will also ask participants to invite other people with rare diseases and caregivers of people with rare diseases to participate in the study by using snowball sampling.

We will use snowball sampling, as it is difficult to identify and reach people with rare diseases and their caregivers. We will start with an initial group of participants contacted through the National Contact Point for Rare Disease, conduct interviews, and collect data, followed by an explanation of the snowball sampling process. We will ask the initial participants to provide us with their contact details or to facilitate communication with those who are eligible and willing to participate in the study.

In addition, the research team will contact the pediatric clinic and collaborate with the doctors in the Department of Family Medicine by email. The email will include a presentation of the study explaining the purpose, methodology, potential benefits, and the importance of participation in identifying suitable participants, as well as relevant study documents such as an information leaflet, consent forms, and contact details of the research team. These documents will serve as a reference for the pediatric clinic to inform eligible participants about the study. Approval and cooperation from the relevant authorities at the pediatric clinic will be obtained before contact is made. The aim of contacting the pediatric clinic is to invite eligible caregivers of people with rare diseases to participate in the study, and the aim of contacting the Department of Family Medicine is to invite adult patients with rare diseases.

To avoid overrepresentation of a particular rare disease in the sample, we will follow the guideline that for each rare disease included, a maximum of 2 participants (either the adult patient or the caregiver) will be included.

Sample Size

Braun and Clarke [28] suggest that studies of experiences and needs collected through interviews require a sample size of 15

to 30 people in order to effectively uncover patterns while maintaining a focus on individual experiences.

Considering the concept of information power, which suggests that a broader study aim, a less specific combination of participants for the research question, and the inclusion of cross-case analysis may require a larger sample size, we decided on a target sample size of at least 40 participants [29]. This includes 20 adults with rare diseases and 20 caregivers of people with rare diseases. As Malterud et al [29] suggest, the appraisal of information power will be repeated during the process, supported by an initial analysis. After the first 3 interviews, an initial review of the data will be done and first suggestions of relevant theory will be made [29].

We will also try to identify and document the reasons for nonparticipation, which will contribute to the transparency and reliability of the study.

Setting

This study is being conducted in Slovenia. It includes health care providers at all 3 levels of health care (primary, secondary, and tertiary care). Data will be collected either in our research offices or participants will have the option of a home visit or digital interview. As caregivers of people with rare diseases may have ongoing care needs [30], we decided to offer them the option of a home visit or digital interview. This gives participants the opportunity to take part at a time and place that is convenient or safe for them [31]. The individual interviews with adults diagnosed with a rare disease will be conducted independently. Caregivers will have the option to participate in the interviews either separately or, if they prefer, together with the person they care for. This flexibility aims to accommodate the preferences and comfort levels of both participants and caregivers.

Description of Sample

We will include adult patients with rare diseases and caregivers of people with rare diseases in our study. It is important to emphasize that our research will focus on rare, nonmalignant diseases. To determine the rarity of the disease, we will use the European definition of rare diseases, according to which rare diseases are categorized as those that affect less than 5 in 10,000 people in the population. To ensure a comprehensive representation of experiences, we aim to include people with different rare diseases. In addition, our sample will indirectly include people with impaired decision-making capacity, such as those with developmental or cognitive impairments, by involving their caregivers. This decision is in line with ethical considerations, as we recognize that it is difficult for people with developmental disabilities to give fully informed consent due to the nature of their condition. Involving caregivers is seen as an ethical strategy to ensure a full understanding of the research topic while upholding the principles of respect and protection of vulnerable populations. Caregivers can be family members, spouses, unmarried partners, close friends, or other people with direct caring responsibilities. To account for possible regional differences in access to health care and support services, our study will include participants from all 9 health regions of Slovenia. The inclusion criteria extend to people who are directly responsible for people diagnosed with a rare disease.

Data Collection

Separate interview guides will be used to explore the perspectives of adult patients with rare disease and their caregivers. The interview questions were formulated based on a literature review and will be pilot-tested to ensure clarity and effectiveness in data collection. The questions formulated for the interviews are also based on the biopsychosocial model of health [21]. In line with the biopsychosocial model, our interview questions refer not only to biological factors but also to psychological and social dimensions (how the rare disease affects the participants' social life and how these conditions influence psychological well-being and social interactions). If subsequent interviews reveal significant topics not covered previously, already interviewed participants may be contacted for additional exploration of those specific areas. Audio recording will be used to capture interviews, ensuring accurate and complete data representation. Participants will be informed about the recording, and explicit consent will be obtained. Field notes will be taken during or after interviews to document contextual information and observations that may enhance the understanding of participants' experiences. The duration of interviews will be based on the natural flow of the conversation, allowing participants to express themselves fully. Specific timeframes will be tailored to individual preferences and needs. As part of the respondent validation process, we plan to present the results of the study to participants and ask for their feedback and comments. While we will not necessarily provide full transcripts, this approach will ensure that participants have the opportunity to validate the results of the study and contribute to their interpretation.

The sociodemographic questionnaire will collect the following data: age, gender, marital status, education level, employment status, relationship to caregiver (caregiver questionnaire), monthly income, housing situation, rare disease diagnosis, year of diagnosis, duration of symptoms, impact of the disease on daily life, nature of costs associated with the rare disease, frequency of medical visits and difficulties in accessing health care services, and the participants' support networks.

Data Analysis

Two researchers will code and compare the data. The coding process will be a collaborative effort to ensure reliability and validity. Themes will be derived through a process. First, a series of initial themes will be developed based on the interview guide and existing literature. Coding will be conducted to provide evidence for these initial themes and to identify additional themes derived from the data. The themes and codes will be refined after the initial coding phase through the development and refinement of a coding template. The final phase of coding will be guided by the final template for theme development. We will use the NVivo program (Lumivero), for coding, editing, and structuring the data. We will also carry out respondent validation, that is, we will present results to the participants and ask them for comments [32]. We will also enrich the data obtained by examining so-called negative cases that deviate from the patterns that otherwise emerge through

data saturation [33]. By examining these cases, we will increase the reliability of the research and gain better insight into the strengths and weaknesses of the research [33].

Eligibility Criteria

The eligibility criteria for this study are listed in Textbox 1.

Textbox 1. The eligibility criteria for this study.

Inclusion criteria for adults with a rare disease

- Aged 18 years or older with a confirmed diagnosis of a rare disease
- Written consent to participate in the study of a person with a rare disease
- Persons who use health services in Slovenia
- Willingness to comply with the study protocol

Exclusion criteria for adults with a rare disease

- Inability to meet the requirements of the study (Participants with severe cognitive impairment or intellectual disabilities will be included in the study indirectly through their caregivers. As qualitative research relies on participants' ability to articulate their experiences, cognitive impairment may limit meaningful participation).
- Unwillingness to meet the demands of the study
- Refusal to fulfill the requirements of the study (refusal to actively participate in the in-depth interviews, to complete a sociodemographic questionnaire, and to consent to data collection)
- Persons who are unable to communicate in Slovene or who are not able to sufficiently understand and express themselves in Slovene will be excluded from the study

Inclusion criteria for caregivers of people with a rare disease

- Family caregivers who directly care for a person with a confirmed diagnosis of a rare disease. Family caregivers are usually relatives (often the patient's parents or spouse) who take on most of the physical and emotional burden of caring for the patient without receiving financial compensation (with the exception of family caregivers who receive payment in the form of social benefits) [34]. They carry out the tasks of monitoring, interpreting, making decisions, taking action, making adjustments, providing care, accessing resources, working with the sick person, and negotiating with the health system [35]
- Written consent to participate in a study of the caregiver of a person with a rare disease

Exclusion criteria for caregivers of people with a rare disease

- Unwillingness to comply with the requirements of the study (refusal to actively participate in in-depth interviews, to complete a sociodemographic questionnaire, and to consent to data collection)
- Inability to meet the study requirements (lack of cognitive ability to participate in the study, such as severe cognitive impairment, Alzheimer disease, or intellectual disability)
- Persons who have not reached the legal age of adulthood in Slovenia (younger than 18 years) will be excluded from the study
- Persons with whom it is not possible to communicate in the Slovene language or who are not able to understand and express themselves sufficiently in the Slovene language will be excluded from the survey
- Persons who provide care in the context of an employment relationship and who are not close persons to the person they are caring for (eg, paid home caregivers or home help, persons employed in social care institutions) will be excluded

Ethical Considerations

The medical ethics committee of the Republic of Slovenia considers the research to be ethically justifiable. The commission notes that all necessary documentation has been included, the statement is written in a way that is understandable for the participants, the security of data storage is guaranteed, and the anonymization of responses is ensured. The document bears the number 0120-47/2022/3. Explicit informed consent will be obtained from all participants. This comprehensive process will ensure participant understanding, adherence to ethical principles, and compliance with the statement approved by the medical ethics committee. The data collected as part of this study will be stored securely in both physical and electronic form, with access to the data restricted to those directly involved in the research. The electronic data will be anonymized by assigning identification codes and stored in a special database located on the premises of the Department of Family Medicine at the Faculty of Medicine in Ljubljana. Before the data are stored in the database, an anonymized version of the research data is created in order to preserve its usefulness while ensuring the confidentiality of the participants. Data protection is ensured by secure passwords, and passwords are stored separately. Participants will not receive any financial or nonmonetary compensation for their participation in this study.

Results

This study was not specifically funded. However, the author TČ is funded by the Slovenian Agency for Research and Innovation under grant number P3-0339. Data collection through

semistructured interviews for the study is scheduled to begin in May 2024 and is expected to be completed on 30 December 2024.

Discussion

Principal Results

This study aims to gain a deeper understanding of the needs and experiences of people living with rare diseases and their caregivers when interacting with health care providers in Slovenia and to shed light on the gap between them. The results of the research will be presented in a thematic map of the needs and experiences of people living with rare diseases and their caregivers. The thematic map will serve as a visual representation that will provide an overview of the interconnected themes identified in the analysis and improve our understanding of the complex relationships between the needs and experiences of the target groups. As identified in the exploratory phase of our research, we spoke informally with representatives of rare disease associations in Slovenia to understand the challenges faced by this community. They highlighted key issues, including the need for psychological support, gaps in palliative care for children, concerns about the attitudes of health care providers, and gaps in respite care. In addition, they highlighted issues around delays in diagnosis, poor communication with health care professionals, stigmatization, lack of information, and poorly coordinated care. Ongoing research will shed further light on these issues and contribute to a comprehensive understanding of the gap between needs and available services. We expect to gain a deeper understanding of the barriers to accessing health services, the impact of these barriers on disease progression, and their psychosocial consequences. We expect participants to express their needs in terms of support services and to give examples of good practices that can later be used for better planning of health services. We hope that the results will also point to previously overlooked areas that have a significant impact on the lives of people significantly affected by rare diseases. Based on the results, we will make recommendations to improve health services for people with rare diseases.

Limitations

A potential challenge of this study arises from the diversity of rare diseases included. Given the uniqueness of each rare disease, it might be difficult to identify commonalities in experiences and needs. While a national register for rare diseases has recently been established in Slovenia, our main resource remains a web-based website that serves as a national contact point for rare diseases. This website lists various associations. Our approach to recruiting participants is a purposive sampling combined with a snowball approach. However, a potential limitation is that individuals who are more involved in supportive communities may be overrepresented in our sample. Consequently, those who are less proactive in seeking the support they need might be underrepresented. To mitigate this bias, we try to use the snowball principle to recruit people who do not belong to these associations and contact participants through doctors. However, it is important to be aware that using the snowball principle may also have a disadvantage. This method could lead to limited diversity among our informants, which could limit the range of perspectives and experiences we can capture [36].

Another challenge is that the study focuses primarily on experiences and needs related to access to health services. However, patients with rare diseases and caregivers of people with rare diseases may face challenges and needs beyond health care, such as education and employment. These aspects may not be fully explored in the study.

Comparison With Prior Work

Previous research has shown that participants have a significant need for information, particularly in relation to psychological and health care aspects [22,37]. In particular, the Depping study highlights the importance of personalized information and the desire for better access to experts and treatments within the health care system [22].

In line with the aims of our study, we found that caregivers and patients often encountered health care professionals whom they perceived as lacking the necessary knowledge and understanding of them or (in the case of caregivers) the person they were caring for [22,37-40]. Consequently, they saw a noticeable gap in their access to vital and necessary care, emphasizing the urgency of better training for health care providers [22,37-40].

Our study protocol represents a step forward in capturing the specific needs and experiences of people living with rare diseases and their caregivers in Slovenia and differs from previous large-scale surveys, such as the comprehensive study conducted in the United States [40]. In contrast to these large-scale initiatives, our focus is tailored to the Slovenian health care landscape and provides a local understanding of the challenges faced by this population. By focusing on the specific context of Slovenia, our study aims to fill existing gaps and contribute valuable insights to the current state of knowledge in rare disease research.

Conclusions

This study will fill an important research gap in Slovenia by exploring the needs and experiences of people living with rare diseases and their caregivers. The results will contribute to the broader field of rare diseases and add knowledge that can inform future research processes and intervention strategies. It also aims to identify neglected areas that have a significant impact on the lives of people with rare diseases. This study is important not only because it addresses the immediate needs of the Slovenian rare disease community, but also because it contributes to a discussion on patient-centered care, health policy design, and the inclusion of psychosocial components in health care.

Acknowledgments

The study was funded by the Slovenian Agency for Research and Innovation (grant P3-0339).

Data Availability

The data sets generated or analyzed during this study are not publicly available due to confidentiality and ethical considerations but are available from the corresponding author on reasonable request.

Authors' Contributions

TČ contributed to the conceptualization and methodology of the project. DRP, ET, and ŠM provided supervision.

Abstract

Background: Patients with gastric cancer experience different degrees of fear of cancer recurrence. The fear of cancer recurrence can cause and worsen many physical and psychological problems. We considered the “intimacy and relationship processes in couples’ psychosocial adaptation” model.

Objective: The study aims to examine the effectiveness of a marital self-disclosure intervention for improving the level of fear of cancer recurrence and the dyadic coping ability among gastric cancer survivors and their spouses.

Methods: This is a quasiexperimental study with a nonequivalent (pretest-posttest) control group design. The study will be conducted at 2 tertiary hospitals in Taizhou City, Jiangsu Province, China. A total of 42 patients with gastric cancer undergoing chemotherapy and their spouses will be recruited from each hospital. Participants from Jingjiang People’s Hospital will be assigned to an experimental group, while participants from Taizhou People’s Hospital will be assigned to a control group. The participants in the experimental group will be involved in 4 phases of the marital self-disclosure (different topics, face-to-face) intervention. Patients will be evaluated at baseline after a diagnosis of gastric cancer and reassessed 2 to 4 months after baseline. The primary outcome is the score of the Fear of Progression Questionnaire-Short Form (FoP-Q-SF) for patients. The secondary outcomes are the scores of the FoP-Q-SF for partners and the Dyadic Coping Inventory.

Results: Research activities began in October 2022. Participant enrollment and data collection began in February 2023 and are expected to be completed in 12 months. The primary results of this study are anticipated to be announced in June 2024.

Conclusions: This study aims to assess a marital self-disclosure intervention for improving the fear of cancer recurrence in Chinese patients with gastric cancer and their spouses. The study is likely to yield desirable positive outcomes as marital self-disclosure is formulated based on evidence and inputs obtained through stakeholder interviews and expert consultation. The study process will be carried out by nurses who have received psychological training, and the quality of the intervention will be strictly controlled.

Introduction

In 2020, there were 1,089,103 new cases of gastric cancer and 768,793 deaths worldwide, accounting for 5.6% and 7.7% of the total incidences and deaths, respectively [1]. The standardized morbidity and mortality rates were 11.1/100,000 and 7.7/100,000, respectively, and the cumulative morbidity and mortality risks of those aged 0 to 74 years were 1.31% and 0.90%, respectively. Gastric cancer ranks second in terms of cancer incidence and mortality in China, with 679,000 cases and 498,000 deaths, followed by lung cancer (733,000 deaths) [2]. The disability-adjusted life years associated with gastric cancer in China is 9.825 million person-years, accounting for 44.21% of the gastric cancer cases globally [3].

Advancements in postoperative chemotherapy for gastric cancer have led to an increase in the 5-year survival rate of patients to 68% [4]. Although surgery and combined chemotherapy have improved the survival of patients to a certain extent, the high postoperative recurrence rate and metastatic rate, as adverse psychological events, have a tremendous psychological burden on patients [4]. The fear of cancer recurrence, which first appeared in the subject of oncologic psychology, has particular specificity and independence, which is different from other mental and psychological diseases [5]. Studies reported that about 72% of patients experienced various degrees of fear of cancer recurrence during cancer, of which about 46% were mild or moderate and about 7% were severe [6]. To our knowledge, to date, there have been no psychological intervention studies explicitly targeting the fear of cancer recurrence in Chinese patients with gastric cancer, and only 1 study has conducted a cross-sectional survey of cancer recurrence fear in patients with gastric cancer, which ignored the effect on spouses [7]. However, a spouse's high fear of cancer recurrence can affect the spouse's physical and mental health and further jeopardize the patient's health [8]. Therefore, designing a brief, practical, and feasible intervention to alleviate the fear of cancer recurrence in Chinese patients with gastric cancer and their spouses is critical.

Researchers, patients with cancer, representatives of patient rights, policymakers, and oncology psychologists from many countries reached an expert consensus, which defined the fear of cancer recurrence as "fears and concerns of patients with cancer regarding possible future cancer recurrence and/or metastasis and/or progression" [9]. The primary manifestations of high-level fear of cancer recurrence have been explained as follows: "highly focused, highly concerned, persistent, hypervigilant of physical symptoms and present for at least 3 months" [10].

The treatment cycle of advanced gastric cancer is long, and the recurrence rate is high. Although the progress of medical technology and the resection rate of advanced gastric cancer have increased, the high postoperative recurrence rate and metastatic rate, as adverse life events, have a tremendous psychological impact on patients [11]. Adverse reactions, such as nausea, vomiting, dry mouth, constipation, and bone marrow suppression, aggravate the psychological burden of patients, making them more fearful of the recurrence and progression of the disease [12].

Several studies [12-14] showed that the level of fear of cancer recurrence (as measured by the Fear of Progression Questionnaire-Short Form [FoP-Q-SF]) among patients with gastric cancer (120-170 cases) was middle to high (score of 35.43-42.3 points), the physical health dimension score was 18.09 (SD 4.52), and the social family dimension score was 17.34 (SD 6.34). The scores of the fear of cancer recurrence were higher in patients with gastric cancer than in patients with breast cancer [15] and early-stage prostate cancer [16]. A previous study [17] found that Chinese patients with gastric cancer have less knowledge of the fear of cancer recurrence. High levels of fear of cancer recurrence seriously affect the health of patients with gastric cancer, resulting in a series of dysfunctional behaviors, including avoidance behavior, hypervigilance of symptoms, and inability to plan for the future, which can reduce quality of life, and at the same time, the unmet supportive needs of cancer patients can lead to lower treatment compliance. These effects can persist for months or even years after treatment, and in severe cases, they can lead to anxiety disorders, posttraumatic stress symptoms, and depression [18].

In the relationship intimacy model of couples' adaptation to cancer by Manne et al [19], the authors emphasized that self-disclosure in relationship-enhancing behaviors is the primary factor affecting the psychological adjustment of cancer patients and their spouses and plays a positive role in the face of cancer. Marriage psychoeducation can help couples understand the value of communicating with each other, provide emotional and problem-focused support, help in the takeover of a spouse's responsibilities and tasks when one spouse is stressed, and help couples work together to cope when both partners are stressed [20]. In the long run, improvements in dyadic coping are more likely to increase relationship satisfaction than improvements in communication skills [21]. In short, dyadic coping is strongly associated with relationship satisfaction. Therefore, incorporating dyadic coping into a relationship enhancement program may benefit couples' relationships [22].

Emotional disclosure is a core component of marital emotional support, and it involves expressing feelings, ideas, and opinions to each other [23]. Couple discussion of cancer-related distress may help spouses understand the needs of patients and provide more effective support. Married patients with cancer tend to rate their spouses as their most important confidant. However, patients with cancer often feel constrained in talking about their concerns with their spouses, and partners often withdraw or distance themselves from the emotional distress of patients [24]. These avoidance patterns are present even in couples with satisfying relationships. The inability of patients to talk openly with their spouses about their cancer-related concerns may reduce the ability of couples to cope with stress and compromise the quality of the patient-partner relationship and the patient's psychological adjustment.

Multiple linear regression analysis results showed that the self-disclosure and intimacy of patients influenced their fear of cancer recurrence [8]. To date, most intervention studies focused

on the impact of self-disclosure on the psychological aspect of patients, and they ignored the role of their spouses regarding the psychological state [25-27] and failed to treat patients and their spouses as a whole [12]. Given the vast differences between Western countries and China in terms of race; cultural background; religious beliefs; economic development; and the adaptability and accuracy of the related theory, evaluation scale, and influencing factor analysis, the study results based on Western cultural background cannot be directly applied to the Chinese population. Research on spousal disease communication has primarily focused on patients recovering from breast cancer, lung cancer, and even prostate cancer [28,29]. The treatment cycle for advanced gastric cancer is extended, and the recurrence rate is high, which can intensify the psychological burden on patients [12]. During chemotherapy, patients with gastric cancer encounter numerous dietary restrictions and potential complications, such as nausea and vomiting, heartburn, and acid reflux, resulting in a loss of appetite for food [30]. In Chinese culture, it is believed that food is of utmost importance to people. Being unable to eat or having no appetite is a sign of worsening disease, which further exacerbates both the psychological and physical burdens of patients. No research has been performed on the spousal communication of patients with gastric cancer. Additionally, the research findings of other types of cancers cannot be generalized to patients with gastric cancer, and it is necessary to implement targeted psychological intervention measures for Chinese patients with gastric cancer.

The main objective of this study is to assess a marital self-disclosure intervention that is suitable and feasible based on Chinese culture and clinical practice, focuses on the fear of cancer recurrence, guides patients to adjust to a positive attitude through couple self-disclosure, and improves cancer recurrence fear and the marital relationship with their spouses. If the intervention is proven to be effective, the intervention can be adopted as a practical strategy of psychological care for patients with gastric cancer in China.

Methods

Aim

This study aims to develop a marital self-disclosure intervention and evaluate the effectiveness of this intervention for improving the fear of cancer recurrence and the dyadic coping ability in Chinese patients with gastric cancer and their spouses. The trial was registered in November 2022 at ClinicalTrials.gov (NCT05606549).

Hypotheses

The main hypothesis is as follows: Compared with the control group, participants (patients with gastric cancer and their spouses) in the experimental group show lower scores on the FoP-Q-SF after the intervention.

The secondary hypothesis is as follows: Compared with the control group, participants (patients with gastric cancer and their spouses) in the experimental group show improvements in the dyadic coping ability measured by the Dyadic Coping Inventory (DCI) after the intervention.

Theoretical Framework

Manne and Badr [31] believed that it is necessary to not only evaluate the psychological adaptation process of patients in the face of cancer, but also evaluate their spouses. On the basis of summarizing multiple theories, such as the resource theory and social cognition theory, Manne proposed the relationship intimacy model of couple adaptation to cancer [32]. This model divides the factors that affect psychological adaptation into 2 parts: relationship-enhancing behaviors and relationship-compromising behaviors. Relationship-enhancing behaviors, including reciprocal self-disclosure, partner responsiveness, and relationship engagement, have a positive effect on intimacy and psychological adaptation, and intimacy also has a positive effect on psychological adaptation. Relationship-compromising behaviors, including avoidance, criticism, and pressure withdrawal, have a negative effect on intimacy and psychological adaptation. In this model, Manne et al [19] emphasized that reciprocal self-disclosure in relationship-enhancing behaviors is the primary factor affecting the psychological adaptation of patients with cancer and their spouses, and plays a positive role in the face of cancer stressors. This model provides a theory basis for this study to analyze the effect of marital self-disclosure on the fear of cancer recurrence and dyadic coping ability from a binary perspective.

Methodology and Design

A quasiexperimental study with a nonequivalent (pretest-posttest) control group design will be used to examine the effect of marital self-disclosure on the fear of cancer recurrence and dyadic coping ability among patients with gastric cancer and their spouses. The study will be conducted at 2 tertiary hospitals in Taizhou City, Jiangsu Province, China. Considering the time constraints, sample availability, and prevention of contamination, the research will be conducted in the oncology departments (digestive system) of 2 hospitals. The 2 hospitals will be assigned randomly. A total of 42 patients with gastric cancer undergoing chemotherapy and their spouses will be recruited from each hospital. Eligible patients with gastric cancer undergoing chemotherapy who agree to participate and sign the informed consent form will be included in this research. Participants from Jingjiang People's Hospital will be assigned to the experimental group, while participants from Taizhou People's Hospital will be assigned to the control group. Patients with gastric cancer share similar characteristics, such as demographics, treatment, and nursing care plans. The treatment methods refer to the "Guidelines for Diagnosis and Treatment of Gastric Cancer" [32]. The chemotherapy scheme is selected according to the patient's actual situation, which is predicted for 4 to 6 cycles. The study includes 4 stages of face-to-face interventions. The researchers will take measurements at 3 time points: baseline and 2 and 4 months postintervention.

Study Setting and Recruitment

The study will recruit patients and their spouses who are interested in the study. The nurse practitioners will inform the researchers of the patients' interest, and the researchers will explain the research methods and requirements, and the ethical information in detail to the patients. Nurse practitioners from

the Oncology Department of the 2 hospitals will screen the eligible patients based on the inclusion criteria and will inform the patients and their spouses about the study. The patients who agree to participate will sign a written informed consent form.

Participants

Inclusion Criteria

Patients

The inclusion criteria for patients are as follows: (1) the disease meets the diagnostic criteria of the "Guidelines for Diagnosis and Treatment of Gastric Cancer" [32], the preoperative gastroscopy and pathological diagnosis indicate advanced gastric cancer, and the postoperative pathological classification is type II, III, or IV; (2) age ≥18 years and ability to write and communicate effectively; (3) the main caregiver is their spouse; (4) clear consciousness and no understanding barriers; and (5) written informed consent to participate in this study.

Spouses

The inclusion criteria for spouses are as follows: (1) age ≥18 years and ability to write and communicate effectively; (2) the main caregiver is the spouse; (3) clear consciousness and no understanding barriers; and (4) informed consent to participate in this study.

Exclusion Criteria

Patients

The exclusion criteria for patients are as follows: (1) another diagnosis of gastric cancer or another type of cancer, with severe complications, such as gastrointestinal obstruction and perforation; (2) received or is currently receiving psychotherapy from a psychiatrist or psychologist; (3) cognitive impairment or mental impairment; and (4) severe visual, hearing, and speech impairments.

Spouses

The exclusion criteria for spouses are as follows: (1) presence of serious physical diseases or acute diseases, such as cancer, stroke, and cardiovascular or cerebrovascular diseases; (2) received or is currently receiving psychotherapy from a psychiatrist or psychologist; (3) cognitive impairment or mental impairment; and (4) severe visual, hearing, and speech impairments.

Sample Size

The sample size will be calculated using the following formula for sample size based on the study by Charan and Biswas [33]: sample size = 2 (SD) 2 × (Zα/2 + Zβ)2 / D2. It is based on the FoP-Q-SF (primary outcome) from a previously published study [15]. It showed a 95% power to detect a mean difference of 2.88 points between the control and experimental intervention groups in 61 Chinese patients with breast cancer. Statistical significance will be calculated to achieve a statistical power of 0.9 at a 5% significance level for 70 participants in each group. A 2-tailed test will be used to test the hypothesis. The sample size of each dependent variable is 35. To address dropout, an additional 20% is added to the calculation. As a result, the sample size for the experimental and control groups is 42. Consecutive sampling will be used in this study.

Study Interventions

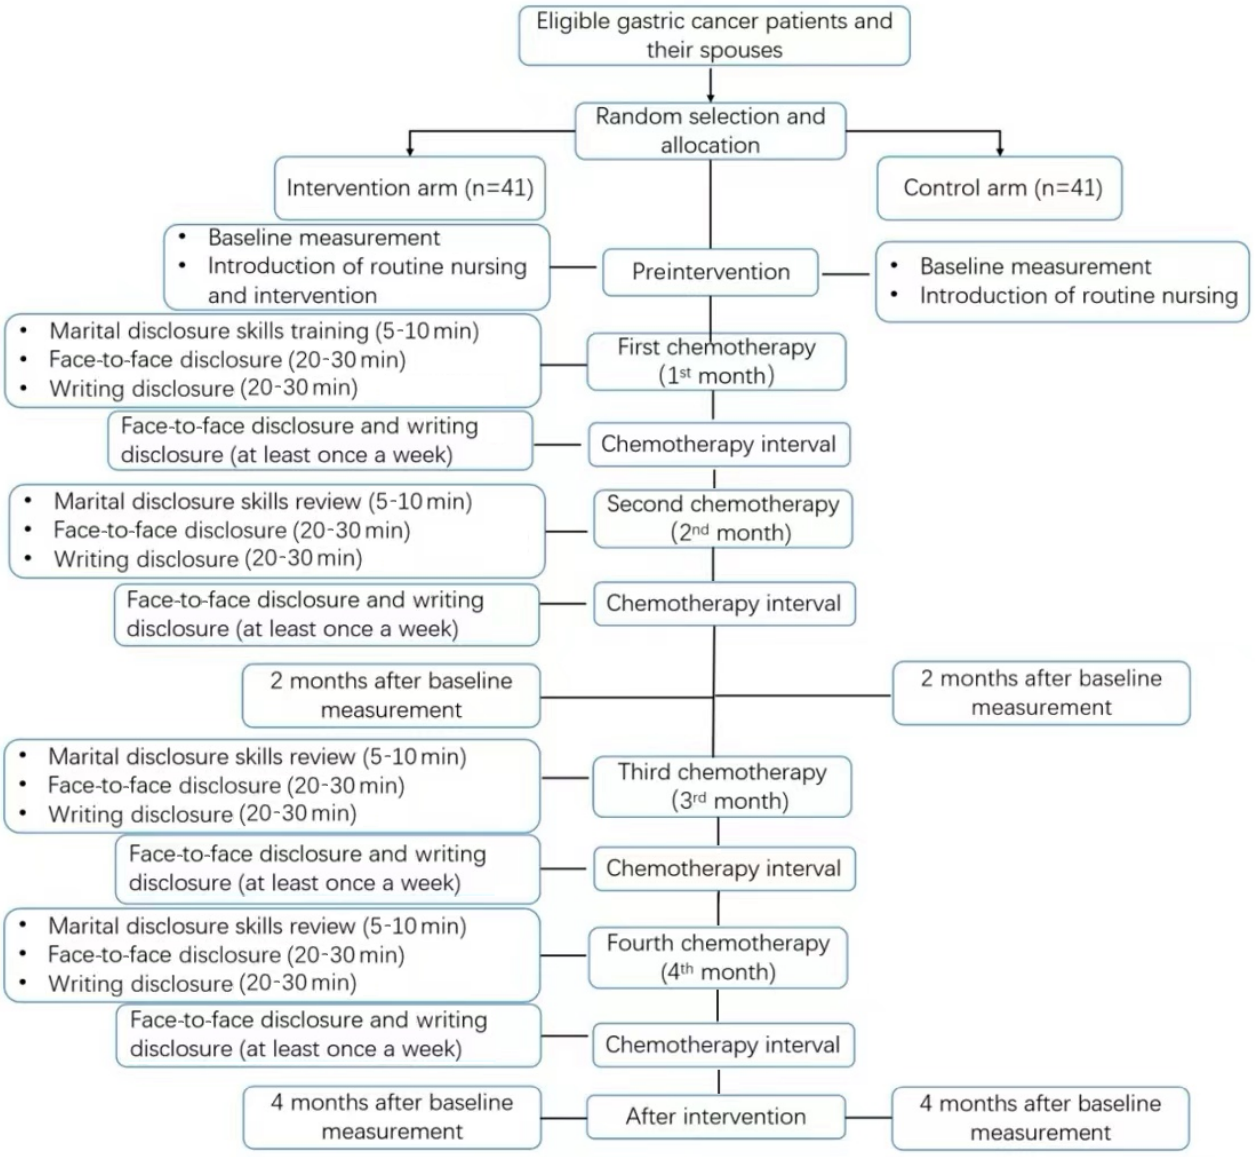
Control Intervention

Participants in the control group will only receive routine nursing care [34]. When patients are admitted to the hospital, apart from routine nursing related to patient treatment, nurses will provide a booklet to patients about gastric cancer and treatment introduction, adverse reactions of chemotherapy, nutrition management, exercise guidance, psychological support (eg, relaxation and music), and life guidance during chemotherapy. In addition, the researchers will contact patients by phone or WeChat every week and send relevant health education messages to reduce the dropout rate. The nurses will not provide patients with any training in communication skills and will not actively encourage couples to discuss cancer-related thoughts and feelings.

Experimental Intervention

The marital self-disclosure intervention is divided into 4 stages. Each stage will be divided into the chemotherapy and hospitalization phase and the interval and home phase. Both phases include verbal and written disclosures, and the intervention will be conducted in 16 weeks. The flowchart of the trial is shown in Figure 1.

Figure 1. Flowchart of the trial. The primary outcome is the score of the Fear of Progression Questionnaire-Short Form (FoP-Q-SF) for patients. The secondary outcomes are the scores of the FoP-Q-SF for partners and the Dyadic Coping Inventory.



Phase 1: Development of the Marital Self-Disclosure Intervention

A previous systematic study [35] by our team found that the most common methods of couple communication are one-on-one and face-to-face communication. They should accept training in marital communication methods before marital self-disclosure, such as how to incorporate the materials from the course into their daily lives through the communication skills learned [36], the strategies for expressing their thoughts and feelings about cancer, and the strategies for accepting and affirming each other's feelings and opinions [23]. Psychological evaluation indicators are stable, and no significant changes are observed in frequent evaluations [15]. Therefore, 3 to 5 weeks per session can obtain a trend change in the index and will not lead to patient evaluation fatigue, which involves better evaluation frequency. Patients with cancer become unwell due to chemotherapy, and short-term interventions (3-6 stages, 40-60 minutes each step) increase memory and application of what couples have learned and increase patient confidence and motivation to manage their disease [37]. In situations where disclosure to a partner becomes challenging or problematic, individuals may gain some benefit from writing a disclosure diary [15,38,39]. The researchers have developed and designed the intervention. The literature mentions the disclosure needs of cancer couples and the changes in cancer patients' fear of recurrence during chemotherapy, and provides information on the interview framework, objectives, benefits, mechanisms, and strategies to implement marital self-disclosure. To further improve the marital self-disclosure intervention, the researchers will conduct in-depth interviews with 3 patients with gastric cancer and their spouses to explore the experiences and needs of marital communication. Furthermore, 6 nurses from the oncology ward will be interviewed to explore the intervention preference and obtain their suggestions for the content of marital self-disclosure. The findings of in-depth interviews will be used to improve the frame, stage, time, and disclosure process of marital self-disclosure.

Phase 2: Panel Evaluation by Experts

An expert panel will be invited to provide expert inputs for developing the marital self-disclosure intervention. The expert selection criteria are as follows: (1) medical staff specializing in oncology, the gastrointestinal system, and psychology; (2) educational background of a bachelor's degree or above; (3) deputy senior title in a medical or nursing position or above; (4) rich experience in the above fields and ability to provide professional advice and guidance for this research; (5) working experience of more than 10 years; and (6) willingness to participate in this study. A total of 12 experts will be selected. Before the consultation, the research background and methods will be explained to the experts to obtain support and cooperation.

The contents and methods of marital self-disclosure are derived from the 2 phases mentioned above.

Chemotherapy and Hospitalization

The intervention time during hospitalization is the first day after chemotherapy, and the intervention is used once per chemotherapy for a total of 4 times for 45 to 70 minutes each time. The intervention includes verbal and written disclosures. The researcher will preside over the marital self-disclosure process and introduce it to patients with gastric cancer and their spouses (definitions of dyadic coping ability, marital self-disclosure, benefits, stages, process, techniques, and time). Both the patient and their spouse will take turns as speakers and listeners, and receive training or undergo review on marital self-disclosure skills for 5 to 10 minutes each time. The training or review details are shown in Table 1. The training will focus on emphasizing the strengths of dyadic coping and distinguishing between problem-solving and supportive communication. Couples will be encouraged to spend more time understanding each other through supportive communication rather than directly addressing communication issues. Couples will practice marital self-disclosure skills through 4 revealing themes. Couples will be encouraged to express their fear of cancer recurrence. When partners disclose information, supporters should allow the speakers to fully express their feelings and should respond positively to the messages of the speakers, showing empathy for them and acknowledging their points of view.

Each stage has different revealing goals, and the disclosure outline set according to the goals differs. The goals of the personal emotional expression stage are to reveal the person's thoughts and feelings after the illness, reveal the person's concerns about the progression of the disease, and express other emotions. The goals of the social cognition expression stage are to disclose the impact of cancer on family or social functioning after the illness, reveal the couple's specific concerns about the progression of the disease, and express other emotions. The goals of the benefit discovery stage are to disclose the benefits of couples from the experience of illness, reveal positive emotions after the illness, and reveal positive changes that have occurred in their life during treatment. The outlook to the future stage aims to disclose the couple's plans, reveal the couple's needs, formulate a cancer recurrence prevention plan, and express other emotions. The patient with gastric cancer and their spouse will disclose information to each other according to the disclosure outline (20-30 minutes) at each stage. When one party is disclosing information, the other party is required to listen actively. After the verbal disclosure, the patient will participate in a written disclosure based on the given topics for 20 to 30 minutes each time. During the written disclosure, the researcher and the patient's spouse are required to maintain silence and respond to the patient timely if there are any questions. After writing, the researcher will take back the notebook. The disclosure topics of the 4 stages are described in detail in Table 2.

Table 1. Disclosure training of the speaker and listener.

Disclosure request	Description
Disclosure request of the speaker	• Share a topic-related experience that evokes strong emotions • Follow your heart and express your thoughts sincerely • Tell your partner about the experience in as much detail as possible, including the event itself and psychological feelings • Do not talk too much at one time; pause occasionally to give your partner a chance to show understanding and support
Disclosure request of the listener	• Try to stand in your partner's role and understand their experience • Avoid immediately solving the problem or giving advice, focus the conversation on how your partner feels, reveal your thoughts when necessary, and facilitate the expression of your partner • Listen reflectively, summarize what your partner has said, pay attention to your tone of voice, maintain eye contact, and nod your head to show understanding

Table 2. Marital self-disclosure topics.

Theme and aspects	Description
First chemotherapy: personal emotional expression	
Verbal disclosure goals (couple)	• Reveal the person's thoughts and feelings after the illness • Reveal the person's concerns about the progression of the disease • Express other emotions
Disclosure outline	• How have you felt since (your partner) became ill? • Are you worried about the progression of the disease? What are the specific aspects? • What other emotions did you experience during the treatment?
Written disclosure (patient)	• Please write down your inner thoughts and feelings during the illness and how they affect you
Second chemotherapy: social cognition expression	
Verbal disclosure goals (couple)	• Disclose the impact of cancer on family or social functioning after the illness • Reveal the couple's specific concerns about the progression of the disease • Express other emotions
Disclosure outline	• What impact does the illness (of your partner) have on your family, work, and social interactions? • Are you worried about the progression of the disease? What are the specific aspects? • What other emotions did you experience during the treatment?
Written disclosure (patient)	• Please write down the couple's specific concerns during the illness and how they affect you
Third chemotherapy: benefit discovery	
Verbal disclosure goals (couple)	• Disclose the benefits for couples from the experience of the illness • Reveal the positive emotions after the illness • Reveal the positive changes that have occurred in your life during treatment
Disclosure outline	• Did you benefit from the experience of being sick? What are the specific aspects? What are the good influences on you? • What positive emotions did you experience after (your partner) got sick? • What positive changes have you made during the (partner) treatment?
Written disclosure (patient)	• Please write down the positive changes and emotions that you have experienced from the illness
Fourth chemotherapy: outlook to the future	
Verbal disclosure goals (couple)	• Disclose the future plans of the couple • Reveal the needs of the couple and formulate a cancer recurrence prevention plan • Express other emotions
Disclosure outline	• What are your plans for the future? • What other needs do you have for preventing disease recurrence and what are your plans to prevent the recurrence of the disease? • What other emotions did you experience during the treatment?
Written disclosure (patient)	• Please summarize and write about your cancer recurrence prevention plan and hopes for the future

Chemotherapy Interval and Homework

With regard to homework requirements, couples will determine the time of disclosure according to the actual situation. The verbal and written disclosures will be conducted at least once a week for 20 to 30 minutes each time. The disclosure outline during the chemotherapy interval is the same as that during the chemotherapy. At the end of every stage, a notebook will be provided to the patient, and the patient will be required to complete homework after chemotherapy.

Phase 3: Marital Self-Disclosure Intervention Workshop for Facilitators

First, 2 oncology nurses with strong nursing and communication skills will gain the trust of patients, screen patients who met the inclusion and exclusion criteria, ask them whether they are willing to participate in this study, and assist the consenting patients in signing the informed consent form. Second, participants in the experimental group will receive the marital self-disclosure intervention delivered by 2 communication-led nurses who have master's degrees in nursing and who are

certified psychological counselors. The communication-led nurse will (1) prevent negative interactions; (2) use the checklist to facilitate the disclosures of patients and their spouses; (3) ensure that the communication does not deviate from the outline; and (4) guide the disclosure content to focus on the speaker's experience. Furthermore, the research nurse will (1) add the WeChat ID of the patient or spouse; (2) provide weekly WeChat reminders; and (3) require the patient or spouse to take photos, upload data, and check in regarding the disclosure execution status and disclosure diary through WeChat. If patients have any nursing or treatment questions, they can consult the research nurse through WeChat. For patients who do not have WeChat, the nurse will follow-up on the implementation status through telephone contact. Moreover, the nurse will record the reasons for patient dropout.

Instruments and Measures

Sociodemographic and Clinical Variables

Variables include the demographic information of patients with gastric cancer and their spouses, including age, gender, education level, employment status, family per capita monthly income, duration of the marriage, and fertility status (couple). In addition, information on clinical variables, including pathological classification, tumor stage, treatment type, and time since cancer diagnosis (patient), will be collected.

Fear of Cancer Recurrence for Patients

The FoP-Q-SF is a 1-dimensional scale based on the Fear of Progression Questionnaire (FoP-Q). The FoP-Q-SF for patients includes 12 items, which are rated on a 5-point Likert scale (1 point indicating "never" and 5 points indicating "always"), with a total score ranging from 12 to 60 and with higher scores indicating higher fear of disease progression [40]. Wu et al [41] translated the scale into Chinese and tested its reliability and validity. The authors found that the Cronbach α coefficient of the total scale was 0.886 and the Guttman split-half coefficient was 0.855. Moreover, the Cronbach α coefficients of the 2 extracted common factors were 0.836 and 0.804, respectively, and the Guttman split-half coefficients were 0.806 and 0.828, respectively, which indicated good content consistency and met the requirements of psychometrics.

Fear of Cancer Recurrence for Partners

The FoP-Q-SF for partners was developed by Zimmermann et al [42] based on the structure of the FoP-Q-SF scale to assess the degree of partners' fear of disease progression in patients. The FoP-Q-SF for partners includes 12 items, which are rated on a 5-point Likert scale (1 point indicating "never" and 5 points indicating "always"), with a total score ranging from 12 to 60 and with higher scores indicating higher fear of their spouses' disease progression. The Cronbach α coefficient of the scale was 0.88. Wu et al [41] translated the scale into Chinese and tested its reliability and validity. The authors found that the Cronbach α coefficient of the total scale was 0.834 and the Guttman split-half coefficient was 0.818. The Cronbach α coefficients of the 2 extracted common factors were 0.835 and 0.699, respectively, and the Guttman split-half coefficients were 0.774 and 0.721, respectively, which indicated good content consistency and met the requirements of psychometrics.

Dyadic Coping Ability

The DCI based on the system interaction model was initially developed by Bodenmann [43], which included 6 dimensions (55 items) and used a 5-point Likert scale. After further improvement, the DCI [44] was revised to 37 items and was measured on a 5-point Likert scale ranging from 1 (not at all/very rarely) to 5 (very often). To assess the stress and coping behaviors of couples, the DCI includes 5 subscales for the patient and a corresponding subscale for the partner: (1) stress communication by self; (2) emotion-focused supportive dyadic coping by self; (3) problem-focused supportive dyadic coping by self; (4) delegated dyadic coping by self; and (5) negative dyadic coping by self. The DCI also assesses 2 common dyadic coping behaviors: emotion-focused common dyadic coping and problem-focused common dyadic coping. Xu et al [45] translated this questionnaire into Chinese. The Cronbach α coefficient was 0.73.

Outcome Assessment

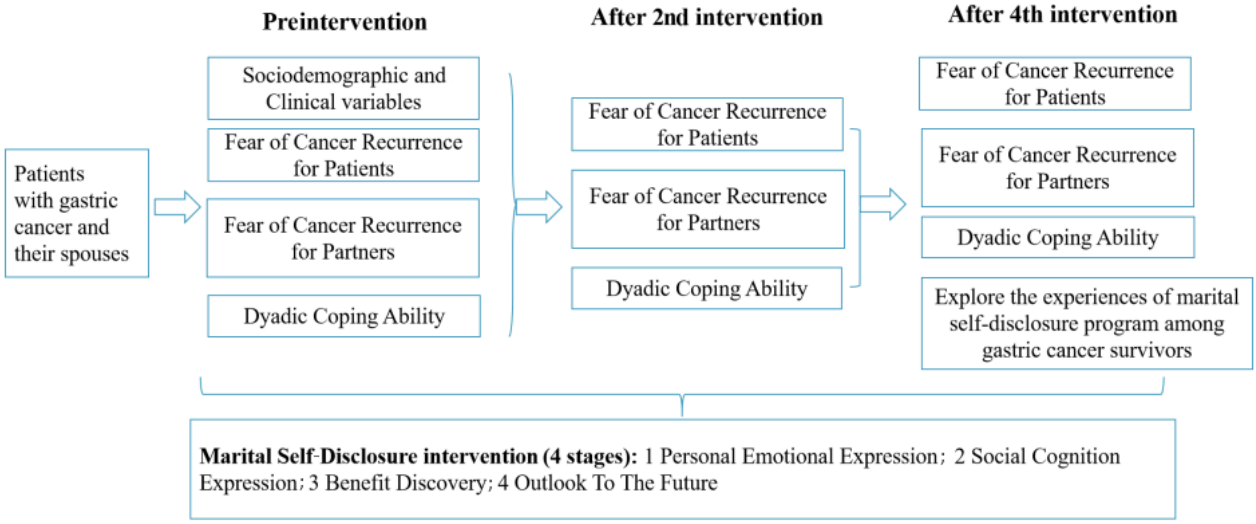
Permission to adopt the 3 questionnaires has been obtained from the original researchers. A trained researcher will assess the outcomes, including sociodemographic variables and psychosocial variables. The sociodemographic variables include demographic and clinical characteristics. The psychosocial variables include fear of cancer recurrence for patients, fear of cancer recurrence for partners, and dyadic coping ability. The psychosocial variables will be repeatedly collected at 3 time points: baseline, after the second session of the intervention (nearly 2 months after baseline), and after the last intervention (almost 4 months after baseline). The control group will be reassessed at the same intervals. Furthermore, participants in the experimental group will be assessed to determine their experiences with the intervention after the last intervention session (Table 3). The conceptual framework is shown in Figure 2.

Table 3. Study measures.

Variable	Outcome (measure)	Time point		
		Baseline	2 months after baseline (after the second intervention)	4 months after baseline (after the fourth intervention)
Inclusion criteria	Sociodemographic and clinical information	Yes	No	No
Primary outcome	FoP-Q-SF[a] for patients	Yes	Yes	Yes
Secondary outcome	FoP-Q-SF for partners and Dyadic Coping Inventory	Yes	Yes	Yes
Intervention experience	In-depth interview	No	No	Yes

[a]FoP-Q-SF: Fear of Progression Questionnaire-Short Form.

Figure 2. Conceptual framework.



Data Collection and Compensation

Upon agreeing to participate in the study, participants will be required to complete a paper-based baseline survey questionnaire. Participants in the intervention group will have the option to receive the marital self-disclosure intervention directly after completing the survey, while participants in the control group will only receive routine care. Both groups of participants will be tracked for a duration of 16 weeks after recruitment, and data will be collected at 3 time points: baseline and 2 and 4 months postintervention.

To ensure participant confidentiality, information collection will be restricted to face-to-face communication and a paper-based questionnaire. Birth dates or participant addresses will not be collected. All data will be stored on secure internal platforms of Hospitals A and B. At the end of the study period, only researchers will have access to the data set.

At each time point, the research team will contact participants via phone or WeChat, according to their preferences. Participants will be notified of upcoming follow-up studies and will be assisted in completing subsequent survey questionnaires. Upon completing each survey, they will receive small gifts, such as a hand sanitizer. Recruitment is expected to last for 12 months, with an additional 16 weeks needed for follow-up with all recruited participants to complete data collection. Data analysis will commence at the end of recruitment.

Allocation and Blinding

This study will recruit an equal number of patients with gastric cancer and their spouses. Participants from Jingjiang People's Hospital will be assigned to the experimental group, while participants from Taizhou People's Hospital will be assigned to the control group. As the study involves a face-to-face psychological intervention, participants and personnel will be unblinded, but the outcome assessment will be blinded. Participant data will be anonymized using individual participant codes, and the database will not contain participant identifiers (eg, birth dates and case numbers).

Data Analysis

Statistical analysis will be conducted using IBM SPSS 21.0 (IBM Corp). The level of statistical significance will be set as α=.05. Descriptive statistics will be used to describe the sociodemographic and psychosocial variables, including percentages, means, and standard deviations. For comparing the baseline characteristics of the 2 groups, the Student *t* test or Mann-Whitney *U* test will be used for quantitative variables and the chi-square test will be used for categorical variables. Two-way repeated-measures ANOVA will be performed to determine the presence of a significant change in the fear of cancer recurrence and DCI in the intervention and control groups in order to analyze the effects of the intervention and compare the control group with the experimental group at baseline and 2 and 4 months postintervention. This analysis will be performed

on an intention-to-treat basis. A *P*-value of <.05 will be considered statistically significant for differences between the 2 groups.

Ethical Considerations

The study protocol has been approved by the ethics committees of Jingjiang People's Hospital and Taizhou People's Hospital (TZRY-LL-AF/SQ-018-3.0 and KY 2022-167-01). A cover letter will be provided to guarantee human rights and ethical transparency, and inform the participants about the aims and benefits of this study. Participants will be informed that they can voluntarily participate and withdraw from the study without any impact on their treatment or nursing care. If they agree to participate, they will be required to sign an informed consent form with detailed information concerning the goals and procedures of the intervention. The data of this research will be kept confidential and anonymous. The trial was registered in November 2022 at ClinicalTrials.gov (NCT05606549).

Results

The research activities for this study commenced in October 2022. Participant recruitment and data collection began in February 2023, with the expectation of completion within 12 months (by December 2024). As of October 30, 2023, a total of 97 gastric cancer patients and their spouses have been recruited, and all baseline data have been collected. Once sufficient participants are recruited, subsequent measures will be performed and data analysis will commence. The primary results of this study are anticipated to be announced in June 2024.

Discussion

Marital Self-Disclosure Intervention and Protocol Design

Improvement of the fear of cancer recurrence and dyadic coping ability in patients with gastric cancer is necessary. To date, few psychological interventions effectively manage the fear of cancer recurrence in patients with gastric cancer. This is the first and only intervention with the explicit aim of improving the fear of cancer recurrence in Chinese patients with gastric cancer. The intervention focuses on personal emotional expression, social cognition expression, benefit discovery, and outlook to the future, with a further focus on the fear of cancer recurrence. This study will provide evidence of the effectiveness of the marital self-disclosure protocol for improving the fear of cancer recurrence compared with routine nursing care.

There are several advantages of the marital self-disclosure intervention. First, the study involves a long-term intervention that spans from the participant's diagnosis of gastric cancer until the end of chemotherapy. In a preview study, among patients with gastric cancer in the first, third, and sixth chemotherapy stages, greater family support was associated with a lower fear of cancer recurrence [7]. Therefore, early and lasting intervention is essential.

Second, the study considers the marital factors related to the fear of cancer recurrence and has developed relevant communication topics in each phase. The husband and wife will be trained in marital self-disclosure, and formal disclosure will be made after both husband and wife have mastered the method of disclosure. Moreover, before each phase, the couple will review the method of disclosure again so that the couple can fully grasp the method of disclosure and return it as a homework exercise, making the research results more credible. Finally, this study combines written and verbal representations to facilitate better participant expression of concerns regarding the fear of cancer recurrence.

Third, the study is based on not only a literature review but also Chinese cultural background, clinical practice, and stakeholder input to design a feasible intervention for Chinese patients with gastric cancer.

Fourth, the marital self-disclosure intervention will be designed for implementation by nurses, and it may appeal to nurses who seek flexibility and dynamism in their work. The intervention will train nurses to teach patients and their spouses to use the theory of respect, empathy, and positive attention in emotional communication and marital interaction. Stable, friendly, and trusting relationships will be built between nurses and patients.

Limitations

This study has some minor limitations. First, this study involves a long-term intervention, and some participants may not complete the study owing to loss of follow-up or physical deterioration during treatment. Second, missing data may influence the results and must be addressed statistically. To overcome this bias, a 20% attrition rate will be included in the sample size calculation, and an intention-to-treat analysis will be performed during the data analysis. Finally, this study will only include patients during chemotherapy.

Conclusion

This is the first attempt to develop a brief and feasible intervention to manage the fear of cancer recurrence in Chinese patients with gastric cancer. If the marital self-disclosure intervention is effective, it will be implemented at the hospital. This brief and focused intervention will be integrated to enhance clinical practice. Even with null results, participants with gastric cancer and their spouses will obtain more comprehensive self-care nursing knowledge. Furthermore, investigators will obtain a large amount of data to analyze the fear problems of patients with gastric cancer.

Abstract

Background: Children diagnosed with cerebral palsy (CP) often experience various limitations, particularly in gross motor function and activities of daily living. Transcranial direct current stimulation (tDCS) is a noninvasive brain stimulation technique that has been used to improve movement, gross motor function, and activities of daily living.

Objective: This study aims to evaluate the potential additional effects of physiotherapy combined with tDCS in children with CP in comparison with physiotherapy only.

Methods: This is a 2-arm randomized controlled trial that will compare the effects of tDCS as an adjunctive treatment during rehabilitation sessions to rehabilitation without tDCS. Children with CP classified by the Gross Motor Function Classification System as levels I and II will be randomly assigned to either the sham + rehabilitation group or the tDCS + rehabilitation group. The primary outcome will be the motor skills assessed using the Gross Motor Function Measure domain E scores, and the secondary outcome will be the measurement scores of the children's quality of life. The intervention will consist of a 10-day stimulation protocol with tDCS spread over 2 weeks, with stimulation or sham tDCS administered for 20 minutes at a frequency of 1 Hz, in combination with physiotherapy. Physical therapy exercises will be conducted in a circuit based on each child's baseline Gross Motor Function Measure results. The participants' changes will be evaluated and compared in both groups. Intervenient features will be tested.

Results: Data collection is ongoing and is expected to be completed by January 2025. A homogeneous sample and clear outcomes may be a highlight of this protocol, which may allow us to understand the potential use of tDCS and for whom it should or should not be used.

Conclusions: A study with good evidence and clear outcomes in children with CP might open an avenue for the potential best use of neurostimulation.

Introduction

Cerebral palsy (CP) is a prevalent cause of physical disability among children, with reported incidence rates ranging from 2.0 to 2.5 per 1000 live births in developed countries, and even higher in low and middle-income countries, reaching up to 7 per 1000 live births [1]. The treatment goals for CP primarily focus on improving motor function and promoting independence in activities of daily living, as well as enhancing quality of life (QoL) [2]. Despite the efforts made in this area, the heterogeneous clinical presentations and responses to interventions pose a challenge in generalizing information about the effectiveness of specific treatment methods [2]. Guidance from the Cochrane Collaboration in 2019 suggests there is a need to standardize the outcomes studied in interventions, to provide functional and informative results and guide the selection of the most effective interventions and an effective individualized treatment [3].

Children with CP have difficulties in balance, motor function, and movement coordination. Physical therapy is used to improve these disabilities. Transcranial direct current stimulation (tDCS) is a complementary intervention that has been shown to enhance balance and improve movement coordination and gross motor function in children with CP [2,4,5]. There is a difference in oscillation speed when associating tDCS with virtual reality [5]. De Almeida Carvalho Duarte et al [2] have shown that children with CP subjected to 5 sessions of treadmill training stimulated with tDCS for 2 weeks with stimulation in M1 for 20 minutes exhibited improvements in temporal functional mobility, such as gait. The results were still maintained 1 month after the intervention. Balance and functional performance seem improved in children with CP after 5 sessions of tDCS anodal stimulation of the motor cortex plus treadmill training for 2 consecutive weeks.

Just 1 session of tDCS realized in the M1 region for 20 minutes in a group of children with CP showed a momentary increase in cortex activation with a direct influence on motor control and an improvement in gait and balanced outcomes [6]. Permanent effects in the population submitted to tDCS with clinical effects were observed in promoting functional improvement in children with CP [2,4].

According to the previous results, we hypothesized that tDCS use might improve specific motor skills and positively impact QoL in a more homogeneous population with CP. This study was designed to examine the impact of the combination of tDCS and conventional rehabilitation exercises on the improvement of gross motor function in children with CP classified as level I and II in the Gross Motor Function Classification System (GMFCS). The primary outcome measure will be assessed using the scores of the Gross Motor Function Measure (GMFM) dimension E and the secondary outcome is the children's QoL.

According to Castelli and Fazzi [7], rehabilitation is a complex process that aims to promote the best possible participation and QoL for the child and the family. Rehabilitation for children with CP must be timely, intensive, and family-centered [7]. Despite the importance of understanding the effects on children's QoL, QoL is not commonly measured.

Castelli and Fazzi [7] recommend intensive rehabilitation with trained professionals and a multidisciplinary team focused on the child's functional improvement. Rehabilitation is one of the main parts as it involves performing functional assessments, establishing a functional prognosis, constructing a rehabilitation plan, and promoting a multidisciplinary approach [7].

Methods

This study is a single-blind randomized controlled trial (RCT). The participants will be blinded to the treatment allocation during the trial, but the researchers conducting this study will be aware of the treatment allocation. This study will conform to the CONSORT (Consolidated Standards of Reporting Trial) guidelines for nonpharmacological interventions. This study has been approved by the ethics committee in research.

Recruitment

All patients with CP who meet the previously described criteria for inclusion will be invited to participate in this study which will be realized in the Molecular Medicine Center of the Universidad Federal de Minas Gerais in Brazil.

Sample Size

The sample size was calculated using G* Power software (version 3.1; Universität Düsseldorf) [8]. Considering an effect size of 0.5, power of 0.95, and probability of type I error (α) of 5%, the total sample size should be 176 volunteers, with 2 groups of 88 volunteers. The impact of the intervention will be evaluated in the pilot phase to determine a more accurate estimate of the population sample size. The participants will be included from July 2023 to July 2024. After the end of the intervention, the data collected will be separated into groups, these being the intervention group (IG) and the control group (CG). We will carry out the analysis of the pre- and postintervention GMFM variables and the Pediatric Quality of Life Inventory (PedsQL). We will carry out the analysis between groups (CG and IG) and between individuals in the same group, and will compare participants with themselves, to quantify and describe the results. Analysis of covariance will be chosen to observe preexisting differences between groups, allowing for comparison of postintervention scores while controlling for baseline scores.

Participants and Eligibility Criteria

The participants in this study will be recruited through advertisements at clinics and the intervention will take place at the Molecular Medicine Center of the Universidade Federal de Minas Gerais in Brazil. To be eligible, participants must have a medical diagnosis of CP, be classified as GMFCS I or II, be aged between 8 and 12 years, be able to walk independently, and be able to understand commands. Exclusion criteria include other neurological conditions, recent history of surgery, uncontrolled epilepsy, a cranial metallic implant, and the use of a hearing aid. The waiting list group will have access granted afterwards based on the evidence.

Ethical Considerations

This study was evaluated and approved by the local ethical board at Universidade Federal de Minas Gerais (50504021.0.0000.5149). All participants and their guardians will be informed about the research protocols and will be required to sign the free and informed consent form and the free and clarified assent form. Participation will only be allowed when both the child and parent have agreed to participate. All data will be handled as anonymous. Following the national law, participation in the intervention must be voluntary and reimbursement will be available only for research-related transportation.

Measures

Overview

Both instruments will be used with all participants before and after the interventions to assess whether there was a significant improvement in gross motor movement according to the E domain of the GMFM or in QoL.

About GMFCS

This is a scale used to classify the level of impairments of the gross motor function of the CP population [9]. GMFCS allows us to classify functionality about walking, sitting, and standing [8]. It classifies gross motor function into 5 levels, as follows: level I: no access; level II: walks with limitation; level III: walks using a manual mobility device (such as a Canadian crutch, walker, or cane); level IV: self-mobility with a limitation (such as using a regular or automatic wheelchair); level V: patient transported via manual wheelchair by a responsible person. Initially, the entire sample will be evaluated using this instrument [10].

About GMFM

This instrument evaluates quantitatively the change in gross motor function in children with CP. The evaluation has five dimensions: dimension A, bed and roll; dimension B, sitting; dimension C, crawling and kneeling; dimension D, standing; and dimension E), walking, running, and jumping [11]. The scoring system is as follows: a score of zero is assigned if the individual is unable to start the activity, a score of 1 is assigned if the individual starts the activity, a score of 2 is assigned if the individual starts the activity but only completes half of it, and a score of 3 is assigned if the activity is completed. The scores for each dimension should be calculated separately by summing the scores for that dimension and dividing by the total score for that dimension [11].

In the end, the scores for each dimension should be multiplied by 100 to find the percentage that the child achieved in each dimension. Finally, the percentages for all dimensions should be added and divided by 5 (the number of dimensions evaluated), yielding the percentage that the child scored in the GMFM (dimension E). This method is based on the techniques of Luciana Ventura De Pina, PhD and Ana Paula Cunha Loureiro, PhD [12]. Both scales, the GMFM and the GMFCS, have been validated for use with children with CP. The GMFM assesses gross motor function and the GMFCS stratifies the functional level of children with CP. The Gross Motor Ability Estimator (GMAE) program will be used to analyze the GMFM results.

About PedsQL

The PedsQL is a multidimensional tool to measure health-related QoL in children and adolescents. It is a practical scale on the dimensions of health outlined by the World Health Organization, with questions related to the frequency of problems faced in the last month. The 23 item-PedsQL has 8 items for physical functioning; 5 for social functioning; 5 for emotional functioning; and 5 for school functioning, with 15 on patients' psychosocial health.

tDCS Intervention

Overview

The IG will receive 10 sessions of tDCS with a frequency of 5 daily sessions per week, over a period of 2 weeks. The stimulation will be administered during rehabilitation sessions. The electrodes will be 35-cm^2 sponges moistened with normal saline (0.9% NaCl solution). The stimulation will consist of anodal stimulation in the primary motor cortex (M1) and cathodal stimulation in the supraorbital region on the contralateral side, at an intensity of 1 mA and a duration of 20 minutes at a steady-state level, with a ramp-up and ramp-down of 4 seconds. The stimulation will be combined with specific exercises in a circuit format to target dimensions D and E of the GMFM [13]. CG will undergo 10 sessions of sham tDCS associated with rehabilitation activities 5 times per week, for a total of 2 weeks. Activities that target dimension E of the GMFM will be organized as a circuit including running, walking, and jumping. Any change to the trial will be informed along with the reason for the change.

Safety

The device used, tDCS Soterix Medical (Soterix Medical Inc), model number 1300-A and serial number 13ITC0619005, is approved by the Food and Drug Administration for use as an experimental device and some for clinical purposes (ANVISA-80969860041). Further, 3.5-cm^2 electrodes will be used. Bikson et al [13], prove if the purpose is to modulate neurophysiological measures for resting motor cortex stimulation in healthy young people (1 mA intensity), tDCS for 4 seconds induces acute excitability alterations.

Krishnan et al [14] demonstrated adequate safety of tDCS in children and adolescents. Well-accepted threshold of tDCS current density is <142.9 A/m^2 or 14.29 mA/cm^2. Each patient will undergo a thorough health assessment and medications in use will be registered as well as all health conditions. Cardiac frequency, blood pressure, temperature, respiration, clinical assessment of mental and functional status, and physical examination will be measured [15]. Any apparent side effects will be registered, and all changes to the study will be described so that individuals have the option to interrupt the trial; the trial may also be suspended.

Adverse Effects

Adverse effects will be assessed using the tDCS adverse effects questionnaire [16]. The dropout rate will be reported, and dropout reasons will be stated [15]. tDCS is generally well-tolerated with no serious adverse events [14]. The effects reported are rare, mild, and transient, with "redness," "slight tingling," "itching," and "burning sensation" as the most reported events. The intensity of current, density, and electrode size will be optimized to modulate the tingling and itch perception during transcranial stimulation. Furthermore, we will not pass the well-accepted threshold of tDCS current density (<142.9 A/m^2 or 14.29 mA/cm^2) [14].

Allocation

Participants will be randomly assigned to tDCS groups with a 1:1 allocation as per a computer-generated randomization schedule stratified by the patient's age using 5 permuted blocks of 6 participants.

Implementation

All participants will be randomized, and the randomization will be performed by the researcher who will carry out an intervention; the others will not know which group the participant is in. This member will upload the randomization results to the institution's REDCap (Research Electronic Data Capture) database [17]. The researcher who will perform a physiotherapeutic intervention and the researcher who will apply the assessments and questionnaires will not have information about group allocation.

Blinding

This will be a double-blinded study; during this study, the participants will be seen by three different teams: (1) the researcher who performs the assessment and questionnaires, (2) the neuromodulation team who apply the tDCS, and (3) the physiotherapist who performs the physiotherapy exercises. There will be no members working simultaneously on both teams. The results of randomization will only be available to the neuromodulation member responsible for the intervention, and the scales' results will only be available to the researcher who performed the assessment and questionnaires. The results will be held in a different project in REDCap and will be available only to the researcher who makes the assessment and questionnaires.

Emergency Unblinding

Emergency unblinding will be available under the determination of this study staff, in case of safety concerns related to the intervention.

Interventions: Participants

Initially, we will explain to the child how the intervention process will be carried out. The electrodes will be moistened in saline solution and will be placed on the participant's head, which may cause slight discomfort as it will wet the child's head, and, to minimize this discomfort, we will frequently dry their face. Associated with this, the child will perform physical therapy exercises.

CGs for tDCS will receive placebo stimulation for 30 seconds, for 10 sessions to give the child an initial feeling of stimulation. Associated with the placebo, the child will perform physical therapy exercises, focusing on the demands of the GMFM dimension E. The tDCS intervention will receive a current of 1 mA, for 20 minutes, for 10 sessions also associated with physical therapy exercises, focusing on the demands of the GMFM dimension E.

The intervention lasts from 25 to 35 minutes with each participant and will have a researcher exclusively dedicated to it during the intervention period for data collection. There will be 5 sessions with each participant per week over 2 consecutive weeks, with sessions taking place on weekdays and not weekends. All included participants will complete 10 sections of physiotherapy with or without tDCS stimulation. The tDCS device contains 2 electrodes, an anode, and a cathode, in the form of 2 nonmetallic sponges measuring 5×5 cm^2, moistened with saline solution. The anode will be positioned on the M1 of the participant's dominant hemisphere, according to the 10-20 System EEG, while the cathode will be placed on the supraorbital region of the region contralateral to the anode. In the case of the experimental group, a current will be applied to M1 for 20 minutes for neurorehabilitation.

After 10 sessions, the GMFM test will be repeated with each patient along with the PedsQL. Further, 1 researcher will carry out the intervention or the placebo with tDCS and the other researcher will evaluate the results blindly, without knowing which group is the intervention and which is the control. The use of the equipment and the evaluation will be carried out in different rooms to guarantee the researchers' blindness. Only the researcher in charge of using the tDCS will be aware of the allocation of children between experimental and CGs.

It is worth noting that the patients in the CGs learned, at the end of this study, the intervention that had the best effect on their motor function, respecting this study's ethical perspective that all children should receive the best treatment.

Results

There is a compelling need to tailor medical approaches more precisely, catering to individual differences. Achieving successful outcomes requires studies that use informative measures, robust evidence, and are applicable across diverse demographics.

In this proposal, we emphasize the importance of incorporating targeted and universally recognized outcomes, specifically focusing on motor skills impacted by the disorder. These skills are universally acknowledged and play a fundamental role in an individual's daily life. Additionally, we are examining how these interventions influence the overall QoL for affected individuals. Data collection is ongoing and is expected to be completed by January 2025.

Moreover, our study aims to optimize treatment efficacy by exposing participants to multiple sessions. This strategy is designed to fine-tune the intervention's impact, building upon a baseline established using the most credible rehabilitation practices available for this condition.

RCTs are not commonly conducted in pediatric populations, leading to a lack of dedicated information specific to this demographic's unique needs and responses. Addressing this gap is crucial to better understand how interventions impact children with this condition.

Discussion

A randomized controlled protocol using an additional tDCS was designed to improve specific motor skills and positively impact QoL in a homogeneous population with CP. This study aims to examine the impact of the combination of conventional rehabilitation exercises on the improvement of gross motor function in children with CP classified as level I and II in the GMFCS. The primary outcome was assessed using the scores of the GMFM dimension E and children's QoL as the secondary outcome. tDCS seems to improve balance, gross motor function, and gait in children with CP [2,4-7]. Mixed and heterogeneous outcomes of varied motor skills made it difficult to understand who and in what conditions individuals may benefit from tDCS complementary use.

To address this issue, the specific protocol proposed focuses on a homogeneous population of children with CP who have preserved walking skills and will evaluate them for motor features and QoL. By using the GMFCS and GMFM to classify and map the skills and their changes, we aim to improve the evidence, since there is a clear outcome that can be measured, and optimize treatment for a personalized medicine approach in the heterogeneity of CP. Our goal is to gather evidence for a stratified population of children with lower locomotion restrictions, as suggested by de Almeida Carvalho Duarte et al [2], who highlighted the importance of studying more homogeneous populations in the field of CP to better understand gains in the functional independence of these children. This will allow us to know the treatment effect size and for whom it should be a good choice.

The costs and presence of adverse effects will be features considered to reveal the individual cost-effect balance [16], and dropout rates will indicate any potential reason for dropping out [15].

Stimulation has been done on the M1 motor area in children with GMFCS I, II, and III [18]. Children with GMFCS III compared with children classified as I and II present an important difference in the use of aid devices. Children with GMFCS levels I and II are very functional, running and walking independently and having fewer limitations, while children with GMFCS III need an assistive device, such as walker assistance. In places with ramps, they may not be able to go up and down, due to the difficulty in controlling their movements independently. In De Moura et al's [4] meta-analysis, the difference in results was attributed to a high level of heterogeneity, potentially compromising the generalization of results and the understanding of who and in what conditions children would benefit from the use of tDCS. This protocol evaluated TDCS stimulation on the motor standardized measure and QoL outcomes.

Besides the efforts on RCT protocols, there are always the limits related to the artificial scenario observed in RCTs; many things are controlled and compared that differ from natural scenarios. However, the limitation in heterogeneity considering the differences in functional classification in motor skills may be an interesting strategy to decrease heterogeneity and truly understand the role of TDCS in the improvement of motor skills. Reporting quality, including sample size, control characteristics, important outcomes, and the methodology of intervention training and delivery may help in building a body of literature with better evidence [19,20].

QoL and health-related QoL are increasingly being considered therapeutic goals [19]. In the past decades, QoL has been defined as well-being across various domains and has become an important treatment goal, especially in diseases like CP [19]. Many studies have observed that parents report lower QoL for their children with CP than the children themselves report [19]. The emotional and social domains were evaluated equally for children and parents [19]. Furthermore, parents of children with severe impairment often report better QoL in the psychosocial domain [19]. Consistent findings suggest that children with CP can adapt well to their activity limitations and may have a satisfactory QoL despite deficits [19]. Improving QoL represents a crucial treatment objective for children with CP, necessitating precise measurement and targeted interventions aimed at achieving this outcome [19]. In conclusion, CONSORT-based report protocols based on homogeneous sampling and using relevant outcomes seem necessary to improve the evidence for personalized medicine, especially for the pediatric population.

Abstract

Background: Injury is a global health concern, and injury-related mortality disproportionately impacts low- and middle-income countries (LMICs). Compelling evidence from observational studies in high-income countries shows that trauma education programs, such as the Rural Trauma Team Development Course (RTTDC), increase clinician knowledge of injury care. There is a dearth of such evidence from controlled clinical trials to demonstrate the effect of the RTTDC on process and patient outcomes in LMICs.

Objective: This multicenter cluster randomized controlled clinical trial aims to examine the impact of the RTTDC on process and patient outcomes associated with motorcycle accident–related injuries in an African low-resource setting.

Methods: This is a 2-arm, parallel, multi-period, cluster randomized, controlled, clinical trial in Uganda, where rural trauma team development training is not routinely conducted. We will recruit regional referral hospitals and include patients with motorcycle accident–related injuries, interns, medical trainees, and road traffic law enforcement professionals. The intervention group (RTTDC) and control group (standard care) will include 3 hospitals each. The primary outcomes will be the interval from the accident to hospital admission and the interval from the referral decision to hospital discharge. The secondary outcomes will be all-cause mortality and morbidity associated with neurological and orthopedic injuries at 90 days after injury. All outcomes will be measured as final values. We will compare baseline characteristics and outcomes at both individual and cluster levels between the intervention and control groups. We will use mixed effects regression models to report any absolute or relative differences along with 95% CIs. We will perform subgroup analyses to evaluate and control confounding due to injury mechanisms and injury severity. We will establish a motorcycle trauma outcome (MOTOR) registry in consultation with community traffic police.

Results: The trial was approved on August 27, 2019. The actual recruitment of the first patient participant began on September 01, 2019. The last follow-up was on August 27, 2023. Posttrial care, including linkage to clinical, social support, and referral services, is to be completed by November 27, 2023. Data analyses will be performed in Spring 2024, and the results are expected to be published in Autumn 2024.

Conclusions: This trial will unveil how a locally contextualized rural trauma team development program impacts organizational efficiency in a continent challenged with limited infrastructure and human resources. Moreover, this trial will uncover how rural trauma team coordination impacts clinical outcomes, such as mortality and morbidity associated with neurological and orthopedic injuries, which are the key targets for strengthening trauma systems in LMICs where prehospital care is in the early stage. Our results could inform the design, implementation, and scalability of future rural trauma teams and trauma education programs in LMICs.

Introduction

Background

Transport-related injuries are a global public health threat and are anticipated to rank fifth in the global burden of disease by 2030 [1]. Evidence suggests that 90% of the transport-related crash mortality burden disproportionately occurs in low- and middle-income countries (LMICs), such as those in Africa [1], despite concerns of underreporting [2]. The main causes of injury-related mortality in Africa are road traffic accidents [3], which have serious economic consequences. According to Ryan-Coker et al [4], despite high poverty levels and minimal access to insurance and social protection schemes in Africa, which imply out of pocket expenditure, road traffic accidents cost US $119-$178 per injury and US $486-$12,845 per hospitalization, resulting in a gross domestic product (GDP) loss of 0.8%-9%.

Uganda is one of the LMICs in Africa with a high road traffic injury burden [5]. Our recent studies showed that most fatal injuries in Uganda result from motorized 2-wheeler and car collisions, contributing to 52.6%-64.7% of orthopedic and traumatic brain injuries [6-8]. Further, the majority (74%) of Uganda's population lives in rural areas [9], which could partly explain the high injury-related mortality rates. Research has shown that the risk of trauma-related deaths in rural areas increases with remoteness owing to health care disparities, such as large commute distances, scarce resources, delays in referral, and lack of skilled trauma care providers, as well as population-specific and contextual challenges, such as poverty and impassable road networks [10].

Uganda lacks universal access to trauma care and injury surveillance systems owing to limited health care funding. Thus, Uganda has made sluggish progress toward attaining the sustainable development goal (SDG3) for universal health care coverage [11]. As such, in terms of the level of specialty care, the ratio of surgeons to patients is 0.7:25,000 as interns and medical trainees represent the largest proportion of Uganda's health workforce [12,13].

Research has shown than more than half of the trauma patients in Uganda do not receive first aid prior to hospital arrival [6,7]. Moreover, most of these patients arrive at dedicated trauma centers much later than the recommended limit of 1 hour, and they are transported by either public vehicles, such as motorcycles [8], or police vans, without any focus on key factors, such as changes in blood pressure and oxygen circulation, which could lead to death, during transit [7,14]. These aspects have 3 important implications. First, strengthening the capacity for injury care among lay frontline workers. Second, stabilizing patients at rural regional trauma centers prior to transfer. Third, ensuring closed-loop communication between primary (level 3) and tertiary (level 1) trauma centers to enable safely coordinated referrals and adequate preparation at the receiving hospitals prior to patient transfer.

The key challenge that needs to be addressed in Ugandan rural settings is the lack of a formal prehospital care system as evidenced by emergency evacuation and transfer of trauma patients by untrained police staff [14]. Further, there is an immense need to redress the weak immediate care response after an accident as medical trainees are the first point of contact after an accident as opposed to specialists [12]. We will attempt to fix these challenges at the community level and at level 3 rural trauma centers by creating and providing training capacity for rural trauma networks between traffic police and medical interns or trainees at regional referral hospitals.

Rationale

Evidence from 2 systematic reviews has shown that trauma education programs have the potential to improve skill acquisition and knowledge retention among health professionals; however, with regard to LMICs, most of these programs have not been locally contextualized and have been largely assessed based on their theoretical merit rather than their clinical impact on patients [15,16]. A recent observational study in Portugal showed that the European trauma course (ETC) improved self-efficacy and organization skills in individual routine practice, but the authors mentioned that future investigations should be conducted to examine the effect of the training on trauma outcomes [17]. This European study and systematic reviews in LMICs have recommended high-caliber epidemiological studies to evaluate the effects of such educational programs on process outcomes, such as

organizational efficiency, and on patient outcomes, such as morbidity and mortality [15,16,18].

Except for an ongoing pilot trial comparing a primary trauma course (PTC) to advanced life support (ATLS) and routine care in India [19], trauma education programs in LMICs have mostly been evaluated based on nonrandomized studies, limiting their clinical uptake [15]. Moreover, most programs limit the course participants to qualified hospital-based medical providers [18], although interns, medical and allied health trainees, and road traffic law enforcement professionals are the most readily available frontline workers for managing injured patients in LMICs [14]. Inclusive planning while leveraging services that have no trauma designation, such as police services, is critical for expanding and strengthening complex rural trauma systems to improve injury reporting [2].

Locally contextualized trauma training has been identified as one of the most crucial steps for operationalizing nonfunctional rural trauma networks [10]. However, in a scoping review by Brown et al [18], only 12 out of 34 trauma courses in LMICs had been contextualized to suite low-income settings. Moreover, a cautiously executed integrative literature review on the challenges faced by trauma systems recommended that the next step for future research should be an examination of how trauma training impacts the outcomes of patients in remote environments [10]. This multicenter cluster randomized controlled trial will address this gap by examining the effect of the locally contextualized Rural Trauma Team Development Course (RTTDC) of the American College of Surgeons [20] on process and patient outcome measures in Ugandan trauma centers. The trial will focus on musculoskeletal and neurological injuries, which have been recently identified as the most important targets for strengthening health systems in rural Uganda [8], and it has been developed in accordance with the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) guidelines for reporting outcomes in trial protocols [21].

Objectives

Broad Objective

The main objective of this trial is to determine the effect of RTTDC training on the time efficiency of the clinical process and the patient-centered outcomes of motorcycle accident–related injuries.

Specific Objectives

The specific objectives are to (1) determine the effect of RTTDC training on the time interval from the accident to hospital admission and the time interval from the referral decision to hospital discharge (primary outcomes) and (2) determine the effect of RTTDC training on the outcomes of neurological and musculoskeletal injuries (secondary outcomes).

Null Hypothesis

The null hypothesis of this trial is that RTTDC training has no effect on the time efficiency of the clinical process and the outcomes of orthopedic and neurological injuries.

Methods

Trial Design

This will be a pragmatic, 2-arm, parallel, multi-period, cluster randomized, controlled, clinical trial with 1 intervention (RTTDC) arm and 1 control (standard care) arm. The trial was set to start in 2019 but was delayed owing to the COVID-19 pandemic, and the subsequent prioritization of COVID-19–related studies by trial registers and target journals led to the delayed publication of this protocol.

This trial will embrace simultaneous cluster randomization, which is an ideal method for evaluating community-level interventions and overcoming ethical constraints that make randomization at the individual level impractical while avoiding probable contamination between the control and treatment groups [22]. Moreover, simultaneous randomization will enable timely operationalization and concurrent participant enrollment as all the outcomes will be measured as final values and there are no foreseen plans for study modifications in accordance with Esserman et al [23]. This arrangement is based on the fact that our previous studies have already provided insights on the likely rates of loss to follow-up and baseline mortality in our target trauma population and have informed the feasibility and relevance of collecting the intended primary and secondary outcomes [6,7].

Study Setting

This study will be conducted in 6 specialized teaching and regional referral hospitals in Uganda, including Kiryandongo, Jinja, Hoima, Fort Portal, Mubende, and Kampala International University Hospital. These facilities have similar characteristics and serve as teaching, residency, and internship sites for undergraduate and graduate medical doctors and nurses. The hospitals offer 24/7 emergency surgical services for trauma patients through multidisciplinary teams of orthopedic, general, and visiting neurosurgeons, as well as imaging, rehabilitation, and physiotherapy. Each surgical department in these facilities is typically composed of about 1-4 faculty members, 2-4 specialty residents often referred to as senior house officers, 4-6 interns, and 10-30 undergraduate medical trainees.

These facilities are suited for this study as they serve both rural populations and populations in newly created populous cities that are still struggling with urban planning. Uganda is the 8th most populous country in Africa and the 30th most populous country in the world [9], and its trauma surveillance systems are in the infancy stage with weak preaccident and postaccident responses [6,12]. Despite efforts made in the past decade by the Ugandan government to address the unmet need for trauma care through infrastructure development, such as equipping operating theaters and intensive care units (ICUs) in public hospitals, limited standardized preservice and in-service trauma training, prehospital delays, and human resource constraints still contribute to preventable trauma mortalities [14]. To guarantee the quality of data for this project, a prospective motorcycle trauma outcome registry (MOTOR) will be piloted at the participating 6 regional referral hospitals in parallel with this trial.

Eligibility Criteria

Inclusion Criteria

Study Sites

We will include level 3 trauma centers that are teaching hospitals; are staffed with medical trainees, interns, surgery residents, and consultants; and offer 24/7 emergency surgical care with access to blood banks, ultrasound scans, X-ray scans, and computed tomography (CT) scans as locally available or outsourced services.

Trainee Participants

We will include third-year or fifth-year medical or allied health students, interns, or specialty residents in surgery and traumatology clinical rotations who stay at the hospital of attachment for at least 2 months. Medical students may only rotate to a different hospital without crossing the study arm. In addition, we will include road traffic law enforcement professionals concerned with the evacuation of trauma patients from accident scenes.

Patient Participants

We will include patients who sustain motorcycle accident–related injuries and present to the study sites within 24 hours following the accident, as defined in a previous study [6]. These will include passengers on motorcycles, motorcycle riders, pedestrians or cyclists hit by motorcycles, and patients experiencing motorcycle-motorcycle collisions, motorcycle-static object collisions, or motorcycle-car collisions.

Exclusion Criteria

Study Sites

We will exclude trauma centers that do not offer placements and teaching facilities for students, interns, and residents.

Trainee Participants

We will exclude medical students who have not commenced their surgery clinical rotation and those not directly involved with the care of trauma patients at the time of the training, as trainee medical participants are expected to have already been introduced to surgery, emergency trauma resuscitation concepts, and trauma clinical scenarios through clerkships onto which we will be building the rural trauma team concept.

Patient Participants

We will exclude pregnant women, neonates, and infants aged 0-23 months owing to the known teratogenic effects of radiation in this population, as trauma evaluation in this study will involve obtaining radiographs for orthopedic injuries and CT scans for neurological injuries. Patients with documented stroke will also be excluded, as the study outcomes involve assessment for functional, physical, and neurological disabilities directly attributable to trauma. Moreover, mentally incapacitated patients who have no legally authorized representatives to sign an informed consent form and patients who die before hospital arrival or before imaging results are obtained will be excluded. Patients who are passengers in a car or drivers in a car at the time of the accident will be excluded, as the protective casing of the car body would make these patients less vulnerable to direct impacts compared with pedestrians, cyclists, or passengers on motorcycles. In addition, elderly patients older than 80 years will be excluded owing to their increased risk of fragility fractures that could misrepresent the severity of trauma. This cutoff age was used based on a systematic review by Tsuda et al [24], which documented a mean age of 80 years for long bone fragility fractures owing to increased muscle weakness, balance disorders, visual impairment, and dementia that predispose elderly people to falls. The number of ineligible participants and the reasons for their exclusion will be recorded in both arms in the consolidated standards of reporting trials flow diagram.

Ethical Considerations

Research Approval

Prior to recruitment, this study has been approved and registered by the research and ethics committees of the Uganda National Council for Science and Technology (reference number: SS 5082) and Mbarara University of Science and Technology (reference number: MUREC 1/7; 05/5-19).

Consent to Participate

Written informed consent will be obtained from all study participants or their legally authorized representatives prior to participation. The official informed consent form documents for Mbarara University of Science and Technology will be adopted for this purpose. Both trainee and patient participant informed consent documents are provided in Multimedia Appendix 1 and Multimedia Appendix 2, respectively. The ethical committees ruled that trainees involved in the data collection process at control centers do not need to provide any consent as this study will neither directly affect their practices nor collect their personal data.

Collection of Informed Consent

All participants or their legally authorized representatives (for minors and unconscious patients) will endorse a predesignated consent form document with their signatures in the presence of the principal investigator or research assistants (surgery specialty residents).

Additional Consent Provisions for the Collection and Use of Participant Data and Biological Specimens

There will be no biological specimens retained for this study. The informed consent form documents will have provisions for consenting to follow-up and the use of data for approved ancillary studies, and for permission to archive the anonymized data in a public data repository.

Consent for Publication

This manuscript does not contain any identifying individual participant information or images; thus, consent for publication is not applicable.

Privacy and Confidentiality Protection

To protect participants' confidentiality before, during, and after the trial, all hard copy data collection items will be kept under lock and key and will bear unique nonidentifying codes. Soft copies will be kept in password-protected computers, with a second-layer protection login password required for REDCap,

which will be only accessible to the study team. The final data sets will be anonymized prior to archiving and publication. Hard copies of the data will be destroyed 6 months after completion of the trial.

Compensation Type and Amount for Participants

Participation in this trial will be voluntary. However, transport reimbursement of 20,000 Ugandan shillings (US $5.0) will be provided to participants turning up for research follow-up appointments outside of their routine hospital visits. Moreover, time compensation of 10,000 Ugandan shillings (US $2.5) will be provided.

Interventions

Explanation for the Choice of Comparators

The intervention for this trial is based on the fourth edition of the RTTDC of the American College of Surgeons [20], which will be delivered to medical trainees, interns, and traffic law enforcement professionals at the 3 intervention study centers (intervention group). Specialty surgical residents will be trained as faculty who will later serve as trainers since they directly supervise interns and undergraduate medical students in Ugandan settings. The research and ethics committees approved training residents as opposed to specialists to avoid constraining the scarce specialized human resource as this is a trainee-capacity building trauma education program. Moreover, consultants rarely attend to trauma patients for immediate resuscitation as the first point of contact in Ugandan settings. The patient participants at intervention sites will be those with motorcycle accident–related injuries at any of the study sites. The comparator in this trial is a control group of hospitals that will offer standard care to eligible patients, without their care providers receiving the RTTDC training intervention.

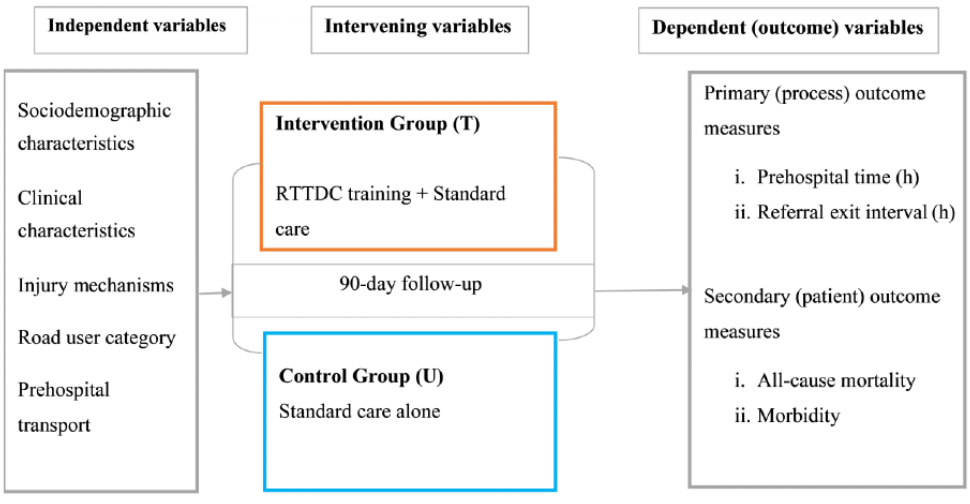
Intervention Description

The 2-day RTTDC interventional training will be conducted in designated spacious multimedia surgical simulation conference rooms at the study sites randomized to the intervention arm and will be delivered in the described standard format [20]. This training model is the most appropriate for Uganda, with its health worker to patient ratio of 1:25,000 and its large population of 48 million [12]. The model dwells on team concepts to improve coordination and efficiency of the existing “skeletal” health structure in the rural environment. We hope to train a total of 66 road traffic police officers, 12 specialty residents, 30 intern doctors, 140 fifth-year medical students, and 264 third-year medical students. These figures have been determined based on the average annual number of traffic police officers and trainees at the respective regional police headquarters and hospitals [25].

Our target is to train at least 80% of each cohort of eligible trainees identified every 1-5 months within the surgery department during the 4-year study period until the required trainee and patient participant sample sizes are attained. If trainees drop out prior to completion of data collection, compensations will be made to maintain the criterion during the next cohort of surgical rotation trainee intake. The details of how the training will be conducted have been provided elsewhere [25]. The research core team has agreed that trainee participants who score more than 60% in posttraining trauma-based multiple-choice questions (MCQs) at the intervention sites will be retained to form a rural trauma team network, which will constitute multiple local 6-member trauma committees of first responders with defined roles (ie, each team having 5 medical trainees and 1 contact road traffic officer).

To enable an active “alarm” activation criterion for the trauma committees, closed-loop communication, and a smooth “handover” process from police officers to medical trainees prior to patient transfer, the trained traffic officers on highways will serve as focal contact persons for the rural trauma teams from the parish (subcounty) level. In the event of a road traffic accident, teammates will freely contact each other both within and across teams to coordinate evacuation, consultation, referral, and arrival at recipient centers, with the support of trained interns and surgery residents as team leaders. Weekly audit meetings will be conducted remotely via Zoom (Zoom Video Communications) to discuss team challenges, otherwise a trained surgery resident will be available 24/7 to advise on referrals, transfers, and treatments in liaison with consultants who may be physically or remotely available. The control hospitals in this trial will be allowed to provide routine standard care without the RTTDC intervention as summarized in Figure 1.

Figure 1. Conceptual framework summarizing the intervention and the interaction of variables. RTTDC: Rural Trauma Team Development Course.



Criteria for Discontinuing or Modifying the Allocated Intervention

The fourth edition of the RTTDC will be delivered in its standardized form [20] without any modifications.

Strategies to Improve Adherence to the Intervention

The RTTDC is the intervention; thus, participants who do not attend all the modules and complete the posttraining MCQs will be excluded. Adherence to teachings in the RTTDC among care providers during clinical practice, such as the time taken from referral decision to execution and improper closed-loop communication leading to loss to follow-up, will be assessed as process measure outcomes.

Relevant Concomitant Care Permitted or Prohibited During the Trial

The baseline quality of care given to trauma patients at each of the participating 6 hospitals is based on the regulations of the Uganda Medical and Dental Practitioners Council (UMDPC), which regulates medical practice, and the National Council for Higher Education (NCHE), which regulates both undergraduate and graduate surgical curricula [26]. The councils require that graduating doctors undergo clinical rotations in surgery and traumatology, perform clerking activities, and present and document trauma scenarios in patient case files.

In addition, medical graduates should demonstrate the ability to initiate emergency resuscitation in accordance with advanced trauma life support protocols [27], such as execution of primary and secondary surveys; carefully discern, request, and comprehend the necessary imaging and laboratory investigations in trauma; acknowledge self-knowledge and resource limitations; and consult or refer patients whose surgical care demands exceed their own skills or the local trauma capacity. Further, upon graduation, Ugandan doctors are required to obtain a minimum of 48 hours of continuous professional development points annually to maintain their licensure.

In terms of the standards of care, both intervention and control facilities have medical trainees, interns, specialty residents, and specialists who provide care for injured patients. The care typically involves receiving trauma patients who may be brought by staffed ambulances, police officers, or public means to accident and emergency units, and these patients may be received by trainees, interns, or surgical residents. These cadres open case files; initiate immediate care through horizontal consultation; request X-ray scans, CT scans, and laboratory workup; and plan definitive care or referral in liaison with a senior surgical resident and in consultation with a multidisciplinary team of specialists on call. As such, procedures, such as surgical suturing and toileting, limb fracture casting and immobilization, and chest tube insertion, are often performed by interns. More demanding procedures, such as splenectomy, external fixation of fractures, and burr holes, are usually performed by specialty residents after notification of the consultant on duty, whereas major cases of polytrauma warrant the decision of the consultant specialist on call before the patient is taken to the operating room.

Imaging and blood transfusion services are often freely available at emergence units as government services but may be outsourced from private hospitals at a cost owing to long waiting times or service maintenance for CT scanners and X-ray machines. Finally, in terms of patient disposition, patients with minor injuries requiring surgery under local anesthesia are discharged on the same day. Moreover, patients with major trauma requiring conservative treatment, such as closed fractures, are treated in surgical wards, whereas those who are deeply unconscious or require critical care after major operations are admitted to the ICU until they are fit for care in general surgical wards prior to discharge. Alternatively due to overcrowding, often with higher bed occupancy rates exceeding the predetermined bed capacity, patients with major trauma may be referred to other centers, and the common reasons for referral include further neurosurgical evaluation with magnetic resonance imaging or further evaluation by a neurosurgeon, need for multiple specialty care and rehabilitation, and need for ICU admission elsewhere when local ICU beds are limited.

Provisions for Posttrial Care

Any participants requiring further care beyond the 90-day follow-up will be linked to their attending clinicians during an additional 3-month period after completion of the trial. There will be no compensation other than transport reimbursement for participants visiting solely for study follow-up outside routine clinical visits as this study was considered minimal risk by the approving research ethics committees. The principal investigator will refund the cost of imaging when the request is approved by attending surgeons and radiologists in cases where the services are unavailable free of charge.

Outcomes

This trial will examine both process measures and patient outcomes. The primary (process) outcomes of this trial will involve comparisons of (1) the time interval from the accident to hospital admission and (2) the time interval from the referral decision to hospital discharge between patients with motorcycle accident–related injuries presenting to the intervention centers and those presenting to the control centers.

The secondary (patient) outcomes of this trial will involve comparisons of (1) all-cause mortality at 90 days from the time of injury and (2) morbidity of motorcycle accident–related orthopedic and neurological injuries between patients presenting to the intervention centers and those presenting to the control centers. The morbidity of orthopedic injuries will be measured based on the Trauma Expectation Factor Score (TEFS) at admission and the Trauma Outcome Measure Score (TOMS) at 90 days as reported to outcome assessors [28]. On the other hand, for neurological injuries, the Glasgow Coma Scale (GCS) at admission and Glasgow Outcome Scale (GOS) at 90 days will be used as documented by the attending clinicians [29].

The tertiary outcomes will involve the effects of the training on provider knowledge based on pretraining and posttraining trauma-related MCQ scores and the barriers to injury care faced by providers during execution of definitive treatment. These will be determined in 2 ancillary studies that have been approved as part of this trial, and the protocols have been detailed

elsewhere [25]. A summary of all outcomes and their case definitions, specific measurement variables, analysis metrics, methods of aggregation, and time points has been provided in Multimedia Appendix 3.

The patient outcomes were selected based on their validity and relevance in previous studies [7,30]. Further, level III evidence suggests that prolonged prehospital times may be associated with increased mortality among trauma patients [31]. However, it is unclear how these results relate to time-sensitive orthopedic and neurological injuries in LMICs that lack formal coordinated prehospital systems [32]. Thus, our process outcome measure variables were selected within the context of evidence-based practice. This practice stipulates that in accordance with the golden hour rule, a major trauma patient should be in the right place within 60 minutes following injury, otherwise there is a risk of mortality or morbidity [33].

These variables align well with the proposed global surgery framework to improve national surgical, obstetric, and anesthesia care provider plans [34]. In addition, the variables expand on outcomes for trauma-informed interventions [35]. All outcomes will be measured as final values but will be discussed in relation to the baseline established in our prior feasibility studies [7,30]. The comparisons of outcomes will be made at both individual and cluster levels, using mixed effects regression models.

Participant Timeline

Initially, cluster randomization of the trauma centers will be performed 3 weeks prior to commencement of the training to determine which centers will receive the training. Potential participants for the training will be screened for eligibility by the hospital and study administrators 2 weeks prior to the training, and eligible trainee participants will be consented and assigned to “rural trauma teams” of 6 members on the first day of the training, during which they will complete a pretraining questionnaire involving trauma-based MCQs. Subsequently, trainee participants will be followed up at 90 days (3 months) to complete posttraining MCQs. The first eligible patient participants at both control and intervention sites will be enrolled concurrently through a motorcycle trauma outcome registry (MOTOR) that will run parallel to the trial.

Informed consent, baseline sociodemographic and clinical characteristics, and prehospital intervals will be obtained at admission, and the GCS score will be determined. The TEFS will be obtained during the first week of admission or prior to discharge on the assumption that patients would have received their definitive surgical intervention or would have been referred for further care during this period. Further, the GOS score, all-cause mortality rate, and TOMS will be obtained at the 90-day follow-up. The GCS will be used to assess the level of traumatic brain injury in the acute phase, whereas the GOS will be used to determine neurological outcomes within the context of the level of independence at a later phase of traumatic brain injury [29]. On the other hand, the TOMS will be used to assess patient-reported trauma outcomes with reference to their expectations (TEFS) at the time of the trauma intervention in relation to the levels of pain, physical function, disability, injury treatment satisfaction, and overall satisfaction [28,30]. Throughout the study period, any individual patient barriers encountered during the pathway to execution of definitive injury care will be documented as summarized in the timeline presented in Multimedia Appendix 4.

Sample Size

To estimate the sample size, we used the open-source R Shiny application for cluster randomized controlled trials with a parallel design and discrete time decay correlation structures for multiple periods [36] available at [37]. Further, we assumed *t*-distribution due to plans for small sample corrections at the analysis stage in accordance with the report by Rutterford et al [38]. The study was approved for 4 years, but the core research team foresaw it feasible to actively collect data for a period of 3 years considering university semester breaks, public holidays, and unexpected events, such as COVID-19–related interruptions, which led to suspension of the trial for 12 months from March 2020 to March 2021. The 3 years (36 months) would yield 12 study periods given the planned training of cohorts of medical students on a 3-monthly basis in accordance with the average duration of internship deployment by the Ugandan Ministry of Health (1-5 months) and the average duration of surgery clinical rotation for university medical students (2 months).

Fixing the study power at 80% for a parallel cluster randomized trial with different cross-sections, considering a discrete time decay period of every 3 months for a total of 12 periods, and assuming correlations to decay with each period, we explored the minimum number of patient participants (cluster size) required per period using the R Shiny application [36]. Assuming a significance level of .05, a within-period intraclass correlation coefficient (ICC) of 0.02 (lower extreme: 0.01, upper extreme: 0.05), and a cluster autocorrelation coefficient (CAC) (ratio of between-period ICC to within-period ICC) of 0.8; allowing for varying cluster sizes with a coefficient of variation of 0.5; and considering a mean difference of 1.02 hours in prehospital transfer time and a pooled standard deviation of 1.64 hours as continuous outcomes reported in a previous observational study from the United States [39], the upper ICC and base CAC plateaued between 5 and 10 participants (Figure 2).

Considering a maximum of 10 participants per cluster period, an 80% power could be attained (Figure 3) and could be met with a total of 3 clusters per arm (Figure 4). This indicates a total of 6 study centers (clusters) drawn from a pool of 17, which reasonably represents 35.3% of Uganda’s regional referral hospitals.

Figure 2. Reduction in the number of clusters required with an increase in the cluster-period size at a fixed power of 0.8. CAC: cluster autocorrelation coefficient; ICC: intraclass correlation coefficient.

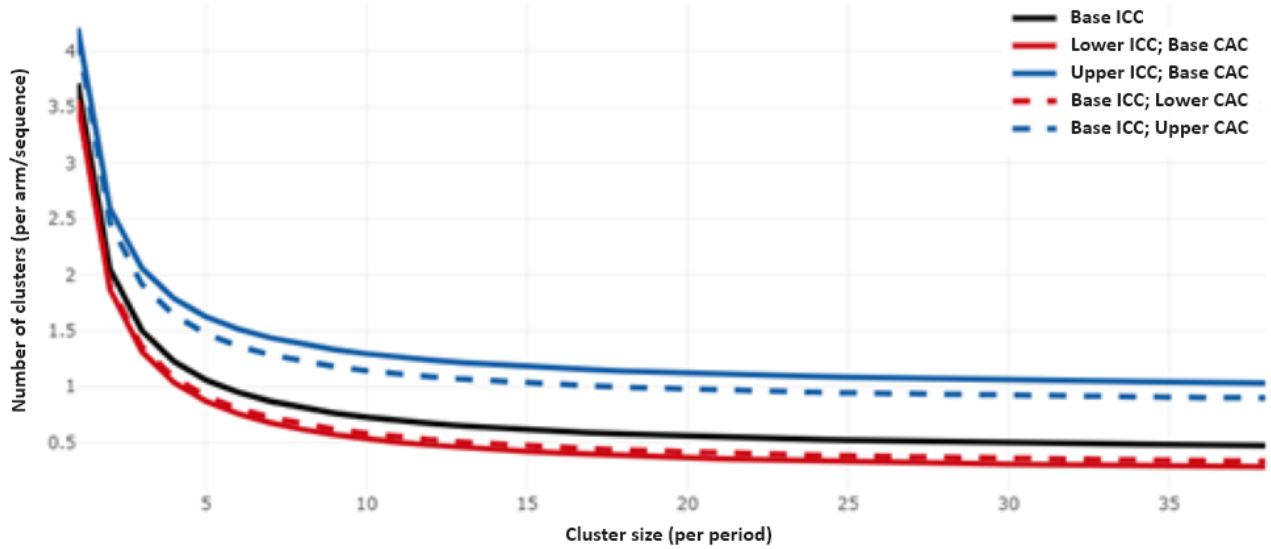


Figure 3. Cluster-period size of 10 meeting the required power of 0.8 for 12 periods. CAC: cluster autocorrelation coefficient; ICC: intraclass correlation coefficient.

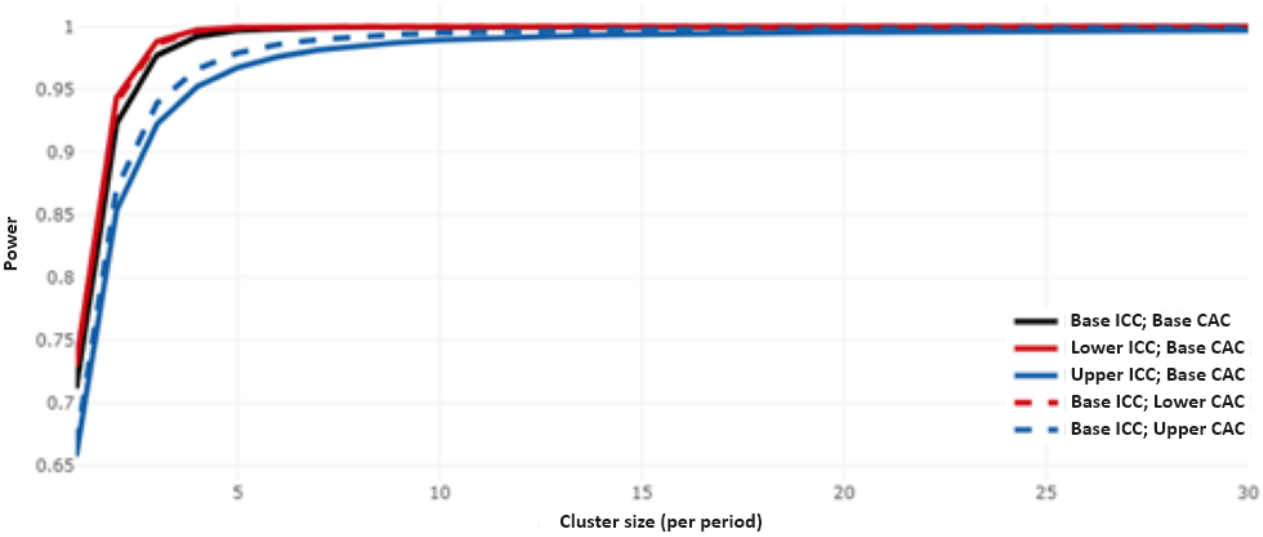

Figure 4. Three clusters per arm meeting the minimum required power of 0.8 for 12 periods. CAC: cluster autocorrelation coefficient; ICC: intraclass correlation coefficient.

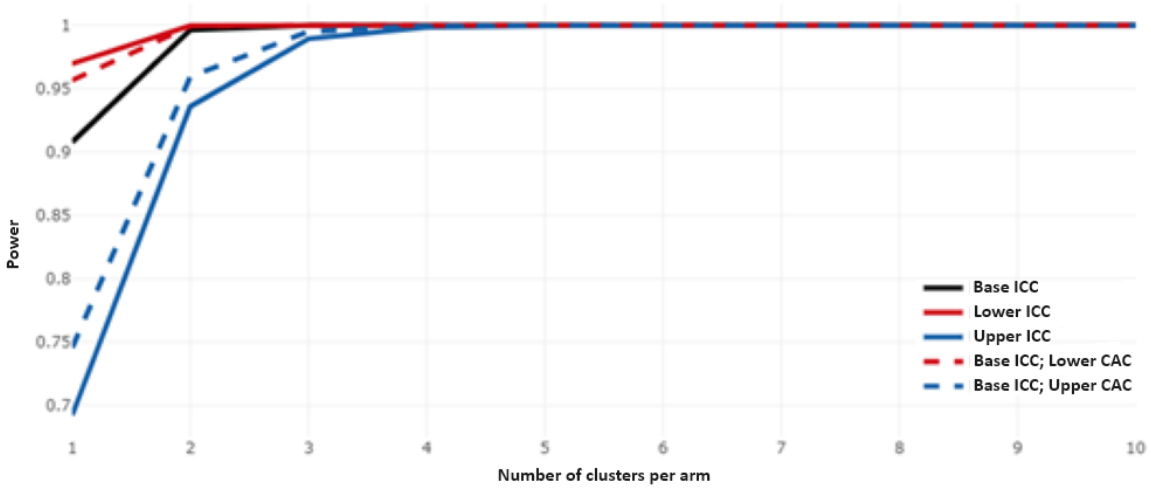

The sample required per arm is calculated as follows: 10 participants per cluster period multiplied by 12 cluster periods multiplied by 3 clusters, yielding a total of 360 participants. The total sample required for 2 arms would be 720. However, we inflated the sample and variance to cater to the clustering design effect based on the assumption that this increases the statistical power in accordance with the repost by Hemming et al [36]. Thus, the derived sample size (s) is calculated using the following formula:

$$s = n (1 + [m - 1] \rho) \quad \textbf{(1)}$$

where s is the required sample size, m is the cluster size per period (ie, 10), and ρ is the within-period ICC (0.02).

This formula yields a total of 850 participants.

We will add a rate of loss to follow-up of 18% assuming the worst scenario based on our previous dropout rate of 9% in a feasibility study [7]. Therefore, the final sample will include approximately 1003 participants. Assuming an equal allocation ratio of 1:1, there will be 502 participants per arm and about 168 individuals per cluster. This sample is deemed feasible considering the high trauma burden in Uganda. According to a study at one of the Ugandan rural regional referral hospitals, a total of 900 motorcycle accident–related injuries were recorded during a 3-year period, of which 30.9% (278/900) and 15.8% (142/900) of patients sustained musculoskeletal and neurological injuries, respectively [8]. We will not compute sample sizes for each individual secondary outcome as previous studies have not reported any difference in mortality [40].

Recruitment

The training will be advertised by hospital administrators, class representatives, and regional traffic law enforcement leaders, and course participants will be recruited by the principal investigator and the respective hospital administrators. The patient participants will be recruited by dedicated project officers at the accident and emergency departments.

Assignment of Interventions: Allocation

Sequence Generation

We will perform cluster randomization for a permuted block size of 6 hospitals (clusters) using an open-source simulation software [41], with seed numbers that will be kept confidential to the offsite study administrator. A list of 6 random codes will be generated to assign hospitals to the intervention or control group. As we plan to perform analyses at both the individual level and treatment arm level, we will not add any stratification factors in the simulation model.

Concealment Mechanism

The allocation sequence and assignment codes will be generated by and kept secret by an offsite study administrator. Both outcome assessors and patient participants will be blinded to the treatment allocation.

Implementation

Trainee participants will be enrolled by the respective university hospital administrators, whereas patient participants will be enrolled by project medical officers at the respective study sites, who will serve as outcome assessors.

Assignment of the Intervention: Blinding

Who Will Be Blinded

Trial patient participants and outcome assessors will be blinded using blocked allocation sequence codes.

Procedure for Unblinding if Needed

Unblinding will only be permissible in the likely occurrence of adverse events among the study participants, which can be directly attributed to the study intervention. Such events will be discussed with the attending physicians. Otherwise, the allocation codes will only be revealed to the biostatistician at the time of interim analysis when half of the sample size is recruited. At this point, unblinding the biostatistician is considered more beneficial to inform termination or continuation of the trial, which outweighs the perceived fear of unknown bias [42].

Data Collection and Management

Plans for Assessment and Collection of Outcomes

Data collection will start simultaneously at all the study sites. Medical officers (blinded outcome assessors) with a minimum qualification of Bachelor of Medicine and Bachelor of Surgery (MBChB) and at least 2 years of clinical experience will prospectively collect data through clinical observations, interviews, home visits, and extraction from hospital and police records. All outcome assessors must be willing to undertake a 1-day budgeted training in the use of data collection tools for this trial and the World Health Organization (WHO) ICD-10 online coding module. The data will be collected daily as medical trainees and interns will attend clinical rotations every day. Upon obtaining informed consent, the venue for data collection, including follow-up information, will be at accident and emergence departments during admission, surgical wards, and outpatient clinics, as well as through home visits and phone calls to patients, care takers, or recipient hospital physicians in the case of referrals.

The study variables will include sociodemographic and clinical variables, such as sex, age, injury mechanisms, including nature of collision and road user category, time of injury, prehospital transit time, prehospital care, mode of arrival, vital signs, nature of physical injuries, radiological findings, and injury severity based on the GCS score and Kampala Trauma Score (KTS) [43]. In addition, data on the nature of the treatment administered; need for referral; referral-exit interval; and outcomes, including the TOMS, GOS score, mortality, and time from injury to death, will be obtained. The data collection tools that will be used in this trial, such as the GCS, GOS, TEFS, TOMS, and KTS, have been shown to demonstrate excellent criterion internal validity, consistence, and reproducibility in previous studies [28,29,43,44].

Further, the tools are recognized for their high interrater reliability, sensitivity to change, and ability to be used as continuous or categorical variables in validation studies [28,29,43,44]. The baseline TEFS, GCS score, and KTS will

be added as covariates whose interaction and confounding will be assessed and controlled since the inclusion of baseline values of outcomes as covariates is arguably one of the strongest factors to reduce ICC estimates [45]. The difference in distribution of baseline characteristics will be compared using means (SDs), medians (IQRs), and ranges for quantitative data; otherwise, frequencies and percentages will be used for categorical variables. All data collection forms for this trial and detailed definitions of assessment tools for patient and trainee participants are available in Multimedia Appendix 5 and Multimedia Appendix 6, respectively.

Plans to Promote Participant Retention and Complete Follow-Up

Coffee breaks will be facilitated during training to optimize participation. Phone and email contacts will be obtained from all medical trainees and law enforcement professionals. In addition, 2 phone contacts will be obtained for each patient participant at the time of enrollment at accident and emergency departments (ie, the patient and their next of kin or legally authorized representative who will in turn be provided with the phone contact of the study nurse coordinators for the purpose of follow-up). Automated reminders will be sent to data collection assistants through mobile phones and the research electronic data capture (REDCap) platform.

Where applicable, home visits will be conducted for participants who are unable to turn up for appointments because of their disability. Transport costs will be reimbursed for traffic law enforcement professionals and patient participants turning up for appointments outside of the routine hospital visits. Participants will be considered as lost to follow-up if they are untraceable by phone, clinic appointment, or home visit. Data on the baseline sociodemographic and clinical characteristics of those lost to follow-up or those who discontinue because of a breach of the intervention protocol will be retained for comparisons between groups, but the data of those who withdraw their consent will be deleted.

Patient and Public Involvement

Using semistructured questionnaires and semistructured interviews, a 1-day consultative meeting will be conducted at each study site with chief residents, heads of interns, patient caregivers, student representatives, and regional traffic police commanders in the month preceding study commencement to discuss their perceived barriers to injury care in order to uncover themes for potential sources of delays ranging from accident scene discovery, evacuation, and prehospital transportation to emergency care, which shaped the final data collection tools.

During this engagement, trainee and caregiver representatives will provide insights on the feasibility of the outcome assessment tools and the time commitment required to respond to the questionnaire, which will inform the data collection time points of day 1, the first week, and day 90. This strategy will strike a balance regarding the feasibility of maximizing response rates and obtaining data while not overloading the already scarce human resources of traffic law enforcement, and trainees and clinicians at accident and emergency departments. Further engagements will be made during RTTDC training sessions and audit meetings, during which bidirectional feedback will be provided on team performance, challenges with individual team dynamics, and proposed areas of improvement to help shape future training. The results of patient and public engagement will be reported in an ancillary study on the barriers to injury care.

Data Management

Due to expected network breakdowns in rural centers, data will be collected in hard copies, coded, and entered into the REDCap secure virtual network hosted by the University of Turku. Data entry will be performed by outcome assessors who will be issued with a confidential login password for REDCap. Later, the data will be exported to Stata version 15.0 (StataCorp) for analysis. The REDCap software was preferred owing to its presumed secure web-based intuitive interface for validated data capture, offering an additional advantage to prohibit dual entry, restrict values, calibrate data ranges, and retrieve audit trails for tracking data manipulation [46]. Further, the software permits seamless data export and download procedures that are compatible with Stata, while allowing for data integration and interoperability with external sources [47]. Any data errors will be resolved during weekly audit meetings in reference to the online codebook with a visible description of variables accessible to the principal investigator and all outcome assessors.

Plans for Collection, Laboratory Evaluation, and Storage of Biological Specimens for Genetic or Molecular Analysis

There are no plans to collect any biological laboratory specimens for storage or for genetic or molecular analysis in this trial.

Statistical Methods

Statistical Methods for Primary and Secondary Outcomes

Primary (Process) Outcomes

The primary (process) outcomes of (1) the time interval from the accident to hospital admission and (2) the time interval from the referral decision to hospital discharge will be compared between the intervention and control groups using a 2-sample *t* test if the data are normally distributed or a 2-sample Wilcoxon rank sum test if the data are not normally distributed. The normality of distribution will be assessed using the Shapiro-Wilks test, whereas the equality of variance will be determined using the Levene test. A difference in means of 60 minutes (1 hour) will be considered clinically meaningful in accordance with the golden hour principle [33].

Secondary (Patient) Outcomes

For assessing the morbidity of musculoskeletal injuries, the validated 10-item TEFS will be used at baseline and the 10-item TOMS will be used at 90 days [30]. The mean difference in the TEFS and TOMS will be compared between the intervention and control groups using the 2-sample *t* test. Further, the TOMS will be dichotomized into favorable (TOMS ≥ TEFS) and unfavorable (TOMS < TEFS) outcomes in accordance with previous studies [30]. The difference in these proportions between the intervention and control groups will be compared

using the adjusted chi-square test if the expected count is >5 or the Fisher exact test at 95% CI otherwise.

Further, subgroup analyses will be performed to determine and control for factors that could be associated with an unfavorable TOMS, using individual-level between-within mixed effects regression models, which inherently overcome the effect of smaller clusters and permit adjustment for covariates in a single stage, assuming equal allocation. The fixed effect variables will be the treatment arms (intervention vs control) as the unit of analysis, with the odds ratios (ORs) and their corresponding 95% CIs as direct estimates of the effect size. The covariates will include age, sex, education level, occupation, employment status, marital status, commute distance, road user category, injury severity score based on the KTS, presence or absence of fracture, nature of fracture if present, number of serious injuries, and treatment (surgical vs conservative).

For assessing the morbidity of neurological injuries, the validated GOS will be used at 90 days after injury. The mean difference in the GOS score will be compared between the intervention and control groups using the 2-sample *t* test. Further, the GOS score will be dichotomized into favorable (GOS score of 4 or 5) and unfavorable (GOS score of 3, 2, or 1) outcomes in accordance with previous studies [7]. The difference in proportions between the intervention and control groups will be compared using the adjusted chi-square test if the expected count is >5 or the Fisher exact test at 95% CI otherwise.

For all-cause mortality, the difference in proportions of all deaths at 90 days after injury will be compared between the intervention and control groups using the chi-square test if the expected count is >5 or the Fisher exact test at 95% CI otherwise. Lastly, we will conduct subgroup analyses to determine and control for factors associated with all-cause mortality using individual- and cluster-level between-within mixed effects regression models. The covariates will include age, sex, injury mechanism (including helmet use), mode of arrival, prehospital interval, referral decision to hospital discharge interval (dichotomized as ≤1 hour or >1 hour), prehospital first aid status, comorbidities, injury severity score based on the GCS at baseline, multiplicity of injuries, head and brain CT-based diagnosis, and neurosurgical intervention.

These variables have been found to influence outcomes following neurological trauma in previous studies [7]. All variables will be analyzed for confounding and effect modification using Mantel-Haenszel statistics to probe necessary interaction terms. Variables with *P* values of ≤0.2 in the bivariate analysis will be included in the multivariate analysis. The median (IQR) of the time to the event, that is, from the accident to death (in days), will be stratified by treatment arm, and the difference will be compared using the Wilcoxon 2-sample test. All analyses will be performed using Stata 15.0, and where appropriate, graphics, such as box plots, will be used to visualize the data.

Interim Analyses

The Uganda National Council for Science and Technology accessed a preliminary report of the interim analysis, which was performed on August 28, 2022, when half of the sample size (n=500) was attained, and at its discretion, it recommended continuation of the study. The requisite characteristics for early termination set by the ethics committee included the occurrence of an index patient-reported adverse outcome definitely attributable to the study in accordance with the framework described by Okoniewska et al [48].

Methods for Additional Analyses

Subgroup analyses will be performed for (1) varying road user categories (pedestrian, passenger, and motorcyclist); (2) injury mechanisms (motorcycle-motorcycle accident, motorcycle-pedestrian accident, motorcycle-static object accident, and motorcycle-car accident); (3) varying injury severities (mild, moderate, or severe based on the KTS and GCS); and (4) multiplicity of serious injuries (one or multiple). To determine the training-effect heterogeneity across time periods, we will use an extension of Hussey and Hughes fixed effects model [49] for determining whether the intervention effect differs for each training period as summarized in the schematic representation of the study design (Multimedia Appendix 7).

For the ancillary study on provider outcomes, the difference in pretraining and posttraining mean scores will be computed with 95% CIs if the data are normally distributed; otherwise, the difference in median and IQR will be reported. For the qualitative ancillary study on the perceived barriers to injury care, directed content analysis of themes of transcribed data will be collated manually and presented as percentages.

Methods in Analysis to Handle Protocol Nonadherence and Any Statistical Methods to Handle Missing Data

We will impute values for participants with missing end points, such as those lost to follow-up, those who withdraw consent, and those who crossover. The baseline sociodemographic and clinical characteristics of such participants will be compared between the intervention and control groups. For individual participants, crossover from the intervention group to the control group or vice versa for any reason will result in ultimate discontinuation from the trial.

Plans to Provide Access to the Full Protocol, Participant-Level Data, and Statistical Code

The full protocol will be published open access, and anonymized participant-level data sets and statistical codes will be shared publicly through a permanent weblink that will be provided by the publishing journal. Since the primary country of recruitment, which approved and registered the study prior to recruitment, lacks a publicly available electronic research register, this protocol has been retrospectively registered with the WHO-approved Pan African Clinical Trials Registry (PACTR202308851460352).

Oversight and Monitoring

Composition of the Coordinating Center and Trial Steering Committee

The principal investigator and a central study administrator will form a steering committee that will run the day-to-day activities

of the trial. The trial will have 2 onsite overseers and 2 off-site supervisors. In addition, the principal investigator will provide organizational support to rural trauma teams at the intervention study centers through weekly audit meetings. Each of the rural trauma teams is composed of a road traffic law enforcement professional, a third-year medical student, a fifth-year medical student, an intern doctor or nurse, and a specialty surgery resident.

Composition of the Data Monitoring Committee, and Its Role and Reporting Structure

The research and ethics committee of Mbarara University of Science and Technology is the designated independent data monitoring committee that will oversee this trial (reference number: MUREC 1/7; 05/5-19). The committee reports directly to the Uganda National Council for Science and Technology. The council, at its discretion, can recommend continuation, amendments, or termination of the trial at any time.

Adverse Event Reporting and Harms

Immediate medical concerns from participants will be reported to their attending clinicians. Any reported adverse events and other unintended effects of trial interventions or trial conduct will be reported to the trial monitoring committee. Patient-reported adverse outcomes resulting from the intervention (study) rather than biological injury progression will be captured during the follow-up interviews and evaluated on a 5-point Likert scale in accordance with the framework described by Okoniewska et al [48] as follows: (1) no evidence that the event is due to the intervention, (2) little evidence that the event is due to the intervention, (3) the event is possibly due to the intervention but most likely due to injury, (4) the event is more likely due to the intervention than injury, and (5) the event is definitely due to the intervention. Case files with 4 to 5 points will be forwarded for external auditing in surgery departmental meetings to ascertain if the adverse event was preventable, ameliorable, or neither.

Frequency and Plans for Auditing Trial Conduct

The trial monitoring committees will independently conduct annual and impromptu audits and may choose to extend or terminate the trial at any time. Such situations that could warranty termination include adverse events directly attributable to the intervention. The investigators will submit annual progress reports to the committees each year as part of continuing review.

Plans for Communicating Important Protocol Amendments to Relevant Parties

Any protocol amendments will be submitted to the data monitoring committee. Any approved amendments will be communicated to the Uganda National Council for Science and Technology and trial participants, and will be updated in the registries within 5 working days following approval.

Ancillary Studies

This trial has been approved with 2 ancillary studies. The first is a study to assess the effect of the RTTDC on provider knowledge, and the second is a qualitative study to assess the barriers to injury care as perceived by traffic police, medical trainee frontline workers, and individuals encountered in the real-time management of patient participants. The data collection team for the qualitative study will be surgery residents at the 6 regional referral hospitals who will be blinded to the cluster or treatment allocation. The results of the ancillary studies will be collected and analyzed separately and will be concealed from the trial team until the analysis of the main clinical trial findings is nearly complete. We hope that the findings of the ancillary studies will complement and inform the interpretation of the trial findings.

Dissemination Plans

Participants of the RTTDC training will receive feedback after the posttest questionnaire evaluation. Patient participants will be advised on the next plans of management during follow-up calls or through outpatient consultations. Before presentation of the study findings at scientific conferences and publication in peer-reviewed journals, copies of the findings in final bound reports will be submitted to the main libraries of the participating hospitals, the departments of surgery, and the internal review boards of Mbarara University of Science and Technology, Kampala International University, and Uganda National Council for Science and Technology.

The implications of the findings will be shared with authorities, including intern and medical student associations, district health officers, hospital directors, regional traffic police commanders, and chairpersons of the motorcycle riders' associations in the respective regions, as well as with the rural trauma networks of first responders. Priority will be made to present the preliminary findings at an international conference hosted in Uganda and at the annual world safety conference. Anonymized participant data sets from this trial will be archived on a publicly accessible permanent weblink that will be provided by the publishing journal within 12 months from the actual date of completion of the trial.

Results

The trial was approved on August 27, 2019. The actual recruitment of the first patient participant began on September 01, 2019. The last follow-up was on August 27, 2023. Posttrial care, including linkage to clinical, social support, and referral services, is to be completed by November 27, 2023. Data analyses will be performed in Spring 2024, and the results are expected to be published in Autumn 2024.

Discussion

Study Implications and Future Directions

This trial is meant to compare (1) the time interval from the accident to hospital admission, (2) the time interval from the referral decision to hospital discharge, (3) the all-cause mortality, and (4) the morbidity of patients with motorcycle accident–related orthopedic and neurological injuries between RTTDC (intervention) and standard care (control) study centers in Uganda, Africa.

This study is anticipated to reveal the overall impact of the rural trauma team development and training on the clinical process time efficiency and patient-centered outcomes of

musculoskeletal and neurological injuries in controlled clinical settings, using validated injury severity scores [43] and trauma outcome and process measures [29,30]. The findings will add value to the emerging evidence from previous nonrandomized studies in high-income countries, which have evaluated the RTTDC. The available evidence suggests that the RTTDC potentially reduces the prehospital interval [50] and referral decision time [50], and enhances trauma team role identity, but has no perceived impact on mortality reduction [51]. It remains unclear how these findings relate to LMICs whose trauma care systems are still in the infancy stage.

Study Limitations

Despite the strengths of this trial, we anticipate some limitations. First, while the authors are ambitious to assume that the study centers are homogeneous, the heterogeneity among the 6 participating regional referral hospitals could cause bias and affect study estimates. Further, the relatively smaller number of clusters could affect the power of the study. However, randomization of 6 out of the 17 trauma centers is within the ethical constraints as this sample already represents 35.3% of Uganda's regional referral hospitals. To overcome the statistical power bias limitation, the sample size is inflated for individual randomization to cater to the design effects in accordance with the report by Hooper et al [45]. Moreover, we plan to use mixed effects regression models, which permit adjustments for covariates at both the cluster and individual levels in a single-stage approach, and plan to use the *t* test, which is robust in terms of normality deviations. According to Borhan et al [52], mixed effects models are deemed suitable for smaller clusters in situations where the primary outcomes are continuous, which is the case in this trial. Further, we hope that the ancillary studies with mixed methods will add value to the overall interpretation of the trial results by providing data from individuals outside the health sector, such as traffic law enforcement professionals.

Conclusion

Existing systematic reviews on trauma education programs in LMICs have identified a critical gap with regard to a lack of robust epidemiological studies that assess the effect of such interventions on patient outcomes within the low-resource context [16]. By relying on the strength of local needs contextualization to extend the training to nontrauma specialists, such as traffic law enforcement professionals, the results of this trial could inform the design, implementation, and scalability of rural trauma team development in similar low-resource settings. To the best of our knowledge, this is the first cluster randomized controlled trial using prospectively collected data to compare the effects of RTTDC training and standard care on patient outcomes and process measures in LMICs.

Acknowledgments

The authors are grateful to the staff of the research and ethics committee of Mbara University of Science and Technology for their technical and ethical guidance during the early phases of this project design. Generative artificial intelligence was not used in writing any portion of this manuscript. This study did not receive any external funding. Author HL received a personal research loan from the Uganda Medical Association to support this study. Author JPP is supported by the Academy of Finland (grant number: 17379) and the Maire Taponen Foundation. The sponsors did not have any role in the design or writing of the protocol, or the decision to submit the protocol for publication.

Data Availability

The anonymized data sets arising from this study will be archived and made publicly available through a permanent weblink to a repository that will be provided by the publishing peer-reviewed journal.

Authors' Contributions

HL is the principal investigator and has contributed to conceptualization, data curation, investigation, methodology, project administration, resources, and writing of the original draft. HL and MM have contributed to formal analysis, software, and visualization. RS, PK, TB, JPP, and MLW have contributed to validation, writing–review, and editing. TB, JPP, and MLW have contributed to supervision and funding acquisition. All authors have read and approved the final manuscript. We plan to include a blinded external biostatistician to validate the final data analyses, and this person will be included as a co-author for the resulting manuscripts.

Conflicts of Interest

JPP has received funding from the Academy of Finland (grant 17379). The authors have no further interests to declare.

Abstract

Background: Tanzania is 1 of 20 countries where the majority of unvaccinated and undervaccinated children reside. Prior research identified substantial rural-urban disparities in the coverage and timeliness of childhood vaccinations in Tanzania, with children in rural settings being more likely to receive delayed or no vaccinations. Further research is necessary to identify effective and scalable interventions that can bridge rural-urban gaps in childhood vaccination while accounting for multifaceted barriers to vaccination.

Objective: This protocol describes a type 1 effectiveness-implementation hybrid study to evaluate Chanjo Kwa Wakati (*timely vaccination* in Kiswahili), a community-based digital health intervention to improve vaccination timeliness. The intervention combines human resources (community health workers), low-cost digital strategies (electronic communication, digital case management, and task automation), a vaccination knowledge intervention, and insights from behavioral economics (reminders and incentives) to promote timely childhood vaccinations.

Methods: The study will be conducted in 2 predominantly rural regions in Tanzania with large numbers of unvaccinated or undervaccinated children: Shinyanga and Mwanza. Forty rural health facilities and their catchment areas (*clusters*) will be randomized to an early or delayed onset study arm. From each cluster, 3 cohorts of mother-child dyads (1 retrospective cohort and 2 prospective cohorts) will be enrolled in the study. The timeliness and coverage of all vaccinations recommended during the first year of life will be observed for 1200 children (n=600, 50% intervention group children and n=600, 50% nonintervention group children). The primary effectiveness outcome will be the timeliness of the third dose of the pentavalent vaccine (Penta3). Quantitative surveys, vaccination records, study logs, fidelity checklists, and qualitative interviews with mothers and key informants will inform the 5 constructs of the reach, effectiveness, adoption, implementation, and maintenance (RE-AIM) framework. The results will be used to develop an implementation blueprint to guide future adaptations and scale-up of Chanjo Kwa Wakati.

Results: The study was funded in August 2022. Data collection is expected to last from February 2024 to July 2027.

Conclusions: This study will address the lack of rigorous evidence on the effectiveness of community-based digital health interventions for promoting vaccination coverage and timeliness among children from sub-Saharan Africa and identify potential implementation strategies to facilitate the deployment of vaccination promotion interventions in low- and middle-income countries.

Introduction

Background

Globally, the number of children missing their first dose of the diphtheria-pertussis-tetanus (DPT) vaccine rose from 19 million in 2019 to 25 million in 2021 [1,2]. The vast majority (14.2 million, 78%) of such *zero-dose* children reside in 20 countries, including Tanzania [3]. As in other low- and middle-income countries (LMICs), substantial rural-urban disparities in routine childhood vaccination exist in Tanzania, with vaccination rates being lower in rural areas than in urban areas [4]. Using data from the 2015-2016 Tanzanian Demographic and Health Survey, we demonstrated gaps in vaccination coverage (receipt of each recommended vaccine dose by age 1 y) and timeliness (receipt of each vaccine dose within 28 d of the recommended age) for Tanzanian children [4]. The coverage of the first dose of the pentavalent vaccine (Penta1, which includes antigens of DPT, *Hemophilus influenzae*, and hepatitis B) was 79.4% nationally in this analysis, with the remaining 21% of children classified as zero dose [4]. We documented receipt of the third dose of the pentavalent vaccine (Penta3) in even fewer children (72.7%), suggesting dropouts in the multidose vaccine series. Finally, rural children had lower timeliness of vaccination (47.8% delayed for Penta3) than urban children (24.2% delayed for Penta3). New interventions are needed to reduce the number of children who are zero dose, receive delayed vaccines, or drop out and to close the rural-urban gap in vaccination [4,5]. Such interventions must consider multifaceted barriers to vaccination and variations in the availability of human resources and infrastructure in rural areas.

In prior research in southern Tanzania, we identified challenges with the availability of, and access to, vaccination services, including challenges with distance and transportation to health facilities, temporary nonavailability of vaccines owing to a lack of reliable refrigeration at health facilities, and vaccine wastage policies that prevented the use of multidose vials when clinics had low volumes of children to be vaccinated [6]. Service unreliability and lack of communication about service interruptions were noted as causes of frustration among mothers of vaccine-eligible children [6]. Our research also identified vaccine hesitancy owing to vaccine-related knowledge gaps and concerns. In general, rural mothers reported more vaccine-related knowledge gaps and concerns than urban mothers [6]. Despite challenges, vaccination intention was high among mothers, and conditional incentives were identified as a potential *nudge* to increase vaccination timeliness [7,8]. In addition, a community health worker (CHW)–delivered knowledge intervention was piloted and determined to be feasible to implement in rural areas. On the basis of the findings of this formative research and other published reports [9], we designed Chanjo Kwa Wakati (*timely vaccination* in Kiswahili, the most commonly spoken language in Tanzania), a community-based digital health intervention to improve childhood vaccination coverage and timeliness. The intervention seeks to combine human resources (CHWs), low-cost digital strategies (electronic communication, digital case management, and process automation), a vaccination knowledge intervention (counseling scripts addressing specific knowledge gaps), and insights from behavioral economics (reminders and incentives) to promote timely childhood vaccination.

Objectives

This protocol describes our planned evaluation of the implementation and impact of Chanjo Kwa Wakati. The study seeks to contribute evidence to the literature in 3 key ways. First, although many studies have evaluated mobile phone–based reminders for promoting childhood vaccinations [10], evidence is lacking [9] for more complex community-based digital health interventions that target multifaceted barriers to vaccinations, such as those identified in our prior research [4,6,7]. Second, few community-based digital health interventions for promoting childhood vaccination have been evaluated using rigorous randomized controlled study designs, especially in sub-Saharan African countries and in rural areas [11-15]. Third, evidence on implementation strategies associated with deploying community-based digital health interventions in LMICs is limited but critically important for supporting scale-up in the context of highly resource-constrained national health systems. To bridge these gaps in the literature, we will use a type 1 effectiveness-implementation hybrid study [16,17] to evaluate the effectiveness of Chanjo Kwa Wakati in improving the timeliness of childhood vaccinations in rural areas in Tanzania and identify strategies that support its implementation. The detailed protocol of the study is presented in the following sections.

Methods

Study Overview and Aims

This type 1 effectiveness-implementation hybrid study [16,17] uses a cluster randomized trial to evaluate intervention effectiveness and mixed methods to describe implementation outcomes. A cluster randomized design was chosen because the delivery of the intervention is organized at the cluster level. In addition, there are ethical concerns with the randomization of intervention activities, including incentives, at the individual level in rural communities in Tanzania. The evaluation of the Chanjo Kwa Wakati intervention will be guided by the reach, effectiveness, adoption, implementation, and maintenance (RE-AIM) framework. The methods used in this study are described in accordance with the CONSORT (Consolidated Standards of Reporting Trials) checklist for cluster randomized studies (Multimedia Appendix 1). The study aims and hypotheses are described in the following subsections.

Aim 1

The first aim is to evaluate the effectiveness of Chanjo Kwa Wakati for increasing the timeliness of childhood vaccinations due by age 1 year compared with the standard of care. The effectiveness of Chanjo Kwa Wakati will be evaluated in a cluster randomized trial with 1200 mother-child dyads enrolled from the catchment areas of 40 rural health facilities (*clusters*) in 2 regions in Tanzania. Clusters will be randomized into an early or delayed onset study arm. The intervention will target the mother-child dyad; outcomes will be assessed at the child level. Our hypothesis is that Chanjo Kwa Wakati is effective for increasing the timeliness of childhood vaccinations due by age 1 year compared with the standard of care. The primary outcome measure used to evaluate intervention effectiveness will be a continuous measure of the timeliness of the third dose of the pentavalent vaccine (Penta3), due at age 14 weeks, and determined using the birth and vaccination dates abstracted from official vaccination cards issued for the child. A secondary outcome will be a binary measure of timeliness, defined as receipt of Penta3 within 28 days of the due date. Other outcomes measures include the timeliness and coverage of all other vaccine doses due by age 1 year.

Aim 2

The second aim is to evaluate the implementation factors associated with variation in intervention effectiveness and develop an implementation blueprint for intervention scale-up to other settings. Study logs, fidelity checklists, quantitative surveys, and qualitative interviews with mothers and key informants will be used to inform other constructs of the RE-AIM framework, specifically reach, adoption, implementation, and maintenance. Two key implementation outcomes of interest are participants' reports of the receipt of intervention components (intervention fidelity) and their reports of intervention acceptability. Analyses of variation in intervention implementation at the cluster level and systematic variation in the effectiveness for aim 1 outcomes across children will guide the future optimization of Chanjo Kwa Wakati. The results will be used to develop an implementation blueprint to guide future adaptations and scale-up of Chanjo Kwa Wakati.

Study Setting

The study will be conducted in 4 rural districts in Mwanza and Shinyanga regions in Tanzania. Both regions have large numbers of unvaccinated or undervaccinated children. The populations of Mwanza and Shinyanga region were estimated to be 3,699,872 and 2,241,299, respectively [18]. In 2022, only 56% of children aged 12 to 23 months in Mwanza region and 32.2% of children in Shinyanga region were estimated to have received all basic vaccinations, including one dose of Bacillus Calmette-Guerin vaccine, 3 doses of polio vaccine, 3 doses of DPT-containing vaccine, and one dose of measles-containing vaccine [19]. Fewer children aged 12-23 month were considered fully vaccinated according to the national vaccination schedule shown in Table 1 (32.8% in Mwanza and 2.5% in Shinyanga) [19]. Notably, 3.3% of children aged 12-23 months in Mwanza and 14.5% in Shinyanga were reported to have received no vaccinations. [19].

Table 1. Routine childhood immunizations recommended in Tanzania before age 1 year.

Antigen	Age at vax due date
Bacillus Calmette-Guerin (BCG) and oral polio vaccine (OPV) 0	At birth or first contact
OPV1; pentavalent vaccine comprising antigens of diphtheria, pertussis, tetanus, *Hemophilus influenza* B, and hepatitis B (Penta) 1; pneumococcal vaccine (PCV) 1; and rotavirus vaccine (Rota) 1	6 weeks
OPV2, Penta2, PCV2, and Rota2	10 weeks
OPV3, Penta3, PCV3, and injectable polio vaccine (IPV)	14 weeks
Measles and rubella 1	9 months

Intervention Components

Chanjo Kwa Wakati focuses on individual-level barriers to timely vaccination to complement the Tanzanian government's efforts to strengthen vaccination systems and reduce structural barriers [20]. Chanjo Kwa Wakati comprises the following individual-level intervention components: a vaccination knowledge intervention, reminders about upcoming vaccination due dates, service notifications, and conditional incentives for timely vaccination (Table 2). The intervention's target population is the mother-child dyad from the time of pregnancy (third trimester) until the child is aged 1 year. Intervention activities are targeted toward the mother, whereas the timeliness of Penta3 (primary outcome) and other vaccinations recommended before age 1 year (secondary outcomes; Table 1) is assessed for the child.

Table 2. The Chanjo Kwa Wakati intervention.

Timing	Activities	Detailed description of activities
Last trimester of pregnancy	• Enrollment • Registration in digital health system • Knowledge intervention • Baseline assessment[a]	• Informed consent[a] • Register pregnancy and phone numbers in the digital health system • Identify knowledge gaps for an individualized knowledge intervention based on a study by Vasudevan et al [6] • Assess postintervention change in vaccination knowledge and attitudes as well as potential correlates of coverage and timeliness[a]
≤4 wk after the date of delivery	• CHW[b] phone call or home visit	• Ascertain date and place of birth as well as the receipt of vaccinations due at birth • Register the birth, record the 6-wk vaccination due date, and update phone numbers in the digital health system
Before each vaccination due date (6, 10, and 14 wk, and 9 mo)	• SMS text message reminders with incentive offers • Backup: CHW phone calls or home visits • Knowledge intervention	• Messages are sent to the mother and vaccine advocates 7 d and 1 d before each vaccination • Messages are individualized and account for information on service interruptions • Messages include conditional incentive offers • Individualized knowledge intervention focused on vaccinations due at an upcoming visit
≤1 wk after each vaccination due date	• CHW phone call or home visit	• Verify vaccination status and date against vaccination card and issue incentive as appropriate • Update vaccination due dates (and thus reminders) as necessary
12-15 mo after birth	• Follow-up assessment[a]	• Validate vaccination coverage and dates using vaccination cards[a] • Issue incentive as appropriate

[a]Research activity. All other activities are intervention activities.

[b]CHW: community health worker.

Individualized Knowledge Intervention

The knowledge intervention consists of 9 true or false statements that assess key knowledge gaps about childhood vaccinations. A brief counseling script is provided with each statement that will be read out by the CHW after an incorrect response. Statements are based on prior research in Tanzania [6]. Statements and counseling scripts were tested extensively for content, comprehension, and cultural appropriateness with national key informants from Tanzania's Immunization and Vaccines Development program, regional and district health officials, CHWs, and pregnant women from rural Tanzania. In addition to the in-person individualized vaccination education provided by CHWs, SMS text message–based vaccination promotion messages, sent via the Chanjo Kwa Wakati digital health system, will be individualized to each participant's knowledge gaps and aligned with the child's vaccination schedule.

Vaccination Reminder Messages

CHWs will verify the due date for the next vaccination using the child's vaccination card and update the child's information in the Chanjo Kwa Wakati digital health system. The system will automatically schedule SMS text message reminders to be sent 7 days and 1 day before each vaccination due date. The SMS text messages will include the name of the intended recipient, the child's name, the vaccination due date, and other relevant information.

Service Notifications

In the event of stockouts or service nonavailability, SMS text messages with relevant information will be sent to mothers whose children are due for vaccination.

Incentive Offers

Conditional incentive offers will be specific to each child's vaccination schedule. In our prior work [7,8], we identified a set of incentives (eg, pharmacy vouchers and birth certificates) that are likely to be acceptable to mothers. The specific incentives, their value, conditionality, and the timing of disbursement will be determined in discussion with local key informants.

Implementation Strategies

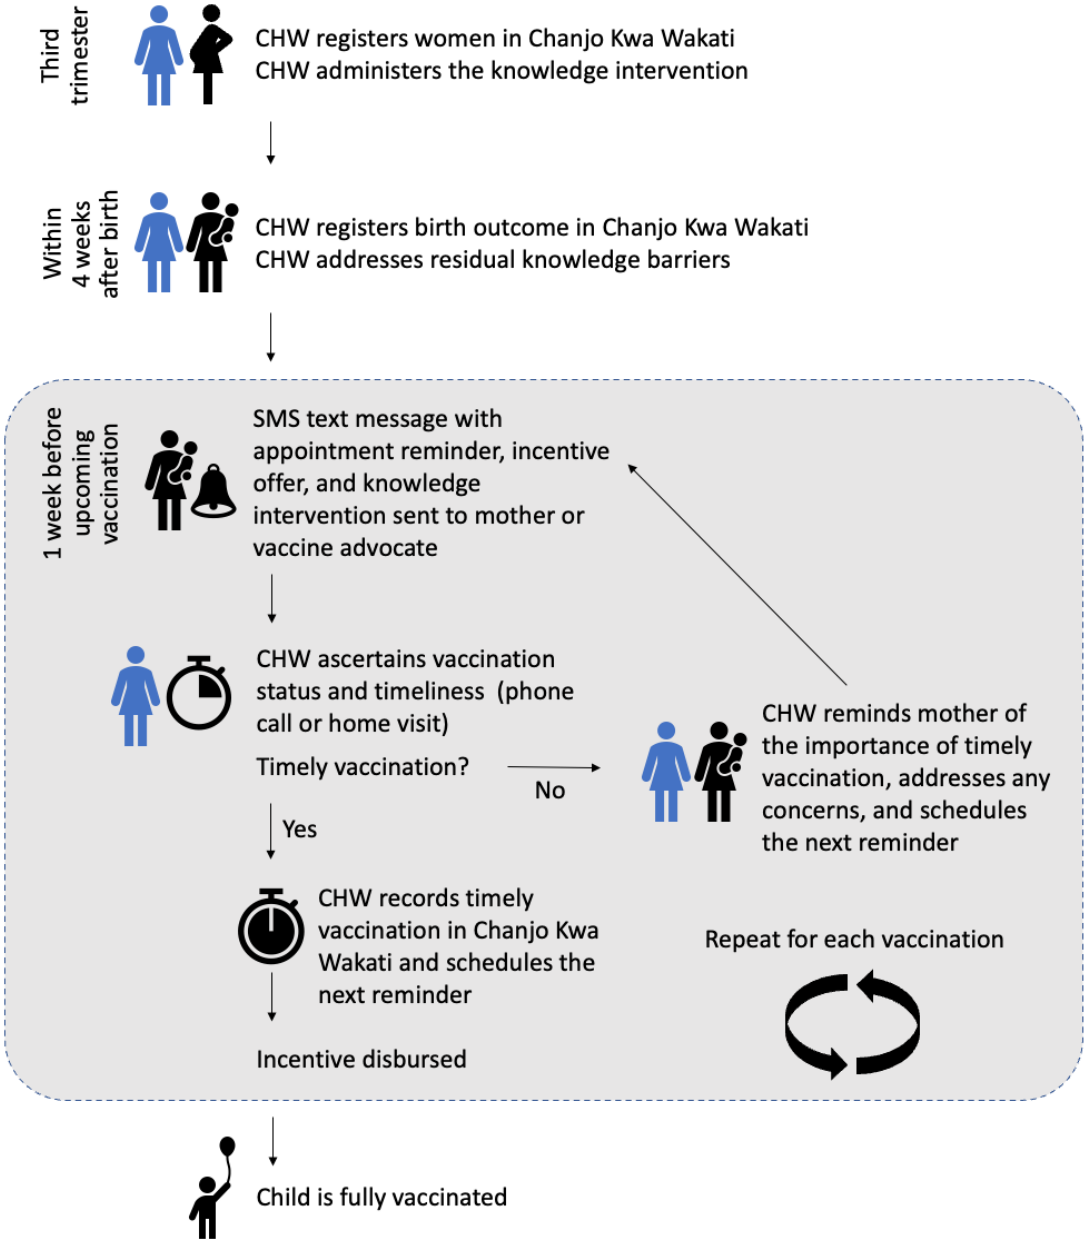
Relevant implementation strategies will be identified in collaboration with local key informants, and a detailed logic model will be developed to guide study activities.

Intervention Activities

Figure 1 describes the sequence of intervention activities. Pregnant women, enrolled in their third trimester, will receive a home visit from a CHW before the birth of their child, be registered with the Chanjo Kwa Wakati digital health system, and receive an individualized knowledge intervention to screen and counsel for common knowledge gaps and concerns about routine childhood vaccinations. After the birth of the child, the

mother will receive individualized SMS text message reminders for upcoming vaccinations, messages aimed at mitigating persistent vaccination knowledge gaps, service notifications (eg, related to stockouts or service nonavailability), and conditional economic incentive offers aimed at encouraging timely vaccinations. CHWs will use the digital health system for work planning, recording vaccination dates and due dates, and following up on missed vaccination appointments and backstop the digital health system with phone calls and in-person visits as needed for vaccination reminders and assessing and addressing mothers' knowledge gaps.

Figure 1. Sequence of intervention activities. CHW: community health worker.



Study Population

Sampling Area

The sampling area comprises 2 rural districts in Mwanza region and 2 rural districts in Shinyanga region, selected based on district-level information about vaccination rates, logistical considerations, and input from key informants.

Cluster Eligibility

Twenty clusters will be selected in each region for a total of 40 clusters. Clusters are defined as the catchment area of eligible health facilities in the sampling area. Eligible health facilities include public and public-designated (private not-for-profit facilities that serve the functions of public health facilities) hospitals, health centers, and dispensaries. Facilities must be operational, offer routine prenatal care and childhood vaccination services, have at least 2 active CHWs operating in the catchment area, and have reported at least 100 pregnancies or births in the year before study implementation. Eligibility will be determined initially using administrative data obtained from district offices and verified using surveys with health facilities.

Study Participants, Eligibility, and Recruitment

The study population will include 3 groups of participants.

Cross-Sectional Retrospective Cohort

This cohort (n=400) will be used for retrospective assessments of children's vaccination records during their first year of life. Eligible participants will be mothers or legal guardians (henceforth referred to as *mothers*) of children aged 12 to 23 months, aged ≥15 years, and residing in the sampling area since the birth of the child.

Before recruiting this cohort, CHWs, with help from local key informants (eg, village leaders, health care providers, and traditional birth attendants), will compile a list of children aged 12 to 23 months residing in each cluster. The lists will be randomized, and mothers will be approached by the research team for eligibility determination, informed consent, and enrollment until 10 mother-child dyads from each cluster are enrolled into the study. Up to 40 additional women, who are not necessarily living in the study area but meet the other eligibility criteria, may be enrolled to pilot-test the study instruments.

Longitudinal Prospective Cohort

This cohort (n=800) will be used for prospective assessments of children's vaccination records during their first year of life. Eligible participants will be pregnant women in their last trimester of pregnancy, aged ≥15 years, residing in the sampling area, and expected to reside in the sampling area until the child reaches age 1 year.

Before recruiting this cohort, CHWs, with help from local key informants (eg, village leaders, health care providers, and traditional birth attendants) will compile a list of pregnant women residing in each cluster. The lists will be randomized, and pregnant women will be approached by the research team for eligibility determination, informed consent, and enrollment until 10 pregnant women from each cluster are enrolled into the study. One additional eligible woman will be enrolled from each cluster during each prospective enrollment round to account for loss to follow-up (refer to the *Retention* subsection).

Participants in Qualitative Feedback

This group will be used to obtain feedback on the RE-AIM constructs. Eligible participants will be key informants at the national, regional, or local levels (target: n=12), health providers from participating facilities who are responsible for childhood vaccinations (target: n=40, approximately 1/cluster), CHWs in study clusters (target: n=80, approximately 2/cluster), and women enrolled in the prospective cohort (target: n=60).

To recruit these participants in qualitative work, a combination of purposive and snowball sampling strategies will be used. The numbers of participants represent target numbers; additional participants will be enrolled if saturation is not reached. Key informants, including policy makers, decision makers, and implementers at the national, regional, or local levels (eg, officials from Tanzania's Immunization and Vaccines Development program as well as regional, district, and local health officials) will be asked to participate in qualitative interviews on implementation factors and to recommend other individuals who can provide relevant information. Health providers who are responsible for childhood vaccinations will be enrolled from participating health facilities. CHWs will be enrolled from participating clusters. Women will be purposively selected from the prospective cohort based on data collected during enrollment or follow-up surveys, study logs, or the digital health system during study implementation.

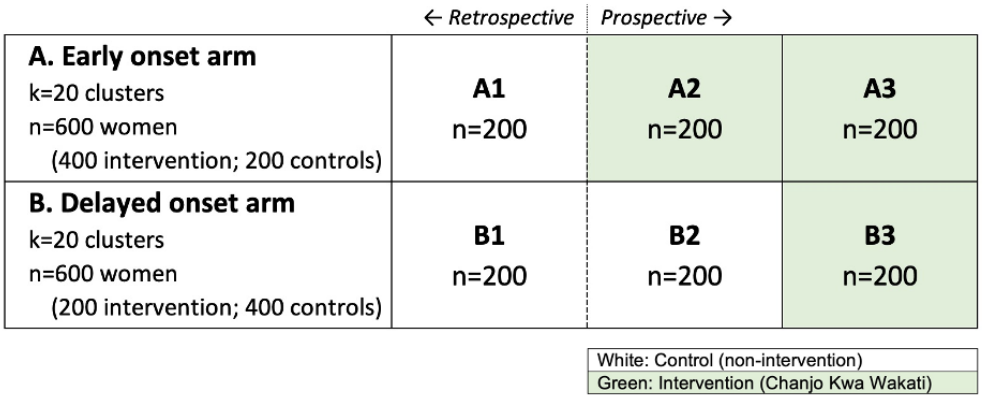
Study Design

Cluster Randomized Trial Design

Forty rural health facilities and their catchment areas (*clusters*), 20 per region, will be randomized to an (A) early or (B) delayed onset study arm (Figure 2). From each cluster, 3 cohorts of 10 mother-child dyads (1 retrospective cohort and 2 prospective cohorts) will be enrolled into the study. For the retrospective cohort, 400 mothers of children aged 12 to 23 months (10/cluster) will be enrolled as a cross-sectional sample for retrospective assessments of children's vaccination records during the first year of life. These cohorts, denoted by A1 and B1, will be part of the care-as-usual control group. For the longitudinal prospective cohort, 800 pregnant women in their last trimester of pregnancy will be enrolled during 2 rounds of enrollment (10 women/enrollment round/cluster) for prospective assessments of their children's vaccination records during the first year of life. These cohorts are denoted by A2, A3, B2, and B3. In the first round of enrollment, 200 (50%) of the 400 prospective participants (those enrolled from early onset clusters; A2) will receive the intervention, and the other 200 (50%) participants (B2) will be part of the care-as-usual control group. In the second round of enrollment, all 400 participants (A3 and B3) will receive the intervention. In total, vaccination uptake and timeliness will be observed for 1200 children (n=600, 50% intervention group children and n=600, 50% nonintervention group children) during their first year of life. The nonintervention group children represent the *care-as-usual* control group in the trial.

The trial design, which analytically resembles a difference-in-difference design, allows for an analysis of the effectiveness of the intervention even in the context of contemporaneous changes in the rate and timeliness of vaccinations at the national level (eg, through national vaccination campaigns or changes in the vaccination schedule).

Figure 2. Design of the 2-arm cluster randomized trial (n=1200).



Evaluation Framework

The evaluation of the Chanjo Kwa Wakati intervention will be guided by the RE-AIM framework. Quantitative survey data will be the primary source of information for the analysis of the effectiveness of the intervention. These data will be complemented by study logs, fidelity checklists, and qualitative interviews with Tanzanian key informants, facility-based health workers, CHWs, and mothers to assess the acceptability, reach, and fidelity of Chanjo Kwa Wakati, as well as factors that may inform sustainability and scalability in the future.

Outcomes Assessments

Vaccination outcomes are described in Table 3. Vaccination coverage and dates will be ascertained for each study child using government-issued vaccination cards, which will be photographed, scanned, or copied and entered by research staff. For the retrospective cohort, the enrollment survey will assess vaccination outcomes for the child; their participation will end after the enrollment survey. Outcome data for the prospective cohort will be collected during an endline survey 12 to 15 months after the birth of the child. All vaccination doses of all vaccination series will be tracked. For women who cannot provide vaccination cards at the time of the survey, consent will be sought to access their children's paper-based or electronic vaccination records at their local health facility.

Table 3. Outcome measures for the cluster randomized controlled trial.

Outcome measure	Type	Source
Timeliness of the third dose of the pentavalent vaccine, Penta3 (number of days delayed)	Primary	Vaccination cards
Timeliness of Penta3 (≤28 days delayed)	Secondary	Vaccination cards
Timeliness of all other vaccine doses recommended by age 1 y (number of days delayed)	Other	Vaccination cards
Coverage of all vaccine doses recommended by age 1 y	Other	Vaccination cards

Study Procedures

Cluster Randomization

In each district, all eligible health facilities will be assigned random IDs. Random IDs will be generated using a random number generator in Stata (version ≥16; StataCorp LLC) with a fixed seed to ensure reproducibility. In each district, the 10 clusters with the smallest random IDs will be allocated to either the early onset arm (odd ranks) or delayed onset arm (even ranks). Facilities that are not willing to participate or are deemed ineligible will be replaced with the next odd- or even-ranked facility, respectively. If the distributions of key characteristics of clusters (eg, the number of pregnant women/y, the number of births/y, the percentage of home births, vaccination coverage, and the number of days vaccinations are offered each wk) differ significantly between study arms, a covariate-constrained randomization [21,22] approach will be used to maximize the balance of these characteristics across study arms.

Blinding

Owing to the nature of the intervention, there will be no blinding of investigators, implementers (CHWs), data collectors, or participants.

Enrollment

Participants may be enrolled at their homes, health facilities, or other mutually agreed-upon locations. The potential risks and benefits of research participation will be carefully explained during the informed consent process (refer to the *Ethical Considerations* subsection). To maximize the reach of the intervention, participants without mobile phones will be able to designate a vaccine advocate of their choice to receive mobile phone–based messages.

Retention

Retention only applies to the prospective cohort. To ensure the retention of study participants, extensive contact information, including the names and mobile phone numbers of both parents, vaccine advocates, and other contacts, as well as expectations for the place of delivery, travel plans after birth, and GPS

coordinates of homes will be documented at enrollment. In the event of child death, maternal death, or participant withdrawal, intervention activities related to the mother-child dyad will be suspended, and the dyad will be withdrawn from the study. In the event of child relocation or family travel during study activities, efforts will be made to collect outcomes data for the child using a combination of mobile phone–based surveys; a review of the child's records at the local health facility; and proxy reports from the father, other legal guardians, or other informants. As the intervention involves local CHWs, for participants relocating outside their cluster for the remainder of the study period, intervention activities will stop after relocation.

Data Collection

Overview

Trained research assistants will conduct enrollment and data collection in Kiswahili. Survey instruments will be developed in English, translated into Kiswahili, and back-translated into English. The development of the surveys will be informed by prior surveys [6,8].

Enrollment Survey

All participants will complete an enrollment survey. The survey will last approximately 45 minutes and assess knowledge and attitudes, sociodemographic characteristics of participants and their households, access barriers, digital literacy, residual knowledge gaps, and other correlates of vaccine uptake and timeliness. The mother's engagement in prenatal care will be assessed via self-report and scanned prenatal care cards. For retrospective participants, the enrollment survey will also assess vaccination uptake and timeliness (Table 3), whereas for prospective participants, extensive contact information will be collected (refer to the *Retention* subsection).

Follow-Up Survey

Prospective participants will complete a follow-up survey 12 to 15 months after their child's birth. The survey will last approximately 30 minutes. The primary purpose of the follow-up survey is to collect data on vaccination outcomes (Table 3). The follow-up survey will include the knowledge intervention that addresses each woman's vaccination-specific knowledge gaps and assess vaccination attitudes and experiences with vaccine uptake and timeliness during the study period. The follow-up survey will also be used to update information on mothers' engagement in prenatal care via self-report and scanned prenatal care cards. For intervention group women, the follow-up survey will also assess implementation measures, experiences with the intervention, and the acceptability and perceived efficacy of Chanjo Kwa Wakati.

Facility Survey

During the enrollment and follow-up work, we will conduct a survey of the health facility in each cluster. The purpose of the facility survey is to assess the implementation context. The survey will collect service information (eg, information on vaccine stockouts and facility closures), procedural knowledge (eg, vaccination dates, scheduling, and rescheduling), and contact information.

Qualitative Data

In-depth interviews (IDIs) will elucidate wide-ranging feedback on all constructs of the RE-AIM framework. IDIs will be conducted by local trained study staff in English or Kiswahili. Study staff will follow a semistructured interview guide. IDIs will be recorded to facilitate transcription and data analysis. Depending on the availability of the participants, IDIs may be conducted by phone or in person. IDIs are expected to last 45 to 60 minutes.

Statistical Power

The aim 1 cluster randomized trial will include 1200 women, enrolled from 40 different clusters, across 3 distinct enrollment phases, with 10 women enrolled from each cluster in each phase. This equates to k=120 statistical clusters with n=10 women per cluster. Half of these clusters (k=60/120, 50%; n=600/1200, 50%) will be allocated to the intervention arm and half to the control arm. Assuming that the primary outcome—the timeliness of the Penta3 vaccine—has an SD of 28 days, the power of the trial to detect an intervention-related difference of 7 days is 0.95 with an intracluster correlation coefficient of 0.05; the power is 0.88 with an intracluster correlation coefficient of 0.10.

The aim 2 qualitative formative work will yield data from IDIs with key informants (n=12), facility-based health workers (up to n=40), CHWs (up to n=80), and mothers (up to n=60). Prior research suggests that thematic saturation can be achieved with 12 interviews, with metathemes presenting as early as 6 interviews [23-25]. Thus, these proposed sample sizes should be sufficient to achieve thematic saturation of implementation barriers and residual barriers to timely and equitable vaccinations, as well as to identify any regional variation in reasons for delayed vaccinations.

Data Analysis

Quantitative Analysis of Intervention Effectiveness

The primary outcome measure of interest will be a continuous measure of vaccination timeliness, expressed as the delay, in days, between the vaccination due date and the date on which the vaccination was received for the third dose of the pentavalent vaccine, Penta3, due at age 14 weeks (Table 1). The secondary and other outcome measures include the timeliness and coverage of all vaccine doses recommended by age 1 year. Owing to the randomization, a comparison of mean outcomes between participants in the intervention group and those in the nonintervention group yields an unbiased estimate of the effect of the intervention.

To control for variation in sociodemographic characteristics across participants, seasonal effects, and other potential correlates of vaccination timeliness, outcomes will also be analyzed in a multivariable regression framework using accelerated failure time models with the completed vaccination dose as the failure event, age in days describing time to failure, and membership in the intervention versus control groups as the primary covariate of interest.

Robust SEs will be estimated to account for the clustering of observations across mother-child dyads enrolled from the same geographic clusters at the same time.

Analysis of Implementation Outcomes

We will generate summary measures (eg, means) for continuous data and use proportions to summarize categorical data. For outcomes assessed using validated measures (eg, the Acceptability of Intervention Measure [26]), we will present composite scale scores. Qualitative implementation outcomes will be analyzed as described below.

Analysis of Qualitative Data and Integration With Quantitative Data

Thematic analyses will be facilitated by qualitative software (eg, NVivo [Lumivero]) and a codebook made up of a priori and emergent structural codes based on the interview guide and 4 interrelated steps: reading, coding, data display, and data reduction [27]. The data will be used to fully map the Chanjo Kwa Wakati process from the perspectives of the mother and the CHW and characterize the opportunities and limitations of using digital and in-person resources to support vaccination timeliness. Using convergent mixed methods, we will use joint displays and narrative integration to connect the quantitative and qualitative data [28-30].

Analysis of Systematic Variation in Effectiveness

Extensive sensitivity analysis for the aim 1 primary and secondary outcomes analyses will characterize variation in intervention effectiveness with population, setting, and implementation factors. Variation in intervention effectiveness will be evaluated using interactions between geographic, maternal, or child characteristics and the intervention variable. Statistically significant parameters on interaction terms are indicative of differential intervention effects for different subgroups. To account for variation in implementation, sensitivity analysis will include per-protocol (as-treated) and intention-to-treat analyses in which a vector of variables describing the fidelity of the different intervention components will be used in place of the binary intervention variable.

Missing Data

The *Study Limitations and Adaptations* subsection in the *Discussion* section discusses considerations regarding missing data on outcomes and covariates and their handling in the analyses.

Ethical Considerations

The study protocol, informed consent forms, and procedures have been reviewed and approved by the Health Sciences South Carolina Institutional Review Board (the reviewing institutional review board [IRB]; Pro00120675) and the ethics review committee of the National Institute for Medical Research in Tanzania (NIMR/HQ/R.8a/Vol.IX/4242), as well as the relying IRBs at Duke University (Pro00111772), Emory University (STUDY00005518), and the University of North Carolina at Chapel Hill. Informed consent will be sought from all study participants.

To maintain confidentiality, interviewers will conduct the consent process in a private space or in a mutually agreed-upon location where other people are not present. The interviewers will read out the consent form to potential participants and answer any questions. The potential risks and benefits of participation as well as the details of data confidentiality and use will be carefully explained in culturally appropriate and understandable language. Participants can refuse to participate and will only be consented after the research staff is satisfied that they understand all substantive provisions of the informed consent document. Persons with obvious psychological or psychiatric disorders that preclude informed consent will be excluded. Participants will be asked to provide written consent. They will be provided with a copy of the consent form. Informed consent documents will be developed in English, translated into Kiswahili, and back-translated into English.

Participants in the trial will be aged ≥15 years and either pregnant in their last trimester of pregnancy or mothers or legal guardians of children aged 12 to 23 months. For adolescents aged 15 to 17 years who are pregnant or mothers of children aged 12 to 23 months and are otherwise eligible to participate in the study, we obtained a waiver of parental consent. Tanzanian national policy indicates that adolescents aged <18 years who are sexually active and pregnant have the right to access reproductive health services (eg, HIV testing, care, and treatment [31], as well as family planning [32]) without parental or spousal consent, and they can make associated medical decisions on their own behalf. Given that these adolescents have this *adult* right to medical decision-making, we posit that they are also able to consent to research participation for themselves without parental or spousal consent. Risks from participation in this study are considered commensurate with ordinary daily life.

Protocol amendments will be submitted to the relevant IRBs for approval before implementation. Adverse events will be reported to the ethics review committee of the National Institute for Medical Research in Tanzania and the US-based IRBs.

Participants will be compensated for the time they spend participating in study activities. Ethically and culturally appropriate compensation will be established in collaboration with community advisers and other key informants. Subject to IRB approval and discussions with key informants, incentive amounts may be adjusted during the study period to account for exchange rate fluctuations and cost-of-living increases.

Results

Results are pending. The study was funded in August 2022. Data collection is expected to last from February 2024 to July 2027.

Discussion

Relevance

The Chanjo Kwa Wakati intervention and proposed evaluation are aligned with the strategic priorities of the Immunization Agenda 2030 and Tanzanian priorities for digital health and community health workforce development [33,34]. Specifically, our study builds on a Tanzanian digital health investment road map [35] to digitize health care data and is in line with Tanzania's 2020 National Operational Guideline for Community-Based Health Care Services, which seeks to build a strong community health workforce for health promotion,

including for child health [36]. The relevance of our study extends beyond rural Tanzania. The low-cost strategies developed and evaluated in this study are applicable to other rural contexts where some populations are less likely to be vaccinated, experience poor vaccine access, or express low confidence in vaccinations, and our study may inform the development and implementation of multipronged programs to promote timely vaccinations in such settings.

Contributions to the Literature

Our study is expected to make several important contributions to the scientific literature on digital health and vaccination interventions. First, numerous studies have documented low timeliness of vaccinations for children from LMICs, with a disproportionate burden for rural children [4,6,37-41]. Our study is significant because it seeks to evaluate an intervention for promoting vaccination timeliness for rural children. Second, lay health care workers such as CHWs play a critical role in delivering health services in LMICs. Our study will use a hybrid digital and in-person approach and contribute evidence on effective and scalable strategies for supporting lay health workers with digital health tools to promote childhood vaccination equity. Third, although many studies have evaluated mobile phone–based reminders for promoting childhood vaccinations [10], evidence is lacking for community-based systems that target multifaceted barriers to vaccinations. Our study will contribute data on the effectiveness of a community-based digital health intervention to promote equitable and timely vaccination in LMICs. Fourth, research studies support the use of screening tools to identify vaccination knowledge gaps and deliver targeted interventions to combat vaccine hesitancy. Our study will integrate CHW outreach and mobile phone–based vaccination education to bridge gaps in vaccination knowledge, respond to parental concerns, and reduce hesitancy. Finally, our study will contribute evidence on strategies to bridge the *digital divide* in rural areas and the *gender gap* in mobile phone access by using a combined digital and in-person approach.

Study Limitations and Adaptations

Unknown Number of Eligible Women per Cluster

Although we estimate that 20 clusters per region are required to reach our enrollment targets for the cross-sectional and longitudinal samples, neither the number of eligible women per cluster nor the number of refusals are known a priori. If the sample size across clusters is too small, sampling may be extended to additional clusters until sample size targets have been reached in each region and study arm.

Randomization

If the distributions of key characteristics of clusters vary greatly between the initially specified study arms (based on randomized IDs), a covariate-constrained randomization approach may be used that maximizes the balance across study arms in the distribution of key characteristics of clusters.

Spillover and Contamination

Cluster randomization is expected to minimize spillover effects; however, contamination may exist for participants living at the boundaries between intervention and nonintervention clusters. Sensitivity analyses will evaluate potential spillover effects by including geographic proximity to an intervention cluster as a covariate for the nonintervention group women in our models.

External Events

A potential threat to validity stems from the possibility of a local vaccination campaign or selective stockouts among subsets of clusters during follow-up. Given our collaboration with regional and national stakeholders, enrollment from multiple clusters, multiple vaccination time points for each participant, and the robust design, the likelihood and potential impact of such external events on our findings is low. The effects of stockouts on timeliness will be assessed in the *per-protocol* sensitivity analysis.

Missing Data

If vaccination cards are missing for >10% of the cross-sectional sample, and their vaccination information cannot readily be ascertained from records at the local health facility, enrollment into the cross-sectional cohort will continue until key outcome measures can be ascertained for the target number of 400 mothers. This may include the expansion of enrollment to additional clusters. Enrollment into the longitudinal cohort will be increased proportionately. Missing data on other characteristics will be addressed using full information maximum likelihood estimation or sensitivity analyses [42-45].

Mobile Phone Access and Use

In the target population, mobile phone access and use is not universal, and mobile phones may be shared within households. Chanjo Kwa Wakati is specifically designed to compensate for gaps in mobile phone ownership and coverage, including through the designation of vaccine advocates who will receive reminders and in-person outreach by CHWs to those who are not reached by mobile phone.

Sustainability of Reminders and Incentives

Reminder messages and incentive offers, which were informed by our prior work, will be carefully reviewed by investigators and key informants to ensure their ethical implementation and sustainability for a scaled-up intervention.

Generalizability

To assess the generalizability of the study's context and findings, study data and the relationships among key variables of interest will be compared with information in publicly available survey data and administrative data sources.

Interpretation and Dissemination

If successful, this study will contribute data on the effectiveness and implementation of the Chanjo Kwa Wakati intervention that engages recent mothers to increase the timeliness and coverage of routine childhood vaccinations in rural Tanzania. Key findings will be presented in peer-reviewed manuscripts, presentations at national and international conferences, and media outlets. Policy and programmatic recommendations will be developed in collaboration with key informants and decision makers at the national, regional, and district levels.

Acknowledgments

The authors would like to thank the Duke Global Health Institute Research Design & Analysis Core staff for their input on cluster randomization and sample size calculations. The research reported in this publication was supported by the Eunice Kennedy Shriver National Institute of Child Health and Human Development of the National Institutes of Health (R01HD110844). The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

Data Availability

The data from this study will be available from the National Institute for Medical Research, Muhimbili Research Centre, Dar es Salaam, Tanzania, but restrictions apply that are governed by consent forms and data transfer agreements. Data may be made available by the authors upon reasonable request and with the permission of the National Medical Research Review Committee of the National Institute for Medical Research, Tanzania. The open-source digital health system will be made available to interested researchers and practitioners.

Authors' Contributions

LV, JO, and EN designed the study with critical input from JNB, NT, DS, MvZ, and AH. LV and JO wrote the first draft, and EN, JNB, NT, DS, MvZ, and AH contributed to revisions. All authors read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Infertility—the inability to achieve pregnancy despite ≥12 months of focused attempts to conceive—is experienced by 1 in 6 couples. Women typically carry a disproportionate share of the psychological burden associated with infertility, experiencing poor quality of life, and 30%-40% experiencing depressive mood or anxiety. Unfortunately, currently available psychological interventions targeting infertility-related distress are associated with modest effects.

Objective: Our team, in collaboration with patient advisors, has designed a self-help intervention for infertility-related distress involving 7 weekly 10-minute videos addressing the cognitive, behavioral, and interpersonal challenges associated with infertility, delivered through a mobile app. A feasibility study suggests that it is well accepted and highly effective in reducing symptoms of anxiety and depressed mood among distressed individuals dealing with infertility. This study represents the next step in this line of research: a fully powered randomized controlled trial comparing the intervention to a waitlist control group.

Methods: We will recruit 170 individuals struggling to become pregnant in Canada or the United States to be randomized to our 7-week self-help program or a treatment-as-usual condition. The primary outcome will be fertility quality of life, while secondary outcomes will include depressive symptoms, anxious symptoms, and relationship quality, assessed before and after the program as well as biweekly for 16 weeks following completion of the program. Self-reported health care use and the presence of diagnosed mood and anxiety disorders, assessed through a structured psychiatric interview, will also be assessed immediately following the intervention and at the 16-week follow-up assessment. Treatment adherence and retention will also be recorded throughout the intervention. Multilevel modeling will compare the intervention arm to the treatment-as-usual condition in terms of all continuous outcomes across the 9 measurement points. Logistic regression will be used to assess the occurrence of mood and anxiety disorders in the 2 treatment arms at the posttreatment assessment as well as at the 16-week follow-up. Sensitivity analyses will examine potential treatment moderators: membership in the LGBTQIA+ (lesbian, gay, bisexual, transgender, queer, intersex, and asexual) communities, baseline fertility quality of life, cultural background, disability status, and pursuit of conception through medical intervention.

Results: We expect our intervention to be more effective than treatment-as-usual in improving all mental health parameters assessed and decreasing health care use related to both mental and reproductive health. Effects are expected to be larger with decreasing baseline quality of life and equally effective regardless of membership in the LGBTQIA+ communities, cultural background, or disability status.

Conclusions: If our intervention is successful, this would suggest that it should be scaled up and made publicly available. The availability of this program would fill an important gap in light of the high rates of psychopathology among those experiencing infertility and considering the current lack of effective psychotherapy approaches for infertility.

Introduction

Overview

The Canadian Community Health Survey reveals that 16% of Canadian reproductive-aged couples are currently infertile [1], defined as being unable to achieve pregnancy despite ≥12 months of focused attempts to conceive. Although male- and female-factor infertility are equally prevalent, women bear the brunt of the infertility-related burden as treatments require that women monitor their menstrual cycles, attend near-daily ultrasounds, self-inject gonadotropins, and undergo invasive and painful procedures. Women who travel for fertility treatments face additional psychosocial burdens, including schedule disruptions, time off work, and coordination of care among multiple health care providers. It is therefore not surprising that women carry a disproportionate share of the psychological burden associated with infertility, with infertile women consistently reporting lower self-esteem, more instances of depressed mood and anxiety, and lower life satisfaction than their male partners [2]. Lesbian couples pursuing sperm donation experience similar distress, with the intended pregnant individual being at higher risk for depression and anxiety relative to their partner [3].

Around 30%-40% of women presenting for the evaluation of infertility report clinical symptoms of depressed mood and/or anxiety [4-7]. In addition, research from our team [8] suggests that the COVID-19 pandemic has exacerbated distress amid fertility treatment suspensions and delays. Untreated symptoms of depressed mood and anxiety among women with infertility may, in turn, reduce the likelihood of achieving pregnancy, given that psychological burden is the most commonly cited reason for prematurely discontinuing fertility treatments [9]. In a study of 450 couples who were offered 3 government-funded in vitro fertilization (IVF) cycles, 54% did not complete all 3 cycles despite not achieving pregnancy, with "psychological burden" being the primary reason for discontinuing IVF [10]. It is critical that women with infertility who are distressed receive effective mental health treatment to reduce distress and improve conception rates.

Despite high rates of distress among women with infertility, currently available psychological interventions are often ineffective or associated with relatively small benefits. In our recent systematic review of psychological interventions for infertility-related distress [11], we observed that typical interventions are associated with a small beneficial effect on anxiety but a nonsignificant effect on depressive mood, marital quality, or quality of life. Our conclusions confirm findings from a previous meta-analysis [12] and those of a recent review [13] concluding that "a new intervention (targeting infertility-related distress) should be developed."

Intervention Development

This trial seeks to test the efficacy of a novel infertility-specific intervention. In developing a treatment that is designed to improve upon the limitations of current approaches, we have used a methodical and evidence-based framework in designing and refining our intervention, using the Medical Research Council [14] and National Institute of Health's ORBIT Model [15] for trial design interventions as guides. Specifically, we have completed the following milestones to date: (1) completed a systematic review of available interventions, (2) conducted a needs-based assessment using qualitative research methods, (3) carried out an evaluation of potential intervention components, and (4) performed a preliminary test of the acceptability and effect of our newly developed intervention. These steps are described in greater detail below.

Systematic Review and Meta-Analysis

As a starting point, we conducted a systematic review and meta-analysis of psychological interventions for infertility [11,16], which included an examination of treatment moderators such as psychotherapeutic approach (eg, mindfulness-based approaches vs cognitive behavioral therapy) and therapy format (eg, self-administered vs group). This process not only confirmed that currently available interventions were largely ineffective but also revealed that neither therapeutic approach nor format significantly impact treatment benefits.

Qualitative Needs Assessment

Our team then used semistructured interviews with women with infertility and mental health professionals specializing in infertility to identify the unique aspects of infertility-related distress [17]. Table 1 depicts the themes and subthemes identified. Unique features include the avoidance of infertility reminders (eg, pregnant women and children), excessive cognitive and behavioral focus on one's infertility to the exclusion of previously enjoyed activities, and negative interactions with loved ones perceived as insensitive.

Table 1. Themes and subthemes of infertility-related distress identified through a qualitative research project by our team [17].

Theme 1: anxiety	Theme 2: mood disturbance	Theme 3: threat to self	Theme 4: threat to couple	Theme 5: weakened social support
Anxious rumination	Emotional lability	Unmet expectations for self and one's future	Differences in coping	Strained romantic relationship
Avoidance of infertility reminders	Helplessness	Shame	Sexual dysfunction	Social stigma
Narrowed focus on infertility-related activities	Emotional exhaustion	Self-blame	Financial stress	Social isolation
Excessive information seeking	N/A[a]	N/A	Disagreement on next steps	Dismissal by health care providers

[a]N/A: not applicable.

In addition to identifying clear psychological targets for our intervention, this study also aimed to clarify which interventions were currently being used by practicing clinicians. Our findings indicated a near-universal use of an eclectic and unstructured approach associated with the widely held opinion that no existing therapeutic approach sufficiently addresses all of the biopsychosocial factors contributing to infertility-related distress.

Evaluation of Potential Intervention Components

The next step in our intervention development was to identify and consider all candidate techniques that might effectively target the psychological challenges identified as being common in infertility. To do so, we identified all of the psychotherapeutic approaches endorsed by the American Psychological Association's Clinical Section as being evidence-based for the treatment of anxiety, mood disorders, relationship difficulties, and chronic illness. The 5 identified approaches were then further broken down into their component procedures, resulting in a total of 14 different psychological techniques. In collaboration with a panel of patient advisors and using lay language, we described how each of these techniques would look when applied to infertility-related distress and what their purpose would be. We then surveyed a total of 644 women from online infertility-specific support groups [18], asking them to rate the perceived usefulness of each of the 14 techniques while asking them to identify up to 5 that were "most liked" and "most hated." Participants were also given the opportunity to provide written feedback on each of the techniques, such as how they might be better tailored to infertility. We then presented the results of this survey to our panel of patient advisors and collaboratively decided on the content of our intervention. We decided on 6 core modules plus a bonus module, the content of which is described in Textbox 1 [18].

Textbox 1. Chosen modules based on a survey of 644 women with infertility [18] and collaboration with patient advisors. Mean helpfulness ratings for each module, as assessed in a feasibility study of 21 women, are shown.

Modules and focus

- Cognitive restructuring: identifying and challenging the extreme negative thoughts that contribute to a depressive and anxious mood (eg, "In vitro fertilisation will never work").
- Challenging core beliefs: identifying and challenging unhelpful deep-seated beliefs about themselves, other people, and the world that are perhaps not based on reality (eg, "nothing ever works out for me"). It involves looking for patterns in one's thinking from the first module.
- Behavioral activation: identifying activities that have been dropped or engaged in less because of an increased focus on infertility. Aim to reintegrate these previously enjoyed activities into their day-to-day lives.
- Sharing your grief: learning about different styles of coping and how clashes in coping styles can lead to conflict within a couple. The individual is instructed on how to engage their partner in a structured conversation about how each can help the other in times of grief, such as following a negative pregnancy test.
- Strengthening your relationship (bonus module): provides evidence-based information about how to better connect with one's partner in general. Was offered along with Module 4 for those experiencing relationship distress.
- Living your values (ie, stopping avoidance): reflecting on one's overarching life values and considering how one's daily actions align with those values. Indirectly addresses avoidance that is common among individuals with infertility (eg, withdrawing from friends and family and avoiding children and pregnant women). Encourages the individual to consider ways in which they can reduce avoidance without worsening their distress.
- Summary or wrap up: providing an overview of the program's content and encouraging the individual to reflect on what's been accomplished as well as areas for further development.

When it came time to decide on the format of our intervention, a self-help internet-delivered intervention was chosen for several reasons. First, the findings from our systematic review indicate that self-administered interventions are as effective in improving mental health as other, more costly formats. Second, when asked what format a new intervention should take, 71% (15/21) of women from our needs assessment qualitative study responded that it should be self-delivered through the internet. Third, we reasoned that this format could be most effectively scaled up and made accessible to diverse populations of women and in

regions with limited access to psychological services. Thus, in close collaboration with our patient advisors, each module was translated into a 10-minute PowerPoint (Microsoft Corp) slideshow with professional voiceover. A mobile app was then developed to increase accessibility to the modules.

Preliminary Testing of Our New Infertility-Specific Intervention

With a new program developed and fully vetted in consultation with our patient advisory panel, we conducted a pilot study of 21 women recruited through local support groups, assessing intervention acceptability [19]. All participants exhibited clinically significant levels of infertility-related distress, as indicated by a Fertility Quality of Life Scale (FertiQoL) score ≤52 [20]. Enrolled through a Zoom (Zoom Video Communications)-administered enrollment session, participants received 1 module per week through email and were asked to view the 10-minute slideshow within 24 hours of receipt. Midweek, they received an email reminder of the homework assignment, encouraging them to apply their homework assignment throughout the week. At the end of each week, participants were asked to rate the extent to which the module and homework were perceived as helpful in lowering their distress (0-10). At baseline and each week, participants completed the Generalized Anxiety Disorder-7 (GAD-7) and 9-item Patient Health Questionnaire (PHQ-9); the FertiQoL was completed at baseline and after the intervention. Each week and in an interview at the end of the study, participants provided written and verbal feedback, respectively, on the intervention.

Of the 21 women enrolled in the study, 2 became pregnant and were removed from the program prematurely (all outcomes assessed until the point of pregnancy were analyzed). Of the remaining 19 women, 15 completed all 6 modules, and 4 completed a portion of the program. Data from all 19 women were included in the analysis. The average helpfulness rating of each module was found to be 7.4 or above out of 10. Fertility quality of life increased by an average of 12 points out of 100, translating to a Cohen *d*=0.9. Large reductions in both mean symptoms of anxiety and depressed mood were observed (pre-to-post Cohen *d*=–1.2 and –1.3, respectively, where effects above 0.8 are considered large), corresponding with clinically meaningful improvements. In addition, 85% of participants experienced a clinically significant decline in either anxious or depressive symptoms (defined as a change of 4 points on the GAD-7 [21] and 5 points on the PHQ-9 [22]).

While the intervention was successful, areas for improvement were identified. For example, homework assignments were modified to include examples of completed homework. Participants reported that our “bonus” relationship module deserved to be a core part of the program, extending it to a total of 7 weeks.

The Current Trial

Over the last 3 years, our team has carefully designed a self-help intervention for infertility-related distress that is patient-informed and developed using best practices in intervention design. Results from this feasibility study suggest that it is well accepted and effective in increasing quality of life and reducing symptoms of depressed mood and anxiety among women with infertility-related distress. The proposed project, a sufficiently powered randomized controlled trial comparing the intervention to a treatment-as-usual control group, is the next step in this line of inquiry. It is hypothesized that the intervention will result in greater increases in fertility quality of life and relationship quality as well as decreases in symptoms of depressed mood and anxiety relative to a treatment-as-usual condition, and that these improvements will be maintained over a 16-week follow-up assessment period.

If the proposed trial confirms that the intervention is effective in improving quality of life and mental health symptoms among those with infertility, our next step will be to make this program widely available to women, including making the intervention available through YouTube and engaging our collaborating knowledge users and partner organizations to promote it widely. We will also aim to tailor the program for diverse and marginalized underserved groups.

Methods

Trial Design

The proposed research is a single-blind randomized controlled trial comparing the above-described self-help program to a waitlist control condition. As the project requires no in-person contact, we will recruit women living throughout Canada and the United States. Fertility quality of life, infertility-related distress, symptoms of depressed mood and anxiety, and relationship quality will be assessed before and after the program, as well as every other week for 16 weeks.

Treatment Conditions

Intervention Condition

Participants will be given access to a 10-minute module video per week through a mobile app created for this trial. Midweek, participants will receive an automated email reminder of the homework assignment for that week, encouraging them to incorporate the homework into their daily lives. Participants will be permitted to engage in any other psychological interventions they wish but will be asked to report other psychological interventions accessed at the end of their participation.

Treatment-As-Usual Control Condition

Participants assigned to the control condition will be instructed to continue their pursuits to conceive without accessing the self-help program. They will be permitted to access other psychological resources that are available to them, though, like the intervention condition, they will be asked to report any treatments accessed in the postintervention survey. They will complete the outcome measures at the same time as participants in the treatment condition. Following completion of the study, the control group will be offered the program in the same manner as the treatment group.

In the original funded grant protocol, we had proposed a waitlist control condition in which participants were not permitted to access other mental health services; however, we have since changed the control condition to treatment-as-usual in order to

more accurately estimate the real-world effectiveness of the treatment. This change also allows us to open the trial to individuals reporting suicidal ideation because these participants will likely require additional mental health services while participating in the current trial.

Randomization Scheme

The Clinical Research Support Unit at the University of Saskatchewan will create the randomization scheme and provide the principal investigator with opaque envelopes containing treatment assignments, ensuring that the research team has no control over the assignments. Randomization will take place at the end of each enrollment session, after the baseline surveys have been completed, and will be stratified based on whether a woman is undergoing fertility treatments or attempting to conceive without medical intervention, as this will be a potential moderating variable.

Protecting Against Sources of Bias

A number of strategies will be used to protect against bias. First, the trial will be registered with clinicaltrials.org before any data collection commences. Second, as described above, the randomization scheme will be created by a third party, and the study research assistants will be instructed to strictly adhere to the randomization protocol without exception. Third, though it is not possible to maintain full blinding of either the participant or research team given the nature of the intervention, all outcomes will be collected by a research assistant who is blind to the participant's treatment allocation. Fourth, an intent-to-treat approach will be taken in analyzing the results—every effort will be made to continue to collect outcome data on all participants, regardless of whether participants dropped out of the intervention early or not. Final, we will follow the CONSORT-SPI (Consolidated Standards of Reporting Trials for Social and Psychological Intervention Trials) reporting guidelines [23] in reporting the results of the trial, strictly adhering to the original trial protocol. Any deviations will be clearly described and justified.

Participants

Inclusion and Exclusion Criteria

Based on our sample size calculations, we will recruit 170 women, recruited through the web. The inclusion criteria will include the following: is infertile as defined as either actively attempting to conceive for ≥12 months without success or is currently undergoing fertility treatments (eg, ovulation induction medication, IVF, and intrauterine insemination). This definition ensures that this study is inclusive of both individuals who cannot afford fertility treatments and women who are in same-sex couples and cannot conceive naturally. Though the original funded protocol excluded individuals reporting active suicidal ideation, those already receiving psychotherapy, and those with high levels of fertility-related quality of life (FertiQoL above 70), we have since decided to remove these exclusion criteria in order to closely estimate the program's anticipated real-world effectiveness. Rather than exclude individuals based on baseline quality of life, we will perform secondary analyses, considering baseline quality of life as a treatment moderator.

Sex and Gender Considerations

In light of research finding that the intended pregnant individual experiences the most distress in the context of infertility, we will only recruit individuals who have a uterus. However, we will ensure that this study is welcoming to individuals of all gender identities and sexual orientations, as this study will aim to contribute to current knowledge surrounding the psychological experiences of individuals from minority genders, and sexual groups experiencing infertility. This study materials including advertisements, will use inclusive language. Advertisements will not use the word "woman" but instead "individuals attempting to get pregnant but experiencing infertility." The intervention itself has also been designed with inclusive language, a gender-neutral design, and pictures of individuals from diverse backgrounds and sexual orientations. To ensure adequate diversity among our participants, we will advertise on subreddits specifically targeting members of the LGBTQIA+ (lesbian, gay, bisexual, transgender, queer, intersex, and asexual) community.

Participant Screening and Enrollment

Prospective participants will be emailed the link to a web-based eligibility survey. If found to be eligible, they will be asked to provide their contact information, and a research assistant will contact them to schedule an enrollment session through videoconference.

During the Zoom-facilitated remote enrollment session, eligibility will be confirmed, a brief introductory video explaining the study and intervention will be presented, and consent will be obtained. An enrollment session in which visual contact is made will ensure that our recruited participants are not simply "bots" posing as eligible participants. During the session, participants will complete the baseline questionnaires through a link emailed to them by the research assistant. Upon completion of the questionnaires, the research assistant will open an opaque envelope, revealing the participant's random assignment to either the treatment or control condition. The research assistant will then ask the participant which day of the week they would like to receive their weekly module video (if assigned to the treatment condition) or weekly outcomes survey (if assigned to the control condition).

Participant Safety

Participants endorsing suicidal ideation on question 9 of the PHQ-9 at baseline will be permitted to participate in the study but will be informed that their level of risk will be reassessed weekly. Specifically, each week, they will receive a survey question, "Please pick out the one statement that best described how you have been feeling during the past week, including today: (A) I don't have any thoughts of killing myself. (B) I have thoughts of killing myself, but I would not carry them out. (C) I would like to kill myself, or (D) I would kill myself if I had the chance." If participants choose either C or D, a message including contact information for 2 suicide hotlines will appear. As well, an automatic notification will be sent to the study therapist, flagging the response. They will then follow up with the participant immediately by phone, at most within 24 hours.

If participants endorse A or B, they will simply be allowed to continue with the program.

In addition, the presence of active suicidal ideation (presence of a plan or intent) will be assessed by the researcher during the Zoom-facilitated enrollment session. Those endorsing active suicidal ideation will be referred to additional in-person mental health resources available in their geographic area. They will be given access to the program for their own benefit but will not be enrolled in the study.

Primary and Secondary Outcomes

Overview

Self-reported psychological outcomes will be assessed immediately postintervention (ie, at the end of the 7th week) and every 2 weeks for 16 weeks. Mood and anxiety disorders will be assessed immediately postintervention as well as 16 weeks postintervention. Finally, health care use will be assessed at postintervention week 16. The control group will follow an identical outcome assessment schedule.

Demographic and Medical Information

Age, ethnicity, gender identity, sexual orientation, marital and parental status, years of education, income, occupation, reproductive health history, and medications will be assessed using a survey created for this study.

Primary Outcome

Fertility-related quality of life was assessed using the 24-item Core FertiQoL [24], yields 4 subscales: mind-body, relational, social, and emotional. High scores on the FertiQoL scale indicate a better quality of life. It is the most widely used infertility-specific measure of quality of life [25] and has been well validated in multiple studies [20]. This primary outcome was chosen in collaboration with our patient advisors as it provides an integrated measure of the emotional, physical, and interpersonal impacts of infertility.

Secondary Outcomes

Secondary outcomes will include depressive and anxious symptoms, instances of mood and anxiety disorders, relationship quality, and health care use. Treatment adherence and acceptability will also be assessed.

Depressive Symptoms

Self-reported symptoms will be assessed using the PHQ-9 [26], a 9-item measure assessing symptoms in the last 2 weeks that closely parallels the criteria for major depressive disorder as defined by the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5) [27]. Internal consistency coefficient (ICC) has been estimated at α=.89 and test-retest reliability at r=0.84. The PHQ-9 has been shown to be superior to other questionnaires in detecting changes in depressive mood following treatment [28]. Participants endorsing suicidal ideation on item 9 of the PHQ-9 will be required to answer a weekly question.

Anxious Symptoms

Self-reported symptoms will be assessed using the GAD-7 [29], a 7-item measure that asks about symptoms in the last 2 weeks and closely parallels the DSM-5 criteria for generalized anxiety disorder. ICC is α=.92. The GAD-7 has been shown to be superior to other questionnaires in detecting change in anxious mood following treatment [30].

Mood and Anxiety Disorders

These will be assessed using NetSCID (TeleSage), the computerized version of the Structured Clinical Interview for the DSM-5 (SCID). Though the originally funded protocol proposed to use the Primary Care Evaluation of Mental Disorders (PRIME-MD), we decided to switch to the SCID because of the availability of the computerized version of this interview. The SCID is also the gold standard assessment for psychiatric diagnoses.

Relationship Quality

Relationship quality will be measured through the 7-item Relationship Assessment Scale. Internal consistency among individuals with infertility has been found to be high, with α=.83 [31].

Health Care Use

The questionnaire on health care consumption and productivity losses for patients with a psychiatric disorder will be administered 16 weeks following the intervention, asking participants to report on health care use in the last 4 months. This survey has shown good agreement with hospital- and employer-confirmed data. An additional section has been added to specifically ask about the receipt of fertility treatments.

Treatment Adherence

The total number of minutes spent accessing each moule video will be tracked through the mobile app. Homework completion between the weekly module videos will be tracked using Qualtrics, a web-based survey platform that facilitates scheduled survey distribution, notifications, and reminders. Homework compliance will be further measured at the end of each week through the 12 items contained within the Homework Rating Scale, which assesses comprehension of homework assignments as well as effort spent on assignments [32].

Treatment Acceptability

The Credibility Expectancy Questionnaire [33] will be administered at baseline to assess participants' initial expectations about the intervention. Postintervention, the Treatment Acceptability and Adherence Scale [34] will be used to assess treatment acceptance. The Negative Effects Questionnaire [35] will assess any potential adverse events perceived to be related to the intervention. Final, participants will be invited to provide written feedback about any of the modules or the program as a whole, including suggestions for further improvement and refinement.

Outcomes Assessment

A research assistant who is blinded to the participant's treatment condition will email the participant a link to a web-based survey containing the outcome measures. If a participant fails to complete the survey within 48 hours of receipt, they will receive up to 3 reminders through email, voicemail, and SMS text messaging. Though participants will not be compensated for

completing the intervention, they will be compensated US/CAD $10 (or its equivalent depending on their location) for each postintervention survey completed (postintervention +8 biweekly follow-up surveys) and an additional US/CAD $20 for each of the 2 postintervention interviews, for a maximum total of US/CAD $130, to maximize the chances that even those participants who abandoned the intervention prematurely will complete the outcome surveys.

Statistical Analyses

Descriptive statistics will examine treatment acceptability outcomes as well as the trial recruitment rate. A 2-tailed *t* test will be used to compare the treatment arms in terms of baseline characteristics, assessing randomization success. A mixed model design using the MIXED procedure in SAS (version 9.4; SAS Institute) applying an intent-to-treat approach will compare the intervention arm to the waitlist control group in terms of FertiQoL, PHQ-9, GAD-7, Copenhagen Multi-Center Psychosocial Infertility Fertility Problem Stress Scale, and Relationship Assessment Scale (RAS) score across the 9 outcome measurement points (ie, at the end of intervention week 7 and biweekly for 16 weeks). Each outcome will be examined in a separate model; subject will be treated as a random effect, and the treatment assignment will be treated as a fixed effect. A repeated statement will identify assessment week as a repeated measure factor. Baseline levels of the outcome will be included as a covariate. This method has been shown to provide optimal statistical power relative to measuring pre- and postintervention outcome change [36]. In using all available data, a mixed model design has also been shown to outperform ad hoc approaches, such as the last-outcome-carried-forward approach [37].

In addition to examining the main effect of treatment assignment on outcomes, the interaction between assignment and assessment week will be examined to determine whether outcomes are maintained across the 9 postintervention measurements. Sensitivity analyses will use a similar approach to examine potential treatment moderators: membership in the LGBTQIA+ communities, baseline FertiQoL score, cultural background, disability status, and pursuit of conception through medical intervention.

The LOGISTIC procedure will assess the occurrence of mood (major or minor depressive episode or persistent depressive disorder) and/or anxiety disorders (generalized anxiety disorder, social anxiety disorder, or panic disorder) in the 2 treatment arms at the posttreatment assessment as well as at the 16-week follow-up.

To limit the family-wise error rate, the Benjamin and Hochberg [38] false discovery rate correction will be applied to all analyses.

Power Calculations

Power calculations were performed using G*Power (Axel Buchner) and are focused on the primary outcome, infertility-related quality of life. Based on SDs observed in the population of distressed women with infertility [18], setting α at .05 and power at 80%, a total of 128 participants would be needed to detect a moderate effect size (Cohen f=0.25), equivalent to a 6-point difference on the FertiQoL (out of 100) between 2 arms. To allow for a 25% (42/170) dropout rate, we will recruit 170 participants (85 per arm), in line with average completion rate of 82% observed in our meta-analysis of psychological interventions for infertility-related distress and allowing for additional drop-out given considering the 16-week follow-up.

Planned Recruitment Rate

We propose to complete the trial within 2 years. The timeline relies on a recruitment rate of 3 participants per week, which we consider to be a highly conservative estimate of what is possible based on our previous experience successfully recruiting participants from this population.

Through our experience in our preliminary work, we have determined that the most successful strategy for recruiting the target population is to advertise through online infertility support or special interest groups—this will therefore be the primary method used to recruit for this study. We have found these groups to be very willing to share our research, and their members are extremely receptive as well as highly likely to be eligible to participate. We have also had great success in recruiting individuals from LGBTQIA+ communities attempting to conceive through IVF. In an ongoing study specifically targeting this population, we approached a pair of social media influencers (a lesbian couple who regularly share their experiences of undergoing IVF) who enthusiastically shared our project with their followers. Within 2 days, we had received over 400 entries in our eligibility survey.

In addition to providing large pools of highly engaged, eligible participants, one important advantage of web-based recruitment is that samples tend to be much more diverse in terms of race, education, and income relative to studies that recruit through fertility clinics, the patients for which are disproportionately high-income. While web-based recruitment can increase the risk of recruiting noneligible individuals posing as eligible participants, the use of a face-to-face Zoom enrollment session greatly reduces this risk. Our research team is also experienced in identifying suspicious survey responses.

Ethical Considerations

This study has been reviewed and approved by the University of Regina Ethics Board (REB #2023-210) as well as registered on ClinicalTrials.gov (NCT06006936). All prospective participants will provide informed written consent before enrolling in the trial.

To protect participant confidentiality, all participant data, including both interview data and questionnaire data, will be saved under ID numbers only, with no identifying information attached. Only the research team will have access to the collected survey data. The team will maintain a document associating participant names with their anonymous subject numbers. This document will be password-protected, opened only on encrypted devices, and stored separately from the rest of the data.

Participants will receive US $10 for each postintervention and follow-up survey completed and US $20 for each of the 2 postintervention interviews, for a maximum total of US $130.

Results

Recruitment will begin in January 2024 and continue for approximately 1.5 years. All data are expected to be collected by January 2026. Results will be uploaded on the ClinicalTrials.gov website shortly thereafter.

Discussion

Significance of the Study

It is expected that participants assigned to the Coping with Infertility program will exhibit improved fertility quality of life as well as depressive and anxious symptoms, with moderate to large effect sizes. We also expect rates of clinical mood and anxiety disorders as well as self-reported health care use to be lower among participants randomized to the treatment arm. Baseline fertility quality of life is furthermore expected to moderate the effect of treatment such that effect sizes will increase with decreasing baseline fertility quality of life. Based on the pilot study results, we expect adherence and retention to be favorable. If our hypotheses are confirmed, these findings would suggest that the Coping with Infertility program is more effective than currently available psychological interventions for infertility. Indeed, a recent meta-analysis by our team identified 58 randomized controlled trials testing psychological interventions for infertility and found that, with the exception of trials conducted in the Middle East, interventions were associated with only small psychological benefits, highlighting the need for more effective interventions [16]. The self-help nature of the Coping with Infertility program also likely makes it more cost-effective than individual psychotherapy, which typically costs US $100-$200 per session.

If our intervention proves effective, we will aim to make our mobile app publicly available through the Apple Store and Google Play Store. Decreased health care use in the treatment arm relative to the treatment-as-usual arm would provide a strong rationale for seeking government funding to upkeep the Coping with Infertility mobile app, which would allow us to make the program available free of charge. We would provide flyers and posters to fertility clinics across North America, to be posted in clinic waiting rooms and physician offices. We will reach out to relevant professional societies and nonprofit organizations, asking them to include the app as a mental health resource listed on their website. Online forums relevant to infertility will also be contacted and asked to share information related to the app. A YouTube channel will be created to house all of the weekly module videos along with a professionally produced animated explainer video introducing the intervention and describing the results from the trial supporting its efficacy. Final, we will publish our findings in open-access journal articles in respected scientific journals.

In addition to disseminating the Coping with Infertility program as a stand-alone intervention, it may also be worthwhile to pair it with other traditional mental health resources. For example, future research pairing the Coping with Infertility program with infertility support groups, or with individual psychotherapy may help target a broader audience of individuals experiencing infertility-related distress who wish to benefit from peer or therapist support. Translating the content of the program into a workbook format may also appeal to a subset of the target population.

Limitations

First, access to the Coping with Infertility program is contingent upon internet access; research participants may therefore not include individuals who do not have such access, such as those who cannot afford internet access or those living in remote communities. Second, due to the nature of the intervention, it is impossible to conduct this trial as a double-blind, randomized trial. Third, health care use will be self-reported and therefore may not capture use as accurately as hospital and clinic records.

Conclusions

This study will test a self-help program for infertility-related distress through a mobile app. If the intervention proves effective, it will provide a highly cost-effective and accessible mental health resource for those struggling with the mental health impacts of infertility. This will fill an important gap in light of high rates of psychopathology among those experiencing infertility and considering the current lack of effective psychotherapy approaches for infertility.

Acknowledgments

The authors would like to thank Canadian Institutes of Health Project Grant (#PJT186221) for the funding to complete this trial.

Abstract

Background: Powered ankle-foot prosthetic devices can generate net positive mechanical work during gait, which mimics the physiological ankle. However, gait deviations can persist in individuals with transfemoral limb loss because of habit or lack of rehabilitation. Prosthetic research efforts favor the design or evaluation of prosthetic componentry and rarely incorporate any type of rehabilitation, despite evidence suggesting that it is critical for minimizing gait imbalances. Given the accelerated rate of innovation in prosthetics, there is a fundamental knowledge gap concerning how individuals with transfemoral limb loss should learn to correctly use powered ankle-foot devices for maximum functional benefit. Because of the recent advances in prosthetic technology, there is also a critical unmet need to develop guidelines for the prescription of advanced prosthetic devices that incorporate both physical and psychological components to identify appropriate candidates for advanced technology.

Objective: The primary goal of this investigation is to examine the roles of advanced prosthetic technology and a device-specific rehabilitative intervention on gait biomechanics, functional efficacy, and pain in individuals with transfemoral limb loss. The secondary goal is to develop preliminary rehabilitation guidelines for advanced lower limb prosthetic devices to minimize gait imbalances and maximize function and to establish preliminary guidelines for powered ankle-foot prosthetic prescription.

Methods: This prospective, multisite study will enroll 30 individuals with unilateral transfemoral limb loss. At baseline, participants will undergo a full gait analysis and assessment of function, neurocognition, cognitive load, subjective preferences, and pain using their current passive prosthesis. The participants will then be fitted with a powered ankle-foot device and randomized into 2 equal groups: a powered device with a device-specific rehabilitation intervention (group A) or a powered device with the current standard of practice (group B). Group A will undergo 4 weeks of device-specific rehabilitation. Group B will receive the current standard of practice, which includes basic device education but no further device-specific rehabilitation. Data collection procedures will then be repeated after 4 weeks and 8 weeks of powered ankle use.

Results: This study was funded in September 2017. Enrollment began in September 2018. Data collection will conclude by March 2024. The initial dissemination of results is expected in August 2024.

Conclusions: The projected trends indicate that the number of individuals with limb loss will dramatically increase in the United States. The absence of effective, evidence-based interventions may make individuals with transfemoral limb loss more susceptible

to increased secondary physical conditions and degenerative changes. With this expected growth, considerable resources will be required for prosthetic and rehabilitation services. Identifying potential mechanisms for correcting gait asymmetries, either through advanced prosthetic technology or rehabilitative interventions, can provide a benchmark for understanding the optimal treatment strategies for individuals with transfemoral limb loss.

KEYWORDS

amputation; limb loss; physical therapy; powered prosthetic ankle-foot device; lower extremity

Introduction

Background

There are approximately 1.9 million Americans with limb loss today, with an estimated 185,000 people who undergo an amputation procedure each year [1]. Over the last 2 decades, the Department of Veterans Affairs (VA) and the Department of Defense (DoD) have experienced an increase in the number of veterans and service members with lower limb loss [2]. Since the start of the most recent conflicts, more than 1700 service members have experienced combat-related limb loss, with the vast majority of these traumatic amputations of the lower limb [2-4]. VA, the largest integrated health care network in the United States, serves this unique population after their separation from active duty and provides care for an additional 41,000 veterans with lower limb loss [5]. Transfemoral limb loss, the second most common level of lower limb loss, accounts for one-fifth of the total limb loss population in the United States [6]. With this already large population expected to grow, effective outcomes-based clinical practice will be necessary to improve mobility, decrease long-term disability, and provide a higher quality of life.

Abnormal Gait Mechanics for Individuals With Transfemoral Limb Loss

Individuals with transfemoral limb loss have unique functional challenges owing to the loss of the knee and ankle joints [7-9]. Gait mechanics of individuals with transfemoral limb loss have been extensively investigated, with abnormalities typically characterized by asymmetries in stance phase biomechanics [10-13]. Individuals with transfemoral limb loss exhibit increased ipsilateral hip extensor activity and hip power, which is thought to be compensation for the lack of ankle power normally provided by the gastroc-soleus complex [14]. Consequently, compensatory mechanisms at joints proximal to the level of limb loss are often used to replace the function normally delivered by the muscles surrounding the ankle joint [12]. Individuals with unilateral transfemoral limb loss also tend to walk with longer stance times on the intact versus prosthetic limb [10], which can lead to a corresponding asymmetrical load distribution [15]. These asymmetrical joint forces place greater demands on the intact limb, which may explain the higher prevalence of musculoskeletal injuries, pain, and joint degeneration of the intact limb compared with uninjured individuals [16,17]. Significant among these secondary conditions is pain, specifically in the intact knee and lower back. In a study of experienced prosthesis users, knee pain in the intact limb was the primary complaint of 75% of individuals with transfemoral limb loss [18]. In a sample of 63 male veterans with traumatic lower limb loss, individuals with transfemoral limb loss were 5 times more likely to have intact knee pain compared with neurotypical participants [16]. Among individuals with lower limb loss (both transtibial and transfemoral), 71% reported back pain within the previous month, but individuals with transfemoral versus transtibial limb loss were significantly more likely to have greater pain intensity [19]. Chronic, persistent pain can lead to limitations in function. There is a significant need to explore the effects of advanced prosthetic technologies and rehabilitative interventions on pain reduction, function, and biomechanics.

Biomimetic Prosthetic Technology

New technologies in lower limb prostheses have attempted to combat gait pathologies by generating biomimetic ankle power through spring-clutch mechanisms or advanced sensor and actuator technology [20]. Recent advances in microelectronics, battery technologies, and the development of several new types of actuators [21,22] have ushered in the development of powered lower limb prostheses that can better replicate the positive work phases of the ankle through the use of actuators, motors, or pneumatic muscles [23-27].

The Empower (Ottobock Inc), which uses a series-elastic actuator and a carbon-composite footplate, is currently the only commercially available powered ankle-foot device [28,29]. The Empower has been investigated in the population of individuals with transtibial limb loss, but it has yet to be fully investigated in individuals with transfemoral limb loss [30-33]. In a study of individuals with transtibial limb loss, the use of a powered versus passive ankle-foot device reduced the peak resultant force and knee adduction moment on the unaffected leg during level ground walking, potentially limiting the risk of secondary musculoskeletal comorbidities [31]. Individuals with transtibial limb loss using the same powered ankle-foot device had improved ankle power, greater net trailing limb step-to-step transition work, and a lower metabolic rate compared with a passive energy storing and returning ankle-foot prosthesis during level ground ambulation [32].

Although biomimetic prosthetic devices can better approximate biological ankle biomechanics, residual gait deviations can persist, either because of habit or a lack of proper rehabilitative training. For example, despite greater ankle power generation with powered ankle-foot device use, individuals with transtibial

limb loss can still walk with compensatory strategies at the proximal joints, which can be attributed to the introduction of new interlimb asymmetries from the uniarticular function of the device [30]. Therefore, device-specific rehabilitation may be needed to minimize or correct the reported deficiencies. Similarly, in the absence of an evidence-based rehabilitation program to correct or minimize preexisting gait asymmetries, instrumented gait analyses that assess the biomechanical function of prosthetic devices may be more likely to quantify the physical gait deviations developed through habit or lack of training rather than device-specific attributes [34]. Therefore, it may be more accurate to postulate that powered ankle-foot devices, through the generation of normative ankle power during push off, offer an opportunity to minimize gait deviations and normalize prosthetic function but not without the incorporation of a rehabilitation program to train prosthesis users to reduce existing gait deviations.

Prosthetic Rehabilitation Programs

The current state of prosthetic research efforts appears to favor the design and evaluation of prosthetic componentry, particularly with respect to gait mechanics, and rarely incorporates or reports any type of physical therapy (PT) program or device-specific training [34]. Given the accelerated rate of technological innovation in prosthetic devices, there is a fundamental knowledge gap concerning how individuals with lower limb loss should learn to correctly use this advanced, powered technology for maximum benefit. However, previous investigations have examined the effectiveness of rehabilitation protocols on the outcomes of individuals with transfemoral limb loss who used passive prosthetic devices. Prosthetic gait training based on proprioceptive feedback for individuals with transfemoral limb loss was more effective for improved weight-bearing and temporal-spatial parameters than traditional gait training [35]. Sjodahl et al [36] used instrumented gait analysis to measure the gait parameters of individuals with unilateral transfemoral limb loss before and after a training program and reported improved walking speed and sagittal plane hip kinematic symmetry after training. However, the authors also reported increases in compensatory strategies for the intact limb, including an increase in the intact knee extension moment. Virtual reality–based gait training with real-time biomechanical feedback improved frontal plane hip, pelvis, and trunk motion during level ground walking [37]. Currently, there have been no published studies detailing the effects of a device-specific rehabilitation program on the biomechanical or functional outcomes of individuals with transfemoral limb loss who use a powered ankle-foot prosthesis. In this investigation, this knowledge gap will be addressed, and a benchmark to understand optimal treatment strategies will be provided for individuals with transfemoral limb loss to minimize gait impairments.

Summary

The development of evidence-based health care practices is critical to maximizing prosthetic and health outcomes in the growing population of individuals with transfemoral limb loss. Identifying potential mechanisms for correcting gait asymmetries, through advanced prosthetic technology, rehabilitative interventions, or both, can provide a benchmark to better understand the optimal treatment strategies for individuals with transfemoral limb loss. Despite research suggesting that an evidence-based rehabilitation program that incorporates prosthetic gait training is a critical factor in minimizing compensatory mechanisms [38-40], most prosthetic device protocols fail to incorporate any type of significant rehabilitation or device-specific training. Therefore, this investigation will be the first to elucidate the effects of an advanced powered prosthesis and the role of rehabilitative interventions on gait biomechanics, performance, and pain in individuals with transfemoral limb loss.

Study Objectives

The overarching goal of this investigation is to examine the roles of advanced prosthetic technology and a device-specific rehabilitative intervention in individuals with transfemoral limb loss. The central hypothesis is that powered plantarflexion, coupled with an evidence-based, device-specific PT intervention, will improve biomechanical outcomes, which will correlate with decreased pain and improved functional performance. The objectives of this investigation are as follows:

1. To examine the biomechanical and functional efficacy of a powered prosthesis compared with a passive prosthesis for individuals with transfemoral limb loss
2. To determine the effects of a powered prosthetic ankle-foot device and a PT intervention on lower extremity kinematic and kinetic patterns, functional efficacy, and pain in individuals with transfemoral limb loss
3. To develop preliminary rehabilitation guidelines for a powered ankle-foot device to minimize gait imbalances and maximize function, as well as to establish preliminary guidelines for powered ankle-foot prosthetic prescription

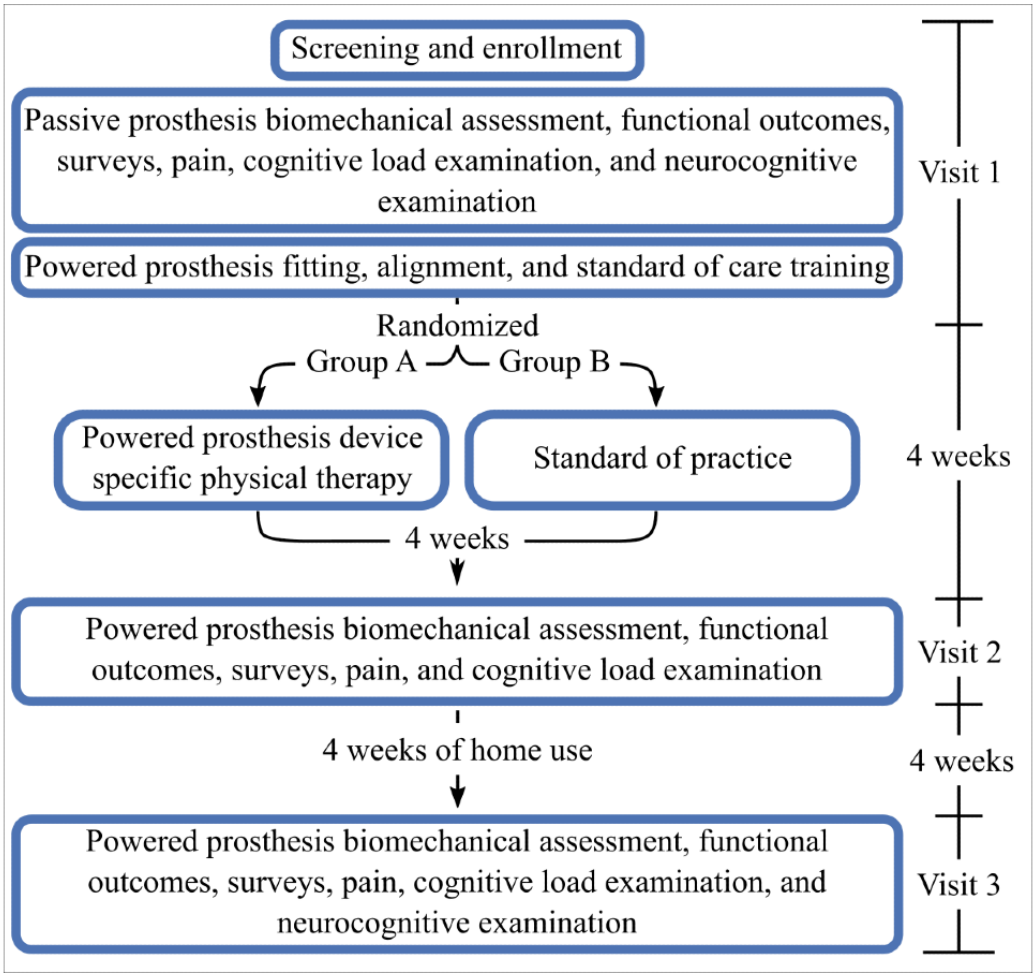
Methods

Study Overview

This investigation will be a prospective, multisite study including VA New York Harbor Healthcare System (VANYHHS), James A. Haley Veterans' Hospital (JAHVH), and Walter Reed National Military Medical Center (WRNMMC). Enrollment began in September 2018, and data collection is expected to conclude in 2024. Briefly, 30 individuals with transfemoral limb loss are expected to be enrolled equally across the 3 sites. For all participants, a full biomechanical gait analysis, functional measures, surveys, neurocognitive assessment, cognitive load assessment, and pain assessment will be captured at baseline with their clinically prescribed passive energy storing and returning ankle-foot prosthesis. The participants will be fitted with a powered ankle-foot device (Empower) and then be evaluated for safe use. The participants will then be randomly assigned into 2 groups: a powered ankle-foot device with a 4-week, 8-session device-specific PT intervention (group A) or a powered ankle-foot device with the current standard of practice (group B), which includes basic device education and training provided by the study prosthetist (outlined in the Powered Ankle-Foot Device Standard of Practice section), but no device-specific PT intervention. Group A will then undergo 4 weeks of

device-specific rehabilitation, while group B will not receive any further PT. All participants will then undergo a full gait analysis as well as assessments of function, subjective preferences, neurocognition, cognitive load, and pain after 4 weeks and 8 weeks of powered ankle-foot device use (Figure 1). A comparison between the 2 groups will help evaluate the efficacy of a powered versus passive prosthesis, as well as elucidate the contribution of device-specific effects to rehabilitation-specific effects for individuals with transfemoral limb loss.

Figure 1. Participant timeline of activities.



Participants

A convenience sample of 30 individuals with unilateral transfemoral limb loss will be recruited for this study (Textbox 1 shows the inclusion and exclusion criteria). All participants will consent to participate before participating in any study activities. The participants will be randomly stratified into 2 study arms: group A, a powered ankle-foot device with device-specific PT (15/30, 50%), and group B, a powered ankle-foot device with standard of practice (15/30, 50%), which includes basic device education and training but no device-specific PT intervention. Recruitment of participants will be on a first-come, first-serve basis among the patients of VANYHHS, JAHVH, and WRNMMC. The participants will be recruited through the VANYHHS, JAHVH, and WRNMMC rehabilitation and prosthetic clinics. All participants will have experience using a microprocessor knee and will currently use a passive-elastic ankle-foot prosthesis.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Unilateral transfemoral limb loss because of any etiology
- Use of a microprocessor knee with >6 months of experience
- ≤8 limb loss–related physical therapy sessions in the previous 6 months
- Aged at least 18 years
- Score of ≥33 on the Amputee Mobility Predictor, corresponding to a high K2 or above ambulator
- Able to walk a minimum of 30 meters without an assistive device
- Able to walk on a treadmill for 5 minutes at self-selected speed with or without the use of handrails

Exclusion criteria

- Inability to tolerate the wearing of a socket or a poorly fitting socket
- Conditions of the intact limb prohibit prosthesis use (eg, ulcers, sores, skin breakdown, burns, poor skin coverage, contractures, and severe heterotopic ossification)
- The length of the residual limb prohibits socket or prosthesis fitting
- Cognitive deficits or a mental health pathology limiting the ability to participate fully in the study or any deficit deemed by the principal investigator to be detrimental to the completion of the study
- Significant comorbidity, which would interfere with the study (eg, neuropathy, uncontrolled diabetes, receiving dialysis, insensate feet, severe phantom pain, or a history of skin ulcers)
- Severe circulatory problems, including peripheral vascular disease and pitting edema
- Pregnant women in the second trimester or beyond or women who will be in the second trimester within the enrollment period
- Weigh >130 kg at screening
- Use of nonprescribed opioids or overuse of any prescription drugs
- Major upper limb loss
- Currently uses a powered ankle-foot prosthesis as a primary prosthesis or used a powered ankle-foot device as a primary prosthesis in the previous 6 months
- Any cardiopulmonary, metabolic, or integumentary diagnosis where walking for 15 minutes is contraindicated

Ethical Considerations

This study was approved by the following institutional review boards (IRBs): VANYHHS IRB (1643), WRNMMC IRB (WRNMMC-2018-0167), and the University of South Florida IRB, which is the IRB of record for JAHVH (IRB STUDY000870). The oversight and protection of human participants was also approved by the US Army Medical Research and Development Command Office of Human Research Oversight (E04081). All participants will provide informed consent before participating in any study activities.

Baseline Visit

Informed Consent, Enrollment, and Randomization

Informed consent for each potential participant will be conducted in person in a private room. The site-principal investigator or qualified designee will explain the study protocol in detail. The participants will be asked to consent to randomization of the treatment group, either to be fit with the powered ankle-foot device and receive device-specific PT (group A) or to be fit with the powered ankle-foot device and receive the current standard of practice that does not include device-specific PT (group B). The participants will be asked to make a commitment to be available for all study-related activities. The individuals will be given adequate time to review and comprehend all information about the study before agreeing to participate, minimizing the possibility of coercion and undue influence. After the study has been explained and consent has been given, the participants will be randomized into the 2 groups using a computer-generated algorithm that block randomizes participants into each group at each site.

Baseline Data Capture

Regardless of the group assignment, all participants will undergo baseline data capture using their current passive energy storing and returning prosthesis. The study prosthetist will ensure proper fit and alignment of the prosthesis before any data collection. Once fit and alignment are confirmed, the participants will complete 3 surveys: an assessment of quality of life, the Prosthesis Evaluation Questionnaire (PEQ), and the PEQ Addendum. Then, pain, cognitive load, neurocognition, biomechanical gait analysis, and functional outcomes will be captured at baseline for all participants on their current passive energy storing and returning prosthesis.

Quality-of-Life Assessment

A single-item assessment will ask the participants to rate their quality of life over the past 4 weeks on a 100-mm visual analog scale.

Assessment With PEQ

The PEQ is a self-reported visual analog–style questionnaire for people with lower limb loss who use a prosthesis to evaluate the prosthesis and life with the prosthesis. The PEQ is organized into 9 domains that may be used independently to measure a specific domain of interest. Domains of utility, appearance, sounds, residual limb health, and ambulation will be used in this investigation. In addition, the PEQ contains items beyond the domains that can be evaluated individually, including questions on satisfaction, pain, and transfers that will be used in this study [41].

Assessment With PEQ Addendum

The PEQ Addendum asks 2 open-ended questions assessing any falls or stumbles that the participant may have experienced over the previous 4 weeks [42].

Pain Assessment

Participants will complete the Patient-Reported Outcomes Measurement Information System Pain Interference Scale 8a, which is a self-report survey that assesses the extent to which pain interferes with physical, psychosocial, cognitive, emotional, and recreational activities [43].

Neurocognitive and Cognitive Load for Prosthesis Use

Prosthesis use requires physical capabilities and the cognitive capacity to learn new techniques across different situations and environments. These skills include spatial organization, memory, attention, and visuospatial function [44]. Powered ankle-foot devices can be more complex than passive devices and may require certain levels of neurocognition and cognitive load for ambulation, especially for higher-level functional tasks. Diabetes and peripheral vascular disease, the most prevalent causes of lower limb loss, are linked to declining neurocognition [45,46]. Importantly, diminished neurocognitive function is not often observed until late in the rehabilitation process (well after prosthetic prescription) [47], which can result in the mismanaged use of staff and patient time and prosthetic resources. If certain levels of neurocognitive abilities correlate with successful prosthetic outcomes with the powered prosthesis, neurocognitive assessment (before prosthetic prescription) can potentially aid in the selection of appropriate candidates for advanced technology.

Cognitive Load Assessment

Cognitive load assessments will be performed at baseline using the passive energy storing and returning ankle-foot prosthesis. Before any cognitive load testing, a self-selected walking speed will be established via treadmill walking. The participants will be encouraged to walk unsupported on the treadmill, if possible. The treadmill console will be covered to prevent number distractions, and the participants will be reminded to hold their gaze straight ahead. To determine the self-selected speed, the participants will begin walking on the treadmill at a comfortable speed in the absence of any additional cognitive load. The treadmill will then be increased by 0.09 m/s every 10 seconds until the participant verbalizes their preferred speed. To avoid quick trigger responses, the speed will be increased by 0.18 m/s and then subsequently lowered by 0.04 m/s every 5 seconds until the participant verbalizes their preferred speed. If the final speed does not match the initial speed, this procedure will be repeated until the participant matches the preferred walking speed.

Cognitive load testing consists of five 1-minute standardized cognitive tasks: 1 serial subtraction task, 3 controlled oral word association tasks, and 1 category task. These tasks consist of auditory and verbal cognitive measures to simulate real-world conditions. Visual tasks will not be used to avoid measures that require reading while walking. The participants will complete each cognitive task while walking on a treadmill at the previously noted self-selected speed. The directions will be read to each participant to ensure protocol consistency. The number of correct answers will be determined for each 1-minute test using a digital voice recorder and paper recordings to ensure accurate documentation of the participants' answers. The participants will complete a practice trial before each task initiation to ensure complete comprehension. The participants will also be allowed to rest between cognitive tests as needed. The cognitive tasks are as follows:

- Serial subtraction: Serial subtraction is a mental arithmetic task [48]. The participants are given a random 3-digit number and asked to continually subtract 3 while they walk for 1 minute. The number of errors will be calculated. The participants are not penalized for multiple errors if 1 error was made; however, they continued sequentially thereafter.
- Controlled Oral Word Association Test: This measure consists of 3 tests that measure verbal phonemic fluency and other neuropsychologic domains [49]. The participants will be asked to list words beginning with a certain letter while walking for 1 minute. The test is then repeated for 2 other letters. The total number of unique words for each letter will be documented.
- Category Test: The participants are asked to list words belonging to a certain category within 1 minute (eg, fruits or parts of a car). Category naming has shown validity and reliability [50]. The total number of unique words for each category will be documented.

After each cognitive load test, the participants will be asked to rate on a 0 to 10 scale (with 0 being "none" and 10 being "a great deal") their focus on walking, their focus on thinking of words or subtracting numbers, and their focus on distractions. This will provide information on the subjective experience of cognitive load.

Neurocognitive Assessment

Following the cognitive load assessment, the participants will take an electronic neurocognitive battery (CNS Vital Signs) [51]. The computerized neurocognitive assessment measures 5 domains (memory, psychomotor speed, reaction time, complex attention, and cognitive flexibility), is designed to be administered serially, and has demonstrated good test-retest

reliability. The neurocognitive assessment consists of the following 7 tests:

- Verbal memory: the participants are instructed to remember 15 words that are displayed 1 at a time every 2 seconds. The target words are then randomly mixed with 15 new words. The participants are instructed to press the space bar when a target word is displayed. This test is repeated at the end of the assessment with the same 15 target words randomly mixed with 15 new nontarget words.
- Visual memory: the participants are instructed to remember 15 geometric shapes that are shown 1 at a time every 2 seconds. The shapes are then randomly mixed with 15 new nontarget shapes. The participants are instructed to press the space bar when they identify a target shape. This test is repeated at the end of the neurocognitive assessment period.
- Finger tapping: the participants are instructed to tap the space bar with their right index finger as quickly as possible during the 10-second test. The test is then repeated with the left index finger.
- Symbol Digit Coding: this test consists of 8 digit-symbol pairs, followed by a list of digits. The participants are instructed to serially type numbers that correspond to the symbols during the 120-second test.
- Stroop test: in part 1 of the Stroop test, the participants are randomly shown the words "GREEN," "YELLOW," "RED," and "BLUE." These words are printed in black. The participants are instructed to press the space bar when they see one of these words. In part 2, the same words appear on the screen but are printed in different colors. The participant is instructed to press the space bar when the color presented matches the word (eg, the word "RED" is printed in red). In part 3, the same words are presented on the screen in different colors. The participants are then instructed to press the space bar when the color presented does not match the word (eg, the word "RED" is printed in green).
- Shifting Attention: in this test, 3 figures appear on the screen. There is a single figure at the top of the screen (either a circle or a square). At the bottom of the screen, 2 figures are presented (both a square and a circle). The figures are randomly mixed to be either red or blue. The participant is then instructed to match one of the corresponding bottom figures with the top figure by shape or color. However, the rules for matching by shape or color change at random. This test occurs for 90 seconds.
- Continuous performance test: during a 5-minute period, the participants are asked to press the spacebar when the letter *B* appears on the screen. The participants are further instructed not to respond to any other letters. The letters are presented at random.

Biomechanical Gait Analysis

Gait analyses will be performed at the biomechanics laboratories at VANYHHS, WRNMMC, and JAHVH. The VANYHHS laboratory is a 133-m^2 space comprising an 11-camera motion capture system (Qualisys, Inc) with 4 multiaxis force platforms (AMTI, Inc). At WRNMMC, the biomechanics laboratory is an 167-m^2 space comprising an 18-camera motion capture system (Qualisys, Inc) and 6 multiaxis force platforms (AMTI Inc). At JAHVH, the motion capture laboratory is a 74-m^2 space equipped with a 12-camera motion capture system (Vicon Inc) and 4 multiaxis force platforms (AMTI Inc). All 3 systems track the positions of passive reflective markers at a rate of 120 Hz, and force platforms sample ground reaction forces at a rate of 1200 Hz. Visual3D software (C-Motion Inc) will be used for the analysis of 3D motion capture data.

All laboratories in this investigation will follow recommendations provided by an interlab reliability study that was conducted between gait laboratories at the 3 military treatment facilities [52]. Specifically, all sites will use identical marker sets, identical anatomical segment definitions, and a single examiner at each site to conduct postprocessing of the respective data to reduce potential variability between the laboratories.

For all participants, biomechanical gait analysis will be performed at baseline using their prescribed energy storing and returning prostheses. All kinematic and kinetic biomechanical measures will be captured using an identical 6-degrees-of-freedom marker set. A custom, full-body passive reflective marker set will be placed on each participant, which tracks each segment independently, allowing for the accurate measurement of movements. As previously described [53], 78 markers will be placed or digitized on the head, trunk, pelvis, and extremities. Marker placements for the prosthetic limb will be matched to those of the intact leg or placed on the centers of rotation of the prosthetic ankle-foot and knee devices. The cluster technique will be used to minimize the surface-to-bone displacements for the thigh, shank, and upper arm–mounted markers [54]. Tracking clusters will be placed bilaterally on the thigh, the tibial crest, and the upper arm. Functional joints, adapted from Schwartz and Rozumalski [55], will also be calculated for the intact ankle and knee as well as bilaterally for the hips.

During each experimental session, the participants will separately walk at 3 speeds across an instrumented walkway until 5 acceptable trials for each foot at each speed are completed. Trials will be considered acceptable when a foot makes full contact with a force platform. Because kinetic outcome measures are speed-dependent, the participants will ambulate at 3 controlled speeds: 0.7, 1.0, and 1.3 m/s. These speeds were selected to represent a slow, moderate, and fast walking speed, respectively, for individuals with transfemoral limb loss. The order of speeds will be randomized for each data collection visit. Auditory feedback will be provided to the participant by the study team to ensure that all participants walk at the targeted speed (−5% to +5%). The main purpose of this session is to collect joint motion, force, torque, and power data at each walking speed. The ranges of motion; speeds and accelerations; and hip, knee, and ankle joint moments of force and generated and absorbed powers will be computed using inverse dynamics methods. Temporal-spatial parameters will also be recorded.

The reflective marker positions will be digitized using motion tracking software. A 15-segment rigid body model (head, trunk,

pelvis, bilateral upper and lower arms, hands, thighs, shanks, and feet) will be created based on the skin-mounted markers and functional joints. Local coordinate systems for each segment will be defined using the International Society of Biomechanics recommendations [56,57]. The data of 5 acceptable walking trials at each speed will be processed using Visual3D. Marker data will be filtered with a 6 Hz Butterworth low-pass filter. Raw analog data will be filtered using a second-order low-pass Butterworth filter with a 25-Hz cutoff frequency. Visual3D will be used to calculate temporal-spatial values, walking speed, and lower extremity kinematics and kinetics. Inverse dynamic analysis will be applied to the kinematics of the biomechanical model and to the location, magnitude, and direction of ground reaction forces acting on the foot to calculate lower extremity joint torques and powers, including ankle, knee, and hip power of the biological and prosthetic limb over the stance phase, as well as the frontal plane knee moments for the unaffected leg.

Functional Outcome Measures

The effects of the prosthetic devices and the rehabilitative intervention on physical performance will be evaluated using agility and mobility tests, including the 6-minute walk test (6MWT) [58], the Amputee Mobility Predictor with prosthesis (AMPpro) [59], and the Comprehensive High-Level Activity Mobility Predictor (CHAMP) [60]. By capturing the functional measures in each group, the effects of the ankle-foot device can be isolated from the rehabilitation effects on physical performance. These measures are as follows:

- 6MWT: the 6MWT measures the distance an individual can walk in 6 minutes without help or encouragement. It is a valid and reliable measure that correlates with physical function and has good interrater and intrarater reliability in individuals with lower limb loss [58].
- AMPpro: the AMPpro is a 21-item instrument designed to measure prosthetic mobility in individuals with lower limb loss [59].
- CHAMP: participants who attain a score of 37 or higher on the AMPpro will undergo the CHAMP, which consists of the following tasks:
    - Single limb stance: participants fold their arms across their chest and then lift their foot above a 15-cm cone or box. The test ends when the foot touches the ground again (or until 30 s) or if the arms uncross. This procedure is performed on both feet.
    - Edgren Sidestep Test: participants sidestep left and then right along a 5-meter line of cones (1 meter apart). The sidestep test lasts for 10 seconds.
    - T-Test: the T-Test measures forward, lateral, and backward walking (or running) and sidestepping in a T pattern.
    - Illinois Agility Test: this advanced agility test requires the participant to run or walk and change direction around multiple cones. Over 60 meters, participants perform 90° and 180° turns 11 times around multiple cones.

Powered Ankle-Foot Prosthesis Fitting

Following all baseline data collection procedures, all participants will then be fit with the Empower. Study prosthetists at VANYHHS, WRNMMC, and JAHVH are highly experienced in fitting all commercial microprocessor knees and the Empower. The study prosthetists will bench align the powered ankle-foot device onto the participant's existing microprocessor prosthetic knee and socket. Once the powered ankle-foot device is fitted and bench-aligned to the prosthetic knee and socket, dynamic alignment of the prosthetic knee and ankle will occur. Initially, the study prosthetist will ensure proper alignment of the microprocessor prosthetic knee with the Empower turned off. The Empower will still function (ie, articulate) with the power off but will not provide net positive plantarflexion torque. The microprocessor prosthetic knee software and prosthesis alignment will be adjusted during standing and walking tasks, as necessary, until the prosthetist and the participant are satisfied with the knee alignment. Once the microprocessor knee setup is completed, the Empower will be powered on and adjusted according to the manufacturer's specifications. Briefly, the participants will sequentially walk at 3 different speeds (slow, self-selected, and fast) while the stiffness and power delivery of the powered ankle-foot device is tuned [33]. If further dynamic adjustments to prosthetic knee alignment are necessary, these adjustments will be made at this point.

Powered Ankle-Foot Device Standard of Practice

Once a stable and comfortable alignment has been established, all participants will be educated by the study prosthetist on the proper use of the Empower, which includes battery handling and charging, understanding low battery indicators, considerations while driving with the Empower (if applicable), and avoidance of exposure to rain and water. Next, the participants will ascend and descend an Americans with Disabilities Act–compliant ramp under the supervision of the study physical therapist or prosthetist. The intent of ramp walking is to trigger the power for ascent but not during descent. Each participant will be given the opportunity to practice the ramp as often as necessary to ensure safe and comfortable use. The participants will then negotiate a standard staircase with handrails under the supervision of the study physical therapist or prosthetist to ensure that they can safely negotiate stairs using the Empower. Proper technique will consist of demonstrating the correct foot placement on each step to activate powered push off during ascent. Participants unable to ascend stairs in a step-over-step pattern will be shown the correct foot placement using a step-to gait pattern. For proper stair descent, participants will be shown the correct foot placement to initiate rollover and not trigger the power. Participants will be given time to practice stair ascent and descent. After stair and ramp ambulation, participants will be asked to demonstrate safe use of the Empower in different situations, including turning, varying speeds, sudden stops, obstacle avoidance, stepping over obstacles, and different surfaces. Once the physical therapist is satisfied that the participant has demonstrated safe use and all questions have been answered, the participant will be released home with the Empower. If the physical therapist feels that the progress is unsatisfactory, the participant will not take the Empower home and will be asked to return for continued

supervised use until the participant demonstrates safe use. The standard of practice to use the powered prosthesis is approximately 30 to 45 minutes after fitting and tuning.

Following the baseline visit, group A will undergo the device-specific PT program, whereas group B will not undergo any further training.

PT Program: Group A

Overview

Participants in group A will complete, on average, 8 PT sessions lasting 30 to 45 minutes each. The exact PT protocol and criteria for advancement are outlined by level in the subsequent section. In brief, level 1 of the PT plan will focus on education, strengthening through therapeutic exercises, and early neuromuscular reeducation. A home exercise program (HEP) will be initiated during the initial sessions and will progress along with the program. Level 2 will include gait training on level surfaces, sit-to-stand transitions, and ramp negotiation. Level 3 will include multidirectional training for both neuromuscular reeducation and gait and the introduction of stair ascent and descent. Training will conclude with level 4 where the previous skills will be further challenged and advanced gait skills, including ambulation on ramps and uneven surfaces, will be introduced. Participants must meet the outlined criteria before progressing through each level. Participants who do not meet the specified criteria will be offered additional PT sessions. The number of additional sessions will be recorded and used to refine the PT program for future use.

Level 1 (Sessions 1 and 2)

Level 1 (Table 1) includes initial evaluation, patient education, gait assessment, training to ensure safe use in the community, therapeutic exercises (including introduction of the HEP), and the initiation of early neuromuscular reeducation training.

Table 1. Level 1 device-specific physical therapy protocol.

Protocol	Description	Criteria for advancement to level 2
Level 1 (sessions 1 and 2)		
Evaluation	Assessment of prosthesis fit and gait to determine deficits	N/A[a]
Strengthening	Strengthening of transversus abdominis and multifidus, gluteus maximus, gluteus medius, and general trunk strengthening	Able to perform HEP[b] independently
Stretching	Address deficits from evaluation, including iliopsoas	Within normal limits for range of motion
Education	Explanation of function of powered ankle-foot device	Verbalizes understanding of function of powered ankle-foot device
Gait training	Safely negotiate level surface without increased falls or stumbles	Able to ambulate 46 meters without an assistive device independently on a flat, level surface; self-reported occurrence of stumbles or falls is no greater than baseline
Mobility training	Side stepping, backward stepping, and turns	Able to ambulate outdoors without increased falls or stumbles with or without an assistive device
Neuromuscular reeducation	Weight shifting and control over prosthesis, intact limb mobility (toes in and toes out, heel in and heel out) to promote weight shifting, static single limb balance training on prosthesis side with upper limb support, and anterior and posterior stepping exercises with the intact limb	Independent in HEP
HEP	Initiated with all therapeutic exercises outlined in level 1	Independent in HEP

[a]N/A: not applicable.

[b]HEP: home exercise program.

Level 2 (Sessions 3 and 4)

Level 2 (Table 2) will include the progression of therapeutic exercises through increased frequency, duration, and resistance.

All strengthening and stretching will be shifted to the HEP by the completion of level 2. Lumbar, abdominal, and closed kinetic chain lower extremity strengthening exercises will progress to more dynamic positions. Single limb stance progressions (neuromuscular reeducation) will include decreased upper limb support for stepping exercises and progressing to step touches with the intact limb. Upper limb support will progress from bilateral support to support provided only on the side of the prosthesis. Anterior and posterior stepping exercises will begin with the support of parallel bars while maintaining weight on the prosthesis.

Table 2. Level 2 device-specific physical therapy protocol.

Protocol	Description	Criteria for advancement to level 3
Level 2 (sessions 3 and 4)		
Evaluation	Reassessment as needed	N/A[a]
Strengthening	Progression to sitting, quadruped, planks, standing, and transitions	Independent in HEP[b]
Stretching	Primarily used for cooldown at completion of each session	Independent in HEP
Education	Description of HEP and purpose of each exercise	Verbalizes understanding of each exercise
Gait training	Improving step length symmetry (eg, verbal cueing to increase step length on nonprosthesis side) and improving rollover on prosthesis side (eg, resistive gait training with TheraBand)	Ability to trigger power in prosthetic foot during gait >50% of steps and increased gait symmetry with verbal cueing for step length as determined through observational gait analysis
Mobility training	Transfers (eg, stand-to-sit), and ramp negotiation	Able to maintain midline center of mass with stand-to-sit transfer
Neuromuscular reeducation	Intact limb mobility (eg, rolling ball under intact limb) to promote weight shifting, static single limb balance training on prosthesis side with minimally necessary upper limb support and stepping exercises (eg, step touches 15-20 cm step in parallel bars and step touches to a cone in the parallel bars)	Independent in HEP
HEP	Includes therapeutic exercises outlined in level 2	Independent in HEP

[a]N/A: not applicable.

[b]HEP: home exercise program.

Level 3 (Sessions 5 and 6)

At level 3 (Table 3), all strengthening will be performed exclusively in the HEP. PT will include neuromuscular reeducation progression, including multidirectional movements.

Stepping exercises will be performed with decreasing upper extremity support at a tolerance demonstrated by the participant maintaining an appropriate body position. Single limb stance activities will include perturbations, such as resistance with movements of a non–weight-bearing intact limb or standing on a foam pad or balance disc. Gait training will include multidirectional stepping with upper extremity support in the parallel bars. Resistive gait training will be introduced to promote proper mechanics for loading the prosthesis in stance and achieving maximal energy return at push off. In addition, manual proprioceptive neuromuscular facilitation will be performed to promote proper anterior pelvic rotation. Multidirectional ambulation will be progressed to outside of parallel bars.

Table 3. Level 3 device-specific physical therapy protocol.

Protocol	Description	Criteria for advancement
Level 3 (sessions 5 and 6)		
Evaluation	Reassessment as needed	N/A[a]
Strengthening	Review as needed	Independent in HEP[b]
Stretching	To be used for cooldown at session completion	Independent in HEP
Education	Gait training and purpose for improving symmetry	Verbalizes understanding of gait training
Gait training	Promoting gait initiation on prosthesis side with anterior pelvic rotation (ie, manual techniques to facilitate or initiate anterior pelvic rotation while in parallel bars with progression to anterior stepping on prosthesis side), relaxed upright posture with ambulation (ie, verbal cueing to keep chest upright), and resistive gait training with TheraBand and verbal cues for increased step length with intact limb	Demonstrates ability to trigger power with at least 80% accuracy during level ground ambulation and increased gait symmetry, including upright posture, step length, and toe break as determined through observational gait analysis
Mobility training	Ramp and stair negotiation	Hill Assessment Index score ≥6 (ie, step past more than half foot length, with assistive device)
Neuromuscular reeducation	Four-directional resistance exercise on intact side while maintaining single limb stance on prosthesis side, static single limb balance training on prosthesis side to be progressed to noncompliant surface (eg, foam), and progression of stepping exercises to increase time in single limb stand on the prosthesis	Able to maintain single limb stance on prosthesis side with or without an assistive device for 15 seconds
HEP	Includes therapeutic exercises in level 3	Independent in HEP

[a]N/A: not applicable.

[b]HEP: home exercise program.

Level 4 (Sessions 7 and 8)

At level 4 (Table 4), PT will include advanced neuromuscular reeducation and gait training, followed by a final PT evaluation.

Neuromuscular reeducation will include single limb squats in the parallel bars with upper extremity support, as needed. Gait training will continue resistive training on even surfaces, proprioceptive neuromuscular facilitation for pelvic rotation, verbal and tactile cueing for symmetrical and appropriate trunk rotation, and negotiation of uneven surfaces.

Individuals who do not meet the criteria to complete the PT program will be offered an additional 8 PT sessions after completion of the study.

Table 4. Level 4 device-specific physical therapy protocol.

Protocol	Description	Criteria for advancement
Level 4 (sessions 7 and 8)		
Evaluation	Re-evaluation at final session	N/A[a]
Strengthening	N/A	N/A
Stretching	To be used for cooldown at session completion	Independent in HEP[b]
Education	Importance of continuation of HEP	Verbalizes understanding
Gait training	Promoting gait initiation on prosthesis side with anterior pelvic rotation, manual techniques and verbal cues to promote increased trunk rotation and trunk rotation symmetry, verbal cueing for symmetrical arm swing and trunk rotation (eg, "relax your shoulders"), and resistive gait training with TheraBand and verbal cues for increased step length with the intact limb and relaxed upright posture	Demonstrates ability to trigger power with at least 90% accuracy for powered prosthetic foot and increased gait symmetry for trunk rotation and arm swing, as determined through observational gait analysis
Mobility training	Ascending and descending ramps and stairs	Stair Assessment Index score of at least 4 (with assistive device, step-to pattern) for ascending and descending stairs, and ambulates in the community without increased participant-reported stumbles or falls compared with baseline
Neuromuscular reeducation	Applied during HEP	Demonstrates increased gait symmetry for step length, push off, anterior pelvic rotation, upright posture, trunk rotation, and arm swing
HEP	Review HEP	Demonstrates independence in HEP

[a]N/A: not applicable.

[b]HEP: home exercise program.

Data Collection Visit 2

After completion of the device-specific PT program, all participants will undergo data collection on the powered ankle-foot prosthesis. The participants will repeat the quality-of-life assessment, subjective surveys, pain assessment, cognitive load assessment, biomechanical gait analysis, and functional measures using the powered ankle-foot prosthesis, as described in the baseline visit. Following visit 2, participants will keep the powered ankle-foot prosthesis for an additional 4 weeks of home use and community use but will not undergo any further device-specific training.

Data Collection Visit 3

After the final 4 weeks of powered ankle-foot prosthesis use, participants will undergo final data collection. Participants will repeat the quality-of-life assessment, subjective surveys, pain assessment, cognitive load measurements, neurocognitive assessment, biomechanical gait analysis, and functional measures, as described in the baseline visit. Following data collection, all participants will be refitted with their energy storing and returning ankle-foot devices, and the powered ankle-foot devices will be returned to the study staff.

Statistical Analysis

Across the study population, outcomes will be assessed with descriptive statistics and compared between each ankle-foot device category as well as by PT intervention (ie, device-specific PT and standard of care). Inferential statistics for ordinal data will be conducted with a repeated-measures Friedman test (α=.05) and a Dunn post hoc test at a 95% CI. To address which measures are the most sensitive to intervention type, a linear mixed-effects model will be used. Separate models will be used for each type of measure (pain, subjective, cognitive, neurocognitive, functional, and biomechanical), and measures that have a significant association with the intervention type in the presence of adjusting (control) variables will be determined. Pair-wise comparisons will be tested for significance using linear contrasts with a Tukey honestly significant difference or by applying a Bonferroni correction, where applicable. The following sections outline the specific analyses that will be performed for each study objective.

Planned Statistical Analysis for Biomechanical and Functional Outcomes

Although there are numerous biomechanical and physiological parameters that can be evaluated following gait analysis [61], this investigation will focus on the biomechanical parameters that are most relevant, commonly used, able to discriminate, and have specific clinical relevance for individuals with transfemoral limb loss. The primary biomechanical outcome measures will include measures of rollover shape, individual characteristics of the 3D ground reaction force, and ankle, knee, and hip joint angles, moments, and powers (on both the intact and affected limbs). To evaluate the load distribution of the medial and lateral knee compartments, the peak resultant ground reaction force, ground reaction force rate, peak knee external adduction moments, and knee external adduction moment rate will be compared between the baseline (passive energy storing and returning condition) and the powered condition at each follow-up visit.

Linear mixed-effects models will be used to identify statistically significant differences in gait temporal-spatial and biomechanical variables for all walking speeds. The fixed effects will be the average differences in gait biomechanical and temporal-spatial variables by prosthetic ankle type (powered vs passive). These models also estimate random effects because of differences in mean biomechanical variables across participants, as well as the random effects associated with minimized variability, as the participants will be tested with both prostheses. For example, a linear mixed-effects regression will be used to examine the relationship between the intact knee peak external adduction moment and the prosthetic ankle-foot condition. Peak intact knee external adduction moment will be the dependent variable, whereas ankle-foot condition will be the independent variable, and participant-by-ankle-foot condition will be modeled as random effects. Pair-wise comparisons will be tested for significance using linear contrasts with a Tukey honestly significant difference or by applying a Bonferroni correction, where applicable. In addition, linear mixed-effects regression will be used to determine the association between prosthetic peak ankle power and foot condition.

Planned Statistical Analysis for Pain Outcomes

The following parameters will be measured and statistically compared between baseline (energy storing and returning condition) and each follow-up visit with the powered ankle-foot prosthesis (weeks 4 and 8):

- Joint reaction forces on the lower back (L5 and S1) and contralateral (intact) knees
- PEQ pain scores
- Functional outcome measures (6MWT, AMPpro, and CHAMP)

Spearman correlations will be calculated to correlate data between pain and lower extremity kinematic and kinetic parameters of interest and pain and functional outcome values across the groups. Linear mixed-effects models will be used to identify statistically significant differences in pain scores and biomechanical variables listed in the previous section for all walking speeds. For example, a linear mixed-effects regression will be used to examine the relationship between peak reaction moments at L5 and S1 and pain for each prosthetic ankle-foot condition. Pair-wise comparisons will be tested for significance using linear contrasts with a Tukey honestly significant difference or by applying a Bonferroni correction, where applicable.

Multiple linear regression will be performed with PEQ pain as the dependent variable. Because of the large number of predictor variables in relation to the number of participants, penalized methods (eg, ridge regression or lasso) will be used to identify variables that contribute the most to the prediction model. Penalized methods add a tuning parameter to the regression model that shrinks the less important coefficients toward 0. Cross-validation will be used to select the best tuning parameter value [62]. The independent variables will be comprised of functional parameters (eg, peak joint reaction forces) and the condition (ankle-foot type and intervention).

Planned Statistical Analysis for Cognitive Load and Neurocognitive Outcomes

Linear mixed-effects models will be performed to examine the differences between the ankle-foot devices on cognitive performance, walking speed, and subjective responses to attention. The parameters in the linear effects model will include prosthetic ankle-foot type, PT intervention, and participants. Ankle-foot type, PT intervention, and cognitive performance will be treated as fixed effects, whereas participants will be treated as random. The total number of errors and the error rates for the cognitive task will be calculated, and the mean error rate will be determined for each cognitive task performed by each participant. Repeated-measures ANOVA will be used to compare the error rates for the 3 cognitive tasks. Fisher least significant difference test will be used to make post hoc comparisons.

For the neurocognitive battery, Pearson correlation coefficients (pair-wise 2-tailed) will be calculated for all variables of interest. Stepwise multiple regression will be performed with the neurocognitive scores (Neurocognitive Index, composite memory, cognitive flexibility, and complex attention scores) as the dependent variable. The independent variables will comprise functional outcomes, pain, and gait biomechanics, including asymmetry index.

Power Analysis and Sample Size Estimation

The sample size was based on a power analysis of 3 biomechanical measures (leading limb work, ground reaction force rate, and knee adduction moment rate) and 1 functional outcome (6MWT distance), and 1 subjective outcome (PEQ—utility) obtained from preliminary analyses, with all measurements obtained at baseline and 2 additional measurements over an 8-week period. The sample size was calculated for the group-by-time interaction, which tests the differences in change over time between the study groups. Assuming an α error rate of 5%, Table 5 presents the power achieved for each measurement for 30 participants, 15 (50%) in each group.

Table 5. Power analysis and sample size estimation.

Measure	Difference, mean (SD)	Power (N=30)
Leading limb work (J/kg)	0.03 (0.04)	85
Ground reaction force rate (N/kg/s)	15 (26.9)	82
Knee adduction moment rate (N m/kg/s)	1.1 (1.2)	98
6MWT[a] distance (m)	60 (61)	96
PEQ[b]—utility	8.4 (8.8)	96

[a]6MWT: 6-minute walk test.

[b]PEQ: Prosthesis Evaluation Questionnaire.

Results

This study was funded in September 2017, with enrollment beginning in September 2018. Data collection is expected to conclude by March 2024. Data analysis of the completed data set is expected to begin after final data collection. The initial dissemination of results is expected in August 2024, with subsequent publication of secondary analyses in December 2024.

Discussion

Expected Outcomes and Anticipated Principal Findings

After the completion of this research project, this investigation will have quantified the dependence of symmetrical lower limb gait biomechanics, physical function, and pain reduction on advanced prosthetic technology and device-specific rehabilitation. Furthermore, a device-specific treatment strategy designed to minimize impairments and maximize function will be evaluated. Finally, an objective measure of cognitive load and neurocognition to guide the prosthetic prescription of powered ankle-foot prostheses will be assessed. As such, the evidence-based outcomes obtained from this research investigation can be appropriately translated into clinical practice as well as drive the future of clinical care in this population.

VA provides care for veterans with limb loss of all generations, including the influx of service members with limb loss from the most recent conflicts [5]. Projected trends indicate that the overall number of individuals with limb loss will continue to increase dramatically, largely attributable to the aging population and the growing number of people with dysvascular disease and diabetes [1]. With this large population expected to grow, considerable resources will be required for rehabilitation and prosthetic services, driving limb loss care to become a high priority for VA. Effective outcomes-based clinical practice will be necessary to decrease long-term disabilities associated with prosthetic use and improve the quality of life. Therefore, it is the goal of this study to examine the effectiveness of a powered ankle-foot prosthesis and device-specific rehabilitation on gait biomechanics, performance, and pain in individuals with transfemoral limb loss. Results from this investigation will provide evidence-based outcomes that can be translated into successful strategies to minimize impairments and maximize function and may drive the evaluation of future advancements in prosthetic technology.

Dissemination Plan

The results of this investigation can help form evidence-based guidelines for individuals with transfemoral limb loss that can serve as a source for lower limb loss clinical practice guidelines. Dissemination of the results of this study within the DoD, VA, and the civilian health care systems will be performed in 3 ways. First, the results will be disseminated to the scientific and clinical community through traditional means, such as peer-reviewed submissions to professional conferences (eg, the Gait and Clinical Movement Analysis Society Annual Conference, the American Congress of Rehabilitation Medicine Annual Conference, and the Military Health System Research Symposium), targeted limb loss and rehabilitation publications (eg, *Archives of Physical Medicine and Rehabilitation*, *Gait & Posture*, and *Frontiers in Bioengineering and Biotechnology*), as well as sharing the data through large data repositories. Second, both VA and the DoD have national, interdisciplinary groups and committees that enable the national dissemination and adoption of best practices among different disciplines. For the VA and DoD limb loss care teams, the Extremity Trauma and Amputation Center of Excellence and the VA Amputation System of Care hold a bimonthly webinar series for clinicians, scientists, and researchers that is available across the entire DoD and VA health care network. This series allows research results to be presented to a large, diverse audience of researchers and health care professionals in limb loss care, which can directly influence the care provided to veterans and service members with limb loss. Finally, the outcomes will be disseminated directly to leaders in the prosthetics industry to provide real-world feedback on their products. The results provided to industry leaders can help in the evolution of lower extremity prosthetic components, which can then lead to improved devices for individuals with transfemoral limb loss.

Limitations

This investigation will not address the varied dosing, timing, frequency, and duration of the device-specific rehabilitation protocol. However, the frequency of PT visits and protocol timing will be evaluated for each participant, which can provide preliminary data for a future study to optimize the rehabilitation strategy. The heterogeneity of the sample population may also limit the generalizability of the outcomes to a more diverse population. In addition, the statistical analysis models will also adjust for specific parameters (eg, age, time since limb loss, and etiology of limb loss), which may limit the sample size and interpretability of the results. The type of microprocessor knee

used by each participant will not be prescribed and may be a confounding factor. This influence of the microprocessor knee type will be evaluated in the statistical models. Finally, a 4-week assessment following completion of the device-specific protocol may not be sufficient to evaluate any PT rebound effects or long-term changes in gait, specifically regarding the effectiveness of the acute PT intervention on gait biomechanics.

Acknowledgments

At Veterans Affairs New York Harbor Healthcare System, the authors would like to acknowledge Mr Michael Poppo for his assistance during data collection and processing; Mr Eric Baksh; Mr Kenneth Breuer; and Mr Eric Hubbs for their assistance in prosthesis fitting and alignment and Dr Cristina Parker, Dr Ellen Godwin, and Dr Jonathan Glasberg for conducting the rehabilitation program. At Walter Reed National Military Medical Center, the authors would like to acknowledge Mr Jonathan Gladish for his assistance during data collection and processing, Dr Ashley Knight for her assistance in project administration, and Dr Allison Symsack for helping develop the device-specific physical therapy program. At James A. Haley Veterans' Hospital, the authors would like to acknowledge Dr Meghan Kern and Dr Lisa Ballestrea for their assistance during data collection and participant training and Ms Anh Du for her assistance in prosthesis fitting and alignment. Finally, the authors would like to acknowledge the Narrows Institute for Biomedical Research and Education for their assistance in grant management. The Congressionally Directed Medical Research Programs, Orthotics, and Prosthetics Outcomes Research Program provided support (grant W81XWH-17-1-0568). This funding source had no role in the design of this study and will not have any role during its execution, analyses, interpretation of the data, or decision to submit results.

Abstract

Background: Black women experience a higher prevalence of poor asthma outcomes and physical inactivity than their White counterparts. Black women comprise a particularly vulnerable group of patients with asthma, with some of the highest rates of asthma in adults, high health care use (emergency department visits and hospitalizations), and the highest crude asthma mortality rate of all race or ethnicity groups. Despite recommendations to engage in regular physical activity, fewer than 15% of Black women meet the 2008 National Physical Activity Guidelines, the lowest of all racial subgroups of adults. Given the connection between physical inactivity and poor asthma outcomes, addressing physical activity among Black women with asthma is imperative.

Objective: This 2-arm randomized controlled trial aims to (1) determine the efficacy of a lifestyle walking intervention on asthma control compared to an education (control) group over 24 weeks, (2) examine the maintenance effects of the lifestyle walking intervention on asthma control at 48 weeks, (3) explore the behavioral mediators (eg, self-efficacy, social support, self-regulation, and daily physical activity levels) and contextual moderators (eg, baseline asthma severity, neighborhood environment, comorbid conditions, and social determinants of health) that contribute to treatment responsiveness, and (4) assess the reach and implementation potential of the intervention.

Methods: The proposed study (ACTION [A Lifestyle Physical Activity Intervention for Minority Women with Asthma]) delivers a 24-week lifestyle walking intervention designed for and by urban Black women with asthma. Participants (n=224) will be recruited through 2 urban health care systems that care for a diverse Black population. Patients will be randomized to one of two groups: (1) ACTION intervention (group sessions, physical activity self-monitoring—Fitbit, and text-based support for step goal setting) or (2) education control (an individual asthma education session and SMS text messages related to asthma education). Outcome assessments will take place at baseline, 12, 24, and 48 weeks. The primary outcome is a change in asthma control from baseline to week 24 as assessed by the asthma control questionnaire-6 (ACQ-6). Secondary outcomes include asthma-related quality of life, health care use, and asthma exacerbations and behavioral outcomes such as self-efficacy, self-regulation, social support, and physical activity.

Results: This study was funded by the National Institute of Minority Health Disparities in August 2022. We pilot-tested our recruitment and intervention procedures and began recruitment in April 2023, with the enrollment of our first participant in May 2023. The anticipated completion of the study is April 2027.

Conclusions: This study will deliver a new approach to physical activity interventions in Black women with asthma and help to provide guidance for addressing physical activity within this subgroup. This study will also provide a potential framework for future studies in minoritized populations with other disease conditions associated with low levels of physical activity.

Introduction

Background

Asthma is a serious global health problem affecting about 358 million people worldwide [1]. Black women comprise a particularly vulnerable group of patients with asthma, with the highest rates of asthma among adults (11.4%), high health care use (emergency department visits and hospitalizations), and the highest crude asthma mortality rate of all racial or ethnic groups [2,3]. There are multiple factors that contribute to this increased morbidity and mortality including, high rates of exposure to environmental pollution, and limited access to quality health care [4]. Low levels of physical activity (PA) are associated with worse asthma outcomes including higher health care use, poorer lung function, lower asthma control, and decreased exercise capacity [2]. Despite recommendations to engage in regular PA, fewer than 15% of Black women meet the 2008 National Physical Activity Guidelines, the lowest of all adult subgroups [5,6]. Given the connection between physical inactivity and poor asthma outcomes, there is a critical need for interventions to address low rates of PA among Black women with asthma.

Lifestyle PA interventions, such as walking, have been shown to be an effective and sustainable way to engage in regular PA. Research shows that people living with asthma prefer low-intensity activities such as walking, which has a low propensity to cause asthma symptoms [7-9]. Yet, only 2 randomized controlled trials (RCTs) of lifestyle PA (walking) interventions have focused on adults with asthma [10,11]. One occurs in a supervised research or academic setting and the other in the community setting. While both studies found improvements in asthma outcomes (asthma quality of life or asthma control), they were conducted predominantly in White women, and neither assessed the maintenance of effects on asthma control.

Research testing strategies to encourage Black women with asthma to increase their PA is a nascent area of study. While asthma is a known barrier to PA participation due to exercise-induced bronchoconstriction, contextual factors influencing PA engagement among people with asthma have also been identified. This includes previous negative experiences with the disease such as frequent asthma exacerbations; marked limitations in daily living due to asthma; and the effect of extreme weather, pollen, or pollution on asthma [10,12-14]. This is in addition to the many PA barriers urban Black women face, such as social and culturally based preferences for hair and body type, neighborhood characteristics (safety and walkability), family or caregiver responsibilities, and lack of role models or social support [5,15,16].

A Lifestyle Physical Activity Intervention for Minority Women With Asthma

Culturally tailored lifestyle PA interventions among Black women without asthma are more effective and sustainable than more generalized interventions [17]. However, similar interventions have not been applied to PA interventions in asthma. Using a theory-informed approach, A Lifestyle Physical Activity Intervention for Minority Women With Asthma (ACTION), was developed as one of the first culturally tailored lifestyle PA interventions for Black women with asthma. Pilot work demonstrated the feasibility and acceptability of the intervention and yielded preliminary findings of improvement in asthma outcomes and moderate PA [18]. This study takes the next step to examine the efficacy of a lifestyle walking program designed for Black women with asthma.

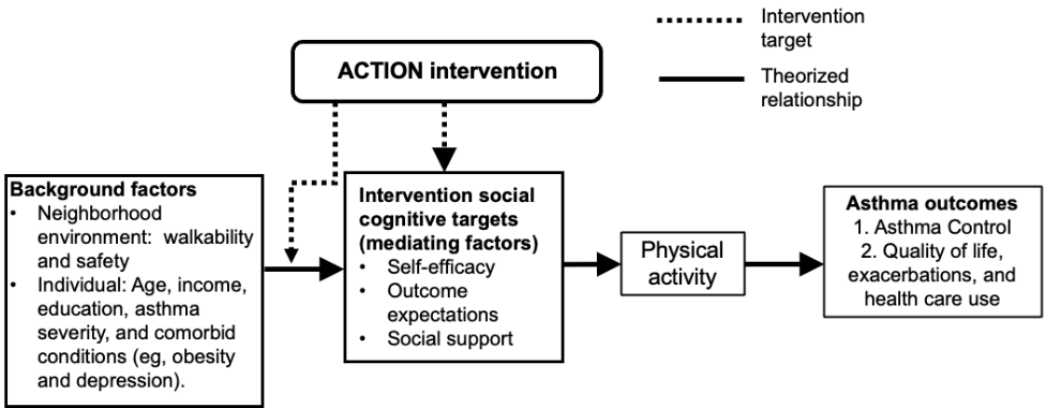
Conceptual Model

The conceptual model that guided this project is shown in Figure 1. Within the conceptual framework, explanatory relationships among various determinants of PA or factors that influence behavior, intervention strategies, and subsequent participant outcomes have been examined. Important contextual factors include individual demographics (age, income, and education), disease severity, comorbid conditions, and neighborhood environment. To explain motivation to become more physically active, the intrapersonal characteristics of self-efficacy (belief in one's ability to perform a behavior), social support, and self-regulation (the process of guiding one's own thoughts, behaviors, and feelings to reach goals) are used [19].

These intrapersonal characteristics can influence an intervention and thereby influence behavior change. The intervention is targeted to the characteristics of Black women with asthma, such as environmental safety factors, current health, and intrapersonal characteristics. The participant outcomes are those elements that are improved by exposure to the intervention, including PA and health outcomes. The framework specifies that participant outcomes are dynamically related; the greater

the tailoring of the intervention to the determinants of the behavior, the greater the likelihood of positive outcomes. Theoretical support for the core elements of the ACTION intervention is derived from social cognitive theory and augmented by self-regulation theory, which stems from social cognitive theory [19,20].

Figure 1. Conceptual framework. ACTION: A Lifestyle Physical Activity Intervention for Minority Women With Asthma.



Objectives and Aims

The proposed study has 3 aims involving a total of 224 sedentary urban Black women with asthma.

- Aim 1A is to determine the efficacy of ACTION intervention on asthma control. We will test the hypothesis that at 24 weeks, Black women with asthma who receive the intervention will have a greater improvement in asthma control (asthma control questionnaire [ACQ]) compared to women in the education control group (efficacy end point).
- Aim 1B is to examine the maintenance effects of the ACTION intervention on asthma control at 48 weeks. We will examine the long-term impact of the intervention on asthma control (eg, control and quality of life). We hypothesize the effects of ACTION on asthma outcomes will be maintained at 48 weeks.
- Aim 2 is to explore the behavioral mediators (eg, self-efficacy, social support, self-regulation, and daily PA levels) and contextual moderators (eg, baseline asthma severity, neighborhood environment, comorbid conditions, and social determinants of health) that contribute to treatment responsiveness. Mediation and moderation analyses will be performed with behavioral mediators and contextual moderators.
- Aim 3 is to assess the reach and implementation potential of ACTION. Reach will be measured by the number of potential participants (based on the recruitment pool) who are randomized into the study. Implementation potential will be measured using a mixed methods approach to identify important explanatory factors underlying the performance of the intervention components.

Methods

Project Overview

This study uses a theory-driven intervention (ACTION) to deliver a 24-week lifestyle PA intervention designed for and by urban Black women with asthma. Participants are recruited through 2 urban health care systems that care for a diverse urban Black population. Patients are randomized to one of two groups: (1) ACTION intervention (group sessions, PA self-monitoring, and text-based support for goal setting) or (2) education control (an individual asthma education session and text messages related to asthma education). Participants are followed for an additional 24 weeks after the intervention to assess for the maintenance of intervention effects on asthma health outcomes.

This efficacy study focuses on asthma outcomes, explores behavioral mechanisms of the intervention, and assesses factors that influence its reach and implementation potential.

Ethical Considerations

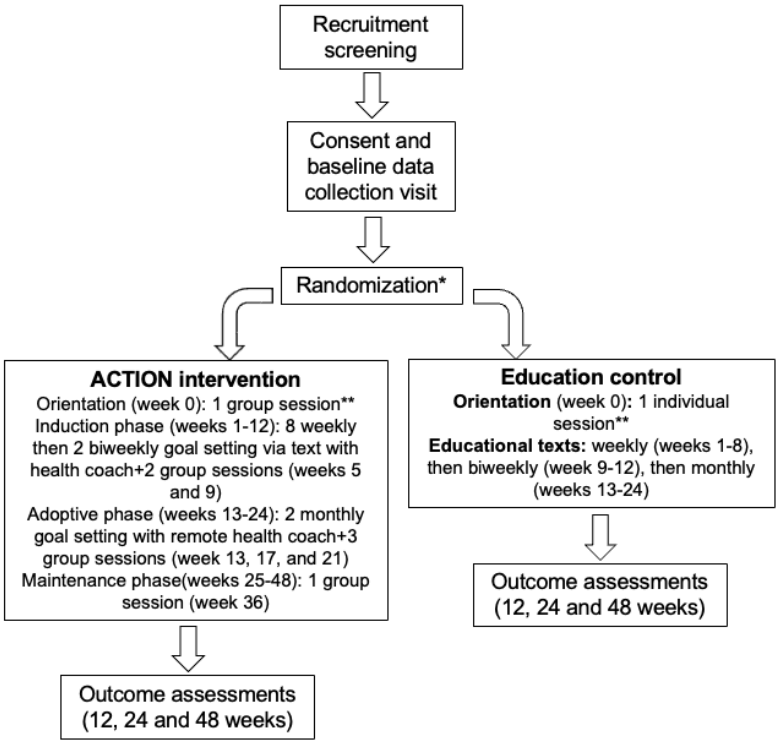
This study is conducted in accordance with the Declaration of Helsinki and the International Conference on Harmonization Good Clinical Practice guidelines and approved by the relevant institutional review boards at the University of Chicago (22-0911). The University of Illinois Chicago and the University of Texas at Austin have ceded institutional review board reliance to the University of Chicago institutional review board. This study has been registered at ClinicalTrials.gov (NCT05726487).

Study Design

This is a 2-arm RCT enrolling participants at the University of Chicago and the University of Illinois at Chicago in which 224 Black women with asthma will be randomly assigned to an education control group or receive ACTION intervention for 24 weeks (Figure 2). The remaining 24 weeks is the maintenance phase, and participants in the intervention group will receive 1 booster group session at ~36 weeks. Assessments will occur at 0, 12, 24, and 48 weeks.

The primary efficacy end point is a change from baseline to week 24 asthma control as assessed by asthma control questionnaire-6. We hypothesize that ACTION will be superior to education control for improving asthma control by week 24. The 48-week time point is important for examining behavioral mediators, contextual moderators, and maintenance of intervention effects.

Figure 2. Study design. ACTION: A Lifestyle Physical Activity Intervention for Minority Women With Asthma. *Participant must return accelerometer and have adequate data (10 hours of data for 3 days or more) prior to randomization **Individual/Group sessions are in-person except group session 3 and 5 which are remote.



Participants and Eligibility

Recruitment

The primary recruitment strategy uses electronic health records to identify patients who meet the basic inclusion criteria: age≥18 years old, female, Black or African American, International Statistical Classification of Diseases, 10th Revision (ICD-10) diagnosis of asthma, and no ICD-10 diagnosis of chronic obstructive pulmonary disease (Textbox 1). An electronic health record data of patients meeting these criteria is obtained for each respective institution. Patient registries, in-clinic referrals, and flyers are also used as recruitment methods. Emails, SMS text messages, and postcards containing information about the study and a link to the eligibility screening survey are sent to randomly selected batches of potential participants.

Textbox 1. Inclusion and exclusion criteria for the study.

Inclusion criteria

- Self-identify as female and Black or African American
- Age≥18 years
- Physician diagnosed asthma that is suboptimally controlled based on Asthma Control Test (<20) or history in the past year of an asthma exacerbation (a need for systemic corticosteroids or hospital admission or emergency treatment for worsening asthma)
- Willing to enroll and provide written informed consent
- Willing to be randomized to 1 of the 2 study arms
- Has a smartphone or tablet with unlimited texting capabilities and uses text messaging at least daily

Exclusion criteria

- Plans to move from the Chicagoland area during the study period
- Unable to ambulate without the use of a wheelchair or scooter
- Currently pregnant, less than 3 months postpartum, or pregnancy anticipated during the study
- Significant medical (eg, unstable heart disease, uncontrolled high blood pressure, active cancer treatment in the past 1 year, and end-stage organ failure) or psychiatric (eg, active bipolar disorder and psychosis) comorbidities
- Diagnosis of chronic obstructive pulmonary disease (emphysema or chronic bronchitis) suggested by patient report of doctor diagnosis or smoking history (≥20 pack year history)
- A contraindication to exercise as indicated by the exercise assessment and screening tool unless written permission by a health care provider
- Participation in another structured physical activity program
- Asthma exacerbation, defined by an urgent care visit for asthma in the last 4 weeks, or the need for an acute course of systemic corticosteroids for asthma in the last 4 weeks
- Family or household member of another participant or staff member
- Inability to speak, read, or understand English
- Investigator discretion for safety or protocol adherence reasons

Eligibility Screening

Potential participants can self-screen using a REDCap (Research Electronic Data Capture; Vanderbilt University) eligibility screening form. This screener is accessed by scanning a QR code on this study's flyers and postcards or through a link that may be emailed or texted to potential participants. This survey is also verbally administered by the study staff over the phone.

If potential participants are immediately eligible, they are asked to schedule their baseline visit. Those who do not immediately meet the eligibility criteria or need medical clearance will be contacted by the study staff.

Baseline Assessment, Randomization, and Blinding

The baseline visit begins with the informed consent process facilitated by study staff. Participants are asked to complete study surveys (patient demographics, asthma demographics, Asthma Control Questionnaire, Asthma-related Quality of Life Questionnaire, Asthma Safety Measures, Adult Asthma Adherence Questionnaire, Patient Health Questionnaire Depression Scale Scored, PROMIS SF v 1.0-Sleep Disturb, SDQ-SA, PWMAQ, Exercise Self-Regulation, Self-efficacy for Walking Scale, Social Support for Walking Scale, Social Support and Exercise Survey, Active Where); baseline spirometry [21] and anthropometrics are obtained by trained study staff. Participants at 1 site are also asked to wear an accelerometer for 7 days.

Eligible participants will be randomized following recruitment and of all baseline measures, using stratified randomization in REDCap at each site after baseline data collection is complete. Stratification will be based on age (18-45 and 46+ years) and current BMI (≤25 and >25 kg/m^2). Blinding of participants is not feasible for this study. Participant's health care providers are blinded to group allocation.

Intervention

Overview

ACTION is a behavioral lifestyle intervention that promotes lifestyle PA in accordance with the current PA guidelines in the United States [17]. This intervention is a 24-week group lifestyle PA intervention consisting of 7 group sessions, PA self-monitoring, and text-based support for goal setting. The active period of the intervention is 24 weeks. Trained interventionists and remote health coaches deliver the intervention via a combination of in-person group walking sessions and text-based goal setting. Trained research staff provide a Fitbit for the participant and deliver the text messaging component of the intervention.

Group Sessions

Session 1

Participants attend an in-person or Health Insurance Portability and Accountability Act (HIPAA)–compliant audio or video

platform (eg, Zoom) group session on "Becoming Physically Active with Asthma." The group session includes a 45-minute asthma education session, based on the American Lung Association's Asthma Basics course, led by a Black, female asthma educator. Participants in the intervention group are given a manual with educational materials, which include information on increasing PA with asthma. Following the education content, each intervention group participant receives a Fitbit Charge 5 for self-monitoring of steps and heart rate. Specific step-by-step instructions on setup and use of the Fitbit monitor are provided with individual support as needed in the group setting. The study team reviews Specific Measurable Attainable Relevant and Time bound (SMART) goal setting [22], assesses text preferences, and sets individualized step goals based on their baseline PA levels.

Sessions 2-7

Women attend a 2-hour, in-person, or video remote group meeting at a convenient time during the induction or adoptive phases (weeks 0-24) and once during the maintenance phase (weeks 25-48). Participants from the individual sites are kept separate and do not attend group sessions together. Group session content is described in Textbox 2.

After 24 weeks of active intervention, participants randomized to ACTION no longer receive remote health coach text messages and attend monthly group sessions. A booster group session at 36 weeks will occur for the intervention group only.

Textbox 2. Content of ACTION (A Lifestyle Physical Activity Intervention for Minority Women With Asthma) group sessions.

Session 1 (week 0)

- Safely exercising with asthma: "Becoming Physically Active with Asthma"
- Receive Fitbit and discuss setting step goals

Sessions 2-7 (weeks 5,9,13, 17, 21, and 36)

- Video (10 minutes) on physical activity topics (eg, identifying realistic expectations for PA outcomes with asthma, handling personal and environmental problems that interfere with physical activity, and handling relapses)
- Group discussion and problem-solving (45 minutes)
- Group stretching and walking (20 minutes)

PA Tracking as an Intervention Component

Each intervention participant is given a Fitbit Charge 5 that counts steps per day, distance, active minutes (time spent in moderate to vigorous activity), sedentary time, and heart rate. Participants work with health coaches (as above) to set their step goals and monitor their PA on the Fitbit App. Participants are required to download the Fitbit app on their phone or tablet. The Fitbit mobile app and device require the creation of individual digital accounts with Google for all study participants. During the study, participants will use their study-created Google account to interact with the features of the Fitbit mobile app. Upon completion of the program, participants will be able to transfer their Fitbit device to an account using their personal Google login for continued use of the device.

Fitbit data are managed through iCardia. The iCardia platform [23] is used to remotely collect real-time PA data from study participants' Fitbit app and to send personalized SMS text messages to participants' cell phones (Figure 3). iCardia (University of Illinois at Chicago) is a secure password-protected system that comprises user-friendly visualization and data exportation tools, allowing key research personnel to view participants' Fitbit data in the form of graphs every time participants sync their wearable tracker with the Fitbit mobile app. Study participants do not have access to iCardia; they will only interact with the Fitbit mobile app and activity tracker. The SMS text messaging feature is integrated with the iCardia clinical dashboard and uses Twilio's application programming interface to send messages via the SMS protocol.

Figure 3. Screenshot of the iCardia platform.

Remote Health Coach and Individualized Step Goal Setting and Tracking

Study participants will work with the health coach through texts to set a SMART goal [22]. This will begin within 1 week of the completion of session 1. The process includes contingency planning (what if…). Goals will be set once a week for 8 weeks, every 2 weeks for weeks 9-12 sessions, and monthly through 24 weeks. We have set a realistic PA goal for intervention participants of 3000 steps per day of moderate intensity above each participant's baseline (based on Fitbit-based step counts per day), recognizing that baseline levels of activity will vary across individuals. Thirty minutes of walking at moderate intensity produces an estimated average of 3000 steps in most free-living adults [24]. Health coach texting will be managed through iCardia (described above). Health coaches can monitor Fitbit steps to evaluate goal attainment and send texts to support self-regulation via the text messaging protocol. The Fitbit data collected in iCardia will be used to generate process indicators but not as the primary measure to assess changes in health-enhancing PA (moderate to vigorous intensity physical activity [MVPA]). Health coaches will be sensitive to health status that may impact the ability to escalate steps. Weekly meetings will be conducted with health coaches to ensure texts are following the SMART goal framework and discuss any safety issues or questions.

Education Control Group

The education control group will receive (1) 1 group asthma education session similar to session 1 described above and (2) text messages with asthma facts and tips (see Table S1 in Multimedia Appendix 1). The asthma education session consists of a 45-minute video on basic asthma education based on American Lung Association's asthma basics content followed by a live Q&A with an asthma educator. The video was culturally tailored using feedback from stakeholders and includes a Black female asthma educator and other Black women with asthma. The SMS text messages with asthma facts and tips were also developed using feedback from stakeholders and will be delivered twice weekly (weeks 1-8), biweekly (weeks 9-12), and monthly (weeks 13-24). At the completion of the study, participants in the education control group will receive the study manual, a pedometer, and access to the videos presented in the ACTION intervention group sessions.

Measures

Asthma Measures

Asthma control will be measured using the validated ACQ [25]. Asthma quality of life will be measured using the mini-asthma quality of life measure, a well-validated survey [26]. Asthma exacerbation will be defined as the need for systemic corticosteroids, hospital admission, or emergency treatment for worsening asthma. This will be self-reported, and the time frame will be captured at 3- and 6-month time frames (Table S2 in Multimedia Appendix 2). Health care use is defined as the number of urgent care or emergency room or hospitalization visits. This will be self-reported, and the time frame will be in 3- and 6-month time frames (Table S2 in Multimedia Appendix 2). Spirometry will be performed using standard procedures at baseline, 24, and 48 weeks. Asthma severity will be assessed per the National Heart Lung and Blood Institute National Guidelines for Asthma management based on current asthma treatment [27].

PA Measures

Given that the intervention centers on increasing PA levels through walking, it is important to accurately assess the changes in health-enhancing PA among intervention and control participants throughout the study period. Health-enhancing PA

is defined as having MVPA and can occur in the domains of discretionary time, travel, home, or work [17]. Our intervention focuses on increasing overall MVPA levels by adding time spent in moderate-intensity PA during discretionary time, through walking. We will measure domain-specific PA through self-reported data for the full sample. We will also measure PA objectively in half of the sample, as this is a more cost-prohibitive assessment instrument.

Accelerometry

MVPA (minutes per day) at baseline (before randomization), 12, 24, and 48 weeks will be assessed objectively using accelerometry. During each assessment period, accelerometer data will be collected over 7 consecutive days using the ActiGraph wGT3X-BT activity monitor (ActiGraph, LLC), a small, triaxial piezoelectric accelerometer (4.6 cm×3.3 cm×1.5 cm; 19 g) that will be worn around the waist on an elastic belt. Accelerometry data will be collected using a standardized protocol. ActiGraph monitors have been extensively validated in laboratory and free-living conditions [28]. At the first data collection appointment, study staff will introduce the accelerometer and provide participants with verbal instructions and a package that includes (1) an initialized accelerometer, (2) detailed written wear instructions, (3) tracking log, (4) contact information, and (5) a padded prepaid trackable envelope to return the devices after concluding the 7-day wear period.

In the tracking log, participants will enter the (1) time they put the monitor on in the morning, (2) time removed it in the evening, and (3) time that the monitor was removed and replaced for ≥30 minutes throughout the day (eg, bathing or swimming activities). Raw triaxial data will be sampled at 40 Hz for 7 consecutive days. Once the accelerometer and tracking log are returned by the participant, data will be downloaded by the study staff and prepared for processing and analysis. Data will be processed using ActiLife software (ActiGraph) through a digitally matched filter, reintegrated up to a 60-s epoch, and screened for wear time using the Choi algorithm [29]. Weekly summary accelerometer estimates will be averaged (across days) for all participants with ≥4 valid days of ≥10 hours per day of wear time (minimum wear time to consider the data valid for analysis). If insufficient wear time is detected, the participant will be contacted and asked to rewear the device to provide valid data. Average accelerometer counts (per minute per day) will be calculated using summed daily counts detected over wear periods, and vector magnitude will be calculated as the square root of the sum of the squares obtained from each axis (ie, 3) of data. Time (ie, minutes per day) spent sedentary and in light-, moderate-, and vigorous-intensity physical will be estimated using Freedson cut points (for adults) based on triaxial data [30]. Data checks, including a descriptive analysis of the accelerometer estimates, will be performed quarterly.

Self-Reported Discretionary Time and Travel-Based PA

Self-report data adds rich context that accelerometers lack [31]. Our self-report measures will provide information on the domain (eg, recreational and transportation) of PA. These data will be important to quantify the effect of the intervention in increasing leisure-time walking (its main intention), as well as any potential unintended consequence in increasing or decreasing time spent on other types of activities. Participants will self-report PA using the Past Week Modifiable Activity Questionnaire (PWMAQ). The Modifiable Activity Questionnaire is a self-report instrument that assesses leisure PAs over the past 7 days [32,33]. The structure of the PWMAQ is similar to the Modifiable Activity Questionnaire and includes questions that quantify occupational activity (eg, sedentary, low, and high active occupations), active transport, and common sedentary behaviors. The PWMAQ includes information on 38 leisure-time PAs common among diverse adults. The PWMAQ has been shown to be a reliable and valid measure of PA compared to accelerometry and physical fitness [34,35].

Additional PA-Related Measures

Self-efficacy for walking, social support for exercise, and self-regulation will also be assessed as they constitute behavioral mediators for attaining increased PA levels, and the physiologic response to increases in PA, respectively. Details on these measures can be found in Table S3 in Multimedia Appendix 3.

Contextual Moderators

Contextual moderators will be collected at the in-person baseline data collection visit. The neighborhood environment will be assessed using a validated survey about neighborhood safety, crime, and areas to engage in PA [36]. Social determinants of health, including age, income, education level, marital status, and economic hardship will be assessed using validated questions that the principal investigator has used in prior studies. These have been chosen as they can impact PA levels [37,38]. The comorbid conditions of interest are obesity and depression as they are known to moderate PA levels and asthma outcomes [39,40]. Obesity is defined as a BMI ≥30 kg/m^2, and depression will be assessed by a validated depression questionnaire, Patient Health Questionnaire Depression Scale-8 [41].

Implementation Measures

We propose an explanatory sequential mixed methods design in which quantitative analyses are followed by qualitative analyses to maximize our understanding of the implementation of ACTION [42,43]. The quantitative data will include detailed process metrics and surveys, and qualitative data will include brief interviews with participants. Process metrics will be collected based on the number of participants screened and randomized. Surveys to assess the acceptability of the intervention components will be collected at the end of each group session and at the end of the intervention (after group session 6). Evaluations of the intervention will be conducted using open-ended questions with intervention participants at 24- and 48-week data collection visits. Questions will focus on aspects of the intervention they found helpful, barriers to engagement in each component of the intervention (eg, groups, remote health coach, and Fitbit), and suggestions for improvement. General prompts will be used to orient qualitative data descriptively on the core intervention components. The qualitative portion of the intervention will be conducted by trained and experienced data collectors at the end of the brief quantitative data collection, audio-recorded, and professionally transcribed.

Data Analysis Plan

Data will be analyzed based on the intent-to-treat principle in this multisite RCT. We will use descriptive statistics to describe the sample by intervention group, and any assumption behind each statistical method will be examined during the analysis. Missing data will be handled by each model's assumption or by using multiple imputation with a fully conditional specification approach, as appropriate [44]. A 2-sided *P* value less than .05 would be considered statistically significant, and the exact *P* value will be reported. All quantitative analyses will be conducted by using SAS (version 9.4; SAS Institute Inc) and R (version 4.0.2; R Core Team).

The primary research outcome for aim 1A is the differences in ACQ score between baseline and 24 weeks for aim 1A and between baseline and 48 weeks for aim 1B. This will be compared between education control and ACTION intervention groups first using 2 sample *t* test to examine the efficacy and the maintenance effect of the proposed intervention, respectively. Two-tailed statistical tests will be conducted throughout the entire analysis unless specified otherwise. A linear mixed model with a subject-level random intercept then will be built on the same outcome in its original scale having time (12 weeks vs baseline; 24 weeks vs baseline; 48 weeks vs baseline), group (ACTION vs education control), and their interaction as the main factors while adjusting for site, recruitment wave, and any imbalanced confounder [45]. This model will allow us to estimate the efficacy of the intervention through the interaction terms after controlling for confounders and subject dependence. Moreover, any missing data can be handled by this model under the missing at random assumption. The estimated coefficients on the mean scale of the outcome will be reported, along with their SEs, 95% CIs, and *P* values. The similar modeling approach mentioned above using generalized linear mixed models instead will be applied to secondary outcomes (asthma quality of life, health care use, and asthma exacerbations) as secondary analyses.

For aim 2, we will explore the potential mediation effects of multiple variables on the relationship between the intervention and clinical outcomes. That is, a portion of the intervention effect on an outcome may be going through the path via a mediator indirectly. Through mediation analysis, the direct effect, the indirect effect also known as the mediated effect, and their total effect will be measured using the approach by Yu et al [46,47] along with their CIs via bootstrapping. The multiple mediators of interest here include social support, self-regulation, self-efficacy, and PA, while the clinical outcomes of interest are the ACQ score and mini-AQLQ score. To avoid the problem of mediation analysis with cross-sectional data, we define the mediation relationship generally noted as *X-M-Y*, using X_{BL} as the exposure at baseline, $M_{j,24w}$ as the *j*th mediator at 12 weeks (j=1,…, 6), and $Y_{k,48w}$ as the *k*th outcome at 48 weeks (k=1,2) [48]. As a secondary analysis, multilevel mediation analysis using the method by Yu and Li [49] will also be considered. For moderation analysis, we will examine moderators including comorbid conditions (depression and obesity), social determinants of health (age, income, and education level), asthma severity (mild, moderate, and severe), and neighborhood environment (walkability and safety) by separately adding their interaction terms with the treatment group to the models mentioned for aim 1A to estimate their moderating effects on treatment responsiveness. We will focus on several plausible behavioral mechanisms. We anticipate improved PA will lead to improved asthma outcomes (control and quality of life) and a reduction in self-reported exacerbations and emergency health care use.

For aim 3, we will report process metrics, such as recruitment rate, monthly to assess reach overall, within key patient subgroups, and each site. Simple descriptive statistics and 95% CIs will be used to summarize measurement for reach and implementation potential at the end of the study. To identify participant characteristics (eg, age, income, and education level) or site-level factors that may be associated with reach, we will examine those associations using the chi-square test or Fisher exact test for categorical variables and the Kruskall-Wallis test for continuous variables. For analysis of qualitative data, the deidentified interview transcripts will be uploaded to the qualitative data software (eg, NVivo [OSR International] or Dedoose [University of California, Los Angeles]). Qualitative assistants will work with qualitative experts to code the data. All coders will initially read all 112 transcripts to become familiar with the data. Thematic interpretation will focus on individual, social, and structural factors associated with acceptability and reasons for variability in uptake and effectiveness of the intervention components. Ten transcripts will be independently coded by all coders. The codes will be reviewed and discussed collectively to develop a shared understanding of how the codes should be applied to the transcripts. This process of independent coding will be repeated ≥2 times until a consistent agreement is reached. Coded transcripts will be sorted to identify thematic groupings. The thematic groupings will be reviewed to identify emergent themes within each domain of the coding framework and quotes that best represent each domain.

Results

This project received funding in August 2022 and received institutional review board approval in July 2022. The first year of this project was focused on hiring and training staff, regulatory approvals, setting up data collection processes, and recruitment. We pilot-tested our recruitment and intervention procedures and began recruitment in April 2023. At the time of manuscript submission, 76 participants have been recruited. We anticipate study completion in 2027.

Discussion

Principal Findings

As one of the first lifestyle PA interventions in asthma to explore behavioral mechanisms, and the only focusing on a group most in need—Black women, this study is expected to contribute importantly to this very limited body of literature and offer useful insights for PA interventions in asthma. Our intervention focuses on walking as a lifestyle approach in urban Black women with asthma, which has been shown to be the preferred method of PA among Black women and people living with

asthma. Walking is affordable, accessible, and sustainable even for Black women residing in urban neighborhoods with high levels of crime or low-resourced neighborhoods. This approach to PA also considers activities done in leisure, household, transportation, and occupational roles. We also use a patient-centered perspective, which has yet to be used in developing PA interventions in adults with asthma. Modifications to the intervention leverage the high levels of technology use in this population while reducing the participant burden associated with in-person sessions [50]. Moreover, from a public health standpoint, interventions using technology-based platforms can provide researchers the ability to reach a large number of people at a relatively low cost, which ultimately leads to a greater public health impact.

Anticipated Challenges and Limitations

As this study will take place in the Midwest, there is a concern that the weather may have an impact on the ability to engage in walking during the winter and even summer months. The intervention addresses this through providing free or low-cost resources on where to exercise indoors during challenging weather. Furthermore, the study team tailors the text messages to local weather and air quality alerts. For example, during the Canadian wildfires in July 2023 when Chicago was experiencing the poorest air quality in the world, we cautioned participants to monitor the air quality index before going outdoors but also provided alternatives to walking outdoors. During our pilot, the participants requested more flexibility with the in-person sessions and have the option to remote in with a secure video platform, which we incorporated into this study. There may still be challenges in having participants attend all the in-person group sessions, but we will work with the participants to find an optimal time to attend, and if needed, allow for a hybrid group session model with some participants in-person and others virtual. Although not an issue in pilot work, it is possible that differential dropout across study groups may occur. To mitigate this concern, participants in the control arm will receive asthma education session text messages at a similar frequency as the intervention participants. In the pilot study, the asthma education session was valued by participants in the control arm. Nonetheless, should problems arise, coinvestigators and a recruitment or retention core will be engaged for input on changes to improve retention. Finally, the information gained from our implementation measures will be critical for revising the conceptual model and rethinking the choice of intervention components to be tested in future studies and will also inform theory development in implementation science.

Conclusions

The findings from this study will provide insight into the next steps for addressing PA in Black women with asthma. It will deliver a new approach to PA interventions in chronic lung diseases such as asthma and a better understanding of the underlying behavioral mechanisms among a high-risk underresearched population. This field is in its infancy and showing the short- and long-term efficacy of a culturally tailored lifestyle PA intervention in a vulnerable patient population, as well as identifying the behavioral mechanisms, are important and will be critical. This study will also set a standard for future studies in minority populations with other disease conditions associated with low levels of PA.

Acknowledgments

The authors thank the Clinical Research Staff at The University of Chicago and UI Health for conducting our study visits. The authors also thank Julissa Acevedo, Senior Systems Analyst, and REDCap Administrator at The University of Chicago for her continued guidance. This research was supported by the National Institute of Minority Health and Disparities under Award Number R01MD017277. The project described was also supported by the National Center for Advancing Translational Sciences, National Institutes of Health (NIH), through Grant Award Number UL1TR002003. The content is solely the responsibility of the authors and does not necessarily represent the official views of the NIH.

Authors' Contributions

ED and ET drafted and edited the manuscript. AC, YFC, DEH, SK, WK, IM, EO, KP, VGP, TR, DS, and BW reviewed and edited the manuscript. LKS assisted with study conceptualization and reviewed and edited the manuscript. SMN conceptualized the study and assisted with drafting and editing the manuscript. YFC drafted the statistical analysis plan.

Conflicts of Interest

SMN reports funding from National Institutes of Health (NIH), Asthma and Allergy Foundation of America, and receives consulting or royalty fees from GlaxoSmithKline, PRIME education, Wolters Kluwer, and Springer. VGP reports funding from the NIH and Agency for Healthcare Research and Quality and receives consulting fees from Humana regarding patient education programming.

Abstract

Background: Individuals with physical disabilities experience higher rates of chronic health conditions than individuals without physical disabilities. Self-management programs that use health coaching are effective at eliciting health behavior change in health outcomes such as goal setting, adherence, and health care use. Additionally, web-based resources such as telehealth-based technologies, including SMSS text messaging, web-based applications, and educational multimedia content, can complement health coaching to improve health-related behaviors and the use of health services. The complexity of studies using these resources requires a fidelity protocol to ensure that health behavior studies are administered properly.

Objective: The My Health, My Life, My Way fidelity protocol provides methods, strategies, and procedures of a multifaceted telehealth program for individuals with permanent physical disabilities and chronic health conditions. This health behavior study is a randomized controlled trial with four study arms: (1) scheduled coaching calls with gamified rewards, (2) no scheduled coaching calls with gamified rewards, (3) scheduled coaching calls with fixed rewards, and (4) no scheduled coaching calls with fixed rewards. To guide the fidelity protocol developed, we used the National Institutes of Health Behavior Change Consortium framework (NIH BCC).

Methods: The fidelity intervention protocol was developed by using the 5 primary domains provided by the NIH BCC: study design, provider training, treatment delivery, treatment receipt, and enactment of treatment skills. Following the NIH BCC guidelines and implementing social cognitive theory, this study is designed to ensure that all study arms receive equal treatment across conditions and groups. Health coaches and providers will be trained to deliver consistent health coaching, and thus participants will receive appropriate attention. Educational content will be developed to account for health literacy and comprehension of the material. Multiple fidelity intervention steps such as coaching call logs, regular content review, and

participant progress monitoring will translate to participants using the skills learned in their daily lives. Different monitoring steps will be implemented to minimize differences among the 4 treatment groups.

Results: My Health, My Life, My Way has been approved by the institutional review board and will begin enrollment in January 2024 and end in December 2024, with results reported in early 2025.

Conclusions: Intervention fidelity protocols are necessary to ensure that health behavior change studies can be implemented in larger real-world settings. The My Health, My Life, My Way fidelity protocol has used the guidelines by the NIH BCC to administer a telehealth intervention combined with health coaching for individuals with physical disabilities and chronic health conditions. This fidelity protocol can be used as a complementary resource for other researchers who conduct similar research using telehealth technologies and health coaching in real-world settings.

KEYWORDS

chronic health conditions; telehealth; health coaching; self-management; intervention fidelity protocol

Introduction

Background

According to the US Centers for Disease Control and Prevention, nearly 60% of Americans currently live with a chronic health condition, such as diabetes, heart disease, or hypertension [1]. The prevalence of individual conditions varies and affects activities of daily living differently for each subpopulation. For example, nearly 10% of Americans live with a version of diabetes, including type 1, type 2, and prediabetes [2]. For heart disease, the most common form is coronary artery disease, which is prevalent in the United States in approximately 7% of the population [3]. For example, individuals with physical disabilities experience higher rates of chronic conditions than individuals without physical disabilities [4,5]. Different approaches have been used to manage chronic health conditions and their related symptoms. Prior research has shown that self-management programs, which refer to one's ability to care for their health, are able to promote positive self-care, increase physical activity, and monitor dietary behavior for individuals with chronic health conditions [6].

Different approaches have been used to provide mechanisms for individuals with chronic health conditions to successfully manage their health. Telehealth interventions have been used as effective strategies for self-management across a variety of chronic health conditions [7-10]. A primary benefit of using telehealth technologies for self-management is the convenience of engaging in programs at flexible times and locations, such as home settings [11,12]. Telehealth programs also provide benefits for clinicians and health care providers, that is, the ability to engage with patients remotely to provide adequate care and promote healthy behaviors. However, there are no accessible and inclusive telehealth programs for individuals with physical disabilities. The lack of inclusive programming for individuals with physical disabilities highlights barriers that this population experiences, including transportation and inadequate time to participate in telehealth interventions [13].

The lack of programming for individuals with physical disabilities demands an immediate remedy. Therefore, we are developing a telehealth program that includes a website with inclusive multimedia educational content combined with access to trained health coaches to provide optimal self-management programming to individuals with physical disabilities. As part of this intervention, we will use an artificial intelligence (AI)–assisted, customized lifestyle program to increase the overall fidelity of the intervention and optimize health coaching resources for telecoaching.

Reporting Fidelity

To ensure that a health behavior intervention is delivered as intended, it is necessary to develop fidelity protocols to minimize issues with protocol implementation. The complexity of telehealth interventions, the research designs used, and the multiple development teams (health coaches, technical staff, etc) introduce several challenges to maintaining overall study fidelity. Because variations exist in health behavior studies, guidelines have been developed to provide recommendations and strategies for using fidelity concepts in future projects. The National Institutes of Health Behavior Change Consortium (NIH BCC) published recommendations for implementing fidelity concepts for health behavior interventions. The specific areas covered by the NIH BCC include recommendations for study design, provider training, treatment delivery, treatment receipt, and enactment of treatment skills [14]. Therefore, we aim to use the guidelines set forth by the NIH BCC to describe and report the fidelity protocol for the My Health, My Life, My Way study. This intervention will use mobile health technology in conjunction with health coaching to create a comprehensive web-based self-management program for individuals with physical disabilities who experience chronic health conditions. Furthermore, the development of this protocol addresses the 5 domains of fidelity monitoring set forth by the NIH BCC and will provide valuable insight into reproducing future telehealth interventions.

Methods

Overview of the Study and Fidelity Protocol

The My Health, My Life, My Way study aims to optimize an AI, telehealth-based self-management program for individuals with physical disabilities and chronic conditions. This program

includes a telecoaching website where participants can communicate with health coaches through different communication mediums (ie, texting and phone calls), access customized, educational material related to their specific health conditions, and track health-related behaviors such as physical activity and nutrition. Additionally, the program aims to actively encourage positive lifestyle changes by incorporating features that promote healthy behaviors. These features encompass aiding users in creating well-balanced meal plans and encouraging regular physical activity. By integrating these elements, the program provides a comprehensive toolset for both fostering healthier habits and receiving expert guidance, ultimately contributing to participants' overall well-being.

Within the website system, AI-embedded technology will be implemented that will have access to an ingredient and recipe database system which will offer personalized dietary suggestions based on the participant's dietary preferences or restrictions, cooking resources, financial status, and cooking skills. Similarly, the system will be able to provide physical activity recommendations based on health status, preferred activities, and climate. Health coaches will have access to participants' web-based website to monitor and approve health behavior changes and goals set by the participants. Individuals will be able to communicate with the health coaches through multiple communication mediums, including smartphone apps, SMS text messaging, phone calls, and conversation agents (ie, Amazon Echo). Educational content provided on the website will be created and tailored to individuals with physical disabilities. The combination of these technologies, with a focus placed on the participant, will minimize the time, effort, and costs of using health coaching staff; promote adherence and regular use of the system; and ultimately promote health self-management.

The purpose of this study is to use the Multiphase Optimization Strategy to pilot-test and identify the optimal combination of intervention components that are effective in improving health-related quality of life in adults with physical disabilities and chronic health conditions. We will be using a pilot randomized controlled trial study design, in which 200 adults with physical disabilities and chronic health conditions will be randomized into 1 of 4 groups with 50 participants in each group: (1) scheduled coaching calls with gamified rewards, (2) scheduled coaching calls with independent rewards, (3) no scheduled coaching calls with gamified rewards, and (4) no scheduled coaching calls with independent rewards. Those not receiving scheduled coaching will be able to communicate with health coaches as needed to discuss health-related behaviors and goal setting. Participants will be able to communicate with the health coaches through communication methods such as SMS text messages, phone calls, and the telehealth website. Recruitment will be conducted nationally through web-based advertisements and social media accounts associated with the National Center on Health, Physical Activity and Disability, and ResearchMatch platform. Inclusion criteria include (1) 18 years of age or older; (2) diagnosis of heart disease, chronic lung disease, or type 2 diabetes; (3) living with a permanent physical disability such as spinal cord injury, spina bifida, multiple sclerosis, or stroke; (4) ability to converse and read English; and (5) smartphone or computer access.

Within the intervention, participants will be randomly assigned to 1 of 4 groups (Table 1). The total duration of the program is 24 weeks (6 months). Those receiving scheduling coaching calls will have weekly coaching calls with trained health coaches who will provide customized recommendations and education based on participant needs, including physical activity, nutrition, and other health-related topics. Those not receiving scheduled coaching calls will have the capability to contact health coaches through the telecoaching website, SMS text messages, or phone call to discuss similar health-related objectives. Participants will also receive a physical activity tracker (FitBit) to track activity during the program.

We incorporated the NIH BCC Treatment Fidelity recommendations to develop our fidelity protocol to monitor fidelity and ensure the external and internal validity of the intervention.

Table 1. Research design.

Gamification rewards	Coaching calls	
	Scheduled coaching calls	No scheduled coaching calls
Gamification-based rewards	Scheduled coaching calls with gamified rewards	No scheduled coaching calls with gamified rewards
Rewards independent of gamification	Scheduled coaching calls with rewards independent of gamification	No scheduled coaching calls with rewards independent of gamification

Ethical Considerations

The protocol for the My Health, My Life, My Way study was approved by the University of Alabama at Birmingham's institutional review board (300009485). Enrollment is expected to begin in January 2024 and study completion is expected to end in December 2024.

Study Design

Overview

The principles of the NIH BCC state that fidelity interventions must make certain that (1) appropriate theory and clinical practice are aligned with procedures and implementation, (2) treatment and dose across participants are equal, and (3) possible setbacks in intervention implementation are addressed. Textbox 1 provides the study design and monitoring plan for My Health, My Life, My Way.

Textbox 1. Fidelity of the study design and monitoring plan.

Goal

- Intervention will be congruent with the presented theory and practice
- Ensure equal treatment and dose are provided across and within all conditions
- Implementation setbacks are addressed

Description from National Institutes of Health Behavior Change Consortium

- Operationalize treatment to optimally reflect theoretical roots and precisely define variables most relevant to the "active ingredients" of the intervention
- Setbacks in implementation are addressed

Fidelity plan for My Health, My Life, My Way

- Monthly review of coaching call checklist
- Monthly review of coaching call logs
- Quarterly assessment of random coaching call audio recordings
- Quarterly assessment of education content provided to participants
- Weekly review of participant journals
- Monthly review of the telecoaching platform and events log
- Quarterly assessment of participant log-ins and time spent on the platform
- Weekly team meetings to discuss participant progress and protocol adherence

Presented Theory and Clinical Practices Are Congruent With Procedures and Implementation

My Health, My Life, My Way is grounded in Social Cognitive Theory and is designed to serve as a support system and communication platform among health coaches, participants with disabilities and their caregivers, and health care providers. The website will allow joint efforts for all parties to promote support among friends and family, regular physical activity and healthy dietary behaviors, and goal settings.

Equal Dose of Treatments Across Participants

As this study is a 2×2 factorial design, half of the participants will not receive scheduled coaching calls, while the other half will receive scheduled coaching calls. The duration and frequency of coaching calls for the scheduled group will be consistent to ensure an equal dose of calls. Those not receiving scheduled coaching calls will be able to contact the health coaches as needed during the study. For gamification elements, half of the participants will receive incremental rewards for engaging with the study. Such engagement includes but is not limited to (1) engaging with the telehealth website, (2) logging health behavior data, and (3) engaging with educational content. Half will receive independent rewards by performing similar tasks, thereby making the requirements for rewards equal across all participants. Additionally, all groups will be subject to the same data collection methods and study protocols.

Protocols for Setbacks in Implementation

All adverse events, emergencies, and issues with participant engagement and intervention will be collected and reported. We will track participant feedback and issues in adherence through the coaching logs and notes collected on the telehealth website, call logs, and staff logs.

Provider Training

All team members in the study have appropriate backgrounds and experiences in conducting every study activity. The multidisciplinary team includes technical, academic, and programmatic personnel who are able to perform all relevant tasks to ensure the successful completion of the My Health, My Life, My Way study. Academic staff include researchers who are charged with the overall administration of the program and trained health coaches who will engage with participants and provide relevant health-related content such as physical activity and nutrition. Technical staff are trained in developing the website that participants will use and will maintain the technological infrastructure through feedback from academic personnel and participants. Textbox 2 shows the strategies that we will use to monitor provider training based on the NIH BCC.

Textbox 2. Fidelity of provider training.

Goal

- Standardized training
- Ensure provider skill acquisition
- Minimize “drift” in provider skills
- Accommodate provider differences

Description from National Institutes of Health Behavior Change Consortium

- Similar training conducted by providers
- Providers trained using predetermined and defined criteria
- Reduce provider skill decay over time
- Ensure adequate training of providers with different levels of skills, experience, and background

Strategy used in My Health, My Life, My Way

- Health coaches will receive equal training through specified a curriculum
- Review and monitor coaching calls and call logs
- Evaluate audio recordings of coaching calls
- Collect audio recordings of coaching calls
- Regular team meetings to monitor participant progress and provider protocol adherence

Treatment Delivery

Overview

The NIH BCC provides guidance on how to ensure that interventions are delivered as intended. By using their guidance, we will address four concerns cited by the NIH BCC for treatment delivery: (1) controlling provider differences, (2) reducing differences within study groups, (3) ensuring adherence to study protocols, and (4) reducing contamination between study groups. Textbox 3 shows the strategies used in My Health, My Life, My Way.

Textbox 3. Fidelity strategy for treatment delivery.

Goal

- Control for provider differences
- Reduce differences within study groups
- Ensure adherence to the study protocol
- Reduce contamination between study groups

Description from National Institutes of Health Behavior Change Consortium

- Monitor and control for subject perceptions of nonspecific treatment effects (eg, warmth and credibility) across conditions
- Ensure that providers in the same condition are delivering the same intervention
- Ensure that the treatments are being delivered in the way in which they were conceived with regard to content and treatment dose
- Minimize contamination across treatment or control conditions, especially when implemented by the same provider

Strategies used in My Health, My Life, My Way

- Coaching call checklist
- Coaching call logs
- Audio recording of coaching calls
- Review of the telecoaching platform and its event log
- Team meetings to discuss participant progress and protocol adherence

Controlling Provider Differences

We have developed several strategies to monitor treatment delivery in the study. First, we have developed several coaching guides and scripts that will inform health coaches on what content to cover during coaching calls. We also plan to track the frequency of coaching calls through call logs. This will allow us to evaluate whether participants are receiving an equal number of coaching calls throughout the program. Next, we will collect audio recordings of coaching calls and randomly select calls to evaluate content delivery. The study team will conduct weekly team meetings to evaluate the progress of participants, health coaching curriculum, and protocol adherence.

Reducing Differences Within Treatment Groups

This study uses AI to enhance the fidelity of coaching sessions and minimize the effort required by health coaches to provide customized telecoaching. The program will use a telehealth website that will be an assistive tool for health coaches to deliver appropriate content to each participant during coaching call sessions. Health coaches will be provided standardized protocols and guidelines regardless of intervention group assignment. All educational content will be developed by experts to be inclusive of individuals with physical disabilities.

Regardless of group assignment, all procedures will be standardized to reduce differences within treatment groups. Coaches will focus on domains of health, including but not limited to physical activity, mindfulness, and nutrition. In these areas of health, the health coach will follow a progressive routine. For example, if a participant has a goal to increase physical activity participation, the health coach will start with lower activity goals with the ultimate aim of meeting physical activity guidelines of 150 minutes of aerobic activity per week. Similar approaches to nutrition and other health-related behaviors will be used. Although half of the participants will not receive scheduled coaching calls, those participants will be able to communicate with the health coaches through on-demand services through different communication methods regarding health behaviors they seek to improve. Health coaches will follow the same standardized protocols and guidelines for these participants as well.

Finally, the My Health, My Life, My Way telehealth website will include multimedia educational content (ie, videos, infographics, and SMS text messages) to deliver the intervention. All participants will have access to the material and can view them at their discretion.

Ensuring Adherence to Treatment Protocols

Health coaches will be given standardized checklists and protocols to ensure adherence to intervention treatment and delivery. The collection of call logs, monthly evaluation of audio recordings, and weekly team meetings will be conducted to further ensure that all protocols are regularly followed. All documents provided to the health coaches will serve as reminders to prepare for any coaching call and discuss relevant content with each participant.

Minimizing Contamination Between Conditions

All enrolled participants will be randomized into 1 of 4 groups (Table 1). Each group will have a developed protocol that will be given to the health coaches to use during the study duration. The coaches will use the same educational material that will be adapted for individuals with physical disabilities.

Receipt of Treatment

A primary element of the success of an intervention is its simplicity and applicability. The NIH BCC emphasizes treatment receipt, which involves assessing the degree to which participants understand the material provided to them and are able to perform health behavior–related skills during the intervention. My Health, My Life, My Way fidelity protocol seeks to achieve goals suggested by the NIH BCC (Textbox 4).

Textbox 4. Fidelity strategy for receipt of treatment.

Goal

- Ensure participant comprehension
- Ensure participant's ability to use cognitive skills
- Ensure participant's ability to perform behavioral skills

Description from National Institutes of Health Behavior Change Consortium

- Ensure that participants understand the information provided by the intervention
- Make sure that participants are able to use the cognitive skills taught in the intervention
- Make sure that participants are able to use behavioral skills taught in the intervention

Strategies used in My Health, My Life, My Way

- Use plain language for content with a target reading at fifth-grade reading level
- Review audio recordings of coaching calls
- Review participant website journals for physical activity, medication, and nutrition behaviors
- Review duration spent on the website by participants
- Conduct study team meetings to review participant progress in the intervention

It is estimated that 80 million US adults have low health literacy, which refers to the inability to listen effectively, read, understand, and interpret text and numerals related to health management, such as food labels, blood glucose measurements, and clinical instructions. Using plain language is important to increase health literacy for individuals with physical disabilities who experience chronic health conditions. As My Health, My Life, My Way is designed for populations with disability, we plan to use language at a fifth-grade reading level for all written content. Such modification to education material is necessary to increase participants' capacity to perform self-management skills.

My Health, My Life, My Way will incorporate principles of cognitive behavioral therapy to counsel participants on diet, exercise, and positive psychological behaviors like motivation and managing stress. Health coaches will use similar techniques derived from cognitive behavioral therapy to provide proper motivational interviewing that will assist participants in creating and following through on creating goals and implement strategies to meet those goals.

Enactment of Treatment Skills

The enactment of treatment skills refers to the ability to monitor and increase the capacity of participants to act on behavioral and cognitive skills in real-world settings that they learned during the study intervention [14]. Because we aim to promote long-term adherence to skills beyond the study duration, this program will use adapted and engaging content designed for individuals with physical disabilities in mind. Such content will include multimedia, textual, and graphical material and access through a telehealth website that will provide access to all content (Textbox 5).

Textbox 5. Fidelity strategy for the enactment of treatment skills.

Goal

- Ensure participant's use of cognitive skills
- Ensure participant's use of behavioral skills

Description from National Institutes of Health Behavior Change Consortium

- Ensure that participants use the cognitive skills provided at the intervention in appropriate life settings
- Ensure that participants actually use the behavioral skills provided in the intervention in appropriate life settings

Strategies used in My Health, My Life, My Way

- Review participant logs for physical activity, food, medication, etc
- Review the number of log-ins and time spent on the telehealth website
- Regular team meetings to assess participant progress and overall protocol adherence
- Review and monitor coaching notes collected during the intervention

My Health, My Life, My Way Telehealth Coaching Dashboard

This program provides a comprehensive telehealth coaching dashboard, a multifaceted solution designed to elevate participant engagement, communication, and monitoring within the realm of health and wellness. This dynamic platform seamlessly integrates 3 essential components. The telehealth coaching dashboard will serve as the pivotal interface enabling participants to establish effective and real-time communication with their designated health coaches. Through a variety of mediums such as SMS text message–based messaging and phone calls, participants can engage in meaningful conversations, seek guidance, and receive personalized support. For participant monitoring and tracking, the platform will offer robust capabilities for monitoring and tracking health-related behaviors, including physical activity, time spent on reading health-related contents, and watching minutes of exercise videos and nutritional choices. This helps health coaches to provide guidance to participants during health coaching sessions. Finally, the user interface for participants will receive an intuitive user interface tailored to their needs. This interface provides them with convenient access to an array of features, such as customized educational materials catering to their specific health conditions, exercise videos, and on-demand health coaching. Moreover, the interface empowers participants to log and manage their activities for promoting positive behavior changes, ranging from effective meal planning to encouraging regular physical activity through goal settings. Overall, through seamless communication channels, comprehensive monitoring tools, and a user-friendly interface, the telehealth coaching dashboard will empower participants to take charge of their health journey while receiving expert guidance and support. Figures 1-3 provide the samples of the telehealth coaching monitoring dashboard.

Figure 1. Sample fidelity monitoring dashboard screenshot—participant monitoring dashboard.

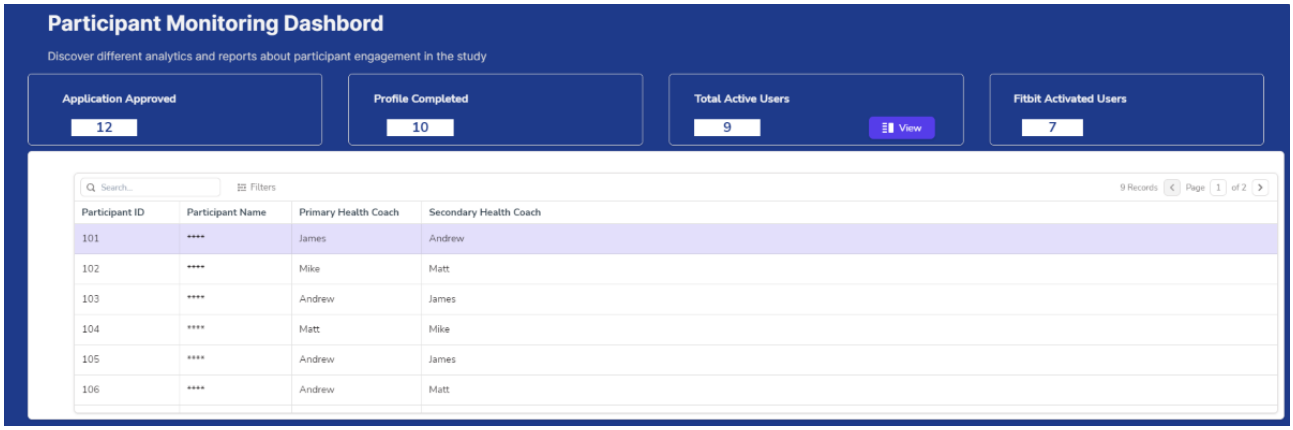

Figure 2. Sample fidelity monitoring dashboard screenshot—log-in analytics.

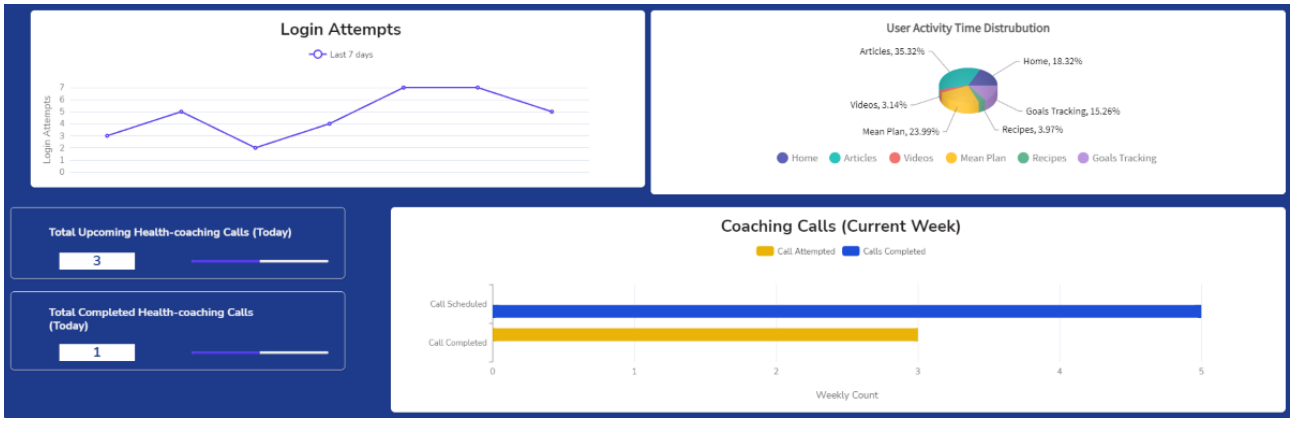

Figure 3. Sample fidelity monitoring dashboard screenshots —summary dashboard.

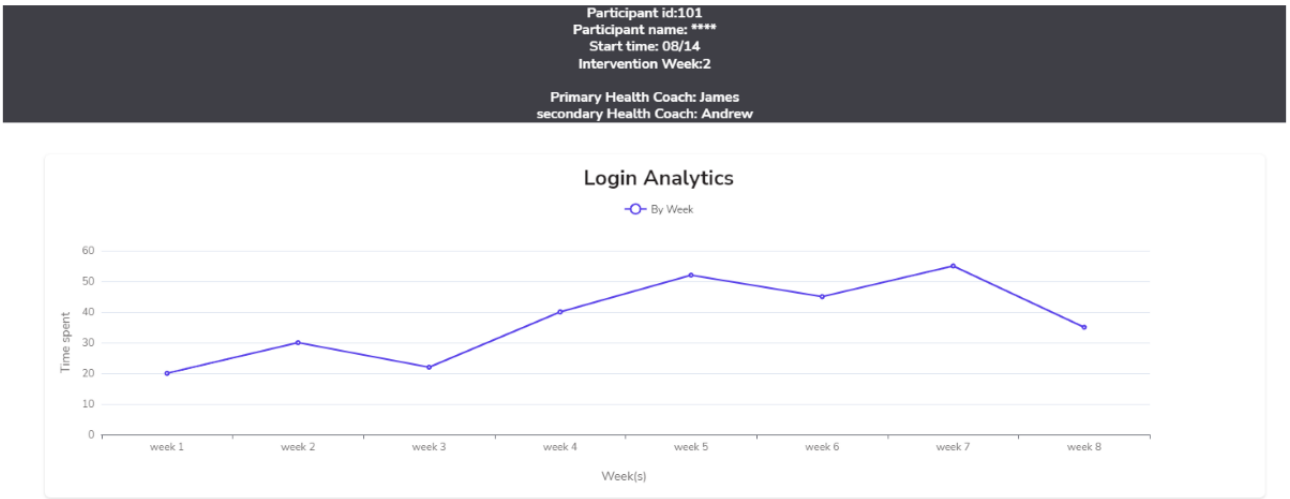

Results

Enrollment for the My Health, My Life, My Way program will begin in January 2024 and will end in December 2024. The results of this study will be reported in early 2025.

Discussion

The purpose of this paper was to outline and describe the intervention fidelity protocol for the My Health, My Life, My Way study. This randomized controlled trial aims to develop and evaluate a telehealth platform, which is paired with inclusive education content for individuals with physical disabilities who experience chronic health conditions. Intervention fidelity refers to mechanisms of monitoring the planned delivery of study interventions [14]. Maintaining strict fidelity throughout study interventions will minimize external influence on both participants and research team members. It will also ensure that results from the intervention are reflective of the participants' behaviors in real-world settings.

By using strategies provided by the NIH BCC, we developed an intensive fidelity intervention protocol addressing the 5 main

domains to monitor, assess, and enhance overall study fidelity. The NIH BCC has provided relevant guidelines and strategies for health behavior interventions to maintain both internal and external validity. Telehealth studies can positively impact self-management skills for individuals with chronic health conditions. The My Health, My Life, My Way program will be the first self-management program for individuals with physical disabilities and chronic health conditions. Because this program is conducted through the web, it has the capability to become accessible, inclusive, scalable, and sustainable. Therefore, by reporting the fidelity intervention protocol for My Health, My Life, My Way, this paper will inform future studies using telehealth technology and health coaching.

The 5 domains to maintain fidelity provided by the NIH BCC addressed in this paper include study design, provider training, treatment delivery, treatment receipt, and enactment of treatment skills. The fidelity monitoring protocol described here was developed in conjunction with a similar telehealth study using similar technology and health coaching for individuals with physical disabilities and diabetes [15,16]. Similar to that fidelity intervention protocol, a challenge of ensuring high fidelity is that My Health, My Life, My Way will use different technological platforms for different fidelity purposes. Examples include using the telehealth website, REDCap (Research Electronic Data Capture; Vanderbilt University) for data collection, and communication platforms for health coaches to engage with participants. Possible implementation setbacks will be addressed, and ongoing collaboration with the multidisciplinary team (ie, research staff, health coaches, and technical support) will reduce variations in fidelity monitoring.

Several steps in program implementation have been conducted prior to fidelity development and standardized protocols have been developed for future steps. In the context of health coaching, strict coaching session guidelines have been developed to reduce variation in conducting health coaching calls, which is a significant concern in telehealth interventions [17,18]. The development of AI that is embedded in our telecoaching website provides convergent communication capabilities that will reduce health coaching workload and need to aid in the personalization of self-management skills for participants. Other monitoring procedures have been created to evaluate the consistency of health coaching sessions, including audio recordings, call logs, and a review of the training used by the coaching team. Such procedures will enhance the internal validity of the protocol and contribute to the creation of effective, evidence-based telecoaching programs.

Abstract

Background: Although melanoma survival rates have improved in recent years, survivors remain at risk of recurrence, second primary cancers, and keratinocyte carcinomas. The National Comprehensive Cancer Network recommends skin examinations by a physician every 3 to 12 months. Regular thorough skin self-examinations (SSEs) are recommended for survivors of melanoma to promote the detection of earlier-stage, thinner melanomas, which are associated with improved survival and lower treatment costs. Despite their importance, less than a quarter of survivors of melanoma engage in SSEs.

Objective: Previously, our team developed and evaluated a web-based, fully automated intervention called mySmartSkin (MSS) that successfully improved SSE among survivors of melanoma. Enhancements were proposed to improve engagement with and outcomes of MSS. The purpose of this paper is to describe the rationale and methodology for a type-1 hybrid effectiveness-implementation randomized trial evaluating the enhanced MSS versus control and exploring implementation outcomes and contextual factors.

Methods: This study will recruit from state cancer registries and social media 300 individuals diagnosed with cutaneous malignant melanoma between 3 months and 5 years after surgery who are currently cancer free. Participants will be randomly assigned to either enhanced MSS or a noninteractive educational web page. Surveys will be collected from both arms at baseline and at 3, 6, 12, and 18 months to assess measures of intervention engagement, barriers, self-efficacy, habit, and SSE. The primary outcome is thorough SSE. The secondary outcomes are the diagnosis of new or recurrent melanomas and sun protection practices.

Results: Multilevel modeling will be used to examine whether there are significant differences in survivor outcomes between MSS and the noninteractive web page over time. Mixed methods will evaluate reach, adoption, implementation (including costs), and potential for maintenance of MSS, as well as contextual factors relevant to those outcomes and future scale-up.

Conclusions: This trial has the potential to improve outcomes in survivors of melanoma. If MSS is effective, the results could guide its implementation in oncology care and nonprofit organizations focused on skin cancers.

Introduction

Background

More than 97,610 cases of cutaneous malignant melanomas will be diagnosed in the United States in 2023, making it the fifth most commonly diagnosed cancer. With incidence rates more than tripling from 1975 to 2020, the population of survivors of melanoma is estimated at >1 million. Among persons diagnosed with localized, regional, or distant-stage melanoma, the 5-year survival rates have improved in the last decade, with 99%, 65%, and 25% survival rates, respectively [1]. Improved survival and increased incidence have translated to an estimated annual treatment cost for melanoma of approximately US $2.5 billion [2].

Survivors of melanoma remain at risk of recurrence, second primary cancers, and keratinocyte carcinomas. Recurrence rates depend on tumor thickness and nodal involvement and range from 3% to 24% among persons with thinner lesions to 51% among persons with thicker lesions or lymph node involvement [3-5]. Recurrent or new primary melanomas occur most commonly during the first 5 years after diagnosis but can arise many years later [6,7]. Recurrent melanoma typically occurs at local or regional sites, and approximately half of distant recurrences present within the skin or lymph nodes [8,9]. Psychosocial morbidity is an issue for patients and survivors, with studies reporting higher anxiety and depressive symptoms than in the general population [10] and elevated anxiety about recurrence.

For survivors of melanoma, National Comprehensive Cancer Network guidelines recommend several actions, including skin examinations by a physician every 3 to 12 months and regular thorough skin self-examination (SSE) [11-13], which entails a deliberate, systematic inspection of all areas of the body using a mirror or the assistance of another person to examine hard-to-view areas [14]. Patient education about SSE by a health care professional is also recommended. Engagement in regular sun protection behavior is also recommended to reduce the risk of subsequent skin cancers as UV radiation from the sun is a contributing factor for melanoma and other skin cancers [2].

Limited data suggest that performance of SSE is associated with differential survival rates among patients with melanoma, and professional recommendations for regular SSE are supported by 3 research findings. First, more than half of recurrences and new primary melanomas are detected by survivors themselves [11,15,16]. Second, individuals who perform SSE are diagnosed with significantly earlier-stage melanomas than those who do not. Detection and treatment of recurrent disease and new primary cancers at earlier stages leads to improved survival, which is not accounted for by lead-time bias [17]. Third, melanomas identified through SSE are thinner than those found incidentally [16,18,19]. Retrospective studies suggest that individuals who perform SSE have lower tumor thickness. Thinner melanomas are associated with better survival [19-23]. Thus, promoting regular SSE will likely enhance the early detection of easier-to-treat recurrences and new primary cancers among survivors. For example, Robinson et al [24] found that 13.4% of patients in their SSE randomized controlled trial (RCT) developed a new melanoma over the 2-year follow-up. Patients in the SSE intervention condition detected 81% of these melanomas, approximately 34% of which were invasive, with only a 1% increase in physician visits. The costs of treating earlier- versus later-stage melanomas are significantly lower [25,26]. In summary, regular thorough SSE is recommended for survivors of melanoma and results in the detection of earlier-stage, thinner melanomas, which is associated with improved survival and lower treatment costs.

Despite its importance, engagement in regular, thorough SSE is low. Compliance rates with thorough SSE range between 7% and 17% among survivors of melanoma [14,20,22,27,28]. Studies document wide variation in SSE performance, with figures dependent upon the way that SSE is measured and the time frame for assessment. When patients are asked whether they have performed any form of SSE in the past 2 months, high rates of performance are observed (71.5%) [29]. SSE rates are higher when specifying any performance in the past year (84.3%) [30]. However, significantly lower rates are found if SSE is defined by its thoroughness. We reported that 13.7% of survivors checked 4 key areas and had someone assist them or used a mirror for hard-to-see areas [30]. Loescher et al [31] found that 16% of women and 7% of men examined each of the 7 designated body parts in the previous 2 months. Mujumdar et al [32] reported that 17% of survivors examined a minimum number of areas of the body (8 out of 9 areas) in the previous 2 months. In our recent work, 65% reported having conducted an SSE in the previous 2 months, but only 7.5% of the sample checked all 15 body parts. Hard-to-see areas were missed, including the scalp (37.9%), buttocks (40.4%), soles of the feet (41.6%), and genitals (44.4%). Less than half (46.2%) [33] reported using a mirror to view hard-to-see places, and only 39% reported asking for assistance. In total, 2% reported using a mole map to guide their most recent SSE.

A limited number of interventions have been evaluated to improve SSE among survivors of melanoma [24,34-37]. Existing interventions have used in-person, print, or web-based delivery modes. Several have demonstrated improvements in SSE [34,35]. Limitations of previous studies include lack of a comparison group [35]; being an in-person or partner-assisted intervention, which compromises the ability to disseminate it [24]; lack of inclusion of long-term outcomes [24]; lack of inclusion of SSE performance [36] as an outcome; and low intervention use and high dropout [35]. No existing intervention is fully automated and, thus, potentially cost-effective and highly scalable. To this end, our team developed and evaluated mySmartSkin (MSS), a web-based, fully automated intervention to improve SSE among survivors of melanoma. MSS is a behaviorally based program that is delivered via the internet, tailored to the user, and fully automated with no human clinical support. MSS was compared with usual care (UC) in an RCT of 430 survivors of melanoma from New Jersey [38,39]. The results indicated a beneficial impact of MSS versus UC on the performance of thorough SSE at all follow-ups up to 1 year [24,34-37]. Effect sizes were in the small to medium magnitude range for SSE, but these effects were not sufficiently strong to scale up for implementation in the existing form.

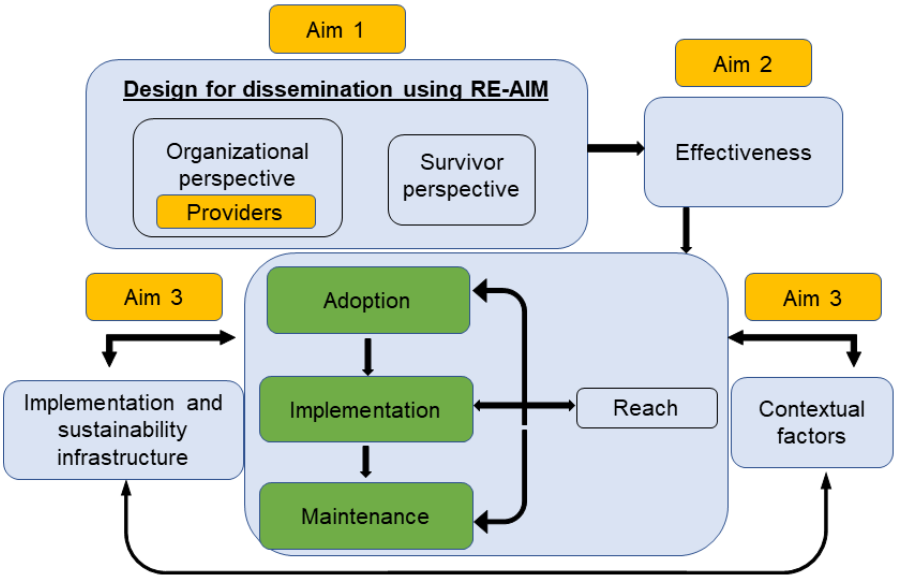
In addition to SSE, professional agencies recommend engagement in regular sun protection behaviors, such as staying in the shade, applying sunscreen with a sun protection factor of at least 30, and wearing protective clothing (eg, hats and long sleeves). Survivors of melanoma report engaging in higher levels of sun protection behaviors than the general population [40], but their sun protection behaviors do not meet the recommended guidelines [30,32,41]. To date, only 2 intervention studies have targeted improved sun protection behaviors among survivors of melanoma [34,38]. Bowen et al [34] reported significant improvements in some sun protection behaviors (eg, wearing sunglasses and staying in the shade). In our prior work [38], we evaluated the effects of MSS on sun protection behaviors, which was included as a component of the original intervention. The effects of MSS compared with UC on sun protection behaviors were only statistically significant at the 24-week follow-up in analyses that did not control for baseline sun protection behaviors or other potential covariates. Stronger and more consistent improvements in sun protection would be an important goal for future work.

Theoretical Frameworks

Previous empirical findings regarding factors associated with SSE [29,30,32,42,43] and sun protection, as well as the preventive health model (PHM) [44,45], inform the content of MSS. The PHM posits that the performance of preventive behaviors is influenced by background, affective, cognitive, and social factors. Background factors include sociodemographic characteristics, risk factors for skin cancer, medical history, and knowledge about melanoma. Affective factors include concerns about melanoma recurrence and distress about the diagnosis. Cognitive factors include perceived controllability of melanoma, self-efficacy, and benefits and barriers. Social normative factors include family and friend support and physician recommendations. In addition to our previous research on skin cancer risk reduction practices among family members of patients with melanoma [46,47], the PHM has been used successfully to understand and promote screening for colorectal and prostate cancer [44,48]. The original MSS focused on improving the perceived controllability of melanoma through the performance of comprehensive SSE; increasing the perceived benefits of SSE and sun protection; reducing barriers to SSE and sun protection; enhancing self-efficacy for SSE and sun protection; and enhancing family, friend, and physician support for sun protection.

A major challenge for intervention research is that most interventions that demonstrate a beneficial impact are not tested in effectiveness or dissemination trials and are not conducive to “real world” delivery or use. As a result, they do not penetrate the general population and, unfortunately, are not received by those who most need them [49]. Our work is guided by the Practical, Robust Implementation and Sustainability Model (PRISM), which extends the Reach, Effectiveness, Adoption, Implementation, and Maintenance (RE-AIM) [50] framework to consider not only implementation outcomes but also multilevel contextual factors influencing implementation. *Reach* refers to the percentage and representativeness of persons exposed to a program. *Effectiveness* refers to the impact on key survivor-level outcomes. As MSS is a free-standing, recipient-facing intervention, *adoption* is defined as the proportion and representativeness of recipients (in this case, survivors) who adopt (ie, at least log into) the program. *Implementation* refers to the degree to which a program is delivered and received as intended. This is measured through costs, engagement, acceptability, feasibility, and appropriateness. *Maintenance* is the extent to which a program and its survivor-level effects are sustained over time. The integration of these models with the study’s aims is shown in Figure 1 [51-55]. In the proposed study, in aim 1, the goal of the iterative process of enhancing the MSS intervention using stakeholder feedback and usability testing is to improve RE-AIM outcomes, which will be assessed in aims 2 and 3. In aim 2, we focus on the effectiveness of the enhanced MSS, testing its effects on survivor-level outcomes, including clinical outcomes (eg, melanomas found). In aim 3, we address the remaining RE-AIM dimensions. In addition, to proactively identify barriers to and facilitators of future scale-up and widespread dissemination and implementation of MSS, we explore multilevel contextual factors identified by key stakeholders drawn from the PRISM domains of recipients, external environment, intervention design, and implementation and sustainability infrastructure. We anticipate that incorporating PRISM and RE-AIM throughout the study aims will ensure that the enhanced intervention is responsive to key stakeholder preferences and that we “design for dissemination” [56], recognizing potential barriers to and facilitators of future scale-up and informing our next stage of developing dissemination and implementation strategies to maximize the public health impact of MSS.

Figure 1. Integration of preventive health model and implementation frameworks with the study aims. RE-AIM: Reach, Effectiveness, Adoption, Implementation, and Maintenance.



Study Objectives

Overview

The purpose of this type-1 hybrid effectiveness-implementation study is to evaluate the effectiveness of a web-based intervention, MSS, and explore its implementation and relevant contextual factors. A type-1 hybrid effectiveness-implementation approach requires the engagement of multilevel stakeholders throughout the research process, focus on evaluating the effectiveness of the enhanced MSS, and identification of critical factors that could promote or prevent wide-scale implementation. The study's 3 aims are guided by implementation frameworks and behavior change theories.

Aim 1

The first aim is to enhance MSS by collaborating with multilevel stakeholders. We will collaborate with stakeholders to enhance MSS through qualitative interviews and usability testing of potential intervention enhancements. Enhancements are based on empirically validated behavior change techniques (BCTs) and lessons learned from survivors' feedback in our previous study. We will use an iterative process that includes (1) key informant interviews with survivors, providers, and professional organization representatives regarding proposed enhancements; (2) conversion to an enhanced mobile-based delivery platform; (3) usability testing; and (4) iterative program refinements.

Aim 2

The second aim is to evaluate the effects of the enhanced MSS on thorough SSE (primary outcome) and examine its impact on the diagnosis of new or recurrent melanomas (secondary outcome) and sun protection practices (secondary outcome). We will conduct an RCT comparing MSS and a noninteractive educational web page with 300 survivors to test the intervention effects on these outcomes.

Aim 2 Hypothesis

We propose that MSS participants will be more likely to perform thorough SSE over the 18-month follow-up period. We will explore the impact of MSS on new or recurrent melanomas and sun protection behaviors. We anticipate diagnosing a greater number of earlier-stage melanomas and observing higher sun protection behaviors among those in MSS compared with those in UC.

Aim 3

The third aim is to assess selected implementation outcomes and identify factors relevant to future scale-up for widespread dissemination, implementation, and maintenance of MSS. We will use mixed methods to assess implementation outcomes and explore perspectives from survivors, care providers, and professional organizations to inform the selection of strategies to best disseminate and implement MSS on a broad scale. The subaims are as follows:

1. Aim 3a is to estimate program costs and assess the cost-effectiveness of MSS relative to control. We hypothesize that MSS costs will be higher than UC costs. We expect that MSS will be a more cost-effective strategy given its previous positive effects on SSE and the identification of new or recurrent melanoma. If our findings support this as expected, exploratory cost-effectiveness analyses from the health care and societal perspectives will be conducted using simulation models of melanoma-related costs, disease progression, and survival over 5- and 10-year analysis horizons.
2. Aim 3b is to examine the reach, adoption, implementation (ie, engagement, acceptability, appropriateness, and feasibility), and maintenance of MSS. For reach, we predict that the demographic characteristics of those exposed to MSS will not differ from those of the general population of survivors of melanoma. For adoption, we propose that the proportion of contacted and eligible survivors randomized to MSS who consent, complete the baseline questionnaire, and log into MSS will be equal to or greater

than the proportion in our previous efficacy trial. For engagement, we propose that 80% of MSS participants will log into the intervention at least once. For acceptability, we predict that MSS will be rated as highly acceptable. We do not have hypotheses regarding appropriateness, feasibility, and maintenance as these data will be evaluated in terms of future implementation of MSS should it have an impact on SSE and sun protection outcomes. For each of these implementation outcomes, we will assess the demographic characteristics of MSS participants to determine whether outcomes differ among survivors in specific subgroups (eg, by age, sex, race, ethnicity, and socioeconomic status).

3. Aim 3c is to identify and describe contextual factors experienced by multilevel stakeholders as key to scale-up and widespread implementation of MSS, including consideration of potential delivery settings, timing of delivery, and resources needed to promote its implementation.

Methods

Ethics Approval

Study procedures were approved by the Rutgers University institutional review board (IRB; protocol Pro2022000948).

Aim 1: Enhancements to the Existing Version of MSS Using Multilevel Stakeholders

Overview

This phase engages multilevel stakeholders in optimizing MSS by targeting multiple RE-AIM outcomes: effectiveness, adoption, implementation, and maintenance. Iterative enhancements will be made to MSS intended to increase the effects on SSE by increasing adoption, acceptability, appropriateness, feasibility, and maintenance. This process will include key informant interviews with survivors, health care delivery stakeholders, and professional organizations to inform the selection of enhancements from the potential theory-based strategies we identified based on the findings and survivor feedback from our previous RCT. This user-centered process will involve assessment of preferences regarding content (eg, "What are your thoughts on the option of uploading pictures of your moles?"), use (eg, "How useful would it be to log in to MSS three months after you complete it and what would you use it for?"), and preferred ways to motivate targeted behaviors (eg, "What are your thoughts about incentives such as free products?"). This phase of our design for dissemination approach will use an iterative process that includes (1) key informant interviews with survivors of melanoma and care providers to inform the selection of proposed theory-based enhancements, (2) conversion to a mobile-based intervention delivery platform incorporating selected enhancements, (3) usability testing with survivors who use the program for 1 month, and (4) program refinement.

Proposed Enhancements

The existing MSS content was guided by PHM and evidence-based BCTs. The original MSS included two categories of BCTs: (1) prompts (participants could set an email reminder to perform SSE on specific dates for the duration of study participation) and (2) planning (participants could set a goal related to SSE and select up to 2 action steps to address barriers). The other material primarily targeted SSE knowledge (eg, how to recognize a suspicious growth) and self-efficacy (building confidence in identifying suspicious growths), which were the mediators of MSS effects on SSE.

Our selection of proposed enhancements was guided by two goals: (1) to optimize engagement with MSS and (2) to increase sustained performance of SSE. A summary of enhancements is shown in Textbox 1. We focused on optimizing engagement as participants who used MSS more were more likely to perform SSE across the follow-up period, which we are now extending. Thus, increasing engagement with MSS should enhance its impact over time.

Textbox 1. Proposed enhancements to mySmartSkin (MSS).

Self-monitoring and performance feedback

- Upload pictures of moles each month on mole map
- Illustrate body parts checked each month
- Bar graph of completed skin self-examinations (SSEs) over time from baseline to 1 year on the MSS home page
- Monthly feedback on progress with SSE

Incentives for success

- Incentives for self-reported SSE, core completion, and SSE and sun protection goal setting: rulers, reminder stickers, sun hats, sunscreen, sun protection factor ChapStick, sun safety checklist magnet, calendars, hanging door signs with the ABCDEFs (asymmetry, border irregularity, color variation, diameter of >6 mm, evolving, and funny looking) of melanoma, sun umbrella, among others (up to 6 incentives)

Prompts

- Personalized text reminder delivered the day before SSE is due each month to perform it, with a link to the self-check program
- Tailored reminder of body parts to remember to check

Goals and planning

- Identification of personal barriers to SSE and sun protection behaviors
- Continued troubleshooting of ways to address SSE barriers and sun protection behaviors
- Regular personalized feedback and ability to track progress on SSE and sun protection goals

Social support

- Discuss the importance of support for change
- Identify someone to support SSE (eg, spouse) and how the patient would like to talk to and involve them
- Provide SSE information via email to authorized support person

To optimize initial engagement, we are implementing four enhancements: (1) enhancing participant-facing recruitment materials (eg, advertisements, emails, and study home page) by including narratives from survivors and oncologists about MSS and the importance of thorough SSE, (2) streamlining enrollment materials and processes (eg, screening and baseline surveys and instructions), (3) reaching out to participants who do not log into MSS by day 3 to provide a brief orientation session fostering ease of access (ie, review modules and topics and the importance of completing modules, show the participant how to log in, and discuss SSE benefits for finding recurrence early), and (4) informing participants about incentives for completion of each core and other tasks within the program.

To improve sustained SSE, we identified 6 categories of BCTs for the proposed enhancements [57]; we included (1) self-monitoring and performance feedback to improve self-efficacy (eg, uploading photos of moles and saving them to compare with the next SSE); (2) behavioral incentives (eg, provided for completing SSE); (3) additional prompts for SSE (eg, programmed reminders about missed areas of the body); (4) adding a more comprehensive approach to setting goals and planning, including continued troubleshooting of barriers; (5) including more content on receiving assistance and support from others in performing SSE (including the option to email an authorized support person about assisting with the participant's SSE); and (6) adding a goal-setting component that fosters habit formation and maintenance of behavior change. We created an in-depth goal-setting section that allows users to track their progress and make updates to their goals and progress over time. The goal-setting component is tailored based on the user's current SSE and sun protection behaviors, and the purpose of this component is to assist in the creation of a plan to improve both behaviors.

In terms of sun protection behaviors, we included a sun safety core with content categorized into chapters addressing (1) learning more about sun safety with topics such as risks of UV rays, risks of unprotected sun exposure, sunscreen education, how to avoid sunburns, and other sun protection behaviors; (2) assessing current sun protection behaviors; (3) increasing confidence in and motivation for sun protection; and (4) setting sun protection goals. A more detailed summary of the content of each core is provided in Table 1.

Table 1. Enhanced mySmartSkin intervention content.

Section	Key content	Interactive features
Tutorial	• Overview of navigation, sections, and features	• N/A[a]
Core 1: learn about spots	• Personal melanoma history • Skin cancer facts and figures • Melanoma risk factors • Risk of recurrence • Purpose of SSE[b] • How to conduct an SSE • The ABCDEFs[c] of melanoma • Your experience doing SSE • What to do when you find a suspicious spot • Importance of SSE and physician skin examinations • Confidence in checking spots	• Mole facts and fiction • ABCDEF-identifying challenge quiz • Suspicious or not mole challenge • Vignette and physician video and audio clips • SSE goal setting
Core 2: sun-safe behaviors	• Sun-safe behaviors • Risks of sun exposure • UV index • Types of sunscreen • Avoiding sunburns during outdoor activities • Risk assessment for outdoor activities • Sun-safe clothing • Limiting sun exposure • Increasing confidence and motivation for sun safety • Prioritizing sun-safe behaviors • SSE goal setting	• Sunscreen FAQs[d] • Sunscreen facts and fiction • Tanning facts and fiction • Assessing current tanning beliefs • Vignette and physician video or audio clips • Sun-safe behavior importance rating • Sun safety goal setting

Key Informant Interviews to Gather Input on Enhancements

This phase of aim 1 has been completed. The procedures are described in the following sections, and the results are described later in the paper (see the *Results* section).

Sample

We planned to recruit 10 survivors of melanoma who had completed treatment within up to 3 years since diagnosis from the Rutgers Cancer Institute of New Jersey (CINJ) through new case ascertainment by research staff using electronic medical records. On the basis of our past experience in qualitative assessments, this sample was expected to provide thematic saturation of the data, although additional interviews could be conducted if needed.

Questionnaire

Following informed consent procedures, participants completed a brief demographic questionnaire before their interview began. Participants self-reported their age, sex or gender, race, ethnicity, education, current insurance coverage, school enrollment, employment, and marital status. Patients also reported current SSE practices.

Procedures

The project coordinator (AS) conducted the interviews, which were audio recorded with participant permission and approximately 45 minutes in duration. During the interviews, participants were shown prototypes and wireframe illustrations of the proposed enhancements. To ensure that feedback was gathered on all aspects of the MSS platform, interviewers highlighted different sections, including the goal-setting activity sequence and skin self-check body map. The semistructured interviews elicited feedback on the proposed enhancements. We included probes about enhancements based on stakeholders' positive, neutral, or negative reactions (eg, "What parts of the site did you think were most interesting and helpful?" and "What parts were less helpful or seemed less relevant to you?"). Phase 1 participants received US $50 for the interviews. These interviews were conducted in person at the CINJ or using videoconferencing software. The interviewer took field notes, and the interviews were transcribed verbatim.

Refining Enhancements

The study team reviewed the field notes and verbatim transcriptions of key informant interviews. The responses to each proposed enhancement were coded as positive, neutral, negative, or mixed. Although potential enhancements were based on findings from the previous RCT, suggestions from participants, BCTs, and proven ways to optimize engagement, if particular enhancements were perceived negatively by multiple stakeholders, we used these interviews to explore alternatives that would be more acceptable. For those enhancements with multiple negative or mixed comments, the team decided whether the issue could be addressed feasibly and crafted changes to the content and approach that were congruent with stakeholder feedback. The stakeholders in later interviews reviewed the changes made in response to feedback given in earlier interviews to provide confirmation on whether the issue was adequately addressed. The study team provided feedback to the web developer, Radiant (Radiant Creative Group LLC), throughout the interview process for changes to be incorporated in a timely manner.

Conversion to a Mobile-Based MSS Platform, Usability Testing, and Refinements With Multilevel Stakeholders

Stakeholder-informed enhancements to content and program features will be incorporated with the existing content and migrated to the mobile-based delivery platform in collaboration with Radiant. Testing will be conducted throughout the preproduction and production stages to ensure the suitability of the content for the intended audience. Weekly meetings with Radiant will be conducted to review uploaded content.

Usability Testing, Feedback, and Refinements

Testing will be accomplished by conducting focused interviews with up to 10 survivors of melanoma, 5 health care providers, and 5 organization representatives who will each receive US $100. Testing is modeled after a National Cancer Institute website design project [58]. The process will involve checking the content with participants for attractiveness, comprehension, acceptability, and persuasion. In addition, participants will be able to use MSS for approximately 1 week before the interview so that we can gather input on features that are planned over time, such as self-monitoring and performance feedback, incentives, and prompts. A series of questions and structured guides will be prepared in advance related to the elements to be evaluated.

In the set of interviews, all enhancements and engagement tools, including reminder prompts, will be activated, providing an opportunity to evaluate all components of the enhanced MSS. After that, we will set up a virtual meeting in which the participant will provide feedback about acceptability, ease of use or intuitiveness, and satisfaction. During this session, we will discuss the topic areas and review MSS using a shared screen to allow participants to react to each screen. Participants will be asked to provide feedback on features. These sessions will be digitally video recorded and transcribed, and AS will take notes. The data will be summarized and reviewed to determine further modifications to be made. These efforts will yield a set of understandable, acceptable, and appealing enhancements to MSS that are customized to the needs, capabilities, and preferences of patients with melanoma, providers, and organizational stakeholders. We will conduct weekly meetings that include Radiant and the study team to review and produce content. Once the final beta website has been agreed upon by the full research team, it will undergo extensive testing by Radiant to ensure that the programming is functioning correctly.

Aim 2: Evaluate Effects of MSS Versus a Noninteractive Educational Web Page on SSE

Overview

Phase 2 is a randomized effectiveness trial in which MSS will be tested in an RCT comprising 2 groups (MSS vs a noninteractive educational web page) and 5 assessments (baseline, 3 months, 6 months, 1 year, and 18 months) with 300 survivors of melanoma. The main goal is to evaluate the effects of MSS on thorough SSE and examine the impact on clinical outcomes (eg, diagnosed early-stage skin cancers).

Recruitment

Overview

We will recruit participants from 2 sources: state cancer registries and Facebook. This approach was adopted to prepare for dissemination by assisting the team in comparing the reach of the 2 methods of recruitment. This will foster our ability to determine future settings. The registries include all patients with melanoma in each state, which facilitates eventual generalizability. We chose NJ and CA registries because the 2 states are geographically disparate and sociodemographically diverse, and we have worked successfully with both registries on current projects (CA2219854 and CA221854). We chose Facebook as a second approach as the vast majority of Americans (84% in 2021) [59] use social media, with use steadily increasing each year. This strategy will reach a broad audience of survivors. In addition, many melanoma and skin cancer advocacy groups are active on social media, which will inform the potential for working with them on future dissemination.

Registries

We will recruit from the New Jersey State Cancer Registry (NJSCR) and the Cancer Registry of Greater California (CRGC). Owing to state laws, allowable recruitment procedures differ. NJSCR procedures entail case ascertainment, a letter to the physician, an address check, a letter mailed to the patient, up to 12 calls to verify that they received the letter, and the provision of verbal consent to send contact information to the CINJ. The CINJ reaches out to the patient to describe the study and send a link to the MSS website. We have enhanced the CRGC procedures to be as similar as possible to those of the NJSCR. The CRGC queries their database, confirms that the patient is alive, and checks this information with the provider. Case information is sent to the CINJ, a letter is sent explaining the study followed by up to 12 calls to the patient to obtain their email address, and a link to the study web page is emailed. The process takes approximately 2 months.

Facebook

We will use paid Facebook advertisements. We will work with a social media marketing company to develop keywords and advertisements targeting individuals with characteristics similar to those of survivors of melanoma (eg, older age). As noted previously, this approach has been successfully used in 2 previous and one current skin cancer–related intervention project [60-62]. This approach will also recruit a broader population of survivors of melanoma than the previous efficacy trial.

Eligibility

The eligibility for this trial is as follows:

1. Diagnosis of primary pathological stage-0 to stage-III cutaneous malignant melanoma
2. Being 3 months to 5 years after surgery
3. No current evidence of cancer
4. No adherence to thorough SSE [14] (ie, did not check the entire body at least once during the past 3 months)
5. Age of ≥18 years
6. Internet access
7. Ability to speak and read English
8. Ability to provide informed consent

The incidence is most common among non-Hispanic White individuals, who have an annual rate of 28 cases per 100,000 compared with 7 in American Indian or Alaska Native individuals; 5 in Hispanic individuals; and 1 in non-Hispanic Black, Asian, and Pacific Islander individuals (92.4% among non-Hispanic White individuals). Consistent with population rates, we will oversample minority groups from cancer registries to ensure a minimum of 7.6% racial and ethnic minority group survivor enrollment.

Sample

The projected sample size is 300. Participants will be recruited using 2 methods. Half of the sample will be recruited from 2 state cancer registries. We expect >10,000 eligible patients with melanoma from the 2 registries during our recruitment period. We will select a random sample from each diagnosis year to balance the year of diagnosis. The acceptance rate for the previous MSS study was 40.9%, but we anticipate a lower recruitment from the registry participants in this study based on our recent work with both CRGC and NJSCR patients (CA221854) [63]. Both cancer registries have a large number of survivors annually. Thus, we will randomly select a subset of cases from each of the retrospective 5-year time frames. The other half of the sample will be recruited via Facebook. We will use paid Facebook advertisements targeted at persons who follow skin cancer–related causes and organizations**.** We will end recruitment from each source when the required sample size is reached.

Enrollment, Randomization, Intervention Delivery, and Follow-Up Surveys

Potential participants recruited via registries will be asked for their email when they verbally consent to participate in the study. Staff will then email these potential participants the link to the study's web page. Participants recruited via social media advertisements will be automatically linked to the study web page when they click on the "learn more" part of the advertisement. Once on the web page, the following automated, completely web-based procedures will be used for enrollment. On the study's web page, there is a screening survey to determine eligibility. Potential participants will complete the eligibility screener. If eligible, the program automatically moves to the electronic consent. Once consent is obtained, the program automatically moves to the baseline survey. After survey completion, the program randomizes the participant to MSS or the comparison condition and automatically moves to either the MSS landing page or the comparison condition landing page. Randomization will be stratified according to disease stage and time since diagnosis (3 months-3 years and 4-5 years) and, then, within strata, block randomized using blocks of 20 participants overseen by the study statistician following standard operating procedures of the CINJ Biostatistics Shared Resource.

Participants who do not log into the MSS program by day 3 will be contacted by a study coordinator via SMS text message, email, or phone 3 times between days 3 and 10 to remind them about logging into MSS. Participants who log in but do not review core 1 by day 5 will be contacted 3 times via email, SMS text message, or calls to invite them to review core 1. These interactions will also serve as an orientation for the participants allowing them to ask any questions about the study or the intervention.

Survey Procedures

Participants will be prompted (via automated email, as well as via SMS text message, telephone, and mail, as necessary) to complete the following web-based surveys: follow-up 1 at 3 months after the baseline, follow-up 2 at 6 months after the baseline, follow-up 3 at 1 year after the baseline, and follow-up 4 at 18 months after the baseline. Participants who do not complete the surveys will be reminded as follows: (1) reminder email and SMS text message with a link to the survey if it is not returned after 1 week, (2) call with a voicemail if no contact is made and email with a link to the survey if it is not returned after 2 weeks, and (3) the same procedure as at 2 weeks if the survey is not returned after 3 weeks. Participants who do not return the survey after a month will be considered lost to follow-up at that time point. Our primary effectiveness analyses will focus on individuals' performance of thorough SSE at 18 months, which will ensure that all participants' SSE practices are assessed over a long time frame and increase the likelihood of detecting new or recurrent melanomas. Participants will receive incremental gift card amounts for each survey (maximum total of US $120).

Intervention Procedures

Participants will have a unique identifying user code and create a password to access the interventions. If users forget their password, they will provide a unique answer to a personal question and the database will return the forgotten password. If users forget both their user ID and password, they can contact the technical assistance hotline. In the previous study, navigation issues were rare. We anticipate that it will take participants approximately 1 hour to complete the entire MSS intervention once and approximately 15 minutes to complete the comparison

condition. Participants will have access to the interventions for 18 months.

Comparison Group

We chose a noninteractive educational web page comparison group for the following reasons: (1) the information incorporated is widely available to the public and used in dermatology and primary care, (2) the digital delivery method is similar to that of MSS, (3) it allows for a comparison of MSS effects with a minimal knowledge-based educational intervention, (4) it permits a comparison of MSS effects with the results of previous studies that used minimal comparison interventions, (5) it presents a standardized intervention rather than a variable treatment-as-usual intervention, (6) a no-intervention control would be unethical for this high-risk population, and (7) we considered using an intervention for another health issue (eg, nutrition) but anticipated that survivors of melanoma would be less likely to participate. We will create a static educational web page whose content will be based on freely available, accurate information relevant to melanoma, melanoma risk, and SSE. Possible topics include the warning signs of melanoma [64], the risk of recurrence among survivors of melanoma, and how to perform an SSE [65].

Aim 2 Measures

Covariates

Demographics

The demographic information collected will include age, sex, race, ethnicity, education, marital status, state of residence, employment, income, and insurance.

Clinical Characteristics

The clinical characteristics collected will be date of diagnosis, stage, and treatment received.

Melanoma Risk

The melanoma risk information collected will be eye color, natural hair and skin color, skin reactivity to the sun, freckling, moles, sunburn history, indoor UV tanning, and family history.

Environmental Factors

The environmental factors collected will be month of assessment, residential location, and average UV index at solar noon over the 3 months before each time point.

Primary Outcome Measure: Skin Self-Check Comprehensiveness

A full list of outcome measures and covariates is shown in Table 2. The primary outcome consists of the following items: (1) “Have you, or anyone else, not including a doctor or other healthcare professional, ever checked any part of your body for signs of skin cancer?” (yes or no), (2) “If yes, in the last three months, did you check your body for early signs of skin cancer?” (yes or no), and (3) “Doing a thorough skin check or skin self-examination means spending time looking at the skin systematically and deliberately. Please indicate whether you thoroughly checked each of the following areas of your body the last time you checked your body for early signs of skin cancer: Scalp, face, neck, shoulders, front of arms, back of arms, chest, stomach, upper back, lower back, front of legs, back of legs, bottom of feet, buttocks, and genitals” (yes or no for each). For all time points, comprehensiveness will be based on the total number of body parts checked among participants who conducted an SSE in the last 3 months. Participants who did not conduct an SSE in the last 3 months will be coded as 0 for this outcome.

Table 2. Aim 2 measures.

Measure	Baseline	Time 2	Time 3	Time 4	Time 5
Covariates					
Date of birth	✓				
Sex	✓				
Marital status	✓				
Race and ethnicity	✓				
Education	✓				
Insurance status	✓				
Employment status	✓				
Time since diagnosis	✓				
Month of assessment	✓	✓	✓	✓	✓
Residential location					
Average UV index at solar noon	✓	✓	✓	✓	✓
Outcomes					
Skin self-examination	✓	✓	✓	✓	✓
Sun protection behaviors	✓	✓	✓	✓	✓
Melanoma diagnosis, stage, thickness, and date		✓	✓	✓	✓
Clinician confirmation of cancer		✓	✓	✓	✓

Secondary Outcomes

Sun Protection Behaviors

Participants report how often they engage in 4 behaviors when outside on a sunny day: wearing sunscreen with a sun protection factor of ≥30, wearing a long-sleeved shirt, wearing a wide-brimmed hat, and staying in the shade [66]. Items are rated on a 5-point Likert scale (1=*never*; 5=*always*).

Clinical Outcomes

Participants report whether a new melanoma or other skin cancer was diagnosed and the stage, thickness, and date. Physician confirmation of this information will be collected.

Analyses of the Impact of MSS on SSE, Sun Protection, and Clinical Outcomes

Analyses of Thorough SSE and Sun Protection

Demographics and baseline variables will be compared between the 2 conditions using chi-square tests and ANOVAs for categorical and continuous variables, respectively. These variables, including outcomes, will also be compared by recruitment source. Missing data will be handled using multiple imputation with 50 imputed samples [67]. Tests of intervention effects on thorough SSE and sun protection will be conducted separately for each wave of postintervention data collection using logistic regression models that treat baseline SSE or sun protection, respectively, as a covariate. Given the large number of potential additional demographic and medical covariates, additional analyses will include the covariates that are significant predictors of the outcome.

Sample Size and Power

On the basis of our previous study, we expect follow-up survey completion rates between 80% and 93% at the 1-year time point and 80% to 85% at the 18-month time point, which will result in an expected final sample size of N=255. In the previous trial, thorough SSE occurred at a rate of approximately 30% in MSS at each time point, and effect sizes for conducting a thorough SSE ranged from w=0.29 (8 weeks) to w=0.21 (6 months). Given that the MSS intervention will be enhanced, we expect that the SSE rate will be higher (45%), which will result in approximately w=0.36. A sensitivity power analysis using G*Power indicated that a sample of N=255 will be able to detect an even smaller effect of w=0.22 with a 2-tailed test, Cronbach α of .05, and power of 0.95. Thus, the expected effect of w=0.36 with a sample size of N=255 will be detectable with a power of 0.99. Given that sun protection behavior is a secondary outcome, we are not powering the trial for this variable.

Analyses of the Impact of MSS on the Diagnosis of New or Recurrent Melanoma

The impact of MSS would be strengthened with data suggesting that survivors who use MSS detect suspicious growths and bring them to physicians for appropriate workup and diagnosis. Given the likely low recurrence rate over the 18 months that participants are followed for in this trial, the study is not powered for testing hypotheses on this end point. Rather, we will conduct an exploratory analysis to examine whether diagnoses differ between MSS and UC. Specifically, the number of diagnoses of earlier-stage new and recurrent melanoma at 18 months will be compared for the 2 conditions using either negative binomial regression models or binary logistic models depending on the distribution of new diagnoses (ie, if there are patients with more than one new diagnosis during the period).

If our findings show that more melanomas are detected in MSS, we will conduct exploratory cost-effectiveness analyses from the health care and societal perspectives by creating simulation models of melanoma-related costs, disease progression, and survival over 5- and 10-year analysis horizons from the start of the trial (aim 3a).

Aim 3: Implementation Outcomes and Contextual Factors Relevant to Future Scale-Up

Overview

The type-1 hybrid effectiveness-implementation approach allows us to obtain vital data to inform future scale-up, dissemination, and implementation. This aim has 3 parts. In aim 3a, we will assess the costs of delivery of MSS and the control condition website; if indicated by the results of aim 2, we will conduct cost-effectiveness analyses. In aim 3b, guided by RE-AIM, we will evaluate the implementation outcomes of MSS from the aim 2 effectiveness trial. In aim 3c, we will elicit actionable feedback on contextual factors relevant to future scale-up, dissemination, implementation, and maintenance from multilevel stakeholders, including survivors, providers, and representatives of organizations invested in melanoma survivorship care. Quantitative and qualitative data from aims 3a, 3b, and 3c will be analyzed and interpreted together to provide valuable insights and directions regarding implementation strategies needed to inform the scale-up and widespread implementation, focusing particularly on reach, adoption, implementation, and maintenance. The results of aim 3 as a whole will answer the following key questions: how can we increase the number of MSS users to maximize adoption? What dissemination channels are preferred to increase our reach to survivors? How can MSS be maintained to provide a sustainable intervention for survivors? What resources or adaptations are needed for organizations and practices to integrate MSS into their survivorship care offerings?

Aim 3a: Costs and Cost-Effectiveness

Assessment of Program Costs

The research team will track the costs of delivering both MSS and the noninteractive educational web page. Costs will first be estimated from a program perspective, capturing the explicit resources required to deliver and maintain the program after all start-up costs (eg, development and programming costs) have been incurred. Costs that are needed to deliver the intervention will be collected to inform the cost of scale-up, but any research-related costs that would not be required for standard program implementation will also be tracked. Sunk costs, which are one-time upfront costs, will be reported separately from ongoing program implementation costs. Program cost data will be collected using a modified version of previous cost surveys developed by the research team and adapted for several interventions [68-73]. The cost surveys capture all relevant labor- and non–labor-related inputs necessary to quantify costs. Labor costs for program staff time (via questionnaires) will be valued using actual or estimated wages. Nonlabor costs will be obtained from program billing records; these include materials and supplies used to support program and intervention activities and costs of facilities and contracted services. The feasibility of including the value of participant time spent on the intervention will also be explored, where participants' time will be valued using age- and sex-specific wage rates. In addition, if the results of the analysis in aim 2 indicate that more melanomas are found among MSS participants than among the educational web page arm participants, costs to the health care sector will be estimated. These include the costs of diagnosing and treating recurrent melanoma. Published estimates of stage-specific medical costs of melanoma will be used to calculate the treatment costs of melanoma by stage at detection [74-79]. To estimate costs from a societal perspective, the costs to each stakeholder group will be summed, including program implementation costs, costs to the health care sector, and the value of participants' time.

Cost Analysis

Total and incremental program costs will be estimated for each arm. Program development costs, a one-time capital investment, will be calculated separately from ongoing implementation costs, or the costs to maintain program delivery for the duration of the intervention. Analyses will distinguish between fixed costs, those that do not vary with enrollment rates (eg, server maintenance), and variable costs, which increase for each participant added. As most costs for MSS are expected to be fixed, the mean cost per participant will be driven largely by the number of enrolled participants. To explore the costs of scale-up, sensitivity analyses will be conducted regarding additional program dissemination efforts and variations in uptake rates. The primary cost-effectiveness analysis will evaluate the additional costs per thorough SSE completed for MSS versus educational web page participants over the 18-month trial. This analysis will be conducted from the program, health care sector (including program costs and costs of health care use for lesions detected), and societal (ie, health care sector plus participant costs) perspectives. The incremental cost-effectiveness of MSS relative to the educational web page will be determined as the difference in mean costs between the 2 arms divided by the difference in mean outcome changes [80,81].

Simulation Models of Melanoma-Related Costs, Disease Progression, and Survival

If the findings show that more melanomas are detected in early stages for the MSS arm relative to the educational web page arm as expected, secondary or exploratory cost-effectiveness analyses will be conducted from the health care sector and societal perspectives by creating statistical simulation models of melanoma-related costs and disease progression over 5- and 10-year analysis horizons from the start of the trial. Assuming the equivalent likelihood of a melanoma recurrence for MSS and educational web page participants, trial data on stage at diagnosis for melanomas detected during the trial (from aim 2) and published estimates of average stage at diagnosis for survivor recurrences in the general population will be used. Melanoma treatment costs beyond the trial period will be simulated for both arms, where the hypothesis is that MSS participants will have lower treatment costs than those in the educational web page arm as earlier detection requires less aggressive treatment. Mortality will also be simulated for both arms to create an effectiveness measure of simulated life years gained (LYGs) for MSS versus the educational web page

comparison group. To estimate LYGs, reductions in melanoma mortality for MSS versus the comparison group will be combined with life expectancy data [82]. As health-related quality of life among survivors of melanoma is similar to health-related quality of life in the general population, there will be no quality adjustment of LYGs as any differences across arms in quality-adjusted life years would be driven by differences in mortality [83-88]. The cost-effectiveness analysis will examine the total incremental costs of MSS compared with the educational web page arm. Incremental costs include program implementation costs (excluding sunk and research costs), health care use costs incurred during the trial and any melanoma treatment costs simulated to occur beyond the trial, and the value of patients' time to participate in the intervention. Incremental effectiveness will be calculated as LYGs for MSS compared with the educational web page arm. Base analyses will discount future costs and life years and use bootstrapping methods to generate 95% CIs for the incremental cost-effectiveness ratio. Sensitivity analyses will explore factors such as rates of detection of thin lesions through SSE, which may make MSS more cost-effective than the educational web page comparator.

Aims 3b and 3c: Exploration of Implementation Outcomes and Contextual Factors Relevant for Future Scale-Up

Sample

MSS Participants

All participants in the intervention trial assigned to MSS will complete surveys assessing specific implementation outcomes. A subset of MSS participants (n=30) will be purposively selected to participate in key informant interviews to reflect a diversity of MSS outcomes, MSS use, ratings of acceptability, and sociodemographic and clinical characteristics.

Additional Stakeholders

To ensure that we obtain a breadth of perspectives on the potential for scale-up, dissemination, widespread implementation, and maintenance of MSS, we will also identify and invite 20 individuals from multiple groups involved in melanoma treatment and survivorship to participate in key informant interviews. These stakeholders will include additional health care providers and representatives from the same organizations participating in aim 1. Participants in aim 3 key informant interviews will receive US $50 for completing the interviews, which will be conducted in person or via videoconferencing software.

Procedures, Measures, and Analyses

Overview

Aim 2 addresses the effectiveness of MSS. Aim 3a addresses the costs associated with delivering MSS, an important factor in the future potential scale-up of the intervention. In aims 3b and 3c, we use mixed methods to focus on the remaining RE-AIM outcomes and PRISM domains using data from the aim 2 RCT combined with surveys and stakeholder interviews.

Quantitative Implementation Outcomes and Analyses

As this is a type-1 hybrid effectiveness-implementation study, our analyses of implementation outcomes are primarily descriptive and meant to inform future planning for scale-up, dissemination, and implementation. Analyses of *Reach* will describe the proportion of contacted individuals who express interest by completing an eligibility survey. The clinical and sociodemographic characteristics of potential participants will be described and compared with those of the population of survivors of melanoma. Analysis of *Adoption* will describe the proportion of eligible participants who enter the intervention website (Table 3). Analyses of *Implementation* will describe the indicators listed in Table 3 and examine their variability by participant clinical characteristics, sociodemographic characteristics, and melanoma risk factors assessed in aim 2. We will also examine the variability in indicators of implementation by recruitment source (registry vs social media advertisements). The Acceptability of Intervention Measure (AIM) is a brief, quantitative measure of intervention acceptability that has demonstrated content and structural validity and test-retest reliability [89] as well as face validity [90]. Participants respond to 4 statements using 5-point Likert-type scales, with higher scores indicating higher acceptability. The AIM will be completed by MSS arm participants at the first follow-up. Acceptability ratings will be summarized using descriptive statistics and compared across clinical, sociodemographic, and risk factor groups.

Table 3. Aim 3 implementation measures.

Outcome	Definition	Measurement	Data source
Reach	• Proportion and representativeness of individuals who express interest in MSS[a]	• Proportion of contacted participants who complete an eligibility survey • Sociodemographic and medical characteristics of individuals who screen vs the population of survivors	• Recruitment and enrollment data • National survivor data set (eg, NHIS[b] and HINTS[c])
Adoption	• Proportion of individuals who begin an intervention	• Proportion of contacted participants who consent, complete baseline survey, and enter the intervention website	• MSS automated data
Engagement	• How much individuals use MSS	• Number of core modules completed • SSEs[d] performed with self-check program • Number of views of MSS • Use of each enhancement (incentives)	• MSS automated data
Program costs and cost-effectiveness	• Total and incremental costs of MSS vs comparison arm; cost-effectiveness of MSS	• Surveys and billing and invoicing documents	• Staff, service provider, and participant surveys; billing and invoicing, including payments; and published literature
Feasibility	• Perception that MSS is feasible for use, dissemination, and delivery	• Qualitative key informant interviews	• Health care providers and professional organizations
Acceptability	• Perception that MSS is satisfactory	• Acceptability of Intervention Measure • Qualitative key informant interviews	• Participant surveys • Survivors, providers, and organizations
Appropriateness	• Perception that MSS is an appropriate fit for intended use	• Qualitative key informant interviews	• Survivors, health care providers, and organizations
Maintenance	• Perceptions of the likelihood, needs, and resources for maintaining MSS delivery	• Qualitative key informant interviews	• Health care providers and organizations
PRISM[e] contextual factors	• Perceived contextual factors related to scale-up and D&I[f]	• Qualitative key informant interviews	• Survivors, health care providers, and organizations

[a]MSS: mySmartSkin.

[b]NHIS: National Health Interview Survey.

[c]HINTS: Health Information National Trends Survey.

[d]SSE: skin self-examination.

[e]PRISM: Practical, Robust Implementation and Sustainability Model.

[f]D&I: dissemination and implementation.

Qualitative Key Informant Interviews

Interviews will be conducted with stakeholders from each group (ie, participants, providers, and organizations) to assess the perceptions of potential barriers and facilitators to consider for future scale-up, widespread implementation, and maintenance. MSS participant interviews will be conducted within the month following their final follow-up during the aim 2 trial. Interviews with other stakeholders will be conducted following completion of the effectiveness trial during the final study year. Semistructured interview guides will include open-ended questions and probes regarding [91] implementation outcomes of feasibility, acceptability, and appropriateness of widespread implementation of MSS for survivors of melanoma. The potential for MSS maintenance will also be explored using open-ended questions and probes, including resources available and needed for the sustainability of the intervention from multiple stakeholder perspectives. In addition, we plan to focus on three PRISM domains: (1) organizational, provider, and patient perspectives on the intervention; (2) characteristics of the recipients of the intervention (survivors); and (3) implementation and sustainability infrastructure (if MSS were to be disseminated and supported by specific organizations outside the research context). To elicit perspectives on the 3 PRISM domains of interest to scale-up, dissemination, implementation, and maintenance, interview questions (as appropriate for each stakeholder group) will focus on (1) current approaches and practices relevant to the promotion of SSE; (2)

the benefits and shortcomings of the MSS intervention; (3) barriers to MSS use (for survivors and those who may suggest it as a resource); (4) possible strategies to disseminate MSS to survivors; (5) pros and cons of suggested dissemination channels and strategies; (6) the "fit" of MSS with the missions and objectives of providers, practices, and organizations; and (7) resources, infrastructure, and other factors needed to sustain MSS.

Qualitative Analyses of Implementation Outcomes

We will follow the guidelines established by the COREQ (Consolidated Criteria for Reporting Qualitative Research) for data collection, analysis, and reporting. The audio recordings of the interviews and focus groups will be transcribed verbatim, deidentified, and imported into the ATLAS.ti software (ATLAS.ti Scientific Software Development GmbH) for analysis. Directed content analysis will be used. This structured method allows researchers to specify constructs of interest a priori (eg, acceptability, feasibility, appropriateness, and PRISM domains) and obtain detailed descriptions or elaborations of them, classifying and coding themes within and across constructs [92]. The study investigators will develop a preliminary codebook for each stakeholder group. A primary and secondary coder will independently code and discuss an initial subset of interviews to explore thematic content and then merge and explore them for concordant and discordant coding. After refining the codebooks, they will recode the first set of transcripts and determine the interrater reliability. After achieving consistency, the coding process will continue. In total, 4 randomly selected transcripts will be identified for double coding and evaluation of discordant coding, followed by any needed modifications and recoding to achieve consensus. Once the initial coding has been completed, 10% of the sample (ie, 1-2 participants from each stakeholder group) will be randomly selected and invited to participate in a member-checking process to determine whether additional data collection is necessary and ensure that valid inferences are made through coding procedures [93]. Following any further corrections, the team will develop a summative grid of emergent themes across and within stakeholder groups.

Synthesis of Quantitative and Qualitative Data to Inform Scale-Up

Mixed methods data will be analyzed and integrated using a concurrent parallel design [94]. As described previously, each type of data (quantitative and qualitative) will initially be collected and analyzed separately. A mapping and matrix approach will facilitate the integration and interpretation of the results, and joint displays will present the integrated results, connecting qualitative themes with quantitative outcomes. The results will be summarized within and across stakeholder groups to allow for consideration of multilevel dissemination and implementation strategies needed for future scale-up, dissemination, implementation, and maintenance.

Data Safety and Monitoring

Before initiating this study, the Rutgers Scientific Review Board will review the study procedures to ensure their scientific merit, safety, legality, and technical feasibility per the established policy. The proposed procedures will then be reviewed for protection against risks by the Rutgers health sciences IRB. Adverse events will be reported through the Rutgers CINJ for processing as per the established policy. This policy includes specific timelines for reporting events that are stipulated by the IRB. In addition to the IRB, the Rutgers CINJ Protocol Monitoring Committee reviews all adverse events for investigator-initiated trials as they occur. The project coordinator, under the direct supervision of the principal investigator, will be responsible for reporting any adverse events that are documented on the safety or adverse events form or reported by the study interventionist. The Rutgers CINJ Protocol Monitoring Committee will oversee the validity and integrity of the data by conducting periodic audits of the study records. The committee is empowered to suspend or close studies with major deficiencies and provides direction to investigators in the development of corrective action plans to rectify and meet identified deficiencies. As part of the Protocol Monitoring Committee function, accrual is monitored for clinical trials. All clinical trials undergo a semiannual review by the Protocol Monitoring Committee, at which time accrual figures are reviewed. Specific accrual rates for each trial are required under protocol monitoring policy. The Rutgers CINJ uses an internal audit program to address retention of participants, adherence to protocol, and data completeness. This audit program is reviewed and governed by the Protocol Monitoring Committee. In addition, there is a Data Safety and Monitoring Advisory Board. This team will consist of a dermatologist, a psychologist, and a survivor of melanoma from the community. The board, along with the study principal investigators, will convene for an in-person or virtual meeting annually. The agenda of the annual meeting will be to review risk procedures, adverse event reporting, and quality assurance. The Data Safety and Monitoring Advisory Board will review any serious adverse events reported as well as investigator adherence to eligibility rules.

Results

To date, we have completed the first phase of aim 1; the remaining phases of this aim are currently in progress. The prototype and content for the MSS intervention were developed in collaboration with Radiant Inc. Following the procedures described in the *Methods* section, one set of stakeholder interviews was conducted with 5 survivors of melanoma who were shown the SSE body map component. A second set of stakeholder interviews was conducted with another sample of 5 survivors of melanoma who were shown the goal-setting module. Participants were shown the prototypes and wireframe. The responses were summarized in field notes, and we reviewed the notes and verbatim transcriptions of key informant interviews. Each proposed enhancement was coded as supportive, neutral, negative, or mixed. For those enhancements that had multiple negative or mixed comments, the team decided whether the issue could be addressed and crafted changes to the content and approach that were congruent with stakeholder feedback.

For the 2 sets of interviews, 19 patients were approached. Of these 19 patients, 10 (53%) were enrolled and 9 (47%) refused. The sample consisted of 50% (5/10) women and 50% (5/10)

men, ranging in age from 32 to 75 (mean 57, SD 14.55) years. They were primarily non-Hispanic White (9/10, 90%) individuals, with 10% (1/10) of the participants identifying as non-Hispanic Black. Most (9/10, 90%) were employed, and 50% (5/10) had a college degree or higher education. In total, 40% (4/10) had conducted a partial SSE in the last year, another 30% (3/10) had conducted a comprehensive SSE in the last year, and 30% (3/10) had not conducted an SSE in the last year.

A summary of the comments regarding design and navigation suggestions is provided in Multimedia Appendix 1. A summary of comments about content is shown in Table 4.

The team provided the recommended changes based on the feedback to the web developer. The interviewees in later interviews reviewed the changes made in response to feedback given in earlier interviews to provide confirmation on whether the issue was adequately addressed.

Table 4. Feedback regarding mySmartSkin (MSS) content and coding for phase 1.

Feedback	Coding	Team decision
Mixed reviews on the incentive options	Mixed	Changed incentive options based on feedback
MSS would be very helpful for survivorship care	Positive	—[a]
Wish MSS was available for public use	Positive	—
Content is thorough but quick to get through, which will motivate patients to use the app	Positive	—
Helps user feel in control of their health	Positive	—
Content seems overwhelming	Mixed	As some users felt that the content was manageable whereas others felt that it was overwhelming, we added a time estimate for each chapter so users will know how long it will take to complete so they can break the content into manageable sessions based on their own schedule.
Make the app more fun	Negative	Included gamification aspects such as badges and prizes that users can win
The importance of SSE[b] and MSS comes through in the content	Positive	—
Content is straightforward, direct, and concise	Positive	—
The app is visually pleasing	Positive	—
User likes the ability to make the text bigger	Positive	—
User likes the use of statistics to reinforce the importance of SSE	Positive	—
Want to share app with family and friends	Positive	—

[a]No decision made as feedback as positive.

[b]SSE: skin self-examination.

Discussion

Principal Findings

Once the analyses are completed, we anticipate that MSS participants will be more likely to perform thorough SSE and sun safety behaviors over the 18-month follow-up period and propose that there will be more earlier-stage melanomas diagnosed in MSS than in UC. In terms of the cost analysis, we expect that MSS will be a more cost-effective strategy given its greater effectiveness in increasing SSE and identifying new or recurrent melanoma. For the reach outcome, we predict that the demographic variables of survivors exposed to MSS will not differ from those of the general population of survivors of melanoma. For adoption, we propose that the proportion of contacted or eligible survivors randomized to MSS who consent, complete the baseline survey, and log into MSS will be equal to or greater than the proportion who adopted the intervention in our previous efficacy trial. For engagement, we propose that 80% of MSS participants will log into the intervention site at least once. For acceptability, we predict that MSS will be rated as highly acceptable, with mean acceptability ratings of ≥4 (out of 5) on the AIM.

Strengths, Limitations, and Unanticipated Problems

The study's strengths are the focus on both effectiveness and implementation through the type-1 hybrid approach; multilevel stakeholder engagement throughout the trial; a novel integration of RE-AIM, PRISM, and health behavior frameworks; the enhancement of a promising fully automated intervention; the scalability of this mobile or web-based intervention; the cost analysis; the longitudinal study design; and the inclusion of clinical outcomes. There are few interventions that have been evaluated to improve SSE among survivors of melanoma. No published intervention is fully automated, which represents a potentially cost-effective and scalable intervention delivery

method. This study will advance the science of cancer survivorship by optimizing a promising intervention for an underserved group of survivors and preparing for widespread dissemination and implementation. Few studies have focused on implementation science aspects of consumer-facing digital interventions. Our use of a type-1 hybrid effectiveness-implementation trial will inform not only our understanding of the effects and implementation of MSS but also our understanding of future large-scale dissemination of self-administered web-based interventions. By evaluating and modeling the clinical outcomes, cost, and cost-effectiveness of MSS, our work will provide information about the costs associated with possible implementation and value.

There are at least 2 limitations. First, some individuals will not use MSS despite its high dissemination. Second, SSE outcomes are measured through self-report. However, this weakness is mitigated by the fact that self-report measures have excellent reliability and validity [14,66,95-100] and self-report has been recommended as the most appropriate assessment approach for wide-scale skin cancer risk reduction research [101].

Future Directions

If effective, MSS could be disseminated and delivered via dermatologist practices, public health organizations such as the American Cancer Society, and nonprofit organizations focused on melanoma or in partnership with existing social media channels. Future research should evaluate potential dissemination and implementation strategies to reach survivors building upon what we will learn in this study about the contextual factors that may impede or promote the future reach, adoption, implementation, and maintenance of MSS.

Acknowledgments

This project was supported by the National Cancer Institute under R01CA265548 awarded to SM and CJH. Services, results, or products in support of the research project were generated by the Rutgers Cancer Institute of New Jersey Cancer Prevention and Outcomes Data Support Shared Resource. The authors acknowledge the following individuals for their valuable contributions to this project: Carolina Lozada, Lisa Paddock, and Radiant Inc.

Data Availability

The data sets generated and analyzed during this study are available from the corresponding author upon reasonable request.

Conflicts of Interest

None declared.

Abstract

Background: Children with mobility disabilities, including those with cerebral palsy, have limited options and limited time to exercise to manage their cardiometabolic health and cardiorespiratory fitness. Regular cardiovascular exercise during childhood is a critical health behavior for preventing health decline in adulthood. Thus, there is an urgent need for accessible, age-appropriate, convenient exercise modalities in this group. Sprint-intensity interval training (SIT), combined with telehealth procedures, may be ideal for children with disabilities. SIT includes repetitive bouts of maximal exercise effort combined with rest periods, which can be effective in eliciting comparable results to moderate-exercise training with very short training durations.

Objective: This phase 1 pilot feasibility randomized controlled trial aims to investigate the potential effects of a 12-week SIT program on indicators of cardiorespiratory fitness and cardiometabolic health among children with cerebral palsy. An ancillary aim is to evaluate the feasibility of the program through several process feasibility metrics.

Methods: This study uses a 2-armed parallel group design. A total of 50 physically inactive children with cerebral palsy (aged 6-17 years) will be randomly allocated into 1 of 2 groups: a 12-week SIT or a waitlist control group that continues habitual activity for 12 weeks. The SIT prescription includes 3 tele-supervised sessions per week with 30 repeated sequences of 4 seconds of maximal arm exercise, with active recovery, warm-up, and cooldown periods (for an approximately 20-minute total session). SIT includes guided videos with child-themed arm routines and music. The exercise sessions will be remotely supervised through a web-based videoconference application and include safety monitoring equipment. Outcomes are measured at pre- and postintervention (weeks 0 and 13, respectively). Health outcome measures include peak oxygen consumption (VO_2 peak), measured by a graded exercise test; high-sensitivity C-reactive protein and blood insulin, hemoglobin A_{1c}, triglycerides, and cholesterol using a finger stick dried blood spot test; blood pressure, using a sphygmomanometer; and body composition (total mass, total lean mass, tissue % lean, and tissue % fat) using dual x-ray absorptiometry. Feasibility will be evaluated by the following metrics: adverse events or problems experienced throughout the intervention related to participant safety; perceived enjoyment; and recruitment, enrollment, and attrition rates.

Results: Recruitment procedures started in November 2023. All data are anticipated to be collected by February 2025. Full trial results are anticipated to be analyzed and submitted for publication by March 2025. Secondary analyses of data will be subsequently published.

Conclusions: This trial tests an accessible and low-cost exercise program that leverages principles of high-intensity exercise to provide a convenient program for children with physical disabilities. Knowledge obtained from this study will inform the development of a larger trial for improving the cardiometabolic health, cardiorespiratory fitness, and well-being of children with physical disabilities.

Introduction

Overview of Cerebral Palsy

Cerebral palsy (CP) is a clinical syndrome that results from a developmental brain injury and is prevalent in approximately 1 million people in the United States and 23 million people worldwide [1]. CP is characterized by disorders of movement and posture due to nonprogressive disturbances of the fetal or developing brain, which is often accompanied by disturbances of sensation, perception, cognition, communication, and behavior [2]. Secondary neurological conditions such as epilepsy, along with other musculoskeletal issues, are also found among people who are diagnosed with CP [2]. Recent innovations in treatments and technology have increased the survival rates of people with CP, resulting in a steadily growing population of adults with CP [3]. Health professionals can now focus on how to help empower young people with CP to live well with a disability, amid a variety of health conditions and socioecological challenges they face with community engagement in adulthood [4,5].

Adulthood and Cardiometabolic Risk

The transitory age between childhood and adulthood is a critical stage for health prevention interventions. As children with CP age into their 20s, they have a substantially increased risk of cardiovascular disease (CVD), related conditions, metabolic syndrome [6], and a 3-fold increased risk of CVD mortality compared to the general population [7-12]. The risk for these cardiometabolic diseases can be lowered by participation in regular moderate-intensity exercise [13-15]. However, recent studies demonstrate that children with CP do not engage in sufficient levels of exercise to obtain health-enhancing benefits, and these levels of exercise participation are far lower than those observed among children without CP [16-18]. Children with CP who exercise regularly are twice as likely to exercise as adults [16]. Consequently, there is a need to identify interventions that promote the early adoption of exercise as a behavior for preventing disease onset, particularly among children with CP who have a mobility disability and have the greatest risk of cardiometabolic disease [19].

Limited Aerobic Exercise Options for Mobility Disability

Conventional exercises that are known to improve cardiorespiratory fitness (eg, walking, running, and cycling) generally require long durations of training that [20] are unsuitable for a large majority of children with CP. As children transition into adulthood, approximately 27% will be unable to walk, 35% will experience decreased walking ability, and 9% will lose their ability to walk [21,22]. Children and adults with CP often experience secondary conditions, such as hemiparesis, fatigue, impaired balance, and joint pain, and these factors impede their mobility to walk or perform types of exercise (eg, cycle) for prolonged periods [22-25]. A recent scoping review demonstrated that a top research priority in the field of disability and exercise is to develop aerobic exercises that are inclusive of wheelchair users [26]. The standard options for exercise training methods require leg work or full body involvement. Aside from arm-ergometry or wheelchair propulsion, there are limited aerobic exercise modalities that are efficacious or effective for people who require seated training, particularly modalities that accommodate hemiparesis [26]. Of note, no randomized controlled trial of exercise has demonstrated a clinically meaningful improvement in cardiorespiratory risk factors in children with CP, likely due to a lack of a sufficient exercise dose [26].

Limited Generalizability of Research Interventions

A second notable limitation of published exercise interventions for CP is low rates of both recruitment and participation [26,27]. Despite over 30 years of research, including 49 published randomized controlled trials, the average sample size for a study was 30 [26]. Most participants were ambulatory, and wheelchair users were typically excluded from participation. These issues hinder the generalizability and transferability of study findings [26-30]. Moreover, low levels of participation in exercise trials were speculated to be due to the following barriers: (1) in-person supervision by a rehabilitation professional or exercise specialist, (2) on-site training at a laboratory or fitness facility, and (3) costly, specialized equipment [26,27]. The identification of an effective evidence-based modality that is inclusive of wheelchair users will require a protocol that can be replicated in a large trial that can provide confirmatory study findings.

Rationale for Sprint-Intensity Arm Exercise

High-intensity interval training (HIIT) has been studied as an effective dose of exercise that has a moderate to large effect on cardiorespiratory fitness and cardiometabolic health while requiring a lower duration of training compared with continuous moderate-intensity exercise [31,32]. Sprint-intensity interval training (SIT) is a form of HIIT that also emphasizes short bouts of exercise with maximum effort at or above a power output associated with a peak oxygen consumption (VO_2 peak) [33]. A meta-analysis [34] found that SIT has a moderate-to-large effect on VO_2 peak that is similar to both moderate-intensity [35,36] and HIIT exercise [33]. Regarding the mechanism, SIT is believed to use anaerobic energy pathways of type IIB muscle fibers, the fast-twitch glycolytic pathways, which are replenished through oxidative metabolism [37], primarily from the kidneys [38]. In other words, extremely short bouts of exercise at maximal intensity can be sustained through the use of lower-intensity aerobic energy pathways. Specifically, higher exercise intensities result in increased renal hypoxemia and, thus, greater production of the hormone erythropoietin. Erythropoietin initiates the production of red blood cells that enhance oxygen use of performing muscles [39] and, thus, VO_2 peak. SIT may further increase VO_2 peak through mitochondrial biogenesis and capillary density [37]. A higher VO_2 peak is linked with reduced risk for cardiometabolic disease [36,40], which is relevant among children with CP who generally have low levels of cardiorespiratory fitness [41]. HIIT with a treadmill has been found to be safe and effective in improving VO_2 peak among ambulatory children with CP [42]. To the best of our knowledge, no randomized controlled efficacy or effectiveness trial has examined a wheelchair-accessible SIT program among children with CP [26,27]. SIT with arm-cycling results in greater gains in VO_2 peak versus leg-cycling (eg, 52% vs 6% increase in VO_2 peak, respectively) [43], likely due to a higher proportion of fast muscle fibers in the arms [43], and this information holds great value for nonambulatory children who can use their arms for exercise.

Telehealth Interventions Foster Enrollment and Attendance

To address low participation, telehealth interventions are especially promising because they remove many of the geographic, environmental, and financial burdens associated with traveling and paying for community programs and classes [44]. Telehealth interventions are especially helpful in delivering health services to children because of reduced burden on the caregiver, who would otherwise have to miss work or other commitments to travel or allocate transportation for the child's appointment [44]. Transportation and time are substantial barriers to exercise participation among people with disabilities [5]. Studies have shown that overall ratings of caregivers toward telehealth appointments are highly positive, and most view telemedicine consultations as at least as effective as those on-site; caregivers had modest reductions in out-of-pocket costs and less missed work costs [45]. In addition, telehealth programs are believed to enhance adherence by providing a sense of accountability, which is created by performance monitoring and social bonds with trusted professionals, as explained by the Supportive Accountability Theory [46]. Home-based exercise programs that incorporate telecommunications and monitoring have achieved the largest sample sizes of people with disabilities [26,27,47]. It is important to note that telehealth interventions that aim to promote strong attendance to an exercise regimen will require remote behavioral coaching strategies to maintain participant engagement. One meta-analysis found that exercise interventions that include behavioral techniques have stronger effects on exercise behavior than those that do not have such techniques [48].

Study Rationale and Purposes

In consideration of exercise barriers (lack of time and transportation) and facilitators of engagement among children (enjoyable exercises and music), this study aims to test a program among children with CP that incorporates (1) age-appropriate prerecorded videos with movement-to-music exercises that are based on child-appropriate themes (eg, superheroes, sports, and pop music), (2) replicable cloud-based telemonitoring procedures, (3) behavioral tele-physical education supervision during exercise, and (4) SIT adapted for varying arm abilities.

Aims

This study has 3 aims, described in following sections.

Aim 1: Examine the Effects of a 12-Week Home-Based SIT Program on Cardiorespiratory Fitness (VO_2 Peak) Compared to a Waitlist Control Among 50 Children With CP

This study will compare pre-post changes in cardiorespiratory fitness between 2 study groups. One group will receive 12 weeks of home-based SIT (n=25), and the second group, waitlist control (WC; n=25), will resume their normal daily activities for 12 weeks. VO_2 peak is the cardiorespiratory outcome of interest, which will be assessed by a graded exercise test using an arm ergometer. We hypothesized that the immediate start group would achieve greater improvements in VO_2 peak versus WC.

Aim 2: Explore the Effect Estimates of SIT on Cardiometabolic Risk Indicators Versus WC

Cardiometabolic outcomes will include high-sensitivity C-reactive protein (hsCRP) and blood insulin, hemoglobin A_{1c} (HbA_{1c}), triglycerides, and cholesterol using a finger stick dried blood spot test, and blood pressure using a sphygmomanometer. Additionally, body composition (total mass, total lean mass, tissue % lean, and tissue % fat) will be measured using dual x-ray absorptiometry (DXA). We hypothesized that arm-based SIT would demonstrate greater improvements in outcomes versus WC.

Aim 3: Evaluate the Feasibility of Arm-SIT Among Children With CP

Feasibility will be measured by process feasibility metrics [49] to inform a larger efficacy or effectiveness trial. Variables will include (1) intervention adherence (class attendance and video minutes through cloud-based analytics), (2) safety (adverse events or problems experienced throughout the intervention

related to participant safety), (3) perceived enjoyment, and (4) engagement (recruitment, enrollment, and attrition rates).

Methods

Study Design and Overview

This phase 1, pilot feasibility randomized controlled trial will include a 2-armed parallel group design to examine the preliminary effects of 12 weeks of arm-based SIT on cardiorespiratory fitness compared to a WC that undergoes habitual activities for 12 weeks. The project will include 50 children with CP (n=25 per arm) and caregivers (n=50 parent-child dyads). One caregiver is required to participate by supporting their child's safety through the intervention and managing the child's exercise schedule. Participants will come to the laboratory for 2 total visits (baseline and week 13) to complete the data collection procedures. Participants will perform the intervention at home, with supervision by a research staff member through telecommunications.

Participants

Textbox 1 contains eligibility criteria for child participants.

Contraindications were informed by guidelines that were established by the American College of Sports Medicine [50] and the Pediatric Physical Medicine and Rehabilitation physician of the study team (DD).

Eligible caregivers will include parents or legal guardians of the child, who can commit sufficient time to support the child in their roles for the study and communicate in English. Caregivers who have complete blindness or deafness will be excluded from participation.

Textbox 1. Eligibility criteria for child participants.

Inclusion criteria

- medical diagnosis of cerebral palsy, as determined by the International Classification of Diseases–Tenth Revision codes
- age 6-17 years
- Gross Motor Function Classification System level 1 to 3 (as determined through participant screening, explained in the Screening and Recruitment section)
- medical clearance from a physician to participate in high-intensity exercise (using the attached medical screening form and explained in the intervention safety, monitoring, and response plan)
- access to a Wi-Fi internet connection in the home through a mobile phone or tablet computer
- a *z* score of ≤–3, indicative of high risk for fracture that could occur from torsion of spine

Exclusion criteria

- physically active (defined as >150 minutes per week of self-reported moderate to vigorous intensity exercise in a typical week)
- cannot use their arms for exercise
- Gross Motor Function Classification level of 4 to 5
- complete blindness or deafness
- pregnant
- uses a pacemaker
- has not been seen by a physician within the previous 12 months of their baseline visit
- uses a g-tube
- any past history of a contraindication to exercise testing: ischemia; myocardial infarction or other acute cardiac event; unstable angina; uncontrolled cardiac dysrhythmias; aortic stenosis; heart failure; pulmonary embolus or pulmonary infarction; myocarditis or pericarditis; aneurysm; low bone-mineral density of the spine (a *z* score of ≤–3, indicative of high risk for fracture that could occur from torsion of spine, determined at baseline data collection through the dual x-ray absorptiometry scan)

Participant Roles

Both the child and caregiver are considered participants in the study, and both will sign the informed consent or assent document.

The child's role in the study is to exercise, following along with exercise videos, 3 times per week for 12 weeks while being supervised through a videoconference web platform by a telecoach.

The caregiver's roles in the study are to (1) attend each videoconference exercise session with the child, (2) schedule and manage the child's exercise schedule, (3) support the safety of the child, and (4) achieve cardiopulmonary resuscitation (CPR) and automated external defibrillator (AED) certification through the Red Cross (certified by the principal investigator, BL, who is certified as a Red Cross CPR/AED instructor).

Screening and Recruitment

Screening for this study will occur in 3 phases. First, contact lists are screened for a medical diagnosis of CP based on the International Classification of Diseases, Tenth Revision (ICD-10) codes. Second, during the initial recruitment contact with a caregiver, research staff will screen participants based

on the study eligibility criteria. As noted previously, to enhance intervention safety, this study aims to enroll children with CP who have only mild to moderate mobility disability and have a low risk of adverse events from exercise. Therefore, the initial recruitment contact through telephone will include the Gross Motor Function Classification System (GMFCS) level [51], using the GMFCS Family Report Questionnaire [52-54]. This assessment will be asked over the phone to avoid wasting participants' time arriving at the laboratory and learning that they do not qualify for the study. Third, a physician (study physician or participants' physicians) will review the patient's medical record and screen the participant for contraindications to exercise testing and risks for participation in high-intensity exercise (based on the Medical Clearance Form, Multimedia Appendix 1). In summary, if an absolute contraindication is identified, the participant will be excluded or withdrawn from the study. If no absolute contraindication is identified, the physician will identify major and minor risks based on the latest information within the patient's medical record and then decide based on major and minor risks to clear the participant for high-intensity exercise training at home. To ensure that record review information is relevant, if the patient has not been seen in the past year, they will have to be seen before obtaining medical clearance and participating in the study.

Candidates will be prescreened and recruited primarily from medical and billing records from the Children's Hospital of Alabama. Medical and billing record databases will be prescreened for potentially eligible patients by patient diagnoses codes (ICD-10, Clinical Modification) related to CP. Contact lists will be generated from the databases. Specific methods of recruitment will include word of mouth and flyers, physician, and staff referrals, mailouts, and phone calls.

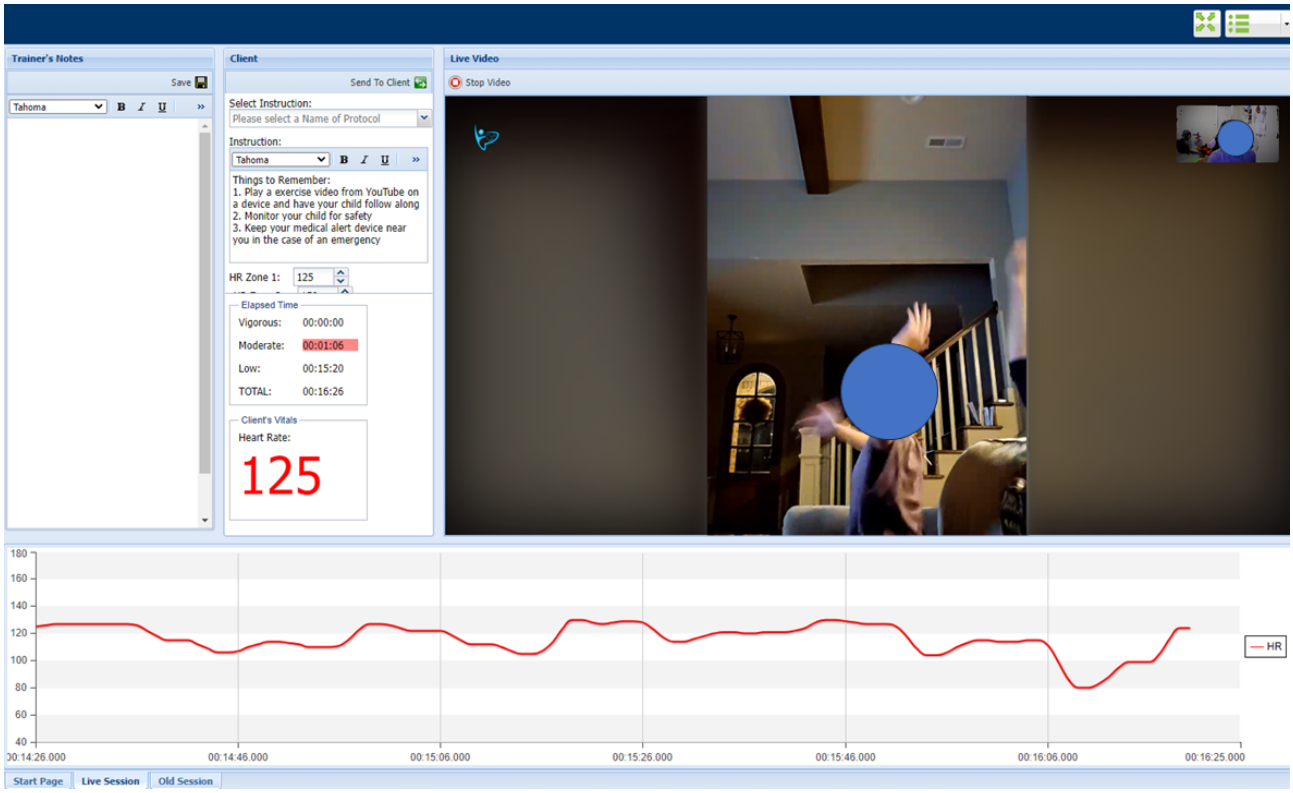
Randomization and Clinical Trial Considerations

Parent-child dyads will be randomized into 1 of 2 groups: arm-based SIT or WC (n=25 per group) with a 1:1 allocation ratio using a permuted block randomization approach. The randomization sequence was generated by the project statistician (RAO) using a computer-generated randomized permuted block design (SAS software, version 9.4; SAS Institute). The project statistician sent the randomization sequence to the database manager (RY) during the study preparation phase. The database manager will unfold the randomization sequence for successfully enrolled participants into 1 of the 2 groups. Study outcomes will be assessed by a research assistant, who will be blinded to group allocation (single-blinded trial design). Recruitment will occur primarily through the Children's Hospital of Alabama. All other activities will be conducted at the Human Performance Laboratory in the Wellness Health and Research Facility at the University of Alabama at Birmingham.

Equipment and Telehealth Monitoring Platform

The study will use a web-based platform with physiologic devices to support remote telehealth supervision of the intervention. The platform, referred to as TeleRehab, includes an Android app that is installed on a computer tablet with Bluetooth capability, which sends data and allows 2-way communications to a secure web server. This setup allows a user on an Android computer tablet to communicate in real time with a member of the research team on a desktop computer. Communication features include videoconference and SMS text messaging. Heart rate data are recorded and transmitted for real-time view by both the user and research staff using a heart rate device (Polar Sense). The heart rate device was placed on a headband and worn on the head to avoid disruption caused by the rapid and vigorous arm movements required for the exercise intervention. Based on internal testing among research staff (nonpublished findings), placement on the head may result in more accurate readings during intervention exercise than when the device was worn on the forearm or upper arm. The device instructions from the manufacturer state that the Polar Sense can be worn on the head, forearm, or upper arm. The TeleRehab app system was an upgraded version of one used previously in a telemonitored feasibility exercise study among people with spinal cord injury [55]. A demonstration of an exercise session in the TeleRehab web portal, as viewed by a telecoach, is displayed in Figure 1. Additional equipment to support the safety of the intervention exercise sessions will include: (1) a blood pressure monitor (Omron HEM-7200/BP7200, 5 Series); (2) a medical alert device (Monitored Medical Alert System), a necklace-worn device that allows 2-way communication between the user and the American District Telegraph (ADT) emergency response team, who is available at all hours of the day to provide remote support for obtaining local emergency response to the user; and (3) a defibrillator (Philips HeartStart OnSite AED Home). Participants will be trained to use all devices at baseline data collection.

Figure 1. Telecoach view of an exercise session with a participant through the TeleRehab app.



Procedures

Participants in the immediate start group will complete a 12-week exercise intervention with 2 data collection visits to the laboratory (pre- and postintervention; weeks 0 and 13, respectively). Participants in the control group will wait 12 weeks before starting the intervention, and they will also complete week 0 and week 13 data collection. Before arrival on a data collection visit, participants will be asked to fast for 10 to 12 hours overnight.

The first data collection visit (week 0) will include the following: (1) study briefing (purpose, procedures, roles, risks, and benefits), (2) informed consent and assent documentation, (3) study questionnaires, (4) cardiorespiratory fitness and cardiometabolic outcome measures, (5) Red Cross CPR and AED training for the caregiver, (6) ADT subscriber agreement form (to receive a medical alert device, shipped to the home from ADT), and (7) intervention or wait briefing (12-week prescription and equipment instructions).

The second data collection visit (week 13) will include (1) study questionnaires, (2) cardiorespiratory fitness and cardiometabolic outcome measures, and (3) debriefing (reviewing pre-post changes in outcomes) for the intervention group or intervention briefing for the control group.

Measures

Questionnaires

The study will include a demographic questionnaire of participant characteristics (eg, age, sex, and BMI) and the Godin Leisure-Time Exercise Questionnaire (GLTEQ). The GLTEQ [56] is a 3-item self-report questionnaire that is used to measure physical activity participation. The GLTEQ asks participants to report the number of times that low, moderate, and vigorous intensity of physical activity was performed for longer than 15 minutes in a typical week. The numbers reported for moderate and vigorous exercise intensity are then multiplied by 7 and 9, respectively, and summed for a score, which is referred to as the health contribution score. A health contribution score of <24 is classified as physically inactive, whereas a score of ≥24 is considered physically active [57]. There is evidence to support the GLTEQ as a valid and reliable measure of physical activity among adults with multiple sclerosis [58] and adolescents [59].

Cardiometabolic Outcomes

Aim 1 Primary Outcome: Peak Oxygen Consumption (VO_2 Peak)

The $V0_2$ peak will be measured during a graded exercise test on an arm ergometer using open-circuit spirometry with a metabolic cart (TruOne, ParvoMedics). Arm ergometers are considered the gold-standard modality for exercise testing among people with disabilities who use wheelchairs or cannot run or cycle for prolonged periods [60,61]. Arm ergometry has been suggested as a valid and reliable method for measuring VO_2 peak among children with CP with mild to moderate disability [62]. Before starting the test, participants rest for 3 minutes. They will then be instructed to maintain a pedaling cadence of 60 revolutions per minute. Resistance is increased every minute by 10 watts until the participant reaches volitional fatigue or achieves 3 of 5 criteria: age-predicted heart rate max of more than 85%; 17 or higher on the Borg rating of perceived exertion (RPE) 6-20 scale; respiratory exchange ratio of 1:1 or higher; plateau in oxygen consumption; volitional fatigue [63]; and subjective signs of exhaustion [64]. Heart rate and oxygen consumption will be measured continuously.

Aim 2 Outcomes: Indicators of Cardiometabolic Health

Cardiometabolic health will be measured through a dried blood spot test, a blood pressure cuff, and a DXA scan.

DXA Scan

DXA scan variables will include total mass, total lean mass, tissue % lean, and tissue % fat. Scans will be analyzed using CoreScan software (GE HealthCare).

Blood Pressure (mm Hg)

Blood pressure will be measured by a sphygmomanometer. Elevated blood pressure during childhood is associated with intermediate markers and hard outcomes of CVD in adulthood [65]. Small changes in blood pressure (–6.4 mm Hg systolic and –4 mm Hg diastolic pressure) can occur from endurance training interventions with durations of up to 12 weeks [66].

Dried Blood Spot Fingerstick Test

A dried blood spot fingerstick test (ZRT Laboratory) will be used to assess blood-related cardiometabolic profiles and include hsCRP, HbA_{1C}, fasting insulin, triglycerides, and cholesterol (total, low-density lipoprotein [LDL], and high-density lipoprotein [HDL]). Dried blood spot tests will be shipped for analysis to the ZRT Laboratory [67]. The ZRT Laboratory blood spot test has been conducted with children [68,69] and has demonstrated excellent validity with venous serum samples (eg, hsCRP, r=0.99; fasting insulin, r=0.93; fasting triglycerides, r=0.95) [67,70].

hsCRP (mg/L): C-reactive protein is a critical marker of inflammation that contributes to proinflammatory and prothrombotic elements of CVD risk. A single hsCRP measure is a strong predictor of myocardial infarction or coronary heart disease mortality, and several other diseases of the circulatory system in people without a history of such conditions [71]. Changes in hsCRP may occur from as early as 8-weeks of exercise [72].

HbA_{1c} (mmol/mol): HbA_{1c} is a measure of red blood cell mean hemoglobin glycation over the previous 3 months. A 1-month exercise intervention without a dietary component can expect a small to moderate effect [73].

Fasting Insulin (µIU/mL): High fasting insulin indicates the presence of insulin resistance, whether an individual shows glucose intolerance. Exercise interventions without a dietary component can expect a small beneficial change in fasting insulin levels after 1 month of training [73].

Fasting Triglycerides (mg/dL): A triglyceride level >150 mg/dL, is supported as an indicator of CVD risk [74,75]. Exercise interventions without a dietary component can expect a small beneficial change in triglyceride levels following 1 month of training [73], even among people with normal triglyceride levels [76].

Fasting Cholesterol (mg/dL): Abnormalities in the lipid profile, including high total cholesterol (TC), high LDL cholesterol, and low HDL cholesterol, are predictors of future CVD among young and middle-aged people [77,78]. Exercise interventions without a dietary component can expect a small effect after 1 month [73].

Aim 3 Intervention Feasibility

Feasibility will be measured using process metrics that will inform a larger trial [49]. Metrics will include adherence to the exercise prescription (measured through an attendance log managed by the telecoaches and TeleRehab cloud-analytics); technological issues; perceived enjoyment after completing the program will be assessed using the Physical Activity Enjoyment Scale (PACES) [79]; recruitment, enrollment, and attrition rates; and adverse events or problems experienced throughout the intervention.

Home-Based Intervention

The SIT intervention will be performed by participants at home and include 3 sessions of exercise per week for a total of 12 weeks. Each SIT session will include 30 repeated sequences of 4 seconds of maximal arm exercise [38], supplemented with active recovery periods of low-intensity posterior shoulder movements to prevent overuse of anterior muscles. Recovery will be gradually reduced from 30 seconds in week 1, 24 seconds in weeks 2-4, to 15 seconds in weeks 5-12 [38]. The total session duration changes from 24 minutes in week 1 to 16.5 minutes in weeks 6-12. Included in the total session duration are a 5-minute warmup and a 2-minute cooldown. A similar leg exercise protocol was found to be effective for raising VO_2 peak [38], and this dose may be optimal for achieving a high training volume while preventing fatigue due to muscle acidosis [38,80]. To achieve maximum intensity, participants are encouraged by the guidance in the videos to perform the 4-second bouts at their maximal effort. Regarding progression, resistance bands (low, medium, and heavy) will be gradually introduced into the exercises so that a participant will report a near maximum intensity (≥7 on the Borg RPE 0-10 scale; explained in detail in the next section) [81,82]. Children with CP from a home-based movement-to-music pilot intervention, from which this study protocol was based, reported that 20-minute videos would be ideal for their attention spans and busy school and care schedules [83]. Sessions will be guided by prerecorded videos that include an adapted exercise instructor (principal investigator BL) and a young adult actor with CP (LB; Figure 2).

Figure 2. Exercise video themes guided by a disability exercise specialist and a young adult with cerebral palsy.

Videos will include 5 themes that were requested by children with CP from our pilot: 3 themes related to superheroes, 1 theme for pop music, and 1 theme for sports. Each theme will include 3 sequential videos that coincide with the rest periods (1 video for week 1, 1 video for weeks 2-4, and 1 video for weeks 5-12), totaling 15 videos. Children with CP can choose to exercise with any themed video that corresponds to their exercise week. Videos include songs that relate to the video themes. Music tempo and volume coincide with sprint and recovery periods. Sprint training incorporates repetitive arm movements that relate to video themes (eg, Spiderman videos include web shooting, football, and arm running or passing). Participants are instructed by the 2 actors in the videos, who demonstrate and guide participants through the exercises. Videos include CP-specific adaptations to enhance engagement [83]: verbal cues, visualized movement adaptations for hemiparesis, slow and repetitive instructions, positive reinforcement, judgment-free atmosphere, and imagery. Videos will be archived within a YouTube playlist. The benefits of archiving videos within YouTube (as opposed to a custom-designed mobile or web application) are that videos are easily accessible on any device, many people are already familiar with YouTube, and this process can easily be replicated. Videos will include themes that are based on copyrighted material, which will only be used for research purposes to adhere to “fair use” for “education” and “research purposes” of the Fair Use Act Copyright Disclaimer, Section 107 of the Copyright Act 1976.

WC participants will be asked to maintain their habitual activity behavior for 12 weeks and then receive the SIT intervention. All participants will be asked to maintain their habitual diet and eating patterns.

Intervention Development

The SIT intervention was adapted from a clinical adult exercise program, referred to as movement-to-music [84]. The program originated from a clinical efficacy trial that demonstrated improvements in lower extremity function and fatigue among adults with mobility disabilities [84]. The success of movement-to-music led to its implementation in larger confirmatory trials among adults with disabilities [85-87]. In contrast, a pilot feasibility trial found that several aspects of movement-to-music required modification to enhance participant engagement among children with CP who had mobility disabilities [69]. Findings from that study informed the development of the present SIT program.

Telecoach and Fidelity

This study will test a high volume of supervised training to ensure children with CP achieve the desired intensity before testing a more scalable self-regulated protocol in a larger randomized controlled trial. All 3 of the weekly prescribed SIT sessions will be supervised through a Zoom (Zoom Video Communications) videoconference by a telecoach. The telecoach will support participants in maintaining maximal effort intensity by monitoring RPE and providing motivational support. Motivational strategies will include positive verbal encouragement to bolster exercise confidence (ie, self-efficacy) and performing the exercises with the participant to enhance learning through observation (ie, vicarious learning). These strategies are informed by social cognitive theory [88], and the research team has used these strategies in other trials [55,83,86,89]. To monitor exercise intensity, the telecoach will ask participants how hard they are working after every change in song (~5 minutes) throughout the session. If participants report <7 RPE, coaches or caregivers will provide positive

verbal encouragement to enhance motivation. Post session, participants will report an overall RPE for the entire bout to determine the need to add resistance bands. RPE has been found to be effective in controlling vigorous exercise intensity in people with spinal cord injury [90]. Since caregiver knowledge and attitude are determinants of participation [91-93], they will be asked to help manage the child's exercise schedule. The telecoach procedure was framed on supportive accountability theory: building a social relationship and bond with a trusted and knowledgeable health professional, with the inclusion of motivation strategies, can enhance intervention adherence [46].

Analyses

Statistical Power

The chosen sample size of 50 participants permits at least 20 in each of the 2 study groups at 12-week follow-up after allowing for up to 20% dropout (in each arm). Power calculations were performed using nQuery (version 8.7) for aims 1 and 2, and SAS (version 9.4) for aim 3.

For aims 1 and 2, baseline measurements will be compared with those obtained in week 13. We obtained estimates of the SD for VO_2 peak of 7.11 mL/kg/min [64], percent body fat (BF) of 8.5% [94], TC of 27.3 mg/dL [95], systolic blood pressure (SBP) of 14.0 mmHg [95], and diastolic blood pressure (DBP) of 11.7 mmHg [95]. With these assumptions and those of a 2-sided 2-group *t* test, an α of .05, and 20 participants per group, the study will have at least 80% power to detect between-group differences of at least 6.47 mL/kg/min in VO_2 peak, 7.7% BF, 24.9 mg/dL in TC, 12.8 mmHg in SBP, and 10.7 mmHg in DBP as being statistically significant (at any time point); with the previous assumptions and those of a 2-sided paired *t* test, an α of .05, and 20 participants, we will have at least 80% power to detect within-group changes of at least 4.70 mL/kg/min in VO_2 peak, 5.6% BF, 18.1 mg/dL in TC, 9.3 mmHg in SBP, and 7.8 mmHg in DBP as being statistically significant (between any 2 time points).

For aim 3, we anticipate adherence to the supervised exercise sessions of this study will be 75%, based on the 70% adherence found from our pilot, which had unsupervised sessions and videos that were not designed for adolescents. For an adherence rate of 75%, and assuming 40 participants in total, with 20 per study arm, complete the study, the corresponding exact binomial 95% CIs are 0.588-0.873) and 0.509-0.913.

Analyses

For all aims, data analyses will follow intent-to-treat principles. Descriptive statistics will be obtained and reported for study variables. The normality of data distribution of the continuous outcomes will first be confirmed using graphical techniques and tests of normality; continuous outcomes that deviate greatly from a normal distribution will be adjusted (eg, transformed) so that the data distribution approximates a normal distribution. All statistical tests will be 2-sided. Differences will be considered significant at $P<.05$. Statistical analysis will be performed using SAS software (version 9.4). Missing data that are not rectified through ongoing review of source documents may be managed with multiple imputations, and the influence of the missing data will be assessed with sensitivity analyses.

For aims 1 and 2, our primary method of analysis will be general linear mixed model techniques, such as mixed model repeated measures analyses, as there will be 2 study groups (SIT and WC) and 3 time points (baseline, 6 weeks, and 12 weeks). Post hoc analyses will be performed using the Tukey-Kramer multiple comparisons test. These models will allow us to assess the between-group effect, the within-group effect, and the group-by-time interaction. Covariates to be included in some models include age, sex, and GMFCS level. Analysis of categorical variables between groups will be performed using the chi-square test (or Fisher exact test, if needed). Pairwise correlations between study parameters will be assessed using Pearson (or Spearman, if needed) correlation analysis.

For aim 3, we will calculate adherence rates, adverse event rates, and other rates of interest and corresponding exact binomial 95% CIs. These rates will be calculated overall and stratified by the study group. Exploratory comparisons of rates between groups will be performed using the chi-square test (or Fisher exact test, if needed).

Ethical Considerations

The protocol and informed consent and assent forms were approved by the University of Alabama at Birmingham Institutional Review Board for Human Use (IRB-300008913) on January 12, 2023. Prospective participants provide written informed consent or assent documentation before participation in the study. Consent and assent forms are completed on the baseline data collection visit.

Before the enrollment of participants, this study was approved by the institutional review board of the university. Written informed consent documentation will be obtained from all participants before their engagement in the study. Participants will receive an electronic gift card that will be loaded for US $500 for each of the data collections completed, for a total of up to US $1000. The rationale for this value is to account for the commitment and time required of both the child and caregiver to complete the study. No artificial intelligence software or program was used in the writing of this manuscript.

Results

This study was approved by the university's institutional review board on January 12, 2023. The study was funded and initiated in May 2023, and the first participant was enrolled in October 2023. As of this manuscript submission on February 7, 2024, a total of 11 people have been enrolled in the study. The study's end date is April 30, 2025. The anticipated publication of the study findings will be in March 2025.

Discussion

Overview

This study will investigate the preliminary efficacy of a home-based, low-cost program for improving cardiorespiratory fitness and metabolic health that is child-appropriate for CP. A program that is short in duration, accessible for various physical

abilities, and can be accessed anywhere through the internet could benefit this population. CP is a low-prevalence disability group that is often geographically isolated from suitable clinics, specialists, and adapted exercise services. Moreover, children with CP have limited options for exercise that are evidenced to improve their health [26,27] and have experienced lower participation in exercise since the outbreak of the COVID-19 pandemic [96].

Strengths and Limitations

Considering that this program can be delivered entirely through an internet video cloud server, YouTube, it has the potential to be carried forward in a scale-up randomized controlled trial of exercise for children with CP. This is important, considering that the average sample size for a randomized controlled trial for children and youths with disabilities has been found to be 27 people, and one of the largest trials included 159 people [27], numbers that are certainly not representative of the diverse needs of children with CP [97]. Another strength of this study is the incorporation of child-appropriate themes and music. Music-based therapy has been found to have an effect on functional ability and goal attainment among children with CP [98]. Child-appropriate themes were requested by this age group and could enhance engagement in therapeutic exercise [83].

This is a preliminary study with a high focus on examining the safety of the intervention and its efficacy under carefully controlled conditions (supervised exercise sessions). Supervised training through telehealth communication provides a sense of accountability that enhances adherence to the intervention prescription [46]. Thus, this study assumes that participants will adhere strongly to the intervention exercise, and the research question is not whether they will perform the exercise; instead, the question focuses on how well they will enhance their health with strong attendance. Should this trial be successful, there will be a need to compare the effects of supervised exercise training versus self-regulated, asynchronous training, which will be the primary format in which prerecorded videos will be used in real-world settings. Supervised training is burdensome for both the research staff and participants.

An additional limitation of this study is the requirement for on-site data collection procedures, which warrants investigation. On-site visitations are difficult for children with CP and their caregivers due to difficulties with transportation and lack of time with busy school schedules, therapies, and daily activities [5,99]. There is a need to develop home-based data collection procedures that provide comparable results to those obtained from in-person testing. The blood spot test can be performed remotely by shipping blood spot test kits to the homes of children with CP. However, to the best of our knowledge, there is no home-based alternative method for measuring cardiorespiratory fitness or body composition imaging, particularly among people with mobility disabilities [20].

Conclusions

Should the findings of this study suggest that the program can improve cardiorespiratory fitness or cardiometabolic health, the study may discover an innovative and, most importantly, scalable method of exercise intervention among children with physical disabilities.

Acknowledgments

The research reported in this publication was supported by the Eunice Kennedy Shriver National Institute of Child Health and Human Development of the National Institutes of Health (award R21HD109358). The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health. Abstract

Background: People living with HIV often struggle with mental health comorbidities that lower their antiretroviral therapy (ART) adherence. There is growing evidence that depression treatment may improve ART adherence and result in improved HIV outcomes. Given that mental health services are severely underequipped in low-resource settings, including in Uganda, new solutions to increase access to mental health care and close the treatment gap are urgently needed. This protocol paper presents the Suubi-Mhealth study, which proposed to develop a mobile health (mHealth) intervention for use among Ugandan youths (14-17 years) with comorbid HIV and depression, taking into account their unique contextual, cultural, and developmental needs.

Objective: The proposed study is guided by the following objectives: (1) to develop and iteratively refine an intervention protocol for Suubi-Mhealth based on formative work to understand the needs of youths living with HIV; (2) to explore the feasibility and acceptability of Suubi-Mhealth on a small scale to inform subsequent refinement; (3) to test the preliminary impact of Suubi-Mhealth versus a waitlist control group on youths' outcomes, including depression and treatment adherence; and (4) to examine barriers and facilitators for integrating Suubi-Mhealth into health care settings.

Methods: Youths will be eligible to participate in the study if they are (1) 14-17 years of age, (2) HIV-positive and aware of their status, (3) receiving care and ART from one of the participating clinics, and (4) living within a family. The study will be conducted in 2 phases. In phase 1, we will conduct focus group discussions with youths and health care providers, for feedback on the proposed intervention content and methods, and explore the feasibility and acceptability of the intervention. In phase II, we will pilot-test the preliminary impact of the intervention on reducing depression and improving ART adherence. Assessments will be conducted at baseline, 1-, 2-, and 6-months post intervention completion.

Results: Participant recruitment for phase 1 is completed. Youths and health care providers participated in focus group discussions to share their feedback on the proposed Suubi-Mhealth intervention content, methods, design, and format. Transcription and

translation of focus group discussions have been completed. The team is currently developing Suubi-Mhealth content based on participants' feedback.

Conclusions: This study will lay important groundwork for several initiatives at the intersection of digital therapeutics, HIV treatment, and mental health, especially among sub-Saharan African youths, as they transition through adolescence and into adult HIV care settings.

Introduction

Overview

Globally, an estimated 39 million people were living with HIV in 2022; of these, 1.5 million were children <15 years [1]. Approximately 84% of new HIV infections among children <15 years occurred in sub-Saharan Africa (SSA) [1]. HIV disproportionately impacts children from poor and disadvantaged backgrounds, and the prevalence of HIV–related complications and mortality are highest among those struggling with poverty and deprivation [2,3]. Poor children living with HIV are more likely to experience compromised health, inconsistent antiretroviral therapy (ART) adherence, and elevated mental health difficulties, including depression, which increases the risk of HIV transmission [2,3]. In Uganda, the focus of this study and one of the SSA countries hardest hit by HIV, over 80,000 children (0-14 years) are living with HIV [4]. Improvements in access and use of HIV services, including testing, care, and availability of free ART have reduced child mortality [5] and resulted in an increased number of children now growing up with a highly stigmatizing and transmittable infection.

Depression is the most common psychiatric disorder among people living with HIV [6,7]. The prevalence of depression among people living with HIV is estimated to be as high as 63% in SSA [8]. Among young people, the prevalence of major depression is estimated between 16% and 40.8% [9]. Depression is associated with compounding and exacerbating negative HIV outcomes [10,11]. While high levels of ART adherence are necessary for young people to benefit individually from ART, as well as for reducing the risk of HIV transmission, depression has been found to significantly impede ART adherence [10,11]. Previous studies have found that patients with depression are nearly 3 times more likely to be nonadherent to medication regimens than patients without depression [12,13]. Depression can impact ART adherence through isolation from social support, impaired adaptive coping skills, apathy, forgetfulness, and hopelessness [14]. In addition, depression-related fatigue, low energy, inconsistent or lack of sleep, and loss of appetite may make it hard to take ART and attend medical appointments [15]. Indeed, due to limited ART adherence and associated medical complications, patients with depression have a higher risk of increased HIV viral load [16], rapid disease progression, and mortality relative to patients who are not depressed [17,18], making this a crucial population with which to intervene. Thus, failure to address the mental health needs of youths living with HIV, including depression, may lead to costly long-term consequences.

There is growing evidence that depression treatment may improve ART adherence and result in improved HIV outcomes [19,20]. Studies have shown that treating depression was associated with up to 83% higher odds of adhering to HIV treatment [19,21]. Among adults, improvements in cognitive processes have been shown to increase confidence and motivation to engage in HIV management behaviors [22,23]. However, few studies targeting the treatment of depression and evaluating the subsequent improvement in ART adherence have been conducted with adolescents [24], and even fewer studies have been conducted with populations from SSA [25]. Therefore, it is crucial to develop interventions for depression that are tailored to the needs of this specific population, given the prevalence of HIV in the region and the elevated risk factors and myriad barriers to care.

Youths are the lowest ART adherent age group and are at the highest risk of dropping out of ART care programs [26-28]. Poor ART adherence among youths is due, in part, to their transition from youth-focused care into adult-focused care that is less accommodating to the needs of this age group who are at the cusp of taking on new roles and responsibilities including their own disease management [29-31]. Moreover, insufficient staff training to support youths living with HIV during this period, lack of pediatric ART formulations in adult clinics, insufficient clinical monitoring, rigid scheduling that interferes with schooling, as well as loss of pediatric clinic relations with peers and clinical support staff all contribute to poor engagement in care during this transition period [27,28]. Indeed, studies indicate that this period in the life course is associated with a significant drop in ART adherence with up to 50% of youths discontinuing their HIV care entirely during this shift [32]. Thus, targeted interventions to improve retention and treatment outcomes during this period are critical.

Cognitive behavioral therapy (CBT) is a promising approach to reduce depression and improve ART adherence [33-35]. CBT is a form of psychotherapy that is focused on changing patterns of thinking and the associated behaviors [36]. CBT has a growing evidence base as an efficacious approach to reducing depressive symptoms and improving ART adherence among people living with HIV [24,33,37-39]. Moreover, evidence

supports the efficacy and effectiveness of CBT in reducing self-stigma for people with mental illness—one of the major barriers to treatment adherence [40,41]. Some key principles of CBT that specifically target ART adherence and depression include instruction for behavioral activation, cognitive restructuring that addresses negative automatic thoughts, problem-solving, and relaxation training [39,42,43]. Despite the promise of CBT, youths with depression living with HIV, particularly those in resource-constrained settings such as Uganda, are challenged by numerous barriers to treatment including lack of access to health care and a severe shortage of trained providers [43-45]. As such, there is a need for interventions developed to take into account these numerous treatment barriers and to structure intervention components and delivery methods to fill the gaps in the current system of traditional assessment and treatment access.

A mobile health (mHealth) intervention is a feasible approach for the delivery of interventions to youths with depression living with HIV in Uganda. Upwards of 85% of countries in SSA have accomplished a high level of mobile phone penetration [46]. According to the 2021 Uganda Communications Commission Report, over 70% of Ugandans own a mobile phone [47]. Indeed, several studies in Uganda have used mobile technology to deliver health interventions, including the promotion of correct HIV or AIDS knowledge and testing [48], improving patient-provider communication [49], increasing clinic attendance among individuals on ART [50], and improving HIV care [51].

However, none have focused on addressing depression among youths living with HIV. Moreover, in our own work in Uganda, 80% of youth indicate access to a mobile phone [52]. In neighboring Kenya, a mobile app tested to deliver individual counseling services and facilitate peer support among youth living with HIV documented positive experiences, peer network development, as well as benefits related to treatment adherence, stigma reduction, and mental and behavioral health [53]. Thus, given the many barriers to care experienced by Ugandan youths living with HIV, as well as the lack of access to trained providers [54,55], the proposed Suubi-Mhealth intervention is a viable and sustainable approach for treating depression treatment in this priority population.

This Suubi-Mhealth study will develop a mHealth intervention for use among Ugandan youth with comorbid HIV and depression, taking into account their unique contextual, cultural, and developmental needs. This mobile app will apply user-centered design methodologies we have used to develop and evaluate similar evidence-based digital therapies [56]. The study will be conducted in 2 phases and will be guided by the following specific aims:

1. Phase 1, aim 1: develop and iteratively refine an intervention protocol for Suubi-Mhealth based on formative work to understand the needs of youths with depression living with HIV (14-17 years).
2. Phase 1, aim 2: based on the results of aim 1, we will explore the feasibility and acceptability of Suubi-Mhealth for use with youths with depression living with HIV on a small scale to inform subsequent refinement for the larger phase of this project.
3. Phase 2, aim 1: pilot-test the preliminary impact of Suubi-Mhealth versus a waitlist control group, on reducing depression (primary outcome) and improving ART adherence, mental health functioning, quality of life, and lowering HIV stigma (secondary outcomes).
4. Phase 2, aim 2: qualitatively examine barriers and facilitators for integrating Suubi-Mhealth into health care settings.

Theoretical Frameworks Guiding the Study

The Suubi-Mhealth study is guided by two complementary frameworks: (1) the mHealth development and evaluation framework [57], and (2) PRISM (Practical, Robust Implementation, and Sustainability Model) [58]. The mHealth development and evaluation framework involves an iterative process for refining a mHealth intervention through integrating various information sources including published evidence, theory, and formative research with the target group [57]. Specifically, this process involves the following steps: (1) formative research to inform the development of the intervention content and regimen; (2) pretesting to determine the acceptability of the proposed intervention, improve and refine the intervention based on feedback; (3) pilot study to test intervention content and regimen as well as the process, including recruitment and data collection; (4) randomized control trial to test the effect of the intervention in comparison with a control group; (5) qualitative research to improve the intervention and implementation issues and methods; and (6) evaluation and implementation to determine the effect of the intervention once scaled up [57].

Similarly, PRISM is a comprehensive intervention development and implementation framework [58]. It emphasizes the following: (1) organizational perspectives on an intervention (eg, feasibility, adaptability, and barriers); (2) external environment (eg, community resources); (3) recipients' characteristics (youths, provider, and parent response); and (4) implementation and sustainability infrastructure (training and supervision supports). PRISM provides a framework to study the interaction of interventions with the characteristics of multilevel contexts or factors that may influence uptake, implementation, integration, and youths' outcomes (youths' responses, provider preparedness, motivation and fidelity, and community-level support).

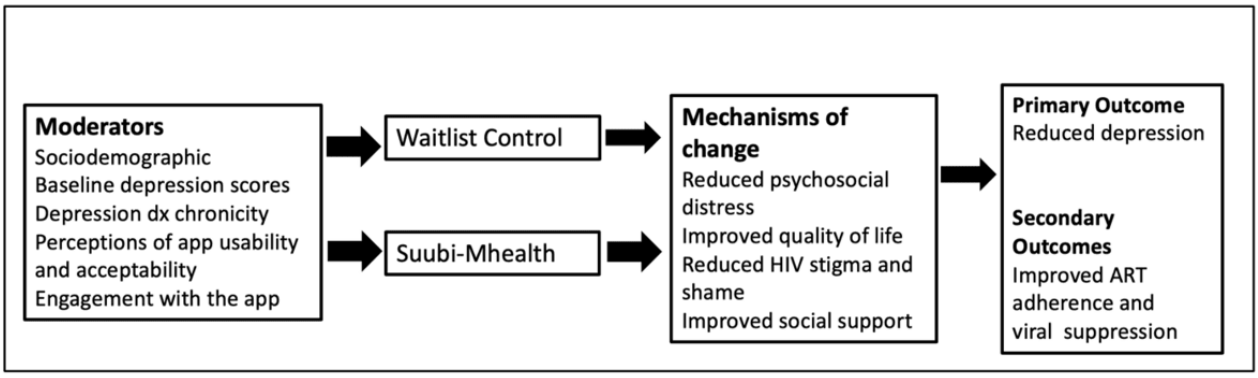
Methods

Study Overview

The overall goal of this study is to develop a mHealth intervention (Suubi-Mhealth) for use among Ugandan youths with comorbid HIV and depression, taking into account their unique contextual, cultural, and developmental needs. In phase 1 of the study, we will conduct 4 focus group discussions, each with 6-8 youths and 2 focus group discussions with health care providers, for feedback on the proposed intervention content and methods. Based on the results from focus group discussions, we will recruit 30 youths to engage with the Suubi-Mhealth app to explore its feasibility and acceptability so as to inform

subsequent refinement for the larger phase of this project. In phase 2, a total of 200 youth from 10 health clinics will be recruited, and randomly assigned to either the Suubi-Mhealth condition or waitlist control condition (5 clinics with 100 youths per condition), to pilot-test the preliminary impact of the intervention on reducing depression and improving ART adherence, mental health functioning, quality of life, and lowering HIV stigma. Upon intervention condition, we will qualitatively examine participants' intervention experiences, as well as barriers and facilitators for integrating Suubi-Mhealth into health care settings. The hypothesized relationships are provided in Figure 1 below.

Figure 1. Suubi-Mhealth conceptual model. ART: antiretroviral therapy.



Research Setting

The Suubi-Mhealth study will be implemented in the greater Masaka region located in Southern Uganda, with one of the highest HIV prevalence in the country [4]. Youths will be recruited from health clinics where the International Center for Child Health and Development (ICHAD), which will house the study, and our collaborating institution, Reach the Youth Uganda, operate. For phase 1, youths will be selected from 2 clinics within 1 district. These clinics will be excluded from phase 2. For phase 2, we will select 10 clinics based on size (total number of youth served) and health facility level (levels II, III, IV, or hospital) in each district. For a health clinic to be included in the study, it will have to be credited by the Uganda Ministry of Health to provide ART and have adolescent-friendly services, for example, adolescent clinic days. The procedures have been used in our other studies implemented in the study region [52,59,60].

Inclusion Criteria

Youths will be eligible to participate if they meet the following criteria: (1) 14-17 years of age with the cognitive ability to understand and comprehend the assenting process; (2) HIV-positive and aware of their status, that is, disclosed to; (3) receiving ART and care from one of the participating clinics; and (4) living within a family, including with extended family members (not in institutions). We will identify youths with depressive symptoms by administering the Patient Health Questionnaire-9 (PHQ-9) [61], which has been validated in rural settings in Uganda [62,63]. Youth scoring ≥10 on the PHQ-9 will be considered for enrollment. Youths will be excluded if they do not meet the inclusion criteria above or are unable to understand the informed consent process, or inability or unwillingness to commit to study completion. Health care providers will be recruited if they are working directly with youths living with HIV at their clinics and agree to participate in the study.

Participant Recruitment and Consent

Procedures tested in our previous and ongoing studies in the study region will be used [59,60,64,65]. Specifically, participants will be identified and recruited from health clinics that are currently collaborating with ICHAD and Reach the Youth in the study region. A list of eligible participants will be created from medical records. Health care providers will present the study to adult caregivers of eligible youth during adolescent clinic days. These are scheduled days when youths visit clinics for ART refills, counseling, and treatment check-ins. If caregivers are interested, verbal consent to be contacted by a research staff (who will be onsite) will be requested. Next, the adult caregiver and the youth will separately provide consent or assent for the youth to be screened. Youths who meet the inclusion criteria and their caregivers (separately) will undergo an informed consent process to participate in the study. The consent and assent forms will clearly state that the youth can withdraw from the study at any time, for any reason, with no explanation, and will not be penalized. Caregivers will sign the consent form consenting for their children to participate. Youths will sign an assent form. If either the youth or the caregiver refuses to participate, the youth will not be enrolled. Health care providers will go through the same process and sign a standard consent form.

Sample Tacking and Retention

The project will take place in a highly stable region of Uganda, where geographical moves are rare. In addition to recommendations garnered by focus group discussion participants in aim 1, we will use several practices to increase retention. During our interviews, youths will be asked to provide details of contacts, including telephone number, and names, addresses, and contact information for 3 people who will always know how to reach them. Participants will be reminded that if the research team were to contact the people listed, the team would never discuss any details about the participant's involvement in the study. A phone call reminder will be made prior to each assessment. Our team has effectively used these

methods in all our research projects, resulting in very low attrition [66-69]. We will keep careful records for those who drop out of the study and test for attrition bias based on data collected prior to study dropout. To the extent that such bias is present, we will limit generalizations accordingly, or, where possible, introduce statistical adjustments to address bias. Retention efforts will be periodically reassessed, reviewing best practices to reduce attrition.

Ethics Approval

We obtained approval for all study procedures from the Uganda Virus Research Institute Research Ethics Committee (Ref: GC/127/919) on August 29, 2022, Washington University in St. Louis Institutional Review Board (IRB; 202209115) on October 06, 2022, and from the Uganda National Council for Science and Technology (Ref: SS1442ES) on November 15, 2022. The study is registered in the Clinical trials.gov database (Identifier: NCT05965245).

Description of the Study Conditions

In phase 2 of the study, participants will be randomized to 2 conditions (100 youths per condition): a waitlist control condition or the Suubi-Mhealth condition, as detailed below.

Waitlist Control Condition

A waitlist control condition method will be used [70]. Participants will be randomly assigned to a waitlist and will receive the Suubi-Mhealth intervention after the active treatment group. In addition, participants will receive a smartphone without the Suubi-Mhealth app at the same time as the intervention group.

Suubi-Mhealth Treatment Condition

Overview

Participants in this condition will receive the Suubi-Mhealth intervention, with the specific components described below. All modules will be available in text, video, and audio format. All app content will be available in Luganda local language.

Evidence-Based Multimedia Psychoeducational Content to Reinforce Treatment Plans

Educational content will be provided within Suubi-Mhealth and broken into 20 modules. Users will be provided access for 2 months and will be instructed to review ≥2 modules per week. The research team has aligned Suubi-Mhealth content with state-of-the-science recommendations for CBT for ART adherence and depression as applied to HIV medication adherence [33]. In addition, the research team has implemented a group- CBT intervention to address depression and HIV-related stigma among adolescents [59,71]. This manualized intervention, developed with close consultations with mental health experts in the region, will be adapted into Suubi-Mhealth content. Core instruction will include psychoeducation on the interplay between HIV and depression; minimizing cognitive distortions related to ART adherence, stigma, and depression; challenging negative automatic thoughts; analysis and development of behavioral skills; reducing environmental stressors; creating support and helping communicate concerns adaptively and clearly; and problem-solving [37,38].

Safety Plan

To ensure safety while using the app, participants will be informed that the social networking center is informational only and not equipped for managing crises. Messages from users will be reviewed by a trained member of the research team within 24 hours. If signs of an imminent crisis are detected, a supervisor will send a crisis referral, make a report, and notify the parent so that no user waits longer than 24 hours to receive support. Emergency contact information will be shown in the corner of the survey page for all assessments.

Goal Setting and Self-Monitoring Features to Enable Self-Management

Our previous mHealth participants have indicated their desire for a goal-setting feature within an app, and studies of mobile apps have demonstrated that goal-setting, self-tracking, and monitoring features are essential to facilitate self-management skills and sustain user engagement [72,73]. With this in mind, there will be an ability to set goals and monitor symptoms of depression over time within Suubi-Mhealth. Rewards within an app have been shown to motivate and sustain healthy behaviors [74]. Our rewards feature will be used to inspire completing psychoeducation content and attaining goals by awarding digital “trophies” for participants who successfully meet a goal or reach a milestone (eg, complete a module on how to challenge negative automatic thoughts).

Clinical Dashboard to Monitor Participants’ Use of Suubi-Mhealth

A clinical management dashboard will make it efficient for the research team to input participant data and monitor participant use of the app and assessment responses.

Data Collection

Data will be obtained through an eligibility screening checklist, computer-assisted, interviewer-administered structured questionnaires, focus group discussions, and semistructured in-depth interviews. All assessments will take place at the clinic, participant’s home, or ICHAD’s field offices in Masaka. Assessments will be conducted by trained Ugandan Research Assistants.

Qualitative Assessments

Focus group discussions and semistructured interviews will be conducted. In phase 1, we will conduct 4 separate 60-minute in-person focus group discussions (6-8 youths each) and 2 focus group discussions for health care providers. Participants will be asked about impressions of expert-suggested content and design and their own suggested components for Suubi-Mhealth that could be of greatest utility for unique needs. They will also be asked for input regarding methods to increase participation and retention for follow-up assessments. All focus groups will be conducted in Luganda, will last approximately 1-hour and will be held in a private location at each clinic. In addition, we will conduct a 30-minute semistructured qualitative interview with each participant to further explore their experiences with Suubi-Mhealth, including perceived benefits and challenges of participation, and suggested modifications to improve specific components of the intervention. Complications or technical glitches with the app, and how it fared in regard to its ease of

understanding, helpfulness, intuitive flow, presentation, and pacing will also be assessed. We will also conduct in-depth interviews with research staff who will be moderating the app.

In phase 2, we will conduct semistructured in-depth interviews with 30 participants upon completion of the intervention to explore their experiences with the intervention as well as barriers and facilitators to implementation and participation. Participants will be purposefully sampled [75], using a combination of high- and low-app users, that is, those in the upper and lower quartiles of engagement with the app (15 participants per group), to take part in a 30-minute semistructured qualitative interview. Interviews will focus on participants' experience with Suubi-Mhealth and how it fared in regard to its ease of understanding, helpfulness for supporting ART adherence and depression, intuitive flow, presentation, pacing, and the likelihood that they would recommend this intervention to a peer. Reactions to specific content and suggestions for improvement will also be assessed. We will additionally perform in vivo observations in which participants actively use the tool during the interviews to more directly observe challenges to use and implementation.

Quantitative Assessments

Quantitative assessments will be administered as follows. In phase 1, interviewer-administered quantitative assessments will be collected at 2 months post intervention to examine the usability characteristics and engagement with Suubi-Mhealth. To assess usability characteristics, we will administer a modified version of the 19-item USE (Usefulness, Satisfaction, and Ease of Use) questionnaire to measure usability characteristics of Suubi-Mhealth [76,77]. The USE will ask participants to rate the ease of use and learning (ie, efficiency), usefulness (ie, technical effectiveness), and likability (ie, satisfaction) of Suubi-Mhealth on a 7-point Likert scale (with 1= strongly disagree and 7= strongly agree).

To assess engagement with Suubi-Mhealth, automatically captured data within the app platform will be used to measure app engagement for each participant, including (1) the number of modules completed, (2) the number of messages sent, (3) the number of times self-monitoring and goal-setting features used, (4) the number of times logged into the app, (5) the time spent in the app once logged in, and (6) the time difference between app log-ins.

In phase 2, assessments will be completed at baseline and at 1, 2, and 6 months post intervention to evaluate whether participants' ART adherence and self-reports on symptoms of depression, mental health functioning and physical health, and quality of life and stigma improve with access to Suubi-Mhealth and whether improvements remain consistent over time. The measures to be used are provided in Table 1 below.

Table 1. Phase 2 assessment measures.

Variable	Measures
Demographics	Sociodemographic questionnaire
Depressive symptoms	Patient Health Questionnaire-9 (PHQ-9) [61] and Brief Symptom Index (BSI) [78]
Physical health	The Medical Outcomes Study HIV Health Survey (MOS-HIV) [79]
Quality of life	Pediatric Quality of Life Inventory (PedsQL 4.0) [80,81]
HIV shame	Shame questionnaire [82,83]
HIV stigma	Berger HIV Stigma Scale [84]
Social support	The Multidimensional Scale of Perceived Social Support [85] and Social Support Behavior Scale (SS-B) [86]
ART[a] adherence	Viral load; self-reports [87]
Intervention feedback	In-depth interviews

[a]ART: antiretroviral therapy.

Data Analysis Procedures and Milestones

Phase 1, Aim 1: to Develop and Iteratively Refine an Intervention Protocol for Suubi-Mhealth Based on Formative Work

Overview

We will conduct 4 focus group discussions, each with 6-8 youths (N=32), and 2 groups with health providers (n=16) for feedback on proposed intervention content and methods to increase participation and retention. Focus groups will be audio-recorded and transcribed verbatim. Transcripts will be translated into English and imported into Dedoose to assist with qualitative data management and coding. Inductive thematic analysis of focus group transcripts will be conducted by 2 research team members using the 6 steps described by Braun and Clarke [88] (getting familiar with the data, creating initial codes, looking for themes, reviewing and refining themes, defining and naming themes, and producing the report).

Milestone for Aim 1

We will have garnered input from youths and health care providers about the proposed Suubi-Mhealth content, features, and design. Participants will provide feedback on additional suggested components for Suubi-Mhealth that could be of the greatest utility for their unique needs. Suubi-Mhealth will be refined accordingly including its technical aspects, features to add or edit, and content updates or revisions. Participants will also be asked for input regarding methods to increase participation and retention for follow-up assessments. The study design and methods will incorporate feedback received from

participants. Specifically, the research team will incorporate relevant suggested content and features into the Suubi-Mhealth intervention protocol before testing.

Phase 1, Aim 2: to Explore the Usability, Feasibility, and Acceptability of Suubi-Mhealth in a Small Sample to Inform Subsequent Refinement for the Larger Phase

Overview

Following the integration of input and feedback from focus groups to update and refine Suubi-Mhealth (phase 1, aim 1), we will β test Suubi-Mhealth among 30 youths. This is within the range of sample sizes for other pilot tests of digital therapeutics [77,89], and the suggested number of participants for pilot studies [90]. This sample size should be sufficient to explore the usability of and engagement with Suubi-Mhealth and for data saturation for qualitative interviews [91]. Participants will be instructed to use all features of Suubi-Mhealth for 2 months for the purpose of this β test. Two months for β testing is similar in length to other pilot tests for mental health apps [92,93], and will allow sufficient time for participants to engage with as many of the modules and features as they would like. Upon completion, we will garner feedback from each participant via mixed methods exploratory design in order to inform further enhancements of Suubi-Mhealth prior to the RCT (phase 2). We will conduct both quantitative assessments to examine the utility and usability of the Suubi-Mhealth and qualitative interviews to explore participants' experiences with the app.

Analysis Procedures

Quantitative assessments will be recorded using Qualtrics, an electronic data capture system. The data will be exported into the Statistical Analysis System for analysis. App usability will be examined using descriptive measures (mean, SD, median, and range) on the efficiency, technical effectiveness, and satisfaction components of the USE questionnaire. Descriptive statistics will also be used to describe engagement with the app (eg, the median number of logins and time spent in the app). Qualitative data will be analyzed in Dedoose following the same procedures provided in aim 1 above.

Adaptation and Feedback Integration Process

We will use procedures similar to those in our other studies for adapting mental health interventions based on target user feedback [94]. Specifically, participants' feedback gathered from content and usability testing, as well as from experiences obtained during in-depth interviews, will be incorporated into the app based on the level of importance and feasibility including cost. The research team, including the research staff overseeing the app and selected youth, will go over each module to make sure that relevant revisions have been incorporated. Together, the research team will review and approve the adapted content and design before launching phase 2.

Milestone for Aim 2

Participants will have, on average, engaged with 75% or more of the mobile app modules and will express enthusiasm over its potential to be a supportive tool. Participants will score Suubi-Mhealth as having high ease of use and learning (ie, efficiency), usefulness (ie, technical effectiveness), and likability (ie, satisfaction). Participants' provided feedback will be integrated into the app design.

Phase 2, Aim 1: to Pilot-Test the Preliminary Impact of Suubi-Mhealth

Overview

During phase 2, participants will be randomized to the intervention condition to engage with the Suubi-Mhealth app or the control condition (waitlist control group) to receive the app after the active intervention period. Assessments will be completed at baseline and at 1 month, 2 months, and 6 months post intervention to evaluate whether participants' self-reports on symptoms of depression, ART adherence, mental health functioning, quality of life, and stigma improve with access to Suubi-Mhealth and whether improvements remain consistent over time.

Participants will also complete the USE measure to assess acceptability and usability, as well as in-depth interviews to explore their experiences with the intervention.

Analysis Procedures

Following guidelines for clinical trial analysis, all primary analyses will be intention-to-treat analyses and missing data will be handled using multiple imputations.

Mixed-Effect Models

The principal strategy to examine primary and secondary outcomes over time between the Suubi-Mhealth group and the control group will be the use of linear mixed models and generalized linear mixed models, including a random intercept to allow for the correlation of within-participant measurements over time. Models will include the fixed effects of the intervention group (Suubi-Mhealth vs control), time, and group-by-time interaction. Effect sizes and 95% CIs will be reported.

Moderation Analysis

First, we will provide descriptive statistics on engagement (session duration, number of modules viewed) and usability scores. We will then use moderation analysis to examine whether Suubi-Mhealth engagement and usability scores moderate the effect of the interventions on our primary and secondary outcomes of interest (ie, depression, ART adherence, psychological distress, overall quality of life, shame, and HIV stigma).

Structural Equation Models

We will use mediation analysis to examine whether depression symptoms mediate ART adherence. We will test for mediation using structural equation models with CIs derived from bootstrapping of indirect and total effects. By applying mediation analyses, we will be simultaneously testing whether the intervention engages the targets and whether intervention-induced changes in targets are associated with clinical benefit. Models will account for baseline scores. For sensitivity analyses, we will use a per-protocol approach to address noncompliance by only including participants who completed the study according to the protocol.

App Engagement and Usability

Basic descriptive statistics will be reported for Suubi-Mhealth engagement (session duration and number of modules viewed), as well as app usability scores (USE scores and subscales of efficiency, technical effectiveness, and likability). To determine the relationships between app usability and engagement, we will use linear regression models with an index of engagement (derived from principal components analysis using the above raw metrics of engagement) as the dependent variable and overall usability score as the primary predictor of interest. Demographics associated with both the usability scores and the index of engagement will be included as covariates in the model. In a separate model, we will include each usability subscale (efficiency, technical effectiveness, and satisfaction) rather than the overall usability score in order to explore which subscale might be most predictive of engagement with the mobile app-based tool. In addition, linear mixed models will be used to investigate the association between the intervention engagement index with the primary outcomes over time. Covariance structures for the models will be selected as described above. Effect sizes and 95% CIs will be reported.

Sample Size and Power

The primary outcome in aim 1 is whether depression decreases between baseline and postintervention initiation. This is calculated from the depression score change between these 2 time points and categorized as yes versus no. The intracluster correlation for clinics is assumed to be 0.093 and the rate of depression decrease in the control group is 5% [95]. Given our total sample (N=200, 100 youths per condition, 5 clinics per condition), we expect to achieve at least 80% power to detect a rate difference of depression decrease when the rate of depression decrease in the intervention group is 40% and the 2-sided significance level of the test is .05.

Milestone for Phase 2, Aim 1

Successful completion of a parallel-group RCT to test the feasibility, acceptability, and preliminary efficacy of Suubi-Mhealth. Participants will not experience any adverse events. Participants will have engaged with Suubi-Mhealth daily for 2 months and engaged with at least 75% or more of the modules.

Phase 2, Aim 2: to Examine the Barriers and Facilitators for Integrating Suubi-Mhealth Into Real-World Contexts

Overview

Upon completion of the intervention, we will conduct semistructured in-depth interviews with 30 participants upon completion of the intervention to explore their experiences with the intervention as well as barriers and facilitators to implementation and participation. Based on prior research [79], we anticipate that barrier themes may include (1) lack of knowledge and self-efficacy in using mHealth tools; (2) participants' inability to receive mobile service due to lack of service coverage and connectivity issues; (3) participants' inability to understand, maintain, or properly use the mHealth tool due to technology literacy issues; and (4) financial sustainability concerns related to the inability to charge a fee for service, bill, or otherwise be reimbursed for services provided via technology. We anticipate that facilitators may include working collaboratively with the app development team to address technical barriers and adapt the app to meet participants' needs and consistently reviewing app use data to inform progress [80]. The perceived relative advantage of the app over usual care, the ease of use and ability to adapt the app to improve participants' use, and awareness of participants' needs and resources will also likely serve as facilitators.

Milestone for Phase 2, Aim 2

Completion of an implementation evaluation in which barriers and facilitators are successfully identified as actionable inputs to inform the integration of Suubi-Mhealth into real-world contexts for youths with depression living with HIV. To ensure that this assessment is constructive in facilitating future implementation, we will map each key barrier and facilitator to a relevant implementation strategy identified in the literature to address a similar barrier or leverage a similar facilitator for maximal benefit [96,97]. For example, if the barriers related to service coverage and connectivity issues are mentioned, then the actionable solution will include working with a different service or network provider. This process will yield a concise yet informative implementation toolkit to support future implementation efforts that may face similar patient, provider, and organization-level challenges.

Data Integration and Triangulation

Findings from qualitative and quantitative data analyses will be integrated during the interpretation and discussion stages [98]. Conclusions and inferences will be synthesized for a more contextualized and thorough understanding of the preliminary impact of the intervention. The mixed methods design will serve two purposes: (1) complementarity and (2) expansion [99,100]. Qualitative findings will be connected to quantitative findings where the former will provide explanations and context for findings produced by the latter. Moreover, qualitative findings will complement our understanding of attendance and participant satisfaction with the intervention.

Results

The team completed the recruitment of phase 1 study participants (phase 1, aim 1) in January 2023. A total of 32 youths and 16 health care providers from 2 health clinics were recruited. Youths and health care providers participated in focus group discussions (4 groups for youths and 2 groups for health care providers). During the discussions, participants shared their feedback on the proposed Suubi-Mhealth intervention content, methods, design, and format, to inform the development of the app. All focus group discussions were audio-recorded to ensure accuracy of participants' responses. Transcription and translation of focus group discussions have been completed. The team is currently conducting data analysis of participants' responses, to inform the development of the Suubi-Mhealth app content. Concurrently, the development of Suubi-Mhealth content is ongoing. Specifically, the team is developing short videos to be incorporated into the app, including those related to depression and its symptoms, strategies to reduce negative thoughts, skill building, daily activities, and goal monitoring, to be incorporated into the app. Upon completion, the app will

be tested among 30 youths to garner feedback on usability (phase 1, aim 2).

Discussion

Overview

People living with HIV, including adolescents, often struggle with mental health comorbidities that lower their adherence to ART treatment [7,9]. There is growing evidence that depression treatment may improve ART adherence and result in improved HIV outcomes [19,20]. This Suubi-Mhealth study will develop a mHealth intervention for use among Ugandan youths with comorbid HIV and depression, taking into account their unique contextual, cultural, and developmental needs. We expect Suubi-Mhealth to be an acceptable and feasible mHealth tool to reduce depression and improve ART adherence and overall mental health functioning among youths.

The study innovates in the following ways. First, while mHealth interventions have been tested and implemented to improve adherence to ART among youths [50,51,53], digital intervention strategies addressing depression plus ART adherence among youths living with HIV in SSA are very limited [101]. This study will generate data-driven knowledge to address depression and ART adherence and will ultimately improve HIV-related health outcomes for youths, including adherence to medication. Second, delivering CBT—a theoretically driven intervention, delivered via a mobile app—has the potential to facilitate timely linkage and access to mental health services for youths, one of the major challenges to addressing mental health in impoverished communities. Previous studies have documented the potential of CBT to improve ART treatment outcomes [102]. Third, the study makes use of existing local institutions—both research and community-based institutions and locally recruited and trained research staff—to deliver its intervention, building research capacity and ensuring eventual scale-up and sustainability. Fourth, partnering with local institutions, including health clinics and community organizations, as well as the youths, grounds the project with a practical understanding of the needs of youths in the greater Masaka region—an area of Uganda hardest hit by HIV or AIDS [4]. Finally, the study takes advantage of the increasing penetration of cellphones and mobile phone ownership in Uganda [46], to test and deliver an innovative, culturally-tailored intervention with significant public health outcomes. Taken together, this study will lay important groundwork for several initiatives at the intersection of digital therapeutics, HIV treatment, and mental illness, especially among SSA youths, as they transition through adolescence and into adult HIV care settings.

Dissemination

The research team will facilitate learning across stakeholders and maximize the use of the evidence generated through dissemination meetings. Uganda's HIV prevention and treatment guidelines and policies recognize the burden and impact of mental health and HIV stigma on HIV treatment outcomes among youths, their families, and communities. If findings warrant, we will leverage these policy guidelines to maximize dissemination of study findings.

Data Sharing

The research team is committed to open, timely, and widespread sharing and dissemination of study findings. The team adheres to the National Institutes of Health's Public Access Policy that requires final, peer-reviewed papers to be submitted to the National Library of Medicine's PubMed Central upon acceptance for publication. We will also make study results available via papers written for professional and layperson publications, presentations at scientific and professional conferences, special lectures or talks in academic and professional settings, websites, and newsletters. Once all data have been deidentified, cleaned, and validated, and the main findings have been published, the investigators expect to share data with the scientific community. The research team will make data sets available to any individual who makes a direct request to the principal investigators and indicates the data will be used for the purposes of research. In sharing participant data, the team will follow Office of Sponsored Projects' data sharing agreements at Washington University in St. Louis, which are similar in their specification of the following conditions to be met before data are shared: (1) a formal research question is specified a priori; (2) names, affiliations, and roles of any other individuals who will access the shared data; (3) the deliverables—for example, paper, conference presentation—are specified a priori; (4) proper credit and attribution—for example, authorship, coauthorship, and order—for each deliverable are specified a priori; (5) a statement indicating an understanding that the data cannot be further shared with any additional individuals or parties without the Principal Investigators' permission; and (6) IRB approval for use of the data (or documentation that IRB has determined the research is exempt).

The research team will strip data of identifiers that would permit linkages to individual research participants and variables that could lead to deductive disclosure of the identity of individual participants. We will share data in electronic format native to the software used by the research team; requestors are expected to handle converting electronic formats. Upon completion of the deliverables, the MPIs will instruct the requestor to destroy all copies of the data. If deliverables have not been produced yet, the agreement to share data will be revisited annually by the MPIs and the research team to decide whether to continue sharing or terminate the sharing agreement.

Acknowledgments

The authors would like to thank our staff and volunteers at the International Center for Child Health and Development (ICHAD) Field Office in Masaka, Uganda, and our implementing partner, Reach the Youth, for their respective contributions to study preparation and implementation. The authors are very grateful to the youth and their caregiving families, participating health

clinics, and expert clients, for agreeing to participate in the study. The study outlined in this protocol is supported by the National Institute of Mental Health (NIMH; Grant R21MH131044; MPIs: PN; PC-R, and JM). NIMH has no role in the study design, data collection, analysis, interpretation of findings, and manuscript preparation. The content is solely the responsibility of the authors and does not necessarily represent the official views of NIMH.

Conflicts of Interest

PC-R is a consultant for Rissana, LLC, PredictView, and Woebot. The other authors declare no conflicts of interest.

Abstract

Background: Computer-assisted clinical coding (CAC) tools are designed to help clinical coders assign standardized codes, such as the *ICD-10* (*International Statistical Classification of Diseases, Tenth Revision*), to clinical texts, such as discharge summaries. Maintaining the integrity of these standardized codes is important both for the functioning of health systems and for ensuring data used for secondary purposes are of high quality. Clinical coding is an error-prone cumbersome task, and the complexity of modern classification systems such as the *ICD-11* (*International Classification of Diseases, Eleventh Revision*) presents significant barriers to implementation. To date, there have only been a few user studies; therefore, our understanding is still limited regarding the role CAC systems can play in reducing the burden of coding and improving the overall quality of coding.

Objective: The objective of the user study is to generate both qualitative and quantitative data for measuring the usefulness of a CAC system, Easy-ICD, that was developed for recommending *ICD-10* codes. Specifically, our goal is to assess whether our tool can reduce the burden on clinical coders and also improve coding quality.

Methods: The user study is based on a crossover randomized controlled trial study design, where we measure the performance of clinical coders when they use our CAC tool versus when they do not. Performance is measured by the time it takes them to assign codes to both simple and complex clinical texts as well as the coding quality, that is, the accuracy of code assignment.

Results: We expect the study to provide us with a measurement of the effectiveness of the CAC system compared to manual coding processes, both in terms of time use and coding quality. Positive outcomes from this study will imply that CAC tools hold the potential to reduce the burden on health care staff and will have major implications for the adoption of artificial intelligence–based CAC innovations to improve coding practice. Expected results to be published summer 2024.

Conclusions: The planned user study promises a greater understanding of the impact CAC systems might have on clinical coding in real-life settings, especially with regard to coding time and quality. Further, the study may add new insights on how to meaningfully exploit current clinical text mining capabilities, with a view to reducing the burden on clinical coders, thus lowering the barriers and paving a more sustainable path to the adoption of modern coding systems, such as the new *ICD-11*.

Introduction

Background

Artificial intelligence shows a lot of promise for many health care applications, but its implementation in clinical settings is still limited [1]. One promising implementation area is clinical coding, which involves clinical staff or trained personnel going through large amounts of clinical text, such as discharge summaries, and assigning clinical codes to the texts. Clinical staff can thus summarize the patient's stay at the hospital using a system of codes such as the International Statistical Classification of Diseases and Related Health Problems (version 10; *ICD-10*[*International Statistical Classification of Diseases, Tenth Revision*]) [2].

A systematic way of summarizing patient care at hospitals is important for multiple reasons. The primary use of such data is to judge both the quality and volume of care. The data also serve as a consideration point for resource allocation. In addition, good coding practice is important for improving the quality of data available for secondary purposes such as research and knowledge generation.

An analysis of the literature reveals at least 2 major uses for computer-assisted clinical coding (CAC) systems [3]. The first type of use is to assist clinical coders in their work in real time, while the other type of use is in auditing the quality of existing coding. Audits are a principal element of quality control, especially since there have been reports of significant coding errors in electronic health record (EHR) systems. For instance, in a Swedish study, Jacobsson and Serdén [4] reported that 20% of the main diagnosis codes were wrong. For this user study, we focus on the former type of use, that is, assisting clinical coders in real time.

Available Knowledge

In terms of the informatics methods that CAC systems use, there is wide variation. Depending on specific use cases, rule-based methods have been successfully used to extract clinical concepts from texts [5-7] or to classify clinical texts into standard terminology such as Systematized Nomenclature of Medicine—Clinical Terms or International Classification of Diseases [8,9]. Rule-based methods appear to work well, but generally, texts have to be tokenized into short phrases or n-grams. Words within each sentence are usually treated independently of each other. Unless considered separately, clinical language peculiarities such as negation [10], uncertainty and speculations, and acronyms and abbreviations [11] can obscure the meaning of words in sentences.

With the advances in deep learning, in particular, transformer architectures, longer text sequences can be processed using contextual embeddings, where the representation of each word is based on its context. This contextual understanding of words makes deep learning an appropriate tool for CAC systems that process long and complex clinical texts. Santos et al's [12] systematic review on the topic shows a clear timeline transition toward deep learning methods, and this finding is echoed in a recent review by Kaur et al [13]. However, occasioned by multiple limiting factors related to the nature of clinical coding, current state-of-the-art (SOTA) performance is still unsatisfactory and lags other application areas of deep learning.

One of the major limiting factors is that assigning clinical codes to large sequences of text is a hard problem, compounded by a very large number of codes that represent the label space (eg, more than 20,000 *ICD-10* codes for Norwegian). In addition to the large number of codes, the level of class imbalance is rather extreme in this use case. Another limiting factor is that many close codes have semantically similar descriptions. An example of 2 semantically similar codes is "Other diseases of tongue (K14.8)" and "Disease of tongue, unspecified (K14.9)." It is challenging for a model to discriminate the two, since they both appear to describe some unnamed condition of the tongue [14]. Combined with other limiting factors such as poor data quality and availability, these factors make the design of automatic *ICD-10* coding systems nearly unattainable, especially for minor languages such as Norwegian and Swedish.

To get around this automatic coding problem, 2 popular approaches have emerged. In the first approach, researchers experiment with just a small portion of the codes, for instance, top-10 [15] or top-50 codes [16]. In many instances, these few top-N codes represent the majority of the data, but such systems perform poorly on rare codes. In the second approach, rather than automatically assigning *ICD-10* codes, multiple possible codes are provided as suggestions, much like recommender systems, with top-N suggestions. It is conceivable that this second work-around approach is useful to clinical coders because it provides potentially meaningful cues and pointers to the correct codes. This is the approach taken by the current user study.

It is important to note that a number of inconsistent findings have emerged from the little that has been published. In a recent study, Chen et al [17] concluded that, while their system improved the accuracy of *ICD-10* assignment, the system did not reduce the time required to assign the codes. In complete contrast to these findings, an earlier study by Wang et al [18] found significant time efficiencies when the CAC system was used, as did Fung et al [19]. We hypothesize that text complexity partially explains the conflict. Since text complexity is a factor that has not been fully explored in existing studies, we base our analysis of accuracy and time on the complexity of the clinical text.

Specific Aims

The aim of the project is to investigate artificial intelligence tools, natural language processing specifically, to improve the

quality of *ICD-10* coding. The goal of the user study is to test whether our Easy-ICD system can reduce the burden of coding and also improve the quality of *ICD-10* coding. The main end points to measure are (1) the individual's coding accuracy averaged across all instances and F_1-score (harmonic mean of recall and precision, each of which is averaged over all instances), (2) time use for assigning codes, and (3) usability based on the system usability scale [20].

Methods

Study Population and Location

The user study will recruit clinical coders (physicians, health care staff, professional coders, etc) from Norway and Sweden on a rolling basis. Even though clinical notes are in Swedish, most of the target population understands both the Scandinavian languages.

Inclusion and Exclusion Criteria

In terms of participants, the main inclusion criterion is that the participant has coded clinical texts before, preferably *ICD-10* coding. Participants could be clinicians, nurses, professional coders, or other health care staff who understand Swedish with any amount of coding experience. We shall exclude participants outside Sweden or Norway.

Study Time Frame

Recruitment of participants commenced toward the end of 2023, and we will continue recruitment on a rolling basis until the target number of participants is reached.

Ethical Considerations

The data curated for this study is available through Permission Dnr 2022-02386-02 from the Swedish Ethical Review Authority. This user study is part of the ClinCode Project approved by The Regional Committee for Medical and Health Research Ethics, Norway (260972). Participation is based on informed consent. A web page with information based on the template from the Norwegian Centre for Research Data is used to provide information about (1) purpose of the project; (2) institution responsible for the project; (3) why the user is being asked to participate; (4) what the user is expected to do as a participant; (5) participation as voluntary; (6) user personal privacy, when and what happens with their data; (7) information about user rights (under the General Data Protection Regulation); (8) who to contact for more information or concerns; and (9) the final section where the user clicks on "Consent" or "Decline." If the user consents to participate, the consent is logged, and the user can proceed to the study. Thus, we have a written record of consent. If the user declines, they are redirected away from the study. It is important to note that no personal or identifying information is collected, and browser cookies are only used to track progress. Thus, all the data we store will be completely anonymous.

Intervention

The CAC system, Easy-ICD, is based on deep learning transformer models, also called language models. The system uses a language model trained in 3 main cycles, based on a typical natural language processing pipeline involving unsupervised or semisupervised training (pretraining) and supervised training (fine-tuning). First, the base model, Kungliga Biblioteket—Bidirectional Encoder Representations From Transformers (KB-BERT), was obtained from the transformers library [21]. KB-BERT is a Swedish general language model that was pretrained by the National Library of Sweden [22] and is publicly available. This pretraining represents the first training cycle. In the second cycle, KB-BERT was further pretrained on 17.8 GB of pseudonymized Swedish clinical text from the Health Bank infrastructure at Stockholm University [11], resulting in the current clinical language model named SweDeClinBERT [23]. In the final training cycle, also called fine-tuning, the model was fine-tuned on a pseudonymized data set, the Stockholm EPR GastroICD-10 Pseudo Corpus II, encompassing 120,000 patients. Using pseudonymized data for training improves security by decreasing the likelihood of private information leakage.

This model achieves SOTA results on this clinical coding task, comparable to results reported for English health data sets like the Medical Information Mart for Intensive Care [24]. This clinical coding task is framed as a multilabel problem, where participants can select and assign more than one *ICD-10* code to the clinical text. Actual performance results of the model are reported in a paper under consideration, and these results will be released in the final reporting of the user study.

Considering the Easy-ICD user interface, instead of displaying only the top label or labels as predicted by the model, we display the top-N predictions, where N is between 5 and 10. Through experimentation, we determined that an ensemble output from the deep learning model and fuzzy logic had the best results. Fuzzy logic is based on word-level and sentence-level minimum edit distance, using Levenshtein distance [25], comparing between *ICD-10* descriptions and the clinical text.

Easy-ICD is implemented as a web application for this user study, but in the future, the functionality will be incorporated into an EHR system. We used the classical model-view-controller pattern involving the deep learning model module, HTML 5 web interface, and a Python back-end controller, respectively. The web interface has the following sections: (1) the clinical note, (2) color-coded visualization to explain the suggestions, (3) the top-N suggestions from where the participant selects relevant *ICD-10* codes to assign, (4) qualitative feedback with star-rating and text feedback, and (5) a lookup feature for *ICD-10* codes.

Disease and Data

We use Swedish clinical notes in the gastrointestinal (gastro) domain in our study. The data used are from the gastrointestinal department of the Health Bank infrastructure at Stockholm University [11]. The data contain both in- and outpatient records of patients receiving treatment at the department, both surgery and other medical interventions. The data originate from a hospital, and no effort was made to include only similar cases; therefore, the cases vary.

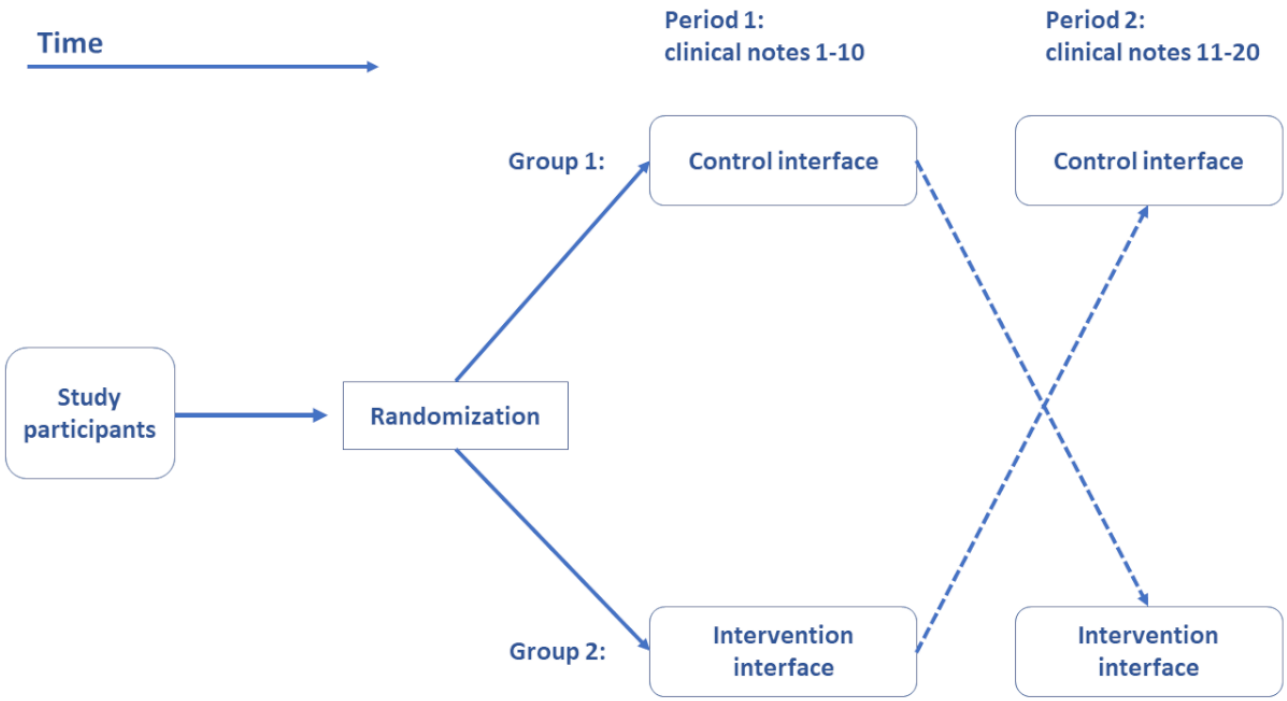
The data are pseudonymized and have been curated by 2 professional clinical coders, so as to double-check the coding

and create a gold standard. The 2 coders reviewed the data independently and reconciled their differences through discussion. This curation process also ensures that it will be possible to assign a code based on the clinical text alone, without the need for further information about the patient. This is important since the user study will not have access to further EHR data such as laboratory results or drug lists.

Study Design

This study is designed as a 2×2 crossover study as illustrated in Figure 1. This design, AB|BA (2 different sequences and 2 periods), is chosen for its uniform and balanced properties, aiming to control the carryover effect between periods. The design is suitable not only for comparing treatments but also for assessing pre-post effect of an intervention [26]. In addition, the crossover design requires a comparatively smaller number of participants than what a randomized controlled trial would ordinarily require.

Figure 1. Crossover randomized controlled trial where study participants are randomized into 2 groups. The first group first uses a control interface and then switches to our Easy-ICD tool, while the second group starts with our tool and switches to a control interface.



We will not incorporate a washout period partly because the learning element in the tasks measured is limited and partly because we do not want to risk losing participants in a long break between periods. The data sets in the 2 periods are different, and this limits any carryover effect in the sense that coders cannot memorize the text or the correct codes.

Once participants are recruited, they are randomly allocated to the 2 groups without allocation concealment. Allocation concealment will not be relevant for coders since it is known whether a participant is assisted or not, and we will not develop a placebo coding assistant. We will, however, conceal the allocation of subjects for the analyses.

In total, participants will code 20 clinical notes, where each note belongs to a single patient. The participants are asked to complete the experiment in 1 sitting without interruptions, and they cannot revisit or go back to previous notes. In the event that participants are interrupted, they are asked to exit the experiment, and any incomplete experiments are discarded as invalid.

In terms of the coding process, both the control and intervention user interfaces have a search utility for looking up *ICD-10* codes. Participants will be free to access any other additional search tools they wish to use without restriction. Since we measure time using a before and after design, the effect of additional tools is not expected to be a significant factor. The time is logged based on the browser button presses such as “Start,” “Next,” and “Complete.”

The user study process can be summarized in the following steps:

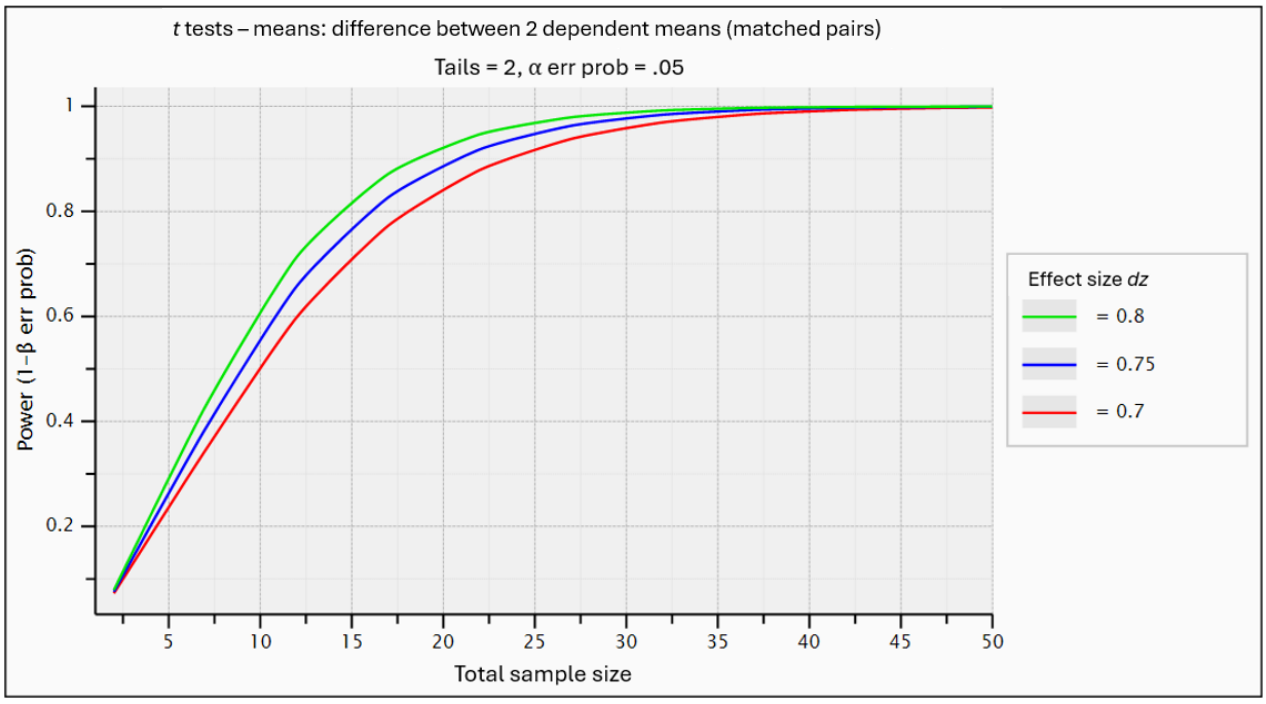
1. Study participants are randomly allocated to group 1 and group 2.
2. To prepare participants for the experiment, a short video tutorial is played after the consent form is signed and right before the clinical coding task commences.
3. In period 1 with 10 clinical notes, group 1 uses the control interface, while group 2 uses the intervention interface.
4. Data are logged in the background using button presses—time, assigned codes, and comments.
5. Then, there is an immediate crossover to period 2 for the last 10 clinical notes.
6. Data continue to be logged in the background using button presses.

7. At the end, participants in both groups will complete the system usability scale.

Sample Size Calculation

This experiment is novel, and we have not succeeded in finding many similar studies from which to estimate test parameters. Therefore, our experiment is important in that it provides baselines that may be useful for similar experiments in the future. We do expect a correlation between periods; the same coders are measured twice on mean performance in time, making a matched 2-tailed *t* test suitable for the task [26]. This matched 2-tailed *t* test (period) is done in 2 sequences, and the sample size calculation must therefore be doubled [27]. Further, each sequence will consist of approximately 10 coding instances, giving extra power to the estimation of the sequence mean. Due to the unknown nature of the expected effect size, the sample calculation in Figure 2 is made with 3 different effect estimates ranging in the upper level of medium to high effect. A pilot study is necessary to establish a probable effect size and adjust sample size estimation if needed.

Figure 2. Statistical power of a 2-tailed t test at the level of 5% depending on sample size per sequence (2-tailed t test with equal SD in both study sequences to compare means).



Based on the plot in Figure 2 derived from power analysis in G*Power [28], we aim to recruit up to 30 participants in total. Multiple methods are used to recruit participants, including contacting hospitals and health authorities directly, announcing at coding seminars and conferences, publishing news in popular science media, and advertising on social media groups and other electronic media.

Measurements and Analyses

The focus of our measurements is on how clinical coders perform with and without our system:

1. Compared with the performance of the unaided user, statistical tests of significance are used to check whether there are significant differences in the quality of coding when Easy-ICD is used, as measured by accuracy and F_1-score.
2. Time spent is the time it takes for a clinical coder to assign a code.
3. System usability survey will be given to all participants to measure usability of the web interfaces, both with and without our Easy-ICD system.

Main analyses are based on hypothesis testing using the paired *t* test and Wilcoxon test to compare the before and after means at a significance level of .05. Table 1 summarizes these hypotheses based on a test of equivalence.

Table 1. Time use and coding quality hypotheses testing to compare the before and after means.

Time use	Coding quality (accuracy and F_1-score)
Null hypothesis: (H_0: $\mu_1=\mu_2$)	
There is no time difference between using CAC[a] and not using CAC for coding Swedish clinical notes	CAC does not affect a clinical coder's coding quality
Alternative hypothesis: (H_1: $\mu_1\neq\mu_2$)	
There is a significant time difference between using CAC and not using CAC for coding Swedish clinical notes	CAC affects a clinical coder's coding quality by a significant margin

[a]CAC: computer-assisted clinical coding.

In additional exploratory analyses, we will examine the effect wrong suggestions have on the coder's performance, and how often coders adopt these wrong suggestions. In addition, the distribution of the different professions between the groups as well as the coding experience will be explored.

To enable us to analyze the main outcomes in relation to text complexity, we distinguish between two categories of clinical texts: (1) short and simple texts (<512 tokens) and (2) long and complex texts (>512 tokens). However, we only consider the length of the text as the complexity dimension, as opposed to the complexity of the case or provided care, for example.

Results

Overview

Our results will be based on the statistical significance of the 2 tests related to time use and coding quality, which will allow us to conclude whether or not our CAC tool, the Easy-ICD, has the potential to impact clinical coding practice in a meaningful way. The expected results to be published summer 2024.

Evaluation Outcomes

The evaluation outcomes are as follows: (1) clinical coders aided by our Easy-ICD system are expected to yield better performance, that is, the accuracy and F_1-score. (2) We expect that the Easy-ICD system will result in time savings during coding tasks. Looking at the 2 categories of clinical notes, it can be expected that the most time savings could be gained with large and complex texts. Such cases take more resources than shorter and simpler texts. (3) We expect the usability of the system to have a system usability score over the generally accepted normal score of 68 [29]. Further, we do not expect any significant differences between the usability of the user interfaces with and without our CAC system.

Discussion

Principal Findings

There are 2 primary areas of interpretation with which our study is concerned. The first relates to the quality or accuracy of clinical coding. If it shows that coders aided by our system perform better than unaided coders, we can conclude that our system is a useful tool to improve the quality of clinical coding. If, on the other hand, no significant improvement in accuracy is noted, we have to look to the other measurement point for complete interpretation. Time efficiency is the other interpretation point, where we would like to see significant time improvement between the intervention and control.

If the accuracy is not better, then the time savings must be significant. If there are no time savings, then the improvement in accuracy must be significant. It can also be argued that the CAC system is still useful even if the timing is slightly worse, while the performance is better by a significant margin.

If neither time nor accuracy improves, then we have to think about improving the system for future studies. Regardless, we plan to publish our findings in an international (or Nordic) peer-reviewed journal or conference and note all the facilitating factors and barriers.

In terms of usability, if there are no significant differences in usability scores, then usability issues can be ruled out. If the CAC system has significantly better usability scores, we expect the usability scores of the standard interface to be no worse than what is considered normal.

Limitations

Perhaps one limitation of this study is that we curate the clinical texts used in the study so that the participants should be able to assign a code simply by assessing the text. In practice, some clinical texts need supporting information from other information sources such as pathology or radiology systems [9]. This supporting information would normally be available in patient record systems.

Another limitation is that we only considered data from the gastrointestinal department (K-codes), and this *ICD-10* chapter has a comparatively smaller number of codes. There were 415 unique codes in the training data, and just over 480 K-codes exist in the Norwegian version of *ICD-10*. In contrast, the whole *ICD-10* system has a total of over 20,000 codes in Norwegian. Therefore, the generalizability of our system is an important factor to consider for future studies when expanding to other clinical domains.

Comparison to Prior Work

Even though there are many papers on experimental work dealing with assigning *ICD-10* codes to clinical text, only a few studies with health care staff exist. The planned user study holds the potential to yield new insights about the usefulness of CAC systems in terms of reducing coding time and improving coding quality, both of which are important impact indicators for reducing the burden on clinical coders.

Conclusions

In terms of impact, positive outcomes from this study contribute to the evidence that supports the adoption of CAC tools to reduce barriers to the implementation of modern coding systems such as the *ICD-11* (*International Classification of Diseases, Eleventh Revision*).

Acknowledgments

The authors thank professional coders at Karolinska University Hospital for their advice during the development of the Easy-ICD system and surgeons at the Gastrointestinal Department at the University Hospital of North Norway for their advice in the project. The publication charges for this paper have been funded by a grant from the publication fund of UiT The Arctic University of Norway. This research is funded by the ClinCode project through the Research Council of Norway (grant 318098 awarded to HD). The funder had no role in study design, data collection and analysis, decision to publish, or preparation of the paper. No generative artificial intelligence was used in this study or the preparation of this paper.

Data Availability

Data sharing is not applicable to this paper as no data sets were generated or analyzed during this study.

Authors' Contributions

TC conceptualized the study. TC, AL, AB, TOS, PDN, KØM, and HD participated in methodology deliberations. TC, AL, and AB developed the software. TC prepared the original draft, and AL, AB, TOS, PDN, KØM, and HD contributed to the review and writing process. TOS and LIH worked on data curation, and LIH provided advice as a domain expert in clinical coding. TOS led the statistical analysis. HD acquired the funding and supervised the study. All authors reviewed the final paper.

Conflicts of Interest

None declared.

Protocol

Integration of an Electronic Screening, Brief Intervention, and Referral to Treatment Program Into an HIV Testing Program to Reduce Substance Use and HIV Risk Behavior Among Men Who Have Sex With Men: Protocol for Intervention Development and a Pilot Randomized Controlled Trial

Abstract

Background: Men who have sex with men (MSM) are disproportionally affected by HIV and drug and alcohol use; however, few effective HIV prevention interventions for MSM who use substances exist. Screening, Brief Intervention, and Referral to Treatment is an early intervention for non–treatment-seeking individuals with problematic substance use and for timely referral to treatment for those with substance use disorders. Electronic screening and brief interventions (e-SBIs) reduce implementation challenges. An e-SBI tailored for MSM at the time of HIV testing might be particularly opportune to strengthen their motivation to reduce substance use and HIV risk behavior.

Objective: This study aims to develop a tailored e-SBI program to reduce substance use and HIV risk behavior among MSM seeking HIV testing at Nexo Asociación Civil, our community partners in Argentina (primary); assess the feasibility and acceptability of integrating the e-SBI into the Nexo HIV testing program (primary); assess the feasibility and acceptability of implementing an adapted Men's Health Project (MHP) at Nexo (secondary); and finally, explore preliminary findings on substance use and sexual risk reduction outcomes (exploratory).

Methods: This mixed methods study has 2 stages. During stage 1 (development), we will use the User Centered Rapid App Design process consisting of focus groups (n=16), individual interviews (n=24), and a pilot deployment of the e-SBI (n=50) to iteratively develop the e-SBI. Quantitative and qualitative assessments at each step will inform the revision of the e-SBI. Furthermore, we will use the assessment, decision, administration, production, topic experts, integration, training, testing framework to adapt MHP. During stage 2 (pilot randomized controlled trial [RCT]), we will randomize 200 MSM coming to Nexo for HIV testing. They will complete a baseline assessment and then their assigned intervention (e-SBI vs screening only) and will be followed-up for 6 months. We will also conduct in-depth interviews with up to 45 participants: 15 participants from either study condition who entered or completed MHP or other substance abuse treatment and 15 from each arm who met the criteria for MHP but did not request it.

Results: The study began recruitment in October 2022, and the stage-1 pilot study is near completion. Preliminary findings from stage 1 show high e-SBI acceptability. Data analysis of the stage-1 pilot is now beginning. The stage-2 pilot RCT will be launched in March 2024, with all data collection completed by May 2025.

Conclusions: This study will allow us to assess the acceptability and feasibility of e-SBI implementation during HIV testing encounters. We will also build the necessary research infrastructure for a subsequent RCT to assess the efficacy of e-SBIs in reducing substance use and HIV sexual risk behavior among MSM in this setting.

Introduction

Background

Men who have sex with men (MSM) are disproportionally affected by HIV and drug and alcohol use [1-11]. Given the association between substance use and HIV risk behavior among MSM [12-25], the dearth of effective HIV prevention interventions for MSM who use substances is striking. However, as in the general population, identifying and engaging MSM with problematic substance use (PSU) in treatment is a significant challenge [26-28] that results in most MSM with PSU never receiving treatment [29].

The Substance Abuse and Mental Health Services Administration recommends Screening, Brief Intervention, and Referral to Treatment (SBIRT) as an early intervention for nontreatment-seeking individuals with risky alcohol and drug use and for timely referral to more intensive treatment for those with substance use disorders [30]. However, implementing SBIRT is a challenge; brief intervention (BI) is often missed and not evidence based, which can diminish its effectiveness. For example, when SBIRT was implemented in sexually transmitted disease clinics in New York City, out of 66,989 positive screens, only 17,474 received BI [31]. In medical settings, factors such as limited staff time, commitment to implementation, training requirements, difficulty in learning evidence-based BIs, skepticism about the effectiveness of SBIRT, and poor fidelity to recommended BI guidelines are all obstacles to the successful implementation of SBIRT [32-39]. These factors limit the BI in a particular setting. BIs can range from providing normative feedback to the individual on their level of severity (at times just a written report), brief advice (10-15 min), or a single 30- to 45-minute session. However, studies have shown that interventions that go beyond normative feedback and provide an empathic [33] or motivational component [34], or consist of multisession interventions for high-risk users, have better outcomes but can be difficult to implement. As a result, sizeable percentages of patients in a setting go unscreened, those who meet the criteria for a BI may not receive it, the BI may be delivered inconsistently, and the BI may not be of sufficient intensity to reduce substance use among those with low or moderate risk use or to improve entry into substance abuse treatment among those with high-risk use or dependence [35].

Electronic screening and brief interventions (e-SBIs) reduce implementation challenges such as extensive training, demands on staff time, and inconsistency in the delivery of BI [32,36-42], while remaining as effective as in-person SBIs [43-46]. Because an e-SBI demands only that a staff member provide an individual with a tablet or computer space to complete both the screening and BI, more individuals can be screened and receive the BI. For example, in an implementation pilot study that used e-SBI in rural clinics, approximately 92% of patients were screened, with over 95% of screen-positive women receiving the tablet-based BI, which far exceeds the rates in trials of person-delivered SBIRT (SJ Ondersma, personal communication). Furthermore, e-SBIs are consistently rated highly for acceptability among users and may facilitate greater disclosure of PSU than in-person SBIs because of concerns of being judged by providers. As such, an e-SBI tailored for PSU and sexual risk behavior among MSM at the time of HIV testing, when a contemplative client is already concerned about his risk behavior and cares enough about his health to seek an HIV test, might be particularly opportune to strengthen his motivation to reduce substance use and HIV risk behavior.

The need for such interventions is particularly acute in Argentina and Latin America, where there is little implementation of evidence-based interventions for MSM with PSU. In *Proyecto LINKS*, our study of 500 MSM in Buenos Aires [47], 61% of the men reported drug use and over 40% reported polydrug use during the previous 2 months. Marijuana, tranquilizers, cocaine, and *pasta base* (cocaine sulfate) were particularly prevalent. Furthermore, over 20% of users of these substances used them daily [9]. Most participants in the study consumed alcohol during the past 2 months: 32% of them reported drinking at least weekly and drinking enough to “feel it a lot,” “get drunk,” or “feel like you might pass out.” Substance use was higher among participants who were younger, unemployed, had greater mood variability, and did not identify as gay [9]. HIV prevalence, at 17% (31% among gay-identified men), and incidence, at 4.53 per 100 person-years (5.60 per 100 person-years in gay-identified men), were also alarming [48]. These findings highlight the critical need for effective, evidence-based HIV prevention interventions for substances using MSM in Argentina.

The proposed study seeks to address this glaring gap by using a user-centered process to develop and pilot a tablet-based e-SBI program tailored to MSM awaiting their HIV test at Nexo Asociación Civil, our community partners in Buenos Aires, who conduct over 1500 HIV tests per year with MSM. The e-SBI will integrate substance use and sexual risk behavior screeners and individually tailored motivational interviewing (MI) as the BI. Furthermore, we will adapt and pilot the implementation of the Young Men’s Health Project (YMHP)

[49], a 4-session MI-based intervention that effectively reduced substance use and condomless anal intercourse among MSM who use substances, as a brief treatment provided at Nexo for participants with moderate-risk substance use or to build motivation to enter specialized substance abuse treatment among those with high risk or dependence.

Study Objectives

As a National Institutes of Health R34 (Clinical Trial Planning Grant) study, the main goal of the study is to develop and pilot all the study components and build the necessary research infrastructure for a subsequent randomized controlled trial (RCT) to assess the efficacy of the e-SBI to reduce substance use and sexual risk behavior. The specific aims of this R34 study are as follows:

1. Develop a tailored e-SBI program to reduce substance use and HIV risk behavior among MSM seeking HIV testing
2. Conduct a pilot RCT of e-SBI versus screening only (3:1 ratio) to assess the acceptability and feasibility of integrating e-SBI into the Nexo HIV testing program and the feasibility of a future large-scale efficacy trial of e-SBI, as measured by the following:
   - Percent of MSM testing clients at Nexo who accept entry into the study (recruitment rate)
   - Percent of participants who complete the e-SBI (retention rate)
   - Retrospective acceptability ratings of the 2 RCT conditions (primary)
3. Assess the feasibility and acceptability of implementing the Men's Health Project (MHP) at Nexo, as measured by the following:
   - The percentage of MSM with moderate or high-risk substance use who enter MHP from either RCT condition (recruitment rate)
   - The percentage of MHP participants who complete all 4 sessions
   - Prospective acceptability of MHP among participants in either RCT condition
   - Retrospective acceptability of MHP among those who received it
   - Percentage of sessions conducted by each MHP counselor that meet the criteria for MI proficiency on the Motivational Interviewing Treatment Integrity (MITI.4) ratings

Methods

Study Design

This 3-year study began on August 1, 2022, and comprises 2 stages. The first stage, *Development*, will consist of developing the e-SBI, adapting the YMHP into MHP, training counselors to deliver MHP, and piloting the e-SBI with 50 MSM coming to Nexo for HIV testing. During the second stage, *the Pilot RCT*, we will randomize 200 MSM coming to Nexo for HIV testing at a 3:1 ratio (e-SBI to screening assessments only) to assess the feasibility and acceptability of the e-SBI among MSM coming to Nexo for HIV testing and establish and pilot the RCT process for a future trial. As a secondary aim, we will assess the uptake, acceptability, and feasibility of delivering MHP to participants with moderate-risk substance use and subsequent referrals to substance abuse treatment among participants with high-risk substance use or dependence. Finally, we will explore the preliminary findings on substance use and sexual risk reduction outcomes.

At the outset of the study, we will convene a Community Advisory Board (CAB) composed of 6 members, including representatives from a local community-based organization focused on policy, training, and social marketing regarding substance abuse; a representative from the Department of Sexual Health, AIDS, and STIs at the Ministry of Health of the City of Buenos Aires; and 4 MSM who report using drugs and alcohol recreationally (these criteria will not be known to others). The CAB will meet study investigators (in person or via videoconferencing) quarterly throughout the study. The CAB will be responsible for reviewing and providing feedback on the e-SBI, MHP, and assessment instruments that will be used in the study before they are used with the study participants.

This study was registered at ClinicalTrials.gov on September 16, 2022. The identifier number was NCT05542914.

Ethical Considerations

Ethics Committee Approvals

The study was reviewed and approved by the Florida State University Institutional Review Board (IRB ID: STUDY00002530) and the Ethics Committee of Nexo Asociación Civil (protocol 26082022).

All participants were provided with a written informed consent form to read before participating in the study. The consent form included an overview of the study, study procedures, risks of participation, procedures implanted to minimize risks of participation, a statement of voluntary participation, and contact information for the principal investigators in Argentina and the United States, along with contact information for the respective institutional review boards. Consent was documented with the signature of the participants and research staff.

The results of the study may be published or presented, but no information that can identify individual participants will ever be provided or released in publications or presentations. To protect the privacy and confidentiality of participants, the study staff will keep any records containing identifying information in a locked cabinet accessible only to the research staff. The computer programs used in tablet-based interventions are compliant with US regulations on personal health information, as are the servers on which the data are stored. All data captured on the tablet, although it does not include identifying information, are encrypted in transit to maintain confidentiality. Any other study data will be stored on a secure computer that is protected by passwords. All records will be kept confidential. This is consistent with the guidelines of the US National Institutes of Health. After removing all identifying information, the remaining deidentified information collected during the study could be used for future research studies or distributed to another investigator for future research studies without additional consent.

All participant incentives will be paid in cash in Argentine pesos. In stage 1, focus group (FG) participants will receive US $25; individual interview participants will receive US $20; and e-SBI pilot participants will receive US $10 and an additional US $10 for those who complete a qualitative interview. In stage 2, RCT participants will receive US $15 for completing the baseline assessment and e-SBI screeners, US $15 for the month 3 follow-up assessment, and US $20 for the month 6 follow-up assessment. Participants who complete the 6-month in-depth interview (IDI) will receive an additional US $20.

Components of the Intervention

MI Intervention

MI is the basis for both the e-SBI and MHP. MI is "a collaborative, goal-oriented method of communication aimed at strengthening an individual's motivation for and movement toward a specific goal by eliciting and exploring the person's own arguments for change." [50] In an MI session, a clinician guides rather than pushes a client toward change, sidestepping resistance, and actively works with the patient's strengths to build self-efficacy toward the desired outcome. MI uses standard tools of counseling and psychotherapy (ie, open-ended questions, affirmations, reflections, and summaries) strategically to elicit and reinforce change talk (patient statements that argue against the status quo, such as "I have been doing crazy things when I use drugs," or for behavior change, such as "I want to have sex sober so I don't want to worry the next day about whether I got HIV") and to inhibit sustain talk (patient statements that argue against change, such as "Sex a little high is fun"). Process research on the mechanisms of action in MI shows that more change talk [51,52] and less sustained talk during a session are related to better outcomes [51,53]. In addition, counselor behaviors such as advising, confronting, directing, and warning clients are associated with greater sustained talk [54,55], whereas affirming a client's strengths or effort, emphasizing client control, and supporting clients are associated with increased change talk [55,56]. Thus, to facilitate behavior change, the goal of an MI counselor is to interact with the client in a way that fosters change talk and inhibits sustain talk [51]. These key aspects of MI will inform the programming of the narrator in the e-SBI (described below), the revision of MHP, and the training of MHP counselors. The e-SBI will be created using the Computerized Intervention Authoring System (CIAS) V.3, which is an authoring tool that allows the creation and editing of electronic screening and intervention packages without the need for a programmer. Interventions built using CIAS feature a synthetic text-to-speech engine that reads all questions and speaks aloud to the participant (via headphones); synchronous interactivity; natural language reflections; branching logic; a clean user interface; and the ability to easily incorporate images, text graphs, figures, or videos. CIAS is consistent with human-computer interaction literature, suggesting that interactive, lifelike software can engage users and promote behavior change [57-61]. Thus, CIAS uses an optional interactive cartoon character capable of over 50 specific animated actions (smile, wave, read a message, express concern, etc) that talk for the entire program. The character acts as a narrator and guide throughout the process and provides occasional comic relief. Everything the character does is specifically programmed during the development phase, including interacting with participants in an MI-consistent manner and reflecting participants' change talk derived from their responses to the assessments. For example, using the participants' responses, the narrator might be programmed to say "You don't drink very often, but when you do, you drink a lot (from Alcohol Use Disorders Identification Test [AUDIT] responses) and you are noticing that it is impacting your physical health and your relationship with others (from responses to the Short Inventory of Problems)." CIAS has been used with thousands of participants (primarily those with low socioeconomic status) and has consistently received high satisfaction ratings [62-66].

YMHP Intervention

YMHP is a 4-session MI-based intervention that was the first intervention to demonstrate reductions in substance use and sexual risk behavior among non–treatment-seeking MSM who use substances [49]. Compared with the time- and content-matched control group, YMHP recipients were 18% less likely to use drugs and 24% less likely to engage in unprotected anal intercourse. On days when drug use and sex co-occurred, drug use reductions led to a decrease in unprotected anal intercourse. Secondary analyses showed that drug use among partnered participants was stable but declined significantly at all follow-up time points among single men [67]. We will adapt and implement YMHP as an in-house brief treatment for participants with PSU, either as a stand-alone treatment (for those with moderate-risk use) or as an intervention to link those with high-risk use or dependence on substance abuse treatment.

Stage 1: Development

Overview

The development of the e-SBI app will be guided by the User Centered Rapid Application Development (UCRAD) process [68-72]. UCRAD merges the streamlined and iterative Rapid Application Development approach with a user-centered design approach, which engages intended users throughout the app development process. This integrated approach aims to develop successful apps with good functionality, simple features, and usable interfaces [69]. As such, the intended users are given access to prototypes of the app, allowing them to provide feedback before the next iteration of the app. The process is relatively brief, approximately 6 to 9 months. UCRAD uses a 3-phase process as follows:

1. Predesign and interface prototyping: Data are gathered from key stakeholders to understand the requirements of the app in terms of content and interface. While continuing to assess user needs, developers offer potential solutions for the design. At the end of this stage, an initial prototype is developed based on the initial requirements.
2. System architecture and coding: The prototype is shared with the intended end users to obtain feedback. The developers update the prototype according to the feedback provided and begin system coding to develop a more complete version of the app. This version is returned to users for another round of feedback and development. The

result of this stage is an advanced but often incomplete product with basic system architecture and system specifications.

3. Deployment: The app is implemented in the field to obtain further feedback from potential end users, and further development of the application is conducted to reach a final product.

Predesign and Interface Prototyping

To accomplish this phase, we will obtain feedback from the CAB regarding the study screening instruments and preliminary plans for the e-SBI content. After incorporating their feedback, we will conduct 2 FGs with MSM (n=16) recruited from Nexo testing clients who were 18+ years of age and self-identified as male. They will complete a substance use screener consisting of an illicit drug use question on the National Institute on Drug Abuse–modified Alcohol, Smoking and Substance Involvement Screening Test (ASSIST) brief screen and the AUDIT-C (a 3-item alcohol use screen). Those who indicate using illicit drugs at least monthly or receive a score of ≥4 on the AUDIT-C will be eligible to participate. After obtaining informed consent, they will complete paper and pencil versions of the screening instruments planned for inclusion in the e-SBI, including:

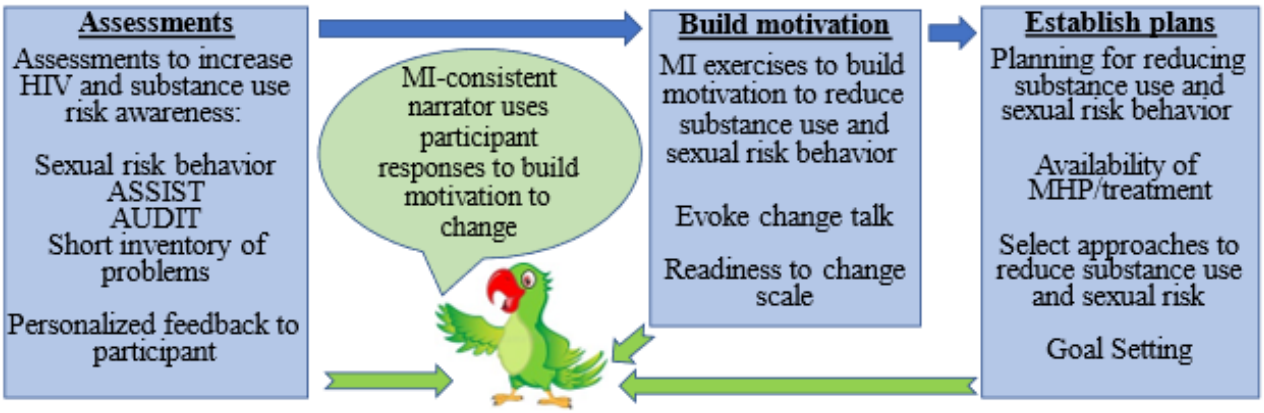
- The *National Institute on Drug Abuse–modified ASSIST* [73,74] substance use assessment, which has high consistency in detecting moderate and high substance use, and high concordance (90%-98%) and correlation (intraclass correlation coefficient 0.90-0.97) for tobacco, alcohol, and drug risk scores [75]. A self-administered computer ASSIST was found to have a 0.93 interclass correlation with the interviewer-administered version [76].
- *AUDIT* [77,78] is a widely used tool developed by the World Health Organization to identify individuals whose alcohol consumption has become hazardous or harmful to their health. AUDIT is a 10-item screening questionnaire with 3 questions on the amount and frequency of drinking, 3 questions on alcohol dependence, and 4 on problems caused by alcohol.
- *Short Inventory of Problems-Alcohol and Drug Use (SIP-AD) for MSM* [79] is a 10-item version of the SIP-AD [80] (α=.95) derived through Item Response Theory, which was found to be highly valid and reliable among non–treatment-seeking MSM. The SIP-AD assesses the frequency (0=never; 3=daily or almost daily) of commonly experienced consequences of alcohol or drug use across the physical, intrapersonal, interpersonal, social responsibility, and impulse dimensions.
- *Sexual Practices Assessment Schedule* [81] asks about the number of partners and occasions of oral, anal, and vaginal sex with male, female, and transgender sexual partners in the past 2 months; use of condoms during sexual intercourse; and assumed HIV status of the partner.
- *Readiness to Change Rulers* for alcohol use, risky sexual behavior, and drug use: although they vary in their specific wording, single-item readiness to change rulers that ask respondents to place themselves on a scale of change from 1-7 or 1-10 have shown concurrent and predictive validity for alcohol use [82-85], drug use [82,86-88], and sexual risk behavior [84,89]. These scales are also often used in MI interventions to strategically evoke change talk and increase motivation to change problem behaviors.

The 90-minute audio-recorded FGs will (1) explore participants' reactions to the screeners and their impact on risk perception and motivation to reduce PSU and risk behavior and (2) evoke content for the BI component to develop options for reasons to change and potential approaches to reduce PSU and sexual risk behavior from which e-SBI users can choose. Within 48 hours of completing the FG, we will initiate a rapid analysis of these data [90,91] using a qualitative matrix [92,93] onto which participants' responses and recommendations will be entered to quickly organize and summarize FG findings. These findings will be used to build a prototype of the e-SBI.

System Architecture and Coding

This iterative app development process will be conducted with waves of 6 MSM recruited from Nexo testing clients, with the same inclusion criteria as in the FGs. They will be recruited during 2-week intervals to maintain a steady pace of feedback and revisions. The participants completed the intervention on the tablet. They then complete a 7-item self-report instrument used by CIAS developers [64] that assesses how much participants (1) liked the e-SBI and fount it to be (2) interesting, (3) easy to use, (4) made up of understandable questions, (5) respectful, (6) annoying, and (7) humorous; each item is rated from 1=not at all to 5=very much. Afterward, participants will be debriefed during an audio-recorded interview to explore (1) their responses to the acceptability assessment; (2) overall reactions to e-SBI; (3) emotional reactions as e-SBI progressed, including heightened risk awareness, concern, or motivation to reduce substance use and sexual risk behavior; and (4) recommendations for improving the ability of the e-SBI to engage MSM with high-risk drug and alcohol use in treatment. The interview data will undergo the same matrix-based, rapid analysis process used for the FG to quickly inform the next revision of the e-SBI. This process will be repeated with waves of 6 participants until mean scores on each acceptability question are ≥4.0 (≤2.0 on annoying), which we expect within 3 to 4 cycles. Figure 1 depicts our current conceptualization of the e-SBI, with specific content informed by the stage-1 findings. The development of the e-SBI will be guided by Choice Theory [94], which has been used extensively to inform goal choice interventions [95-100], including MI interventions to reduce substance use among MSM [97,98]. Rather than preset outcome expectations (ie, abstinence), goal choice interventions highlight personal choice and goal setting to engage individuals in reducing drug and alcohol use. Goal choice interventions are equally effective as abstinence-based interventions, allowing individuals to set their own treatment goals, which appears to increase success rates [99,100].

Figure 1. Conceptualization of the electronic screening and brief intervention (e-SBI) intervention to reduce substance use and HIV sexual risk behavior among men who have sex with men in Argentina; ASSIST: Alcohol, Smoking and Substance Involvement Screening Test; AUDIT: Alcohol Use Disorders Identification Test; MI: motivational interviewing; MHP: Men's Health Project.



Deployment

The initial version of the e-SBI will be deployed with 50 MSM coming to Nexo for HIV testing to be used while awaiting their HIV test. On the basis of the findings from LINKS and Nexo screening data, we estimated that at least 50% will report using drugs and 80% will report using alcohol, and that 20% to 25% will report PSU. As such, a sample of 50 will allow us to explore reactions to the e-SBI from MSM with no, low-risk, and moderate to high-risk substance use. After obtaining informed consent, these individuals will complete the e-SBI and a brief quantitative acceptability assessment and then proceed to undergo their HIV test (to minimize participant distress). Subsequently, up to 25 of these participants will be randomly selected (5 with low-risk substance use and 20 with moderate or high-risk substance use) to undergo an audio-recorded IDI that will be guided by the theoretical framework of acceptability (TFA; see components in Textbox 1) [101], which has been used to guide qualitative and mixed methods research on the acceptability of health care interventions [102-105]. Data from these interviews will also undergo a rapid qualitative analysis as previously described for the FGs.

Textbox 1. Components of the theoretical framework of acceptability.

- *Affective Attitude:* how the individual feels about the intervention
- *Burden:* perceived amount of effort that is required to participate in the intervention
- *Ethicality:* extent to which the intervention has a good fit with an individual's value system
- *Intervention Coherence:* extent to which the participant understands the intervention and how it works
- *Opportunity Costs:* extent to which benefits, profits, or values are given up to engage in the intervention
- *Perceived Effectiveness:* extent to which the intervention is perceived as likely to achieve its purpose
- *Self-efficacy:* the participant's confidence that they can perform the behaviors required to participate in the intervention

Adaptation of YMHP to MHP

In consultation with our CAB, the research team will adapt YMPH while guided by the modified ADAPT-ITT (assessment, decision, administration, production, topic experts, integration, training, testing) framework (Textbox 2) [106]. The adaptation will focus on three main areas: (1) tailoring YMHP to Argentine MSM (including translation and cultural relevance for MSM aged over 29 y); (2) adapting YMPH from a stand-alone intervention to an intervention within an SBIRT program by minimizing duplication with e-SBI content and incorporating content to improve linkage to specialized substance abuse treatment for participants with high-risk substance use or dependence; and (3) adding content to address its poorer efficacy among partnered MSM.

Textbox 2. Overview of the ADAPT-ITT (assessment, decision, administration, production, topic experts, integration, training, testing) framework.

- Assessment phase: completed as part of our earlier studies and discussions with stakeholders
- Decision phase: completed as part of our earlier studies and discussions with stakeholders
- Administration phase: perform theater test to obtain feedback
- Production phase: produce revised intervention, maintain fidelity to core elements and underlying theory. Develop quality assurance and process measures
- Topic experts phase: involve topic experts in adapting the intervention
- Integration phase: integrate content from topical experts; integrate new assessments based on revised content
- Training phase: train staff to deliver the intervention
- Testing phase: test revised intervention in pilot study

Administration

To obtain feedback from members of the target population and key stakeholders, we video recorded a mock YMHP session (conducted in Spanish) that will be shown to the CAB, Nexo counselors (most of whom identify as gay men), and study coinvestigators. As they watch the videos, audience members will be asked to complete a feedback form, divided by portions in the session, so that they can provide feedback on issues they felt needed to adapt from the original. Next, we will discuss recommendations for addressing the issues raised.

Production

Feedback obtained during the administration phase will inform draft 1 of MHP. The revised intervention will be translated into Spanish and manualized to standardize counseling sessions and provide support and guidance for counselors.

Topic Experts and Integration

Draft 1 of MHP will be reviewed by substance abuse experts on the CAB, Nexo counselors, and coinvestigators to identify any other components of the intervention that need revision. Feedback from this review will be integrated into the intervention to create draft 2, which will be pilot-tested during the stage-2 RCT.

Training of MHP Counselors

The training of MHP counselors will be consistent with research on learning MI, which recommends a 2-day workshop with follow-up feedback and coaching [107,108]. As such, we will conduct a 4-day training with MHP providers; the first 2 days will focus on general MI principals and skills and the last 2 days will focus on specifics of MHP. Counselors will then conduct at least 2 mock cycles of MHP, which will be audio recorded and uploaded to a secure internet site for the MI trainer to rate using the MITI.4 scale [109], which captures the counselor's level of fidelity to MI and establishes specific criteria for *Proficiency* in MI. These ratings will be used to assess MI skills that require further development, which will guide videoconference coaching sessions.

Testing

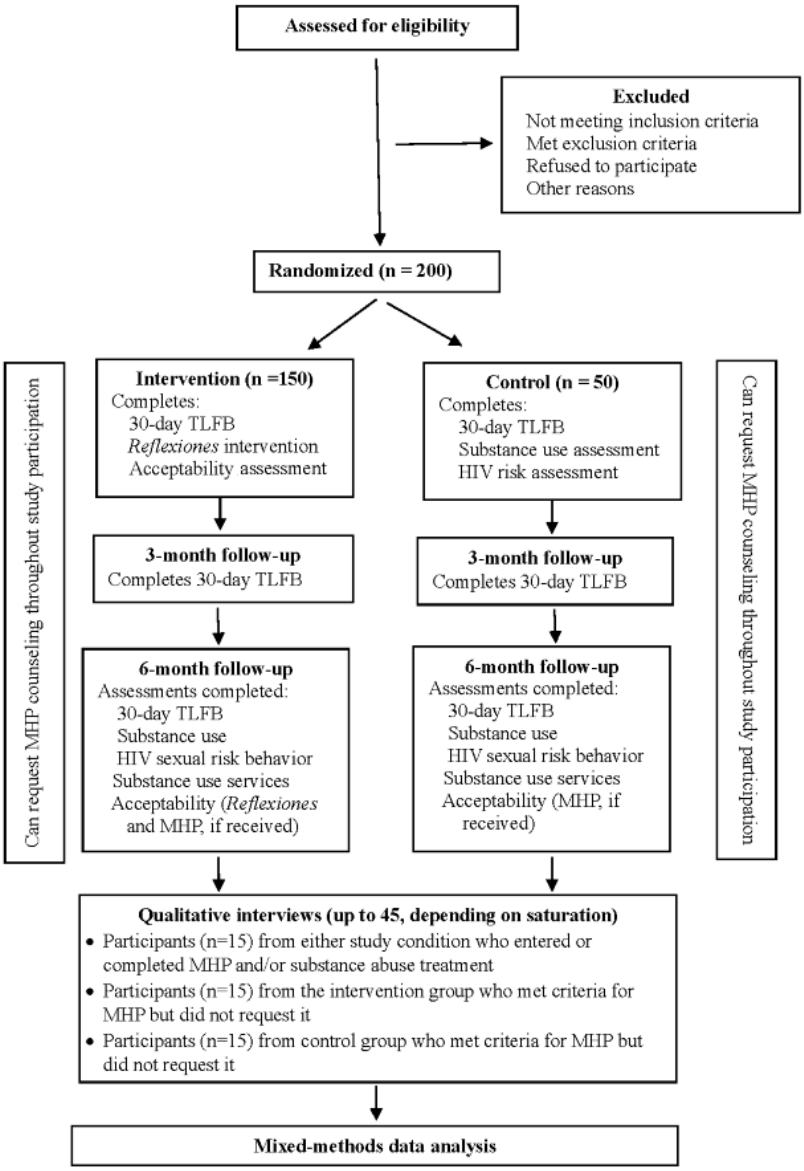
Although the primary aim of this study was to focus on the e-SBI component, as a secondary aim, we will assess the potential uptake and acceptability of MHP during the stage-2 pilot RCT.

Stage 2: Pilot RCT

Overview

With the e-SBI finalized, MHP adapted, and MHP counselors trained, the study will proceed to the stage-2 RCT comparing e-SBI to screening assessment only (see the CONSORT [Consolidated Standards of Reporting Trials] diagram for an overview; Figure 2). We will assess the feasibility and acceptability of e-SBIs and conduct a preliminary exploration of substance use and sexual risk reduction outcomes. On the basis of the findings from LINKS and Nexo data, we estimated that 50% of participants will report using drugs and 80% will report using alcohol, and that 20% to 25% will report moderate- or high-risk use based on the ASSIST and AUDIT criteria, respectively. As a secondary aim, we will assess the uptake, acceptability, and feasibility of delivering MHP at Nexo and the subsequent linkage to substance abuse treatment among those with high-risk substance use or dependence. The RCT process is described below.

Figure 2. CONSORT (Consolidated Standards of Reporting Trials) diagram for the proposed phase-2 pilot randomized controlled trial of electronic screening and brief intervention (Reflexiones). MHP: Men's Health Project; TLFB: Timeline Followback.



Recruitment

To ensure that the flow of participants is manageable during the study in the context of an HIV testing program, we will recruit up to 4 participants per day, 3 days per week, adjusting as necessary based on recruitment patterns to ensure the recruitment of all 200 participants. MSM who come to Nexo for HIV testing and are 18 years of age or older will be offered participation in the study. These clients will be given a flyer that, consistent with goal-choice interventions, will create a low threshold for study participation by stressing personal choice, goal selection, and an intervention tailored specifically for MSM to determine how to best reduce behavior that puts them at risk of HIV infection. Clients who wish to participate will complete informed consent, be randomized immediately, and be given a tablet logged on to their respective study arm (and disposable headphones) to complete their study procedures. Clients who declined participation will undergo the standard HIV testing process at Nexo. The research staff will record the number of clients who refused to participate.

Baseline Assessment

Participants in both conditions will complete a demographics questionnaire and then a self-administered, tablet-based 30-day *Timeline Followback (TLFB)* [110] to track days of drug use; number of alcoholic drinks; and HIV risk behavior, defined as anal sex with (1) an HIV-positive partner who they were not sure had an undetectable viral load or (2) a partner who had not tested HIV negative within the past 3 months. The TLFB has demonstrated good test-retest reliability, convergent validity, and agreement with collateral reports for daily drinking [111] and sexual behavior [112]. The TLFB will be used to assess primary substance use and sexual risk behavioral outcomes (which are exploratory outcomes in this study). After completing the e-SBI, participants in the intervention condition also completed a brief quantitative assessment of acceptability (8 items) based on the TFA [113].

RCT Study Conditions

Participants will be randomly assigned into 1 of 2 study arms.

Intervention Group Participants

After completing the baseline assessment, the tablet will immediately lead these participants to the e-SBI, as finalized in stage 1. The CIAS branching logic allows the e-SBI to tailor the BI based on factors such as participants' substance use risk level (based on ASSIST and AUDIT scores), risk perception, and readiness to change. Thus, BI may range from affirming and sustaining motivation among those with low-risk substance use to actively motivating and encouraging (in an MI-consistent manner) those with moderate or high-risk use to speak with a research assistant to obtain an appointment for MHP. The e-SBI will also target the participant's sexual risk behavior and help them develop a risk-reduction plan, regardless of their substance use. Then, they proceed to the usual HIV testing process at Nexo.

Control Group Participants

After completing the baseline assessment, the tablet will lead these participants to the same screening instruments as in the e-SBI, but with no MI-based BI. Due to ethical considerations, control group participants with moderate- or high-risk substance use based on the ASSIST or AUDIT scores will receive brief feedback on the tablet stating their level of risk, availability of MHP at Nexo, and instructions to see the receptionist for an appointment, if desired. Then, they proceed to the usual HIV testing process at Nexo.

Referral for MHP

All individuals with moderate- or high-risk substance use will be recommended for MHP (either *actively motivated* to enter MHP through the MI component of the e-SBI for those in the intervention condition or recommended to enter treatment and made aware of the availability of treatment at Nexo for those in the control condition). MHP sessions will be conducted in-person at Nexo (later sessions can occur remotely, based on the participant's preference) and will follow the intervention manual as finalized at the end of stage 1, with sessions expected to be 60 minutes in duration. As in the YMHP efficacy study, the 4 MHP sessions can be conducted over a period of up to 2 months. To maximize retention, participants will be offered reminder calls or text before each scheduled visit. For participants with moderate-risk substance use, MHP focuses on reducing substance use and sexual risk behavior. For participants with high-risk use or dependence, MHP sessions focus on building motivation to enter substance abuse treatment. After accepting the referral, the participant and Nexo staff contact the treatment provider to obtain an appointment at the clinic of the participant's choice (ie, closer to home). Nexo staff will offer to accompany the participant to the appointment to provide a *warm handoff* to facilitate linkage to care. To ensure intervention fidelity, all MHP sessions will be audio recorded, uploaded to a secure website, and rated using the MITI.4. MITI.4 ratings will be conducted throughout the study and used to inform weekly videoconferencing coaching sessions for MHP counselors to improve and sustain MI skills.

Follow-Up Assessments

All participants, including those who enter MHP or substance abuse treatment, will repeat the self-administered 30-day TLFB at 3 and 6 months after enrollment to assess drug use, alcohol use, and sexual risk behavior. At 6 months, they will also complete the screener instruments in the e-SBI and TFA-based quantitative retrospective acceptability assessments of e-SBI and MHP (if they enter MHP), all of which will be self-administered. We will also conduct IDIs with up to 45 participants (or less if saturation is reached): 15 participants from either study condition who entered or completed MHP and substance abuse treatment and 15 from each arm who met the criteria for MHP but did not request it. Also guided by the TFA, we expect these IDIs to be similar to those conducted in the stage-1 e-SBI pilot; however, revisions will be made to the IDI guide based on how well the questions elicited the desired material from the stage-1 participants. The use of one framework to guide all of these IDIs and the qualitative data analysis will allow us to more rigorously compare participants with PSU who entered MHP and substance abuse treatment with those who did not to identify factors that might impact their decision to enter MHP. IDIs will be conducted at Nexo, audio recorded, and transcribed.

Data Analysis

Qualitative Data Analysis for Stage-2 IDIs

For the stage-2 pilot RCT, transcripts from the audio recordings will be reviewed for accuracy and uploaded onto Dedoose for management and analysis. Codebook development will begin when 10 transcripts are available. First-level codes will be guided by TFA components, whereas second- and third-level codes emerge from themes identified in the narratives. An initial set of codes will be generated independently by 2 research staff members, compared, and then synthesized to compile shared coding categories and subcategories, all with definitions, inclusion and exclusion criteria, and examples. As transcripts become available, coding will continue, refining codebook definitions that will be used to process the remainder of the manuscript. The coders discussed discrepancies until they achieved 80% intercoder convergence. As per Patton [114], we will identify indigenous (ie, participant-generated) and analyst-constructed typologies. Once data are coded, analysis of coding reports will include categorization, abstraction, comparison (especially between groups in stage-2 RCT), integration, iteration, and refutation of themes.

Integration of Quantitative and Qualitative Data

We seek to exploit the richness of our mixed methods approach, with quantitative and qualitative findings enriching each other. Quantitative assessments allowed us to systematically explore variables of interest across all participants. Qualitative data will add nuances and new insights to quantitative findings. During data analysis, the interpretation of quantitative results will be enriched by the summary of codes for specific components of the e-SBI. In Dedoose, participants will be categorized based on their responses in the quantitative assessment (eg, severity of drug or alcohol use; ratings on readiness to change rulers) and use these categories to compare themes and concepts that emerge from the qualitative data.

Quantitative Data Analysis

Primary Aims

The primary aim of this study is to assess the feasibility and acceptability of integrating e-SBI into the HIV testing process at Nexo by estimating and comparing (1) the percentage of MSM testing clients at Nexo who accept entry into the study among those who are asked (recruitment rate); (2) the percentage of participants who complete e-SBI (retention rate); and (3) the mean score of 7-item e-SBI acceptability ratings between MSM participating in the e-SBI and those in the screening-only group. The secondary aim is to assess the feasibility and acceptability of implementing MHP at Nexo by estimating and examining the group difference with respect to (1) the percentage of MSM with moderate or high-risk substance use who enter or complete MHP; (2) percentage of high-risk enrollees in MHP who proceeded to substance abuse treatment; (3) mean acceptability of MHP and substance abuse treatment among those who received it (based on quantitative assessment to be developed); and (4) percentage of sessions conducted by each MHP counselor that meet the criteria for MI proficiency MITI.4 ratings. The estimation is accomplished by generating a point estimate with its corresponding 95% CI. We will use a 2-tailed *t* test for continuous outcomes and Fisher exact test for binary outcomes for the above comparisons. Adjustment for covariates, if necessary, with control baseline values, will be accomplished using multiple linear (continuous outcomes) or logistic (dichotomous outcomes) regression.

Exploratory Aims

Although this study did not recruit a sufficiently large sample to provide adequate power for assessing the efficacy of e-SBI, we will use data from the 30-day TLFB to explore changes in days of drug use, days of alcohol use, days of heavy alcohol use (5 or more drinks), and occasions of anal intercourse with a risky partner. To examine the efficacy of the above outcomes, a generalized linear model with a log link function was constructed, and generalized estimating equation methods were used to estimate model parameters and their SEs to account for correlation introduced by accessing the participants at multiple time points. Accompanying each of these tests will be point and interval estimates for the parameters of interest (ie, the ratio of the 2 group rate ratios). Although the hypotheses consider several simultaneous measures of effect, for the routine reporting of these results, there will be no adjustment for multiple comparisons.

Power Considerations

The primary goal of this pilot study was to collect preliminary data on the feasibility, acceptability, and target outcomes of the proposed intervention. We will use these pilot data to rule out unusually large or small true effects using standard 95% CI procedures. We confirm that the extrinsic effect sizes are contained within our CIs from the pilot. We examine the distribution of each variable and calculate the summary statistics by intervention condition. We will estimate key intervention parameters with sample means and proportions together with 2-sided 95% CIs and test the primary null hypotheses at the traditional 2-sided level α=.05 (simulation of the subsequent RCT). To plan the RCT, we will also consider 1-sided 90% confidence limits for mission-critical design parameters such as SDs and reference group end-point rates and proportions in the conservative direction. This is because we intend to plan sample size for the RCT so that power will be *excellent* (at least 80% power) for the clinically relevant effect size to be specified. This strategy will make proper allowance for the limited sample size of the pilot study with its consequent uncertainties and still yields appropriate sample sizes for the RCT. *Mission-critical* parameters include proportions for dichotomous variables (eg, recruitment rate and retention rate) and means and SDs for continuous outcomes (eg, days of drug use, days of alcohol use, acceptability of MHP and Substance abuse treatment). Large sample sizes are not required to locate these parameters approximately, but adequately, to plan the subsequent trial, whereas testing the study hypothesis in the pilot will generally not have sufficient statistical power. The estimation of mission-critical design parameters with point and CI estimates will be considered highly important; continuous outcome measures make it feasible to detect promising effect effects even in small samples. Means and SDs were estimated for continuous measures. For approximately normally distributed variables, an upper 1-sided 90% confidence limit for the SD, *sU*, was constructed from $sU = s \times c2n,.10 \times 1/2$, where *s* is the sample SD and *c2n,.10* is the upper 10th percentile of the chi-square distribution with *n* degrees of freedom. For approximately log-normally distributed variables, logarithmic transformation was applied to achieve approximate symmetry and normality. For dichotomous variables (such as the primary and secondary outcomes or the PDR performance criteria), exact binomial methods will be used for the CIs for proportions. As an example, the width of the 95% CI around a point estimate of 50% (eg, MSM with moderate- or high-risk substance use who complete e-SBI and then enter MHP) would be 43% to 57% with 200 participants.

Results

The study began with recruitment for stage 1 in October 2022. Currently, we are nearing the completion of stage 1. As part of the stage-1 development process, we conducted 2 FGs (n=16) and 2 waves of individual interviews (n=12). Consistent with the protocol, we ended the individual interviews after 2 of the 4 possible waves because acceptability scores were consistently high (mean score was >4 out of 5 for all participants). At present, we have almost completed the stage-1 pilot. At the conclusion of stage 1, we will conduct a rapid qualitative data analysis [90,91] to assess any additional changes that need to be made to the e-SBI before the stage-2 RCT, which we expect to launch in March 2024. At that time, we will also begin a deeper analysis of the stage-1 data from FGs, individual interviews, and the stage-1 pilot and include that in a future mixed methods manuscript to describe the intervention and its acceptability among the intended audience. We expect all data collection to be completed by February 2025 and the study results to be available by June 2025.

Discussion

Overview

This study addresses the critical need for interventions that reduce both PSU and HIV risk behavior among MSM in Latin America by adapting 2 evidence-based interventions, e-SBI and YMHP, for MSM in Argentina seeking HIV testing. Given that many MSM seek HIV testing in lesbian, gay, bisexual, and transgender (LGBT) community agencies, these interventions have the potential to reach large numbers of MSM, help them reflect on their use of drugs and alcohol, and help link those with PSU to evidence-based intervention (MHP). The provision of substance abuse treatment within an LGBT community agency can help facilitate entry and retention in treatment, as sexual minority men will not be concerned about the discrimination and microaggressions they might face at agencies serving the public. If proven efficacious in a future RCT, the implementation of these interventions in such agencies will help address a key contributor to HIV risk behavior and infection as well as reduce drug and alcohol use among MSM, who are disproportionately affected by HIV and substance use.

Strengths

A key strength of this study is the iterative development of the intervention based on end user feedback to ensure its high acceptability among intended users. Feedback from end users is essential to create an intervention that achieves its aim of heightening risk awareness of PSU to motivate reductions in use in a respectful, nonjudgmental manner without creating resentment or defensiveness.

An additional strength is that the study and the intervention were developed in close collaboration with a community HIV testing center, where the intervention was designed to be delivered. Development within a community HIV testing program provides an early assessment of the implementation challenges that need to be overcome to maximize access to the intervention and minimize the burden on organizational processes and resources.

Finally, the e-SBI was developed using CIAS. As this system was designed for use by nonprogrammers, the CIAS minimizes costs for developing, revising, and maintaining electronic interventions. In addition, it was designed for long-term sustainability. For example, contrary to a custom-designed platform for a specific task, CIAS is a broad platform for use by many people; supporting only this single platform will automatically support the availability of everyone is work. Its ongoing development is still funded by the US National Institutes of Health for 2 years, and additional funding will be obtained to continue support. In addition, a yearly fee for funded projects provides income to support CIAS in the long term, especially given the high interest in its use. Finally, the source code will soon be made publicly available at no cost; therefore, it can be installed on a local server. This sustainability plan addresses a key challenge to other e-interventions that support falters once study funding has concluded, impeding the use of interventions in community settings.

Limitations

This study and the intervention were designed in close collaboration with our community partners in Argentina. As such, there may be specific characteristics of our community partners and their client populations that may limit the generalizability of the findings to other community HIV testing programs. As a voluntary research study, HIV-testing clients with PSU may decide not to participate in the study, limiting the potential utility of this approach to identifying and engaging MSM with PSU to reduce their substance use. Finally, acceptability data (both quantitative and qualitative) are subject to social desirability. To minimize this risk, we will highlight for participants the importance of openly sharing their experiences and opinions, whether positive or negative.

Conclusions

Completion of this Clinical Trial Planning Grant (NIH R34) will allow us to develop and pilot all the study components and build the necessary research infrastructure for a subsequent RCT to assess the efficacy of e-SBI in reducing substance use and HIV sexual risk behavior among MSM coming to a community agency for HIV testing.

Acknowledgments

This research was supported by a grant from the US National Institute on Drug Abuse (R34 DA055503; Principal Investigator ICB). The authors are solely responsible for the content, which does not necessarily represent the official views of the National Institutes of Health (NIH). We also acknowledge the invaluable contributions of the study participants and the research staff.

Data Availability

Once the study is completed, the data sets generated and analyzed during the study will be available from the corresponding author upon reasonable request. We will compile structured deidentified data sets and make them available for additional and secondary data analyses. For data sharing, the research team will follow the “standards for privacy of individually identifiable health information.” The principal investigator and research team will develop a process to review and approve data release based on concept sheets submitted by interested investigators and whether the data request is for new lines of analysis. Formal data-sharing agreements will be developed to guide and encourage further data mining of the proposed datasets for various purposes.

Authors' Contributions

ICB was the principal investigator of the study, led the design of the study and the development of the interventions, and led the writing of this manuscript. ROM is a coinvestigator of the study and the site principal investigator in Argentina. He significantly contributed to the study design and led the implementation of the study. He critically reviewed the manuscript, provided feedback, and approved the final version. VB collaborated with the implementation of the study and led the qualitative component of the research assessing the acceptability of the interventions. She critically reviewed the manuscript, provided feedback, and approved the final version. SN is a coinvestigator who collaborated on the study design, as it pertains to the adaptation and implementation of the Young Men's Health Project (YMPH). She critically reviewed the manuscript, provided feedback, and approved the final version. YW was the data manager of this study. She collaborated in the design of the various data capture components of the study and will provide data management and statistical support for the study. She critically reviewed the manuscript, provided feedback, and approved the final version.

Abstract

Background: Sexual and gender minority youths (lesbian, gay, bisexual, transgender, nonbinary, and queer individuals) face elevated risks of substance use (eg, alcohol and tobacco) and mental health issues (eg, depressive symptoms and suicidality) compared to their cisgender heterosexual peers. These inequities are hypothesized to be reduced by building supportive high school environments via the training of school staff. An intervention that trains school staff to better understand and support sexual and gender minority youths and engage in positive bystander behaviors that protect them from bullying exposure may reduce disparities in drug and alcohol use among them. Experts, school staff, and sexual and gender minority youths developed Providing LGBTQ+ Adolescents with Nurturance, Trustworthiness, and Safety (PLANTS), a web-based intervention to train school staff on how to support, affirm, and protect sexual and gender minority youths.

Objective: This paper describes the design of the PLANTS pilot trial primarily aimed at assessing its acceptability, usability, appropriateness, and feasibility. We hypothesize PLANTS will have high acceptability, usability, appropriateness, and feasibility as rated by the school staff. Secondary objectives focus on implementation, safety, and pre-post changes in high school staff outcomes, including self-efficacy and skills (eg, active-empathic listening and bullying intervention). Exploratory objectives focus on the impact of PLANTS on student health outcomes.

Methods: In a 2-arm cluster randomized controlled trial, high schools in Massachusetts are allocated to PLANTS or an active comparator group (publicly available sexual and gender minority youths resources or training). High school staff complete pretest and posttest surveys containing validated scales. Primary outcomes are validated measures of acceptability, usability, appropriateness, and feasibility of the intervention completed by staff during posttest surveys. To test our primary hypotheses for each outcome, we will calculate means and 95% CIs and *P* values using 1-sample 2-sided *t* tests against a priori thresholds or benchmarks of success. Secondary outcomes include staff's active-empathetic listening skills, self-efficacy for working with sexual and gender minority youths, bystander intervention behaviors for bullying and cyberbullying, and self-efficacy for PLANTS' change objectives completed during pretest and posttest staff surveys. Staff can also complete a posttest interview guided by the Information-Motivation-Behavior model and Consolidated Framework for Implementation Research. Exploratory outcomes include student-level data collected via the 2021 and 2023 MetroWest Adolescent Health Surveys, a health behavior surveillance system in 30 Massachusetts schools.

Results: School enrollment began in May 2023 and participant enrollment began in June 2023. Data collection is expected to be completed by February 2024.

Conclusions: This pilot trial will yield important information about the PLANTS intervention and provide necessary information to conduct a fully powered trial of the efficacy of PLANTS for reducing the deleterious health inequities experienced by sexual and gender minority youths.

KEYWORDS

sexual minority youths; gender minority youths; cluster randomized controlled trial; web-based behavior change intervention; high school staff

Introduction

Background

Sexual and gender minority youths (ie, adolescents who are lesbian, gay, bisexual, transgender, nonbinary, or queer [LGBTQ+]) are at significantly higher risk than their heterosexual peers for mental health problems and substance use [1-22]. For example, alcohol use is 123%-155% higher among sexual minority youths than among heterosexual youths and up to 250% higher among gender minority youths than among cisgender youths [2,5-7,22]. These substantial persistent health inequities make sexual and gender minority youths a priority population for interventions and were deemed so by national health agencies [3,23,24]. However, there are few efficacious substance use and mental health interventions for sexual and gender minority youths [3].

One way to reduce substance use and improve mental health for sexual and gender minority youths is to foster more supportive and inclusive high school environments by training school staff (eg, teachers, principals, nurses, and counselors) to effectively support and protect them. Sexual and gender minority youths who have support from adults at school, greater school connectedness, and lower bullying exposure also have reduced depressive symptoms, suicidality, and drug and alcohol use [5,25-30].

Unfortunately, sexual and gender minority youths are more likely than their heterosexual peers to lack supportive adults at school, have lower school connectedness, and be exposed to bullying [5,6,25,26,31-39]. An intervention that trains school staff to better understand and support sexual and gender minority youths and engage in positive bystander behaviors that protect them from bullying exposure may reduce health disparities among them. Despite many school staff having a strong desire to support sexual and gender minority youths [40], their primary barrier to supporting this population is a lack of training [40,41]. In 2014, 13% of teachers across the United States and 29% in Massachusetts received training on issues related to sexual and gender minority youths [41], highlighting the need for professional development training related to this population in schools. An intervention for training school staff is further warranted because the presence of gender-sexuality alliances and sexual and gender minority youth–inclusive school policies fail to eliminate health disparities among them [4,42-44].

Providing LGBTQ+ Adolescents with Nurturance, Trustworthiness, and Safety (PLANTS) is a new web-based training program for high school staff. This intervention was informed by the Information-Motivation-Behavior theory to target the skills, self-efficacy, knowledge, and outcome expectations of the high school staff. School staff and other collaborators invested in the well-being of sexual and gender minority youths assisted in developing PLANTS. PLANTS aims to train school staff to support, affirm, and protect sexual and gender minority youths, which is hypothesized to reduce bullying exposure, increase school support and connectedness, and mitigate health disparities among them [45].

Prior to testing efficacy, it is critical to ensure that PLANTS is acceptable to high school staff. This paper describes the design of the PLANTS pilot trial, which primarily tests the PLANTS intervention acceptability (perceptions that PLANTS is tolerable), usability (perceived extent to which PLANTS can be used effectively, efficiently, and satisfactorily), appropriateness (perceived fit and relevance of PLANTS), and feasibility (the extent to which the PLANTS intervention is successfully used and executed) as reported by high school staff. Using a cluster randomized design, this study will secondarily examine the implementation, safety, and pre-post changes in high school staff outcomes within the PLANTS arm and then compare them to an active comparator condition composed of publicly available resources. This study will also explore intervention effects on student-level behavioral health outcomes. The results from the PLANTS pilot trial will inform the development of a fully powered trial of the efficacy of PLANTS for improving health outcomes among sexual and gender minority youths.

Objectives and Hypotheses

The primary objective of the PLANTS pilot trial is to assess the acceptability, usability, appropriateness, and feasibility of the intervention. Investigators expect that high school staff will rate the PLANTS intervention as having high acceptability, usability, appropriateness, and feasibility. Investigators' benchmarks of success are averages of >3.75 out of 5 for acceptability, appropriateness, and feasibility and scores >75 out of 100 for usability.

The secondary objectives are to examine trial implementation, intervention demand, intervention safety, and pre-post changes in school staff outcomes within the PLANTS arm and then

compare them to an active comparator condition. Investigators hypothesize the following results: school staff will have high participation rates in the study (≥50% consent); school staff will have a high retention rate for the follow-up survey (≥75%); high school staff in the PLANTS arm will have high intervention demand (≥75% adhere to PLANTS); high school staff in the PLANTS arm will have low adverse event prevalence (≤20% of PLANTS participants will report adverse events); high school staff participants in the PLANTS arm will report pre-post improvements in active-empathic listening, self-efficacy for supporting, affirming, and protecting sexual and gender minority youths; positive bystander intervention behaviors for bullying; and pre-post differences will be greater in the PLANTS arm than in the active comparator arm.

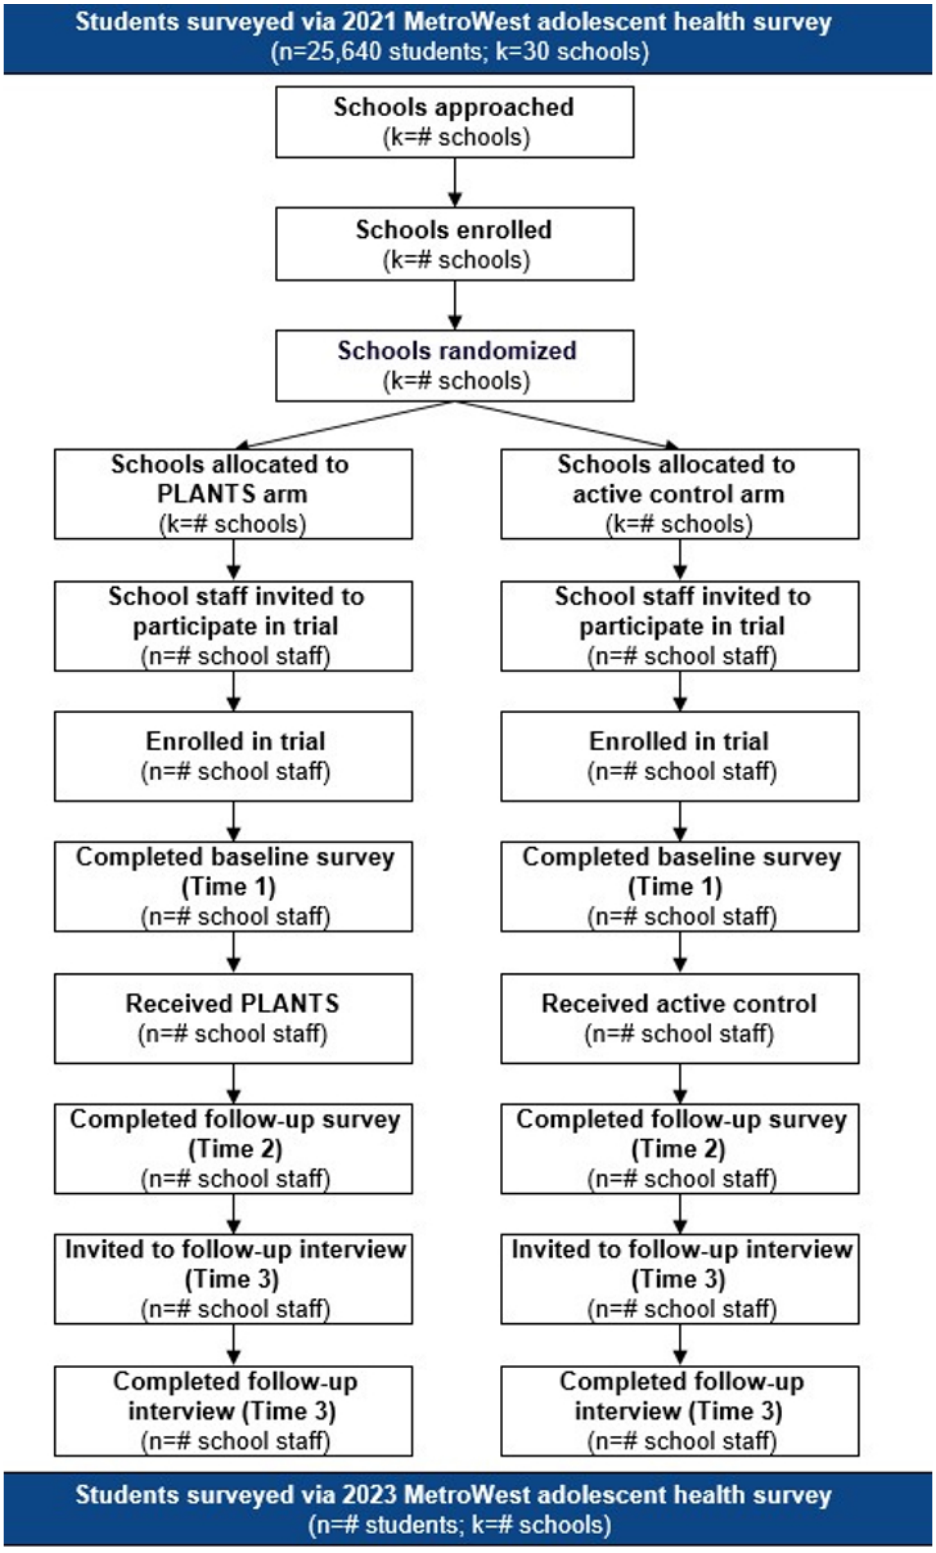
The exploratory objectives concern student-level health outcomes, including substance use, mental health, violence, and school experiences. Investigators hypothesize that sexual and gender minority youths will have greater increases in adult support at school and school connectedness and greater reductions in bullying exposure, depressive symptoms, suicidality, drug use, and alcohol use in PLANTS intervention schools versus active comparator schools, and the differences between sexual and gender minority youths and cisgender heterosexual youths in alcohol use, drug use, depressive symptoms, and suicidality will be more reduced in PLANTS intervention schools versus the active comparator schools.

Methods

Design

The PLANTS pilot trial is a cluster randomized controlled trial with 2 parallel groups and primary end points of PLANTS acceptability, usability, appropriateness, and feasibility among school staff. Such outcomes are aligned with pilot study best practices [46-49]. This unblinded study will randomly assign 4 schools in a 1:1 ratio to the intervention or comparator conditions. Importantly, investigators will analyze both student- and staff-level outcomes before and after the intervention. Figure 1 shows the study flow.

Figure 1. Study flow of the PLANTS pilot trial. PLANTS: Providing LGBTQ+ Adolescents with Nurturance, Trustworthiness, and Safety.



Setting

This study will enroll high schools (grades 9-12) from the 30 schools participating in the MetroWest Adolescent Health Survey (MWAHS) located in and near the MetroWest Region outside Boston, Massachusetts. The PLANTS pilot trial leverages the strengths of the MWAHS research infrastructure, which has biennially collected health surveillance data from a census of students since 2006. To be eligible for the PLANTS pilot trial, a school must have participated in the 2021 MWAHS, plan to participate in the 2023 MWAHS, grant investigators permission to access their MWAHS data, be willing and able to provide email addresses of all school staff, and provide a site permission letter.

Randomization

School-level randomization occurs after schools enroll in the study but before staff are enrolled. The investigators will use

block randomization in a 1:1 ratio, stratified by larger schools (≥1000 students) versus smaller schools (<1000 students). The primary investigator will create the randomization files using the "ralloc" package in Stata (StataCorp). Trained study staff will allocate schools using the REDCap (Research Electronic Data Capture; Vanderbilt University) randomization module. Allocation will be concealed from school personnel.

Study Populations, Sampling, Recruitment, and Data Collection

Students

To be eligible to participate in the MWAHS, students must be enrolled in grades 9-12 at a study school and be literate in English, Spanish, or Portuguese. Students are excluded if they provide an implausible pattern of responses via an evidence-informed algorithm that removes students with extreme responses.

Biennially, MWAHS collects student-level health surveillance data, similar to the Youth Risk Behavior Survey [50] except MWAHS data are collected from a census of students in each high school. The census-like sampling is a major strength of this study, providing a substantial sample of sexual and gender minority youths. Administered via the internet, the MWAHS is voluntary, anonymous, and data are linked at the school level across years (but cannot be linked at the student level). The baseline for intervention efficacy for students will be the fall 2021 MWAHS data, when 30 high schools participated, and 25,640 students completed surveys (83% of all students). The follow-up occurred in fall 2023.

Staff

To be eligible to participate in the PLANTS pilot trial, staff must be currently employed by an enrolled school, be 18 years or older, and consent to participate. Staff are excluded from participation if they do not interact directly with high school students at work.

At enrolled schools, all school staff will be invited to participate via email and advertisements sent by research staff and school administrators. Using REDCap, a personalized link to the screening survey will be provided to staff. If eligible, individuals will be given a digital informed consent form followed by a 30- to 45-minute baseline survey. Intervention and comparator conditions will be delivered to participants over 6 weeks. At the program's conclusion, participants will be sent a follow-up survey. A subset of participants (n=20-30 in PLANTS and n=10-20 in e-Learning to Maximize Academic Inclusion of LGBTQ+ Students [EMAILS] arms) will then be invited for a follow-up interview to explore the implementation outcomes more deeply.

Ethical Considerations

Staff

The Human Research Protection Office at the University of Pittsburgh approved the trial (STUDY23040142). Informed consent is obtained from staff participants. Consent forms describe in detail the study intervention, study procedures, foreseeable risks and discomforts, benefits to the participant, and contact information for the principal investigator. We requested and received a waiver for written consent for all staff participants because consent procedures are happening digitally, the study presents no more than minimal risk to participants, and written consent is not usually obtained for participation in a web-based program or interview outside of a research context.

Privacy and confidentiality protections are in place. For all identifiable data collected, we will remove identifiers and assign a unique study ID to protect the identity of the participant. Coded deidentified data and identifiable data will be stored in separate REDCap surveys and separate folders within a secure password-protected database and will be only accessible to select members of the research team.

To incentivize school staff to complete the baseline survey, we will provide US $20 to each participant and will conduct a drawing of an extra US $30 to 1 in 5 participants who take the survey within each school. To incentivize school staff to complete the follow-up survey, we will provide US $30 to each participant who completes the survey, and we will conduct a drawing of an extra US $40 to 1 in 5 participants who take the survey within each school. For staff who complete the follow-up interview, we will provide a US $50 incentive as a thank you for their time.

Students

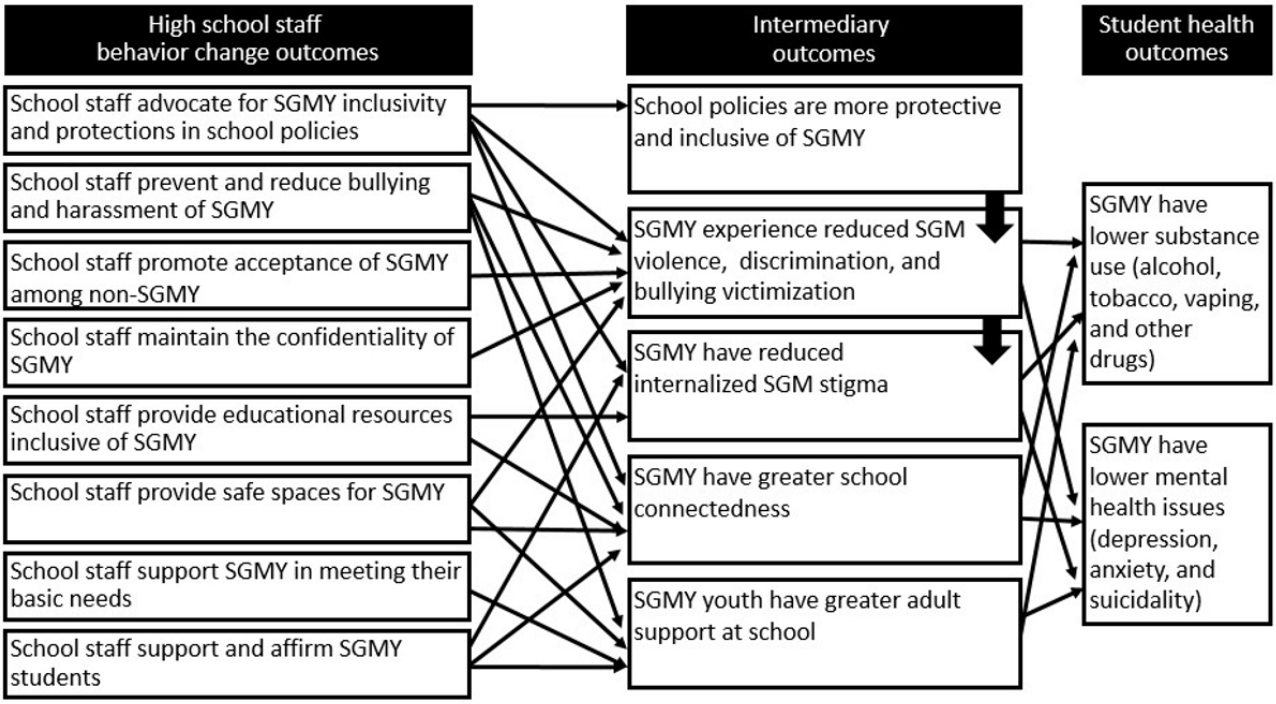
The Education Development Center's institutional review board–approved the MWAHS. Parents or guardians are provided the opportunity to opt their child out of the survey (ie, passive consent), and students provide assent to participate. Assent forms describe in detail the study procedures, foreseeable risks and discomforts, benefits to the participant, and contact information for the principal investigator. Data are collected anonymously, preserving student privacy and confidentiality. No incentives are provided to students for participation.

PLANTS Intervention

The PLANTS intervention is a web-based training program for high school staff. Figure 2 illustrates the PLANTS Behavior Change Model. Staff behavior change outcomes target evidence-based intermediary outcomes rooted in theories of minority health and general adolescent psychosocial health models. In turn, these intermediary outcomes are associated with reduced substance use and mental health issues. The behavior change outcomes are that PLANTS uses asynchronous and synchronous web-based activities to achieve the behavioral change outcomes via targeting the skills, self-efficacy, knowledge, and outcome expectations of the school staff based on Information-Motivation-Behavior theory. PLANTS has 3 primary modules: trustworthiness, safety, and nurturance. Asynchronous activities include voiceover presentations, podcasts with student and staff stories based on research [51], activities, and downloadable resources for future reference. Synchronous activities include three 1.5-hour live Zoom events; each moderated by a trained interventionist and tailored to the needs of participants. The modules were developed by the research team, including undergraduate and graduate students with a variety of academic backgrounds, in partnership with high school staff and other professionals who specialize in

LGBTQ+ youth or education. PLANTS is delivered using Canvas Learning management software (Instructure).

Figure 2. Behavior change model with high school staff behavior outcomes and student health outcomes. SGM: sexual and gender minority; SGMY: sexual and gender minority youths.



Active Comparator: EMAILS

Given the urgent need to support sexual and gender minority youths coupled with the dearth of evidence-based interventions for reducing alcohol and drug use in this population [3], choosing a comparator was difficult. Pragmatically, staff may search the internet to identify training opportunities. Thus, the active comparator, EMAILS, is an email-based intervention comprised of free existing web-based resources for supporting, affirming, and protecting sexual and gender minority youths. Informed by the Information-Motivation-Behavior theory, EMAILS has materials from Adagio Health, the Gay, Lesbian, & Straight Education Network, the American Psychological Association, and the Human Rights Campaign, which include self-paced training modules, YouTube videos, and PowerPoints. There is no direct human interaction in this intervention other than email. EMAILS is 3 hours long and is delivered in 3 modules as in PLANTS. Investigators will monitor active comparator compliance and fidelity by disseminating materials in Qualtrics, which allows for personalized link tracking and short end-of-module questionnaires about uptake or completion.

Outcomes

Primary Outcomes

The primary outcomes are intervention acceptability, usability, appropriateness, and feasibility as reported by school staff. At the follow-up survey, these are measured via scales with strong psychometric properties such as the acceptability of intervention measure (AIM), System Usability Scale (SUS), intervention appropriateness measure (IAM), and feasibility of intervention measure (FIM) [52,53]. AIM, IAM, and FIM each have 4 items with 5-point Likert scale response options. This instrument can be found in Table S1 in Multimedia Appendix 1. Investigators will calculate mean scores (range: 1-5). The SUS has 10 items with 5-point Likert scale response options. Investigators will calculate scores as recommended for the total scale (range: 0-100) [54]. The same outcomes are assessed about EMAILS among comparator participants, but these are not primary outcomes.

Secondary Outcomes

Trial Implementation

To assess the success of the pilot trial in reaching an adequate number of school staff, investigators assess the overall trial participation rate (number of people enrolled divided by the number of people invited to participate) and the follow-up survey retention rate (the number of people who take the follow-up survey divided by the number of people enrolled).

PLANTS Intervention Demand

To assess the school staff's demand for PLANTS, investigators assess PLANTS adherence, which is a composite variable ranging from 0% to 100%, comprised of 55% for module completion (based on the number of completed items divided by the total number of items offered) and 45% for Live Zoom Event attendance (where each event is 15%). These proportions are based on approximate time allocations.

Safety

Investigators assess a myriad of safety outcomes in follow-up surveys, including contact from parents or guardians because there was too much LGBTQ+ inclusivity in the school, contact from people who were upset, the school being attacked, the

school board getting upset or concerned, and LGBTQ+ censorship at the school. Response options include the frequency of each event occurrence. Investigators also assess participants' emotional discomfort with the courses using a 4-point Likert scale. For affirmative responses, open-ended textboxes are provided to describe the safety-related events. Investigators also track the presence or severity of adverse events and unanticipated problems.

Self-Efficacy for Working With Sexual and Gender Minority Youths

Investigators assess participants' perceived abilities for working with LGBTQ high school students using 9 items adapted from the Gay Affirmative Practice Scale [55]. Originally for social work practitioners, investigators replaced therapy-oriented words with school-oriented words (eg, "students" instead of "clients").

Example items include "I am able to help LGBTQ+ students develop positive identities as LGBTQ+ individuals" and "I am able to challenge misinformation about LGBTQ+ individuals in the classroom." Response options include a 5-point Likert scale. Investigators will calculate the mean score. In a prior study, the Cronbach α is 0.90 [56].

Active-Empathic Listening

Investigators measure the valid and reliable Active-Empathic Listening Scale containing 11 items [57]. This scale has 3 domains: sensing (4 items), processing (3 items), and responding (4 items). Response options include a 7-point Likert scale. Investigators will calculate the mean score for the total scale. Prior research showed a Cronbach score of α=0.88-0.90 [56].

Bystander Intervention Behaviors for Bullying and Cyberbullying

Two multidimensional scales (Teacher Bystander Intervention Model in Traditional Bullying and Teacher Bystander Intervention Model in Cyberbullying [58,59]) measure 5 subscales of bystander behaviors for bullying and cyberbullying: noticing the event (3 items), interpreting the event as an emergency (3 items), accepting responsibility to help (3 items), knowing how to help (3 items), and implementing intervention decision (4 items). The psychometric properties of these subscales are acceptable (Cronbach α=0.57-0.88). Investigators will calculate average subscale scores.

Self-Efficacy of PLANTS' Change Objectives

Given the limited research on validated scales of behavior change pertaining to LGBTQ+ inclusive practices in schools, investigators developed items pertaining directly to the self-efficacy change objectives in PLANTS. There are 50 total items across the following domains: provide interpersonal support and affirmation to sexual and gender minority youths; provide educational resources that are inclusive of this population; provide safe spaces for them; promote the acceptance of this population among cisgender heterosexual youths; prevent and reduce bullying, cyberbullying, and harassment of this population; evaluate and advocate for their inclusivity and protections in school policies; and maintain the confidentiality of sexual and gender minority youths.

Exploratory Outcomes

Student-level outcomes will be explored using the MWAHS data. Measures are described in Table S2 in Multimedia Appendix 1, and most have strong test-retest reliability and internal consistency.

Follow-Up Interview Questions

The purpose of the follow-up interview is to better understand trial and intervention implementation. Interviews are guided by the CFIR (Consolidated Framework for Intervention Research) [60]. Question domains include intervention characteristics (relative advantage, adaptability, and design quality), outer setting (external policies and incentives), inner setting (structural characteristics, networks, communication, culture, implementation climate, compatibility, relative priority, and leadership engagement), characteristics of individuals (beliefs about the intervention and self-efficacy), and process (opinion leaders). Interview questions are based on the publicly provided CFIR interview questions [60].

Demographics and Potential Confounders

Staff and student surveys assess many potential confounders. Table S3 in Multimedia Appendix 1 contains measurement details. School-level data will be collected from the Massachusetts Department of Elementary and Secondary Education public website.

Analyses

General Approach

Investigators will calculate baseline descriptive statistics for each study arm and test for differences in potential confounders between intervention and comparator arms using baseline student-, staff-, and school-level data with Rao-Scott chi-square tests and linear mixed models accounting for school clustering. Secondary analyses will adjust for imbalances between arms.

For validated scales, investigators will report internal consistency via Cronbach α. For newly created items, investigators will conduct exploratory factor analyses to examine the dimensions of outcomes using baseline surveys. Investigators will use the most recent version of Stata, 2-tailed tests, and α=.05.

Investigators will also conduct bias assessments. Selection bias assessment will compare participants' demographics to publicly available school-level data. The attrition bias assessment will compare staff respondents who completed follow-up surveys versus those who did not by baseline demographics and outcomes. Investigators will report significant differences as potential validity threats.

Primary Outcome Analyses

To answer the primary research questions, investigators will use best practices for pilot or feasibility studies [46-49]. Investigators will analyze the primary outcomes using descriptive statistics [46-49] and will not correct for multiple tests [46-49]. Among people in the PLANTS arm, investigators will calculate means and 95% CIs for participants' responses to the FIM, AIM, IAM, and SUS [53] and *P* values using 1 sample two-sided *t* tests against a priori thresholds.

Secondary Outcome Analyses

For trial implementation outcomes, investigators will calculate the participation and retention rates with a percentage and 95% CIs in the overall study sample. For PLANTS intervention demand, investigators will calculate average adherence with a percentage and a 95% CI among participants in the PLANTS study arm.

For safety outcomes, investigators will estimate the prevalence of adverse events reported by school staff at any time after intervention or comparator deployment. Investigators will report by study arm: the overall frequency of adverse events; the frequency of each type; and the frequency and percentage of school staff reporting adverse events.

To examine the pre-post changes in high school staff outcomes, investigators will first use descriptive statistics, such as means and percentages at each timepoint within arms. To test for within-arm statistical significance, investigators will use linear mixed models for continuous outcomes and generalized linear mixed models for binary outcomes, which account for within-school and within-person clustering using random effects. Investigators will estimate the intraclass correlations for within-school and within-person effects. These models will adjust for school size (a priori design variable).

Subsequently, investigators will compare pre-post changes between arms using regression models that include a fixed term for school size (a priori design variable), intervention group (intervention or comparator), time (baseline or follow-up), and the interaction of the intervention group×time (variable of interest for between-arm differences in pre-post changes). The intervention effects on secondary outcomes will be primarily based on intent-to-treat (ITT) estimates. Investigators will estimate as-treated and per-protocol effects in secondary models. If there are differences in potential confounders by intervention group, investigators will adjust for them in secondary multivariable analyses.

Exploratory Outcome Analyses

To explore the intervention effects among sexual and gender minority youths (within-group analyses), investigators will conduct ITT analyses using linear mixed models or generalized linear models accounting for within-school clustering effects using random effects. Investigators will restrict the sample to participants who reported a sexual minority identity or gender minority identity. Regression models will include a fixed term for school size (a priori design variable), intervention group (intervention or comparator), time (baseline or follow-up), and the interaction of intervention group×time (variable of interest). First, investigators will estimate ITT effects. Second, because subsetting a randomized sample may lead to naturally imbalanced arms, investigators will adjust for any imbalanced confounders.

To explore the intervention effects on inequities among sexual and gender minority youths (between-group analyses), investigators will use mixed models like previously described, except investigators who will include all student data in these analyses, including cisgender heterosexual youths, to assess reductions in inequities. Regression models will include fixed terms for the intervention group (PLANTS or EMAILS), time (baseline or follow-up), all 2-way interactions between the intervention group, time, and sexual and gender minority youths, and the 3-way interaction of the intervention group×time×sexual and gender minority youths (exploratory variable of interest for this hypothesis). Investigators will primarily explore the ITT effects.

Qualitative Analyses

Investigators will transcribe, deidentify, and check the quality of all data [61-64]. Investigators will perform use CFIR as a guiding framework. Two trained qualitative coders from our research team will independently read interviews and compare coding until they agree. Once the coders agree all major codes have been identified, they will create a final codebook with definitions, rules, and examples for each code [63,64]. Two coders will then recode all data using the final codes. Investigators will calculate inter-rater reliability (Kappa statistic) to examine code application between coders [65]. Coders will discuss any discrepancies until they reach an agreement; the principal investigator (RWSC) will resolve disagreements [63,64]. Investigators will use either a qualitative descriptive coding approach [66] (describing and counting code applications) or axial coding [67] (combining inductive codes into broader categories to define emerging patterns or themes). Investigators will identify and interpret patterns using thematic analysis [68].

Sample Size

Investigators calculated statistical power based on the primary outcomes, a 5% error rate, and best practices for feasibility studies. The median number of teachers at each MetroWest region high school is 86. With 4 schools, investigators anticipate inviting a total of ≥344 school staff (including teachers and other school staff with direct contact with students) to participate in the pilot study. Assuming 50% agree to participate, 50% of participants are in the PLANTS study arm, and 75% of PLANTS participants complete the follow-up survey (reduced n=65), investigators can estimate 95% CI widths ≤0.33 for AIM and IAM, and ≤10.1 for SUS. Such precision levels are sufficient. For qualitative interviews, investigators aim to interview people with a diversity of intervention fidelity, acceptability, usability, feasibility, and appropriateness. This is an exploratory interview study in nature, so idea generation and exploration are the goal, not thematic saturation. Investigators aim to interview PLANTS (n=20-30) and EMAILS (n=10-20) participants, and these sample sizes will provide ample information about the CFIR domains.

Results

School enrollment began in May 2023 and participant enrollment began in June 2023. Data collection is expected to be completed by January 2024. As of December 4, 2023, a total of 99 school staff enrolled in the study. Data collection is expected to be completed in January 2024.

Discussion

Principal Findings

This pilot trial rigorously evaluates the acceptability, usability, appropriateness, and feasibility of PLANTS, a web-delivered intervention aimed at improving school staff's skills, self-efficacy, knowledge, and outcome expectations for working with sexual and gender minority youths. Schools provide an ideal setting for interventions specific to sexual and gender minority youths for health disparities. High school students spend ~1195 hours per year in school [69], and sexual and gender minority youths regularly interact with adults who are professionally bound by certifying bodies to support the needs of students, including this population [70-73]. Implementing interventions in schools is challenging because of schools' limited resources, increasing demands placed on teachers, and difficulty in acquiring school buy-in. By using an economical and easily implementable web-based intervention, and by developing interventions and implementation strategies in collaboration with school personnel, these barriers may be overcome. PLANTS meets each of these criteria. A strength of this study is how it is embedded within the existing surveillance infrastructure. MWAHS conducts a census of students and has high student participation rates, minimizing biases common in convenience samples of sexual and gender minority youths.

Limitations

The primary limitation is generalizability because the study is solely in Massachusetts, a predominantly liberal US state. Selection bias could be present, for example, if school staff with the greatest stigmatizing attitudes toward sexual and gender minority youths do not participate. Investigators will examine if attitudes toward sexual and gender minority youths are associated with retention or attrition. Despite using numerous validated measures, the reliance on self-reported measures for both staff and students can be seen as a limitation. Because there is concern that school staff may be dishonest, investigators include a measure of social desirability bias [74]. Investigators will control for social desirability in analyses if it is high or if it is unevenly distributed among intervention versus comparator schools. For the exploratory student-level outcomes, another limitation is the lack of assessing individual-level change in student outcomes, since MWAHS data are collected biennially and anonymously. Investigators minimize historical and maturation biases by comparing youths in intervention schools to their same-aged peers in comparator schools across the same time periods while also assessing school-level policy and programmatic changes via surveys.

Conclusions

This study will rigorously test the hypothesis that PLANTS will be rated highly acceptable, usable, appropriate, and feasible by high school staff. PLANTS is hypothesized to be more efficacious for improving staff's support of sexual and gender minority youths and therefore reducing health inequities in this population than the active comparator. The results from this pilot trial will inform a fully powered trial of the efficacy of PLANTS for fostering health equity in sexual and gender minority youths.

Acknowledgments

The research reported in this publication was supported by the National Institute on Alcohol Abuse and Alcoholism of the National Institutes of Health under award number (K01AA027564 to Coulter). MetroWest Adolescent Health Survey is funded by the MetroWest Health Foundation in 26 school districts, with 3 additional school districts providing direct funding to Education Development Center, Inc. Funders had no role in the design of this study and will not have any role during its execution, analyses, interpretation of the data, or decision to submit results. The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health or the MetroWest Health Foundation.

Data Availability

The data sets generated and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

RWSC conceived of the PLANTS pilot trial. RWSC and SKS secured funding. RWSC, SKS, EM, and KZA designed the study. IKM, CAL, SKS, ASM, and KB helped with the study implementation and acquisition of data. KZA provided statistical expertise in clinical trial design. RWSC and IKM are conducting statistical analyses. All authors contributed to the refinement of the study protocol and approved the final manuscript.

Conflicts of Interest

EM receives royalties for writing content for UpToDate, Wolters Kluwer. The other authors received no external funding.

Abstract

Background: Rates of melanoma have increased dramatically in the United States over the past 25 years, and it has become among the most prevalent cancers for young adult women. Intentional skin tanning leads to a pattern of intense and intermittent UV radiation exposure that is associated with increased risk of melanoma. Frequent tanning is most common among young women and is linked to a variety of sociocultural pressures that negatively impact body image and drive appearance control behaviors. Unfortunately, there are no established interventions designed for frequent tanners. This intervention addresses this gap with unique content informed by body image and acceptance-based interventions. The intervention is delivered using Facebook secret groups, an approach designed to support behavior change and ensure scalability.

Objective: This study aims to describe the rationale and methodology of a randomized controlled trial of a melanoma prevention program targeting young women engaged in frequent indoor or outdoor UV tanning.

Methods: Participants are women aged 18-25 years who report high-risk tanning (ie, at least 10 indoor tanning sessions in the past 12 months or 10 outdoor sessions in the previous summer). After recruitment and screening, participants completed a baseline survey and were randomly assigned to receive the intervention or an attention-matched control condition. Both conditions were 8-week-long Facebook groups (approximately 25 members each) with daily posting of content. Follow-up surveys are administered at 3, 8, and 18 months after baseline. The primary trial outcome is the combined number of indoor and outdoor tanning sessions reported at the 8-month follow-up. Hypothesized intervention mediators are assessed at the 3-month follow-up.

Results: This project was funded by a National Cancer Institute award (R01 CA218068), and the trial procedures were approved by the University of Kentucky Institutional Review Board in February 2020. Trial recruitment and enrollment occurred in 6 waves of data collection, which started in February 2022 and closed in May 2023. The study is closed to enrollment but remains open for follow-ups, and this protocol report was prepared before data analyses. As of February 2024, all participants have completed the 8-month follow-up assessment, and data collection is scheduled to close by the end of 2024 after the collection of the 18-month follow-up.

Conclusions: This trial will contribute unique knowledge to the field of skin cancer prevention, as no fully powered trials have examined the efficacy of an intervention designed for frequent indoor or outdoor tanning. The trial may also contribute evidence of the value in translating principles of body image and acceptance-based interventions into the field of skin cancer prevention and beyond. If successful, the use of the Facebook platform is intended to aid in dissemination as it provides a way to embed the intervention into individuals' everyday routines.

Introduction

Tanning and Skin Cancer Risk

Prolonged exposure to UV radiation induces a skin tanning process in response to cellular skin DNA damage that can lead to skin cancer [1]. Excessive UV exposure through the use of artificial UV-emitting tanning beds or intense, intermittent sun exposures, like outdoor tanning (eg, sunbathing), has been linked to increased risk for all skin cancer types, including melanoma [2-6]. Excessive UV exposure is most common among young adult women and is likely driving concerning melanoma trends in the United States, including a decades-long climb in overall and site-specific melanoma incidence (eg, melanoma of the trunk) [7]. Melanoma has become among the most common cancers among women aged between 20 and 29 years [8].

Public health and policy efforts have produced an increasing number of federal regulations and state-level restrictions on access to tanning beds among minors in the past 2 decades. These efforts have helped to produce a continuing decline in the overall prevalence of tanning bed use in the United States from a peak in 2009 [9-11]. However, recent studies suggest nearly 7% of adolescents and 13% of adults still use indoor tanning in the United States each year [12], and rates of frequent, higher-risk indoor tanning remain concerning, with 24% of recent tanners reporting tanning 25 or more times in the past year in 2018 compared to 13% in 2007 [13]. Internet search results have revealed that public interest in outdoor tanning may have increased during the widespread shutdowns of tanning salons during the height of COVID-19–related restrictions [14]. National prevalence estimates of outdoor tanning are lacking because the behavior is not routinely assessed in surveillance surveys, but recent studies of young adults have found between 32% and 64% report outdoor tanning [15,16]. A recent analysis of protanning videos on the popular social media platform TikTok showed that outdoor tanning was nearly twice as likely to be portrayed as indoor tanning [17]. Overall, while indoor tanning rates have declined, intentional outdoor UV exposure or sunbathing may have increased in popularity.

Public health efforts and existing behavioral interventions have primarily focused on preventing the uptake of indoor tanning and lack attention to frequent tanning behaviors that increase the risk for melanoma development [18]. Indeed, the *Surgeon General's Call to Action to Prevent Skin Cancer* identified a critical research gap related to an absence of interventions that target high-risk tanners and address underlying motives for tanning, including "the desire to look attractive and healthy and to conform to societal beauty standards" [19]. Further, recent trends support the need for interventions targeting frequent indoor and outdoor tanners. The proposed study addresses a gap in the melanoma prevention field by testing a skin cancer risk reduction intervention targeted to frequent indoor or outdoor tanners.

Behavioral Determinants of Tanning Behaviors

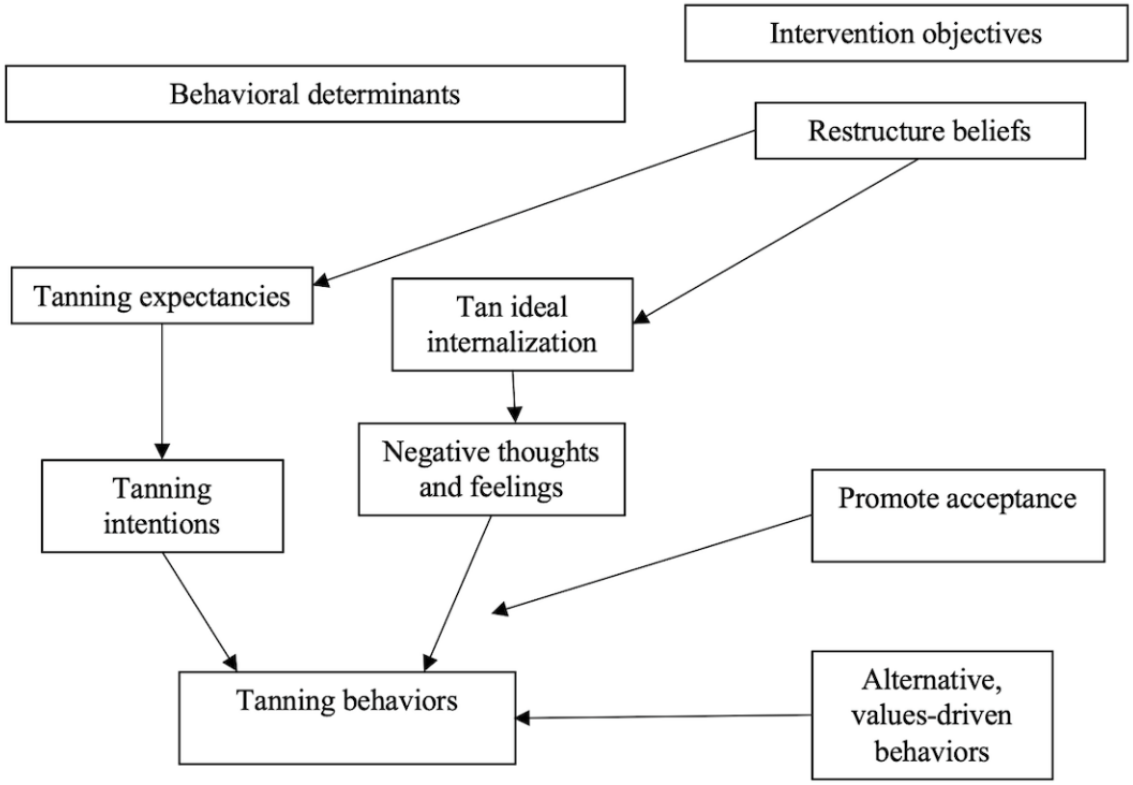
Our intervention is designed to address key factors from our conceptual dual-process model of tanning, which is supported by a body of behavioral research that demonstrates tanning is both an intentional, planned behavior to maintain appearance and a reactionary behavior used to avoid negative thoughts and feelings (Figure 1).

The intentional pathway is supported by studies demonstrating the role of tanning expectancies (ie, the anticipated positive and negative aspects of tanning) on tanning intentions and behavior. Tanners endorse positive aspects of tanning, including perceiving a tanned appearance as attractive, rating others with tans as more attractive than their pale counterparts, viewing indoor tanning as a convenient way to enhance appearance, and believing their peers approve of and engage in tanning [20-24]. Many young women experiment with indoor tanning in preparation for a special event, such as getting a tan before a high school prom or a wedding [25-27]. Those experimenting with tanning may begin viewing it as a regular part of their beauty routine and transition to frequent use [27]. Relaxation expectancies are also a primary motive for tanning [28], which have been reinforced by a marketing approach emphasizing a spa-like experience or fitness or health amenities for tanning [29]. This marketing may contribute to tanners' beliefs that tanning has positive health benefits by contributing to mental wellness or self-care [28,30].

Sociocultural body image theories posit that societal influences and perceived expectations regarding appearance negatively influence body image, including how women think and feel about their bodies, and, as a result, drive them to engage in reactive behaviors they know are physically harmful for the sake of appearance enhancement and relief of body image concerns [31,32]. Research from our team and others has demonstrated that constructs from body image theories relate

to indoor tanning and thus form important skin cancer risk factors among female tanners [33-38]. Tanners are likely to experience perceived pressure to look tan, which is produced in Western cultures that associate being tan as a central aspect of feminine beauty ideals and is reinforced through interactions with peers and family members. Through her buy-in and internalization to the tan ideal, a tanner views being tan as central to feeling attractive and begins actively monitoring her tan. Perceived discrepancies between her current and ideal tan will lead to dissatisfaction and negative appearance-related thoughts or feelings. In this reactive pathway, tanning represents a behavior driven by a desire to avoid such unwanted thoughts and feelings driven by routine thinking that is often flawed, negatively biased, or self-critical.

Figure 1. The dual process model of tanning behavioral determinants is a summary of key tanning motives identified in behavioral studies. The corresponding intervention objectives show how the intervention content is designed to target these key determinants to produce behavior change.



Intervention Content

This intervention incorporates behavior change techniques and content that have been tested in our pilot tanning interventions [39-41] (see Methods section) and are designed to address both intentional and reactionary aspects of tanning (Figure 1). First, our intervention is designed to restructure key psychosocial drivers of tanning, specifically tanning-related expectancies, and body image–related beliefs underlying the internalization of a tan ideal. Participants engaged in risky behaviors may not be highly motivated to change their behavior but are likely to hold views about why they should and should not continue their risky behavior, called behavioral ambivalence [42]. Indeed, most tanners hold positive expectancies about the appearance and relaxation benefits of tanning while also reporting concerns about the appearance-damaging effects of UV exposure and perceiving advantages to reducing their tanning [43-46]. Our intervention is designed to restructure tanning expectancies by encouraging participants to reflect on underlying reasons for tanning and undesirable aspects. Such reflection has been shown to shift the balance of perceived benefits and costs of behaviors, promoting openness to behavioral change [41,42,47,48]. Drawn from body image theory–informed interventions, we also seek to restructure tanners' body image beliefs that underlie tan internalization with content that encourages participants to critique image ideals (in this intervention, through comments in response to intervention content prompts) [49-54]. Body image interventions, including those for tanning [39,40,55], have consistently found that asking participants to consider perspectives that are critical of body image ideals and advocate for counterperspectives can change these underlying beliefs (eg, reduce perceived pressure to tan), which can ultimately reduce buy-in to these beliefs (ie, reduce internalization) and associated body image dissatisfaction. These approaches can be particularly powerful when this process occurs in a group-based setting [53,56]. Accordingly, we use Facebook groups to deliver intervention content to frequent tanners.

Although body image beliefs can be changed in brief interventions, it can be challenging because of the pervasiveness of societal messages focused on women's appearance. Thus, the intervention is also designed to raise awareness of the impact of self-critical thoughts and negative feelings on behaviors such as tanning. The intervention messaging is consistent with the acceptance and commitment therapy (ACT) perspective that uncomfortable thoughts and feelings that accompany some deeply held beliefs cannot be controlled and attempts to do so often perpetuate self-critical thinking and maladaptive coping behaviors [57-59]. Our acceptance-based content encourages

participants to embrace an acceptance mindset, defined as an increased tolerance for experiencing negative thoughts and feelings that can drive unhealthy behaviors, rather than attempting to control them through such behaviors. The intervention also includes mindfulness skill–building exercises, which are critical for enacting acceptance through increasing the ability to identify and sit with negative thoughts and feelings as they occur [57,59].

Finally, our final intervention encourages participants to focus on healthier self-care behaviors as a substitute for tanning. Consistent with ACT principles, the intervention encourages participants to consider the importance of making daily choices guided by higher-order values to ensure they spend time on the things that are truly important to them (eg, healthy lifestyle, helpful self-care, self-compassion, acceptance, and personal growth) [57,60,61]. Participants identify their core values and contrast them with the values underlying societal messages about appearance that often drive critical self-talk. Participants are then asked to consider whether their ongoing behaviors, including tanning, are consistent with their core values (eg, healthy lifestyle) and, if not, consider approaches for enacting alternative behaviors better aligned with these core values.

Trial Objectives and Design

This randomized controlled trial (RCT) aims to examine the intervention's efficacy versus an attention-matched control group on reducing tanning behaviors among high-risk tanners. Both interventions are delivered through the secret groups feature of Facebook, with a target group size of 25 members each. Participants were frequent tanners (indoor or outdoor) recruited from across the United States. After completing an eligibility screening and a baseline survey, participants were randomized with a 1:1 allocation ratio to each condition after finishing the baseline survey. The 8-week intervention and control groups began 1-3 weeks after baseline completion. Self-reported surveys captured tanning-related beliefs and behaviors at baseline, with follow-ups at 3, 8, and 18 months after baseline. Our primary outcome analysis will compare the tanning rates of intervention and control participants at the 8-month follow-up study. Our study is also designed to explore the impact of hypothesized mediators of intervention efficacy collected on the 3-month postbaseline survey. We hypothesize that intervention participants will report lower tanning rates at the 8-month follow-up, and these effects will be mediated by psychosocial constructs, including increasing tanning expectancies, tanning-related body image factors, and openness to changing indoor tanning. Exploratory outcomes include tanning intentions and an 18-month long-term follow-up assessment to test whether any observed intervention effects extend to the following year.

Intervention Delivery

Intervention content is delivered within secret groups on the social media site Facebook. Participants are invited to join a Facebook group and receive twice-daily intervention content posts from a study moderator. Participants are asked to read and react to posts through the "like" feature or by commenting on them. Facebook groups provide a remotely delivered opportunity to facilitate group-based interactions within the intervention, which can facilitate stronger attitude and behavior change in disordered eating dissonance–based interventions (typically delivered within small groups) [54,56,62,63]. Further, participants in group-based social media interventions often share information and receive and provide motivation to others [64,65], which may facilitate intervention goals related to boosting positive body image and adopting healthy behaviors. Facebook remains the most popular social media site among all adults and is used by 70% of individuals on the internet who are aged between 18 and 29 years [66]. Our preliminary research found that 72% of high-risk tanners used Facebook at least once a day [67] and that Facebook-delivered tanning interventions are feasible and acceptable to our target audience.

Choice of Control

The control condition is administered using the same procedures as the intervention, including delivery through secret Facebook groups. However, the post content differs, with posts related to nontanning health topics of interest identified in our pilot research (eg, physical activity, healthy eating, alcohol misuse prevention, stress reduction, and sleep). An attention-matched control ensures that the conditions are matched on total social media exposure, amount and type of content delivered, and intervention engagement. The design also avoids threats from demoralization among control users who expect but do not receive health content in a no-treatment control.

Methods

Participants

Study Setting

Study participants were young adult women recruited with web-based methods with reach throughout the United States. Recruitment and screening procedures were conducted primarily in partnership with Qualtrics and using Facebook advertisements. A few participants were recruited through additional methods, including posting on social media pages and recruitment flyers posted on a US college campus. Participants completed all study procedures electronically (ie, surveys and participating in Facebook groups) from their chosen location. All study enrollment, tracking, and participant engagement were conducted at the University of Kentucky. Moderating and monitoring of the Facebook groups was performed by research personnel at both the University of Kentucky and the University of Connecticut.

Eligibility

Eligible participants were women aged between 18 and 25 years who reported high-risk tanning (defined as using an indoor tanning bed or intentionally tanning outdoors at least 10 times in the previous 12 months) [68-70]. The study population was limited to young women due to the intervention's emphasis on body image theory and the use of content targeted to this group. We also required that participants report regular use of Facebook (defined as self-reported use of Facebook at least 4-6 times per week in the past 4 weeks). Social media use requirements are standard in trials to ensure that participants have incorporated the chosen platform into their daily media activities and are likely to engage in the intervention [71-74].

Procedures

Recruitment and Screening

Participants were primarily recruited by the internet research recruitment company Qualtrics Sample Providers using their participant panels that comply with or exceed all applicable industry standards [75]. Qualtrics emailed a randomly selected sample frame of panel participants with a study invitation, which contained a brief description of the study procedures and a brief screening eligibility assessment. Qualtrics also supplemented recruitment with web advertisements posted on various websites and platforms of their partner organizations. Additional recruitment approaches included Facebook advertisement posts with study information and links to access the screening assessment and printed flyers with QR codes to access the screener on a US college campus.

Study announcements and advertisements included a link to a 7-item brief screening assessment. Screener items assessed the eligibility criteria of gender, age, Facebook use, and past 12 months of indoor and outdoor tanning. The 2 additional health behavior questions related to the frequency of physical activity and fruit and vegetable intake were included to mask the purpose of the study. The screening survey was programmed with skip logic to identify eligible participants based on their responses. Eligible participants were provided a brief description of the study procedures immediately following the screening assessment and asked if they were interested in getting additional detailed information about the study. If they clicked yes, participants provided their contact information, which was recorded with their screening results. Screening data were reviewed for quality control to identify potentially fraudulent responses or bots. Specifically, we reviewed the pattern of responses, the total completion time, and IP addresses to identify responses that were likely from duplicate or fake respondents (including bots). Suspicious responses were removed from consideration for the study at the time of screening.

Study Procedures

Following screening, eligible participants who indicated their interest were emailed by study staff a link to a web-based baseline survey that also included the implied consent form. The baseline survey (and all follow-up surveys) were programmed using Research Electronic Data Capture (REDCap) survey software (Vanderbilt University) with encrypted responses collected on the University of Kentucky's secure servers.

After completing the baseline survey, participants were randomized with a 1:1 allocation ratio to either condition. We used a permuted block randomization design to create 2 randomly shuffled assignment lists (ie, intervention or control) in each of 2 strata (ie, indoor tanning: n=500 and outdoor tanning: n=500). These lists were used to assign participants sequentially based on tanning status (within the 2 strata) following their completion of the web-based baseline survey. Following randomization, participants were invited to their assigned group using the group email feature on Facebook. As secondary options, we emailed participants to remind them to join the Facebook groups and asked participants to "friend" the moderator's Facebook account to add them to the appropriate group manually [72].

At 3 months after baseline, each participant was invited by email to complete the first web-based follow-up survey (follow-up 1). Additional follow-ups occur at 8 months (follow-up 2) and 18 months after baseline (follow-up 3). All surveys were designed to be completed in 30 minutes. Incentives were US $30 gift cards for completing each baseline and 3- and 8-month follow-ups and US $40 for the 18-month follow-up based on similar incentive structures that have produced high retention rates in our previous indoor tanning intervention studies [76,77]. High-risk tanners often use indoor tanning throughout the year, with a peak in use in spring (ie, March-May) and outdoor tanning peaks during the summer [25,77,78]. Accordingly, our intervention was designed to be delivered during peak indoor tanning season, with the 8-month follow-up distributed near the end of the year to capture indoor tanning and cover outdoor tanning during the North American summer season. The 18-month follow-up survey will determine if intervention effects extend to tanning behaviors in the subsequent year.

Intervention

Preliminary Data

Our first pilot intervention trial was designed to test the feasibility, acceptability, and preliminary efficacy of the content and messaging strategy that form the foundation of the current intervention [39]. The text-based intervention was delivered through a self-paced, single-session website. Participants were provided psychoeducation content, encouraged to reflect on their tanning behavior, and prompted to type responses to counterattitudinal perspectives to the tan ideal. We conducted an RCT in 2014 with 186 young women who reported indoor tanning at least once in the previous year assigned to receive the website or a waitlist-control condition. We found preliminary evidence of efficacy as intervention participants reported 2.29 times higher odds of abstaining from indoor tanning over a 6-week follow-up period than participants in the waitlist control ($P<.05$). Intervention participants also reported significantly lower intentions to tan. Participants also provided positive overall acceptability and favorability ratings of the website and content focused on body image and behavioral reflection.

Our subsequent pilot trial was to adapt this website intervention content for delivery across 8 weeks through posts to a secret Facebook group [40]. Website content was divided and delivered using 2 daily posts in the group, and participants responded to the reflection posts using the comments feature. We conducted a small, single-arm feasibility trial of the adapted intervention in a study of 17 young women who used indoor tanning beds. On average, participants viewed 92% (26/28) of all posts, reacted to (eg, "liked") 32% (9/28), and commented on 27% (2/28) during the 8-week intervention group period. Further, 82% (14/17) of participants indicated they would recommend the intervention to a friend, and all agreed that they would continue to check the group if it were to continue. Responses to evaluation questions indicated that participants felt connected to and identified with the group, both of which are important for sustaining interest in Facebook groups [79]. Importantly, participants reported a lower number of average past-month

indoor tanning sessions at the postintervention assessment (mean 0.69, SD 2.3) compared to the baseline (mean 2.31, SD 4.4; Cohen *d*=0.47).

Intervention Refinement

Together, our pilot work demonstrated that our intervention content and delivery platform were feasible and acceptable and had the potential to reduce tanning intentions and behavior. Before this RCT, we conducted 2 formative studies with tanners to refine our content and messaging approach further. The first was a 2018 focus group study of indoor tanners (4 focus groups [total n=20]) designed to (1) refine our planned advertising, recruitment, and enrollment strategies; (2) receive feedback on our general Facebook strategy as well as our examples of planned intervention posts; and (3) receive recommendations for how to best integrate indoor tanning as a discussion topic within the intervention. Although most participants shared that Facebook was not their most frequently used social media platform, most were active users, and they felt the Facebook group feature was uniquely valuable in connecting them with larger groups of friends or others with shared interests. Participants in all 4 groups suggested broadening the intervention purpose and post topics beyond a tanning-specific focus to promoting physical and mental wellness as part of a healthy lifestyle. Messaging related to body acceptance and female empowerment was also suggested as key desirable topics associated with a healthy lifestyle. Participants also expressed interest in content design to help them establish healthy routines and habits (eg, eating, going to the gym, and sleeping). Most participants viewed tanning as a bad habit but not necessarily as inconsistent with a healthy lifestyle. For example, tanners did not often equate tanning with other behaviors considered to be "unhealthy," such as smoking or poor diet. However, when asked to reflect on the harms of tanning, members acknowledged that it is indeed a risky behavior and consistent with other unhealthy lifestyle choices. Finally, most participants felt they commonly encountered body image messaging and recommended we expand the discussion of body image to more broadly reflect pressures that young women experience beyond physical appearance, such as the pressure to live a "perfect" life that may cause mental stress and be inconsistent with their personal preferences.

We made several changes to the planned intervention based on this feedback. First, we refined the intervention framing, messaging, and post content to focus on promoting healthy self-care and empowerment to embrace a physical and mental wellness lifestyle. We named the intervention "empowerfulme" to reflect this focus. We also incorporated the concept of helpful self-care behaviors (ie, those with health benefits) as a contrast to unhelpful self-care behaviors, which were defined as "things we do that feel like self-care but often cause problems." We crafted new intervention content that encouraged participants to reflect on the short- and long-term consequences of unhelpful self-care, using tanning as an example of how unhelpful self-care may be perpetuated by idealistic thinking and societal messaging. Our incorporation of messaging and exercises based on ACT approaches was also in response to the described interest in learning more about self-acceptance and living by internal values over externally imposed values.

After content refinement, we conducted a usability trial in a sample of 29 frequent tanners using the same procedures as the fully powered RCT (except for multiple follow-up assessments). We experienced a slower-than-expected rate of recruitment and enrollment that delayed enrolling a sufficient number of tanners into Facebook groups to start groups with a targeted size of 25 participants. This led to an expansion of our recruitment strategy and study description. We also examined participants' interactions with our posts in this version and modified those that received low levels of engagement.

Intervention Engagement and Posting Strategy

Our intervention is administered within a study-specific "secret" Facebook group with membership and content limited to invited group members. Facebook groups ran for 8 weeks and contained 25 members each. Given that ideal intervention length and group size have not been empirically established and differ based on intervention content and objectives [74], we modeled our intervention on our pilot Facebook study. Our intervention included strategies found to boost participant involvement and group engagement in Facebook group–delivered health interventions for young adults [40,71,72,80,81]. We provided clear expectations, including checking the group study account at least once a day and "icebreaker" activities to increase comfort with commenting. We also used a young woman as the intervention moderator; all posts came from this account. Under the research team's guidance, the moderator commented or reacted to various posts (ie, liking them) to reinforce participant activity and encourage engagement.

Intervention content was delivered through posts made by the group moderator twice daily for 8 weeks, for a total of 112 posts. Each week addressed a thematic topic introduced in the first weekly post (Monday morning), with corresponding goal-setting and monitoring activities throughout the week (Table 1). Other posts were designed with activities and prompts to address change objectives, reinforce intervention messaging, or promote group engagement [40]. We also structured the content and timing of our posts to maximize engagement. Posts were written in a conversational tone and designed to take less than 3 minutes to read and comment on. A graphic designer enhanced the visual appeal of our posts and included relevant photos and videos [82]. We included polls and prompts in our posts for participants to share tips and successes with others [74,83].

Table 1. A description of the types, frequency, purpose, and content of the posts used for intervention and control group content.

Post type	Weekly frequency	Purpose and content
Goals	3	Participants set a goal related to the weekly topic (Monday evening), completed monitoring or check-in related to progress (Thursday morning), and reported back about goal progress (Sunday).
Reflection and discussions	5	To restructure key expectancies and beliefs with content that is discussion-based and designed to encourage reflection on one's ongoing behavior or speaking out against idealistic perspectives.
Reinforcement messages	2-3	Posts drawn from popular sources and designed to reinforce intervention messaging. Unlike other "active ingredient" posts, content may change between waves to accommodate ongoing events or provide recent and relevant articles.
Sharing content	2-3	Memes, inspirational quotes, and humorous posts intended to promote engagement and provide positive messaging.

Intervention Content

Our intervention strategy and content were developed through a mapping process [84] that included (1) identifying specific behavioral determinants (ie, factors that lead to tanning behavior) to target for change (described previously); (2) developing specific performance objectives (POs) to specify the changes in these targets that must occur to produce the overall behavioral outcome of reducing tanning; and (3) applying behavior change theory and techniques to produce intervention content to meet the POs.

POs 1-3 (Table 2) are designed to restructure tanning expectancies and body image beliefs that drive tanning intentions and idealistic thinking. Initial intervention content is framed within the context of considering that "self-care" behaviors can be either helpful (eg, exercise) or unhelpful (ie, they may provide some immediate benefit but have costs in the short- or long-run). Participants are asked to reflect on their self-care and reflect on their view of whether tanning is helpful or unhelpful self-care (POs 1 and 2). Participants are asked to consider the balance of benefits and problems with various forms of self-care and consider plans to increase helpful and reduce unhelpful self-care. Tanning-specific content encourages participants to reflect on underlying reasons and undesirable aspects of tanning to restructure beliefs by shifting the balance of pros and cons and thus promoting openness to behavioral change [41,42,47,48].

PO 3 also seeks to restructure beliefs by incorporating counterattitudinal advocacy techniques that effectively alter risky body image beliefs [49-54]. This approach has the person speak out against and question commonly held idealistic thoughts. If done effectively, the alternative perspectives considered during these exercises will conflict with idealistic thinking, producing psychological discomfort (ie, cognitive dissonance) [63]. The person is then motivated to seek psychological relief by altering their original unhealthy beliefs to be more consistent with the healthier perspective being advocated. Creating dissonance is optimized when participants share counter perspectives in group-based settings, which leads to more robust attitude and behavior change [53,56]. Accordingly, the intervention approach is to solicit counterattitudinal comments as responses to our Facebook group posts.

POs 4 and 5 are guided by the ACT concept of promoting acceptance. It can be difficult to completely change and mitigate the impact of strongly ingrained beliefs, such as those underlying idealistic thinking. ACT defines fused beliefs as routine thinking that can be self-critical and may lead to unwanted thoughts and feelings that drive habitual behaviors that are often unhealthy in an attempt to control these difficult experiences [57-59]. The intervention provides psychoeducational content and messaging that thoughts and feelings cannot be controlled and attempts to control them can create additional problems and perpetuate self-critical thinking. The intervention messages emphasize the value of willingness to experience negative thoughts and feelings by using mindfulness skills [57-59].

Finally, PO 6 encourages participants to consider the importance of making daily choices guided by higher-order values [57,60,61]. The intervention content encourages participants to consider the importance of broad values (eg, healthy lifestyle, helpful self-care, self-compassion, acceptance, and personal growth) and consider their alignment with societal messages and expectations promoting tanning. Participants identify their core values and contrast them with the values underlying societal messages about "perfection" in appearance and other aspects that often drive self-critical thinking. They are also asked to consider whether their ongoing behaviors are consistent with their core values and engage in goal-setting for enacting behaviors aligned with them [57,60,61].

Table 2. The intervention performance objectives (POs) that guided the content of corresponding intervention posts.

POs	Intervention content
PO 1: engage in helpful self-care behaviors	1a. Describe helpful self-care behaviors
	1b. Identify benefits of helpful self-care behaviors
	1c. Identify and enact plans for increasing helpful self-care behaviors
PO 2: reduce unhelpful self-care behaviors (with tanning as an example)	2a. Identify unhealthy forms of self-care, including tanning
	2b. Describe how tanning is not aligned with helpful self-care. Describe problems with tanning.
	2c. Identify and enact plans to reduce unhelpful self-care
PO 3: reduce buy-in to appearance messages about ideal women	3a. Critique societal expectations for women that lead to negative affect and unhealthy behaviors like tanning
	3b. Describe the messages underlying these expectations and their sources
	3c. Speak out against the problems caused by self-critical appearance values
PO 4: increase acceptance and willingness to experience uncomfortable feelings	4a. Identify problems with trying to control thoughts and feelings through behaviors like tanning
	4b. Understand the concept of acceptance
	4c. Express a commitment to adopting an acceptance mindset
PO 5: practice mindful acceptance	5a. Enact general skills for self-observation (ie, mindfulness skills)
	5b. Practice identifying self-critical beliefs and related feelings and sitting with them
PO 6: engage in behaviors that are consistent with personal growth values	6a. Describe the most important personal growth values
	6b. Evaluate alignment of current behaviors with growth values
	6c. Identify and enact plans to ensure values-consistent behavior

Measures

Self-Report Survey Items

Our primary outcomes are self-reports of indoor and outdoor tanning at the 8-month follow-up (Table 3). We chose items that are expert-recommended [85] and commonly used in tanning intervention trials [39,41,77]. Outcomes have open-ended response options to increase reporting accuracy and have been shown to be reliable compared to daily diary reports of behavior assessed over the same period [77,86]. Mediators and other measures are also listed in Table 3 and include measures adapted for tanning and validated in our previous research [38].

Table 3. The trial measures captured with self-report surveys.

Construct	Description of measures
Primary outcomes (measured at 8-month follow-up)	
Indoor tanning	• Open-ended reporting of the number of times participants used a tanning bed or booth in the past 8 months [85]
Outdoor tanning	• Open-ended reporting of the number of times spent outdoor tanning in the most recent summer (eg, between June 1, 2023, and August 31, 2023) [86]
Secondary outcomes	
Tanning intentions	• Intentions to use indoor tanning or spend time outdoor tanning (2 separate questions) in the next 12 months [39,41,77]
Long-term tanning	• Indoor and outdoor tanning outcomes assessed at the 18-month follow-up
Primary mediators (measured at 3-month follow-up)	
Tanning expectancies	• Beliefs related to tanning benefits (eg, tanning is attractive and relaxing) and risks (eg, appearance damage and skin cancer risk), tanning attitudes, and temptations to tan [87,88]
Tanning-specific body-image factors	• Items adapted from the Objectified Body Consciousness Scale to assess actively monitoring and comparing one's tans with others [38,89] • Internalization of the thin and tan ideal [21,35,38,88] • Appearance conversations with friends [90] • Items adapted from the Multidimensional Body Self-Relations Questionnaire to reflect tan dissatisfaction [38,91]
Openness to changing tanning	• Perceived difficulty in stopping indoor or outdoor tanning (2 separate questions) [92] • The Readiness to Change Questionnaire adapted to tanning behavior [93]
Exploratory mediators	
Values and values-consistent living	• Valued Living Questionnaire [94] • Valuing Questionnaire [95]
General body image acceptance	• The Acceptance and Action Questionnaire II [96] • Beliefs About Appearance Scale [97]
Perceptions and use of tanning alternatives	• For both sunless tanning products and spray-tanning, past 12 use, intention, attitudes, and self-efficacy [77,85]
Mindfulness	• Mindful Attention Awareness Scale [98]
Covariates	
Demographics	• Age, education, race, ethnicity, urban, rural, and SESa
Sun protection habits	• Typical use of sun protection (eg, shade and sunscreen) [99]
Use of social media	• Frequency of use of popular social media sites and integration of Facebook within social behaviors and daily routines [67,100]
Melanoma risk factors	• Natural hair color, eye color, skin type, skin reactivity to the sun, and history of sunburns [101]
Depression, anxiety, and stress	• The Depression Anxiety Stress Scale-10 [102]
Other health behaviors	• Alcohol use [103] • Cigarette use [104] • Physical activity [105] • Sedentary behavior [106] • Sleep [107] • Diet [108]

[a]SES: socio-economic status.

Facebook Engagement

The 3-month follow-up survey contained several Facebook-specific evaluation items, including perceived connectedness with a group, identification with posts and other group members, enjoyment, and ease of participation [79,109,110]. Items from the Audience Engagement Scale were used to measure key aspects of engagement with intervention content, including personal involvement (ie, was information judged to be personally relevant) and personal reflection (ie, was the knowledge acquired used to reevaluate personal conduct) [111]. Software (GRYTICS [112]) was also used to capture objective measures of participants' engagement, including comments and reactions to our posts or comments from others within our posts.

Statistical Analysis

Power

The primary outcome will be a sum of the 8-month indoor tanning outcome and the number of outdoor tanning sessions in the summer. One of the only intervention trials to focus on high-risk tanners was an in-person counseling intervention that produced significantly lower tanning rates among intervention participants at a 3-month follow-up [113]. This analysis suggested means for indoor tanning sessions of 4.40 (SD 7.74) for the intervention group and 11.78 (SD 13.03) for controls for a between-group difference of 7.38, which corresponded to a moderate to large size effect (0.69). Because our intervention is less intensive than a counseling intervention, we powered our study based on the scenario that the treatment effect will be at least 60% of the counseling study (corresponding to an effect size of 0.41). In our usability trial baseline data, the mean number of previous 3-month measures of indoor tanning and past summer outdoor tanning was 22.5 (SD 22.9; our means will likely be higher in the trial since the past 8-month indoor tanning will be used). Assuming similar means in our trial control group, an intervention effect of 0.41 would produce a mean of 13.1 (SD 22.9) tanning sessions in the intervention group, a difference of 9.4 total tanning sessions. Assuming these estimates from our follow-up means (ie, tanning control: mean 22.5, SD 22.9; tanning intervention, mean 9.4, SD 22.9), we will achieve 80% power with at least 186 participants (93 in each group). We anticipated a 70% follow-up rate at the primary 8-month outcome, which led us to target the enrollment of 266 participants to test the effects adequately.

Primary Outcome Analyses

Using intention-to-treat analyses, 2-sided tests for the effect of treatment will be conducted at the 0.05 level. If less than 10% (26/266) of outcomes are missing, we will consider data to be missing at random and apply multiple imputations. If missing data are more than 10% (27/266), we will examine patterns of missing data, including comparing demographics for those with and without missing outcomes. If missing data are not random, we will consider alternative missing data approaches. We will also conduct sensitivity analyses by first comparing baseline characteristics by condition and modifying the analyses to adjust for differences.

Multilevel models (eg, random coefficient) will test the primary study hypothesis that participants who received the intervention will report less total tanning behavior at 8-month follow-up compared to those who received the control. The level 1 model represents individuals nested within Facebook groups (the level 2 model). In particular, the effect of the intervention will be considered a random effect that may vary by block (ie, Facebook group). Thus, the model for analysis will use the following form as a starting point: $Y_{ij} = \beta_{0j} + \beta_{1j}T + \varepsilon_{ij}$, where Y_{ij} represents the number of tanning sessions used for the *i*th individual within the *j*th block, T is an indicator for whether the individual was randomized to the treatment or control. As such, the analysis accounts for (by including the random intercept β_{0j}) random differences between blocks (eg, previous tanning behavior) and allows the effect of the intervention to vary by block (with β_{1j}). If necessary, sensitivity analyses may control for individual-level covariates and appropriate transformations (ie, square root), or additional analysis methods will be considered if the normality assumption is strongly violated.

Mediation Analyses

Mediator analysis will be used to assess whether participant attitudinal factors (level 1 variables), including tanning expectancies, tanning-related body image factors and change perceptions, mediate the effect of the intervention. In particular, for each potential mediator, the 4 component steps [114] will be examined through regression models similar to those described above. The contribution of the mediated effect will be assessed directly using the approach recommended by Kenny and colleagues [115]. For multilevel models, we will calculate the product of the 2 pieces of the mediating path (from intervention group assignment to the mediating variable and from the mediating variable to the outcome). Bootstrap procedures will be used to formally test for the significance of the mediating pathway.

Ethical Considerations

The University of Kentucky Institutional Review Board reviewed and approved all study procedures before data collection (review number 56153 2019). A web-based informed consent form was included as the first page of the baseline survey, and it described the study procedures, privacy, confidentiality, risks, benefits, and data protection. Participants provided implied consent by agreeing to the consent form and starting the survey. All survey data were collected with a deidentified approach, using a unique participant identifier in place of a name or other personal information. The engagement data downloaded from Facebook were deidentified before storage or analysis by replacing participant names with their unique identifier. Our consent form also provided a description of the certificate of confidentiality provided by the National Institutes of Health as part of their funding support. Participants were emailed Amazon gift card incentives in the amount of US $30 for completing each of the baseline, 3-month, and 8-month surveys and US $40 for the 18-month follow-up.

Results

This trial was funded by the National Cancer Institute (R01 CA218068) in July 2017 and approved by the University of Kentucky Institutional Review Board in February 2020. Trial recruitment and enrollment occurred in 6 waves of data collection, starting in February 2022 and closing in May 2023. The study is closed to enrollment but remains open for follow-up. This protocol report was prepared before data analyses. As of February 2024, all participants have completed the 8-month follow-up assessment, and data collection is scheduled to close by the end of 2024 after the collection of the 18-month follow-up.

Discussion

Frequent tanning has been linked to an exponential increase in melanoma risk, but there are no established interventions targeting this group. This is the first study to test an intervention for frequent tanners in a fully powered trial. The prevailing approach to tanning interventions has been to raise awareness about the health risks as well as the appearance-damaging effects of tanning (eg, premature skin aging and wrinkling) [77,116-120]. These interventions have been delivered as educational-based interventions in various formats, with some incorporating UV facial photographs showing existing skin damage in combination with health risk information. Several trials have demonstrated the efficacy of these appearance-focused interventions when tested among typical tanners (eg, participants who have tanned at least once). However, the efficacy of this approach is likely to be limited among more frequent tanners [121] who generally report knowledge of and perceived susceptibility to the appearance risks of tanning but believe the immediate benefits outweigh the longer-term risks [20,122,123].

Beyond their primary focus on occasional tanners, appearance-focused interventions do not address key motives that are likely driving frequent tanning, including sociocultural influences, body image, and tanning dissatisfaction. This intervention approach represents an extension of the previous intervention literature by attempting to change core motives and influences that make tanning "worth the risks" among frequent tanners as well as incorporating key elements of an acceptance-based intervention. A small number of studies have demonstrated the potential value of using dissonance-based, body image–focused intervention strategies in melanoma prevention efforts [39,40,55,124]. This trial extends this work by (1) testing a fully powered skin cancer prevention program delivered entirely through social media; (2) delivering the intervention to both frequent indoor tanners and sunbathers; (3) broadening the intervention content focus beyond body image ideals to also challenging general expectations of how young women should look, think, and act; and (4) translating concepts from ACT principles to create acceptance-based content that encourage participants to accept that negative thoughts and feelings will happen and consider the importance of making daily choices that are guided by higher-order values.

Existing indoor tanning interventions have not been widely disseminated. The use of social media to deliver intervention content embeds the intervention into a platform that has become ingrained in the lives of our target young adult population and is a preferred method for exchanging information and communicating with peers [125]. A Facebook-delivered intervention can be integrated into individuals' existing, routine social media habits and avoids the burden of requiring users to find and use a stand-alone, unfamiliar website. The impact of this work lies in the potential for dissemination in a variety of contexts, given the use of a familiar and freely available intervention platform. This study will produce an intervention guide and content library of posts that could be implemented with minimal costs and staffing. Further, the intervention allows for social connection and self-expression among participants, which are key reasons people use social media [109]. These intervention features, along with the focus on positive body image, may increase the interest of potential intervention participants and thus lead to a more impactful intervention.

Limitations

Potential limitations to using Facebook include the fact that the nascent social media literature lacks firmly established, empirically based guidelines for effective practice. Thus, several of our choices (eg, content, length, and group size) are based on our experiences in pilot studies and available best practice guidelines. An alternative to the proposed Facebook approach would be retaining the previously tested website intervention. Websites have advantages, including increased control over content, easier user tracking, and the ability to deliver more in-depth content. However, website interventions have restrictive barriers for the target population, including the need to direct them to an unfamiliar website and a possible lack of interest in engaging on the website for any substantive period of time (as noted in our focus group research). The group discussions critical to the success of dissonance-based intervention are more easily implemented on the freely available Facebook setting but are more difficult to achieve with a website. There are also limitations in using Facebook to deliver content across several weeks. Developers of Facebook group support interventions for smoking cessation have raised concerns about the "empty room phenomenon," which describes the hesitancy of some social media users to engage with strangers [64]. We have engaged in several formative user-centered studies to inform the messaging and content of our intervention, but low engagement can occur in social media–delivered interventions. It is possible that users could alter the topic of discussion in ways not conducive to indoor tanning prevention or make unfavorable comments. We attempt to prevent this behavior by providing general guidelines for posting, daily monitoring, and following an established intervention manual for moderators.

Conclusions

This trial will contribute unique knowledge to the field of skin cancer prevention, as no fully powered trials have examined the efficacy of an intervention designed for frequent indoor or outdoor tanning. Our intervention builds from and meaningfully extends existing skin cancer interventions and incorporates innovative elements from body image and acceptance-based

interventions in its content and delivery. If efficacious, findings can inform best practices in skin cancer prevention and provide evidence of the value of translating principles from body image and acceptance-based interventions to target other behavioral contexts. The use of Facebook groups allows group-based interactions among participants, which can facilitate stronger changes in attitudes and behaviors and provide a platform to embed the intervention into individuals' everyday routines.

Acknowledgments

This work was supported by the National Cancer Institute (award R01CA218068; principal investigator JS), the Patient-Oriented and Population Sciences and Biostatistics and Bioinformatics Shared Resources of the University of Kentucky Markey Cancer Center (P30CA177558), and the National Institutes of Health (NIH)–funded National Center for Advancing Translational Sciences (UL1TR001998). Abstract

Background: Chronic pain is common among individuals with opioid use disorder (OUD) who are maintained on medications for OUD (MOUD; eg, buprenorphine or methadone). Chronic pain is associated with worse retention and higher levels of substance use. Treatment of individuals with chronic pain receiving MOUD can be challenging due to their increased clinical complexity. Given the acute and growing nature of the opioid crisis, MOUD is increasingly offered in a wide range of settings, where high-quality, clinician-delivered, empirically validated behavioral treatment for chronic pain may not be available. Therefore, digital treatments that support patient self-management of chronic pain and OUD have the potential for wider implementation to fill this gap.

Objective: This study aims to evaluate the efficacy of Integrating the Management of Pain and Addiction via Collaborative Treatment (IMPACT), an interactive digital treatment program with asynchronous coach feedback, compared to treatment as usual (TAU) in individuals with chronic pain and OUD receiving MOUD.

Methods: Adult participants (n=160) receiving MOUD and reporting bothersome or high-impact chronic pain will be recruited from outpatient opioid treatment programs in Connecticut (United States) and randomized 1:1 to either IMPACT+TAU or TAU only. Participants randomized to IMPACT+TAU will complete an interactive digital treatment that includes 9 modules promoting training in pain and addiction coping skills and a progressive walking program. The program is augmented with a weekly personalized voice message from a trained coach based on daily participant-reported pain intensity and interference, craving to use opioids, sleep quality, daily steps, pain self-efficacy, MOUD adherence, and engagement with IMPACT collected through digital surveys. Outcomes will be assessed at 3, 6, and 9 months post randomization. The primary outcome is MOUD retention at 3 months post randomization (ie, post treatment). Secondary outcomes include pain interference, physical functioning, MOUD adherence, substance use, craving, pain intensity, sleep disturbance, pain catastrophizing, and pain self-efficacy. Semistructured qualitative interviews with study participants (n=34) randomized to IMPACT (completers and noncompleters) will be conducted to evaluate the usability and quality of the program and its outcomes.

Results: The study has received institutional review board approval and began recruitment at 1 site in July 2022. Recruitment at a second site started in January 2023, with a third and final site anticipated to begin recruitment in January 2024. Data collection is expected to continue through June 2025.

Conclusions: Establishing efficacy for a digital treatment for addiction and chronic pain that can be integrated into MOUD clinics will provide options for individuals with OUD, which reduce barriers to behavioral treatment. Participant feedback on the intervention will inform updates or modifications to improve engagement and efficacy.

KEYWORDS

chronic pain; digital treatment; medications for opioid use disorder; methadone; opioid use disorder

Introduction

Background

Despite increased attention from the media, policy makers, researchers, and clinicians, the opioid epidemic in the United States remains a significant public health crisis. Approximately 107,000 US adults died by drug overdose in 2021, with increases in every age group and an overall age-adjusted 14% increase from the previous year [1]. An estimated two-thirds of overdose deaths involved synthetic opioids other than methadone (eg, illicitly manufactured fentanyl) [2]. Medications for opioid use disorder (MOUD), including buprenorphine and methadone, are protective against mortality in individuals with opioid use disorder (OUD) [3,4], reducing overdose death and all-cause death by 8 and 2.5 times, respectively [5]. Furthermore, longer retention in MOUD is associated with a continued reduction in mortality [5]. Retention of at least 6 months, and often longer, is needed to obtain full benefits, including a return to work and improvements in fulfilling family and social responsibilities [6,7]. Despite these benefits, only 36% of individuals who initiate are retained in MOUD for 6 months, with retention rates falling to 22% at 1 year [8]. Therefore, developing interventions that support MOUD retention and address co-occurring conditions that interfere with retention is essential to enabling people with OUD to obtain the full benefits of MOUD treatment.

Role of Pain in the Development of OUD

One condition that commonly co-occurs with OUD is chronic pain, frequently defined as pain that persists for 3 months or more. Chronic pain is a widespread affliction in the United States, affecting approximately 1 in 5 adults [9], and is more common among people with OUD. A large study of electronic health records revealed that 64.4% of individuals with OUD also had a chronic pain condition [10]. Chronic pain can be a pathway to OUD, with 4 out of 5 individuals who use heroin reporting their initial exposure to opioids was through a prescription for pain treatment [11,12]. It is a common misconception, even among addiction providers, that methadone and buprenorphine provide adequate pain treatment for individuals with OUD [13]. Unsurprisingly, chronic pain typically persists when MOUD is the sole treatment modality. Among individuals enrolled in methadone or buprenorphine treatment, estimates of chronic pain range from 40% to 80% [14-17].

Chronic Pain Negatively Affects MOUD Outcomes

The presence of chronic pain may undermine the effectiveness of MOUD. A large randomized, controlled multisite trial of buprenorphine in individuals with OUD found greater pain severity significantly increased the odds of opioid use in the following week [18]. Follow-up analyses revealed that variability or volatility in pain intensity was associated with craving, relapse to opioid use, and poorer outcomes [18,19]. Furthermore, the experience of pain has been cited as the most common reason for returning to use while engaged in MOUD [20]. Finally, few people receiving MOUD receive adequate evidence-based pain care; this has been recognized as an important gap in the treatment of comorbid OUD and chronic pain [15,21-24].

Individuals with chronic pain receiving MOUD, compared to those without chronic pain, have higher rates of psychiatric and medical comorbidities, including sleep disturbances, and higher rates of health service use and levels of functional impairment [21,25-27]. Comprehensive treatment for individuals with concurrent chronic pain and OUD may require interventions that address mood, anxiety, sleep, and functional difficulties to maximize OUD treatment outcomes, such as MOUD retention. That is, chronic pain with OUD does not necessarily indicate more severe OUD; rather, it represents a concurrent disorder that may have a different clinical course and treatment response than OUD alone [22,28]. Accordingly, treatments should consider the relationship between chronic pain and opioid use while addressing barriers to engagement in resource-limited MOUD clinics.

Cognitive Behavioral Therapy Is an Evidence-Based Treatment for Both Chronic Pain and Substance Use, but it has Limited Accessibility

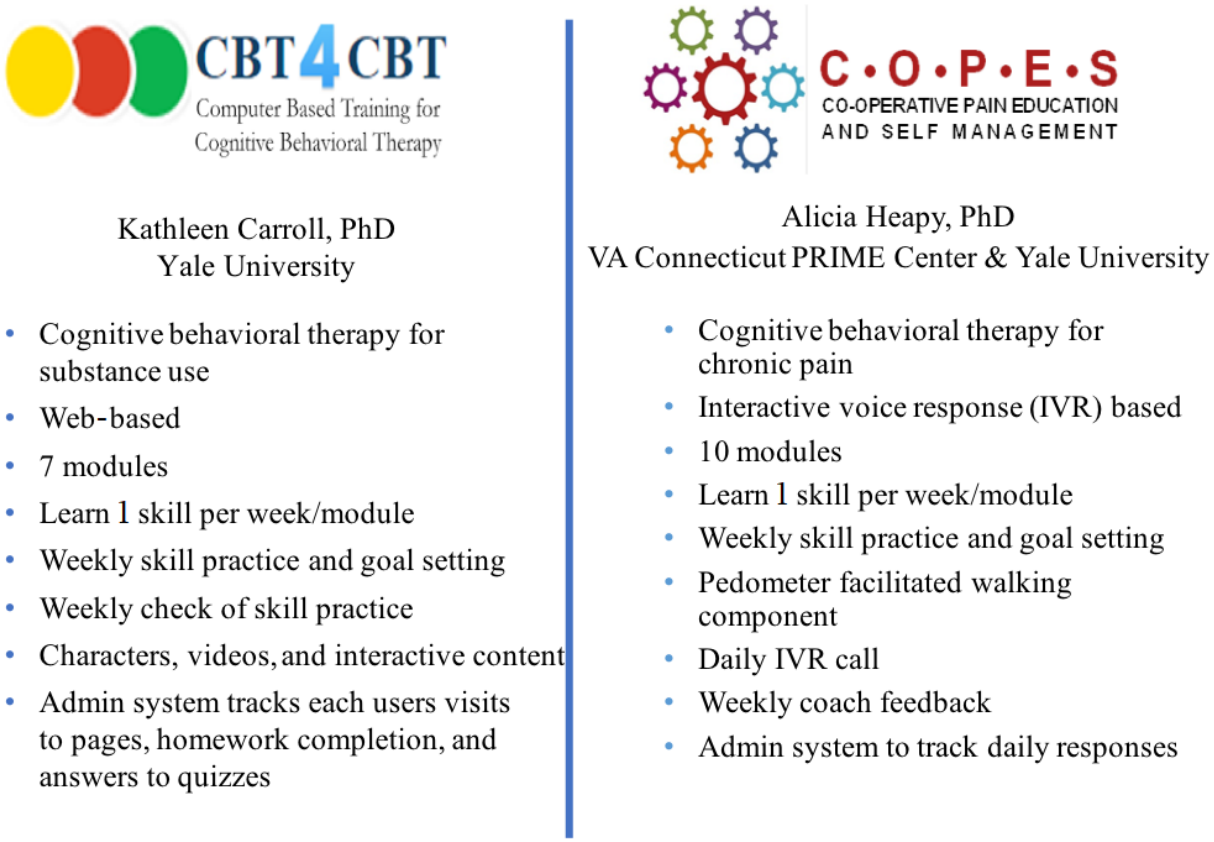
Cognitive behavioral therapy (CBT) has a strong evidence base for the treatment of chronic pain [29] and substance use disorders [30-33]. CBT for chronic pain has been recommended by the Centers for Disease Control and Prevention and the National Institutes of Health (NIH) as a first-line treatment to reduce pain and improve function [34,35]. Although MOUD clinicians report interest in nonpharmacologic pain treatment, very few report confidence in their own ability to address chronic pain [36]. Similar to chronic pain, CBT for substance use disorders has been shown to have moderate effects on reducing substance use, promoting abstinence from substances, increasing the use of coping skills, and promoting other positive psychosocial outcomes in individuals with addiction [37]. Engagement in CBT for substance use disorder is a mainstay

in outpatient and inpatient treatment, but, akin to CBT for chronic pain, implementing CBT with high fidelity is challenging due to the lack of trained clinicians in the setting [38,39]. For these reasons, offering adjunctive CBT in MOUD clinics has resulted in mixed findings [40-42]. Taken together, there is a critical gap in treatment where individuals with OUD receiving MOUD have few options for addiction or pain treatment. Accordingly, there has been a recent call to develop rigorous, evidence-based digital treatments for individuals with OUD, which can be integrated into MOUD clinical settings [43].

Development of Integrating the Management of Pain and Addiction via Collaborative Treatment

Integrating the Management of Pain and Addiction via Collaborative Treatment (IMPACT) combines 2 evidence-based digital CBT treatments: Computer-Based Treatment for Cognitive Behavioral Therapy (CBT4CBT) and Cooperative Pain Education and Self-Management (COPES) treatment programs (Figure 1). CBT4CBT is a web-based program designed to improve behavioral and cognitive coping skills that have been evaluated in a range of substance use disorders [44-47], including 2 trials indicating its effectiveness and durability for individuals with OUD on methadone maintenance [48,49] and office-based buprenorphine maintenance [50]. COPES is an interactive voice response–based treatment for chronic pain that is delivered asynchronously through telephone [51] and has been shown to be similarly effective in reducing pain intensity and improving physical functioning, sleep quality, and quality of life as real-time CBT with a therapist [52]. IMPACT was designed to provide an easily accessible, standardized evidence-based intervention for those with OUD and chronic pain that could ultimately be easily integrated into MOUD clinic settings.

Figure 1. Core program features of the Computer-Based Treatment for Cognitive Behavioral Therapy (CBT4CBT) and Cooperative Pain Education and Self-Management (COPES) programs.



This study was funded by the National Center for Complementary and Integrative Health's Behavioral Research to Improve Medication-Based Treatment (BRIM) program. The goal of BRIM, funded by NIH's Helping to End Addiction Long-Term (HEAL) initiative, is to examine the role of behavioral interventions in improving the outcomes of MOUD, particularly MOUD access and retention. The R61/R33 award described here consists of 2 phases: a preparatory R61 phase used to develop the intervention and identify recruiting sites and the R33 clinical trial that is the focus of this protocol.

Study Objectives

The study is designed to evaluate the efficacy of IMPACT along with treatment as usual (IMPACT+TAU) versus TAU only at 3 months post randomization (primary end point). The primary OUD outcome is verified retention in MOUD treatment, defined as enrollment in MOUD (ie, yes or no), with evidence of MOUD use in the week before the 3-month time point. Secondary treatment outcomes will include pain interference, physical functioning, MOUD adherence, substance use, craving, pain intensity, sleep disturbance, pain catastrophizing, and pain self-efficacy at 3 months post randomization. The secondary aim is to evaluate the durability of effects for MOUD retention

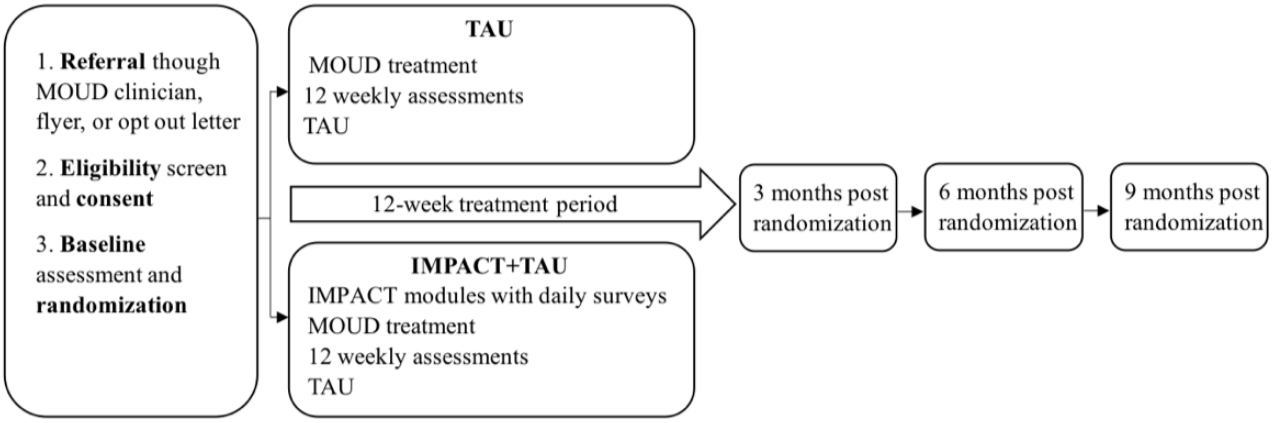
at 6 and 9 months post randomization. The tertiary aim is to examine treatment usability and quality through qualitative interviews with individuals randomized to IMPACT.

Methods

Study Design

This is a randomized clinical trial comparing the efficacy of IMPACT+TAU relative to TAU among individuals enrolled in MOUD treatment who have chronic pain. Outcomes will be assessed at baseline, 3, 6, and 9 months post randomization (Figure 2).

Figure 2. Study protocol for Integrating the Management of Pain and Addiction via Collaborative Treatment (IMPACT). MOUD: medications for opioid use disorder; TAU: treatment as usual.



Study Population and Setting

Participants will be 160 individuals with chronic pain receiving MOUD (methadone or buprenorphine) at participating outpatient opioid treatment program (OTP) sites located in Bridgeport, Danbury, and Waterbury (Connecticut).

Ethical Considerations

The study was approved by the Yale University Institutional Review Board on September 4, 2019 (2000026276). Subsequent modifications were implemented to add posttreatment qualitative interviews to assess treatment satisfaction and usability, as well as to refine recruitment materials and add recruitment sites. The study was subsequently approved by the Veterans Affairs Connecticut Human Subjects Subcommittee because, although not enrolling Veteran Affairs patients, several study staff are employees of the Department of Veterans Affairs.

Study Population

Textbox 1 contains inclusion and exclusion criteria for patients.

Textbox 1. Eligibility criteria for patients.

Inclusion criteria

- Be 18 years of age or older
- Meet the

  Diagnostic and Statistical Manual of Mental Disorders (Fifth Edition) criteria for opioid use disorder and be enrolled in methadone or buprenorphine treatment at the participating medications for opioid use disorder (MOUD) clinic
- Receiving a stable (ie, unchanged in 2 weeks) dose of MOUD as judged by the prescribing clinician
- Report bothersome or high-impact chronic pain defined by the Graded Chronic Pain Scale–Revised
- Have a self-reported ability to walk at least 1 block

Exclusion criteria

- Inability to read, write, and speak English at a third-grade level
- Untreated or inadequately treated bipolar or psychotic disorder or current suicide risk for the previous 2 weeks before screening (identified using baseline measures)
- Life-threatening health conditions that would impede participation (eg, end-stage renal failure, malignant cancer requiring chemotherapy)
- Planned surgical treatment related to pain
- Pending legal action or planned relocation that would interfere with participation

Justification for Criteria

Participants will be adults receiving a stable dose of MOUD because, until the dose is stable, pain ratings may fluctuate and obscure the intervention's effect. We require bothersome or high-impact chronic pain (ie, moderate to severe pain that limits life and work activities on most days or every day in the past 3 months) because, compared to individuals with mild chronic pain, it is more commonly associated with negative health indicators addressed in cognitive behavioral treatment for chronic pain (eg, negative pain coping beliefs, pain interference, and psychological distress) [53]. IMPACT contains a progressive walking program; therefore, to ensure participant safety, participants must be able to walk at least 1 block. Individuals with low literacy (ie, <third grade) or medical or psychiatric diagnoses that would interfere with their ability to meaningfully participate in the IMPACT treatment, such as severe mental health conditions (eg, unmedicated or untreated bipolar or psychotic disorder, current suicide risk, or diagnoses requiring palliative or end-of-life care), are excluded. Individuals with circumstances that may predictably interfere with participation (eg, legal actions with imminent incarceration) or produce large changes in pain (pain-related surgeries) will be excluded. Women of childbearing age will be included, as there is no contraindication for CBT for pain or substance use disorder for pregnant women. Participants who do not have a digital device (eg, smartphone or tablet) for participating in IMPACT will be supplied with one for the duration of the study.

Recruitment, Screening, and Consent Procedures

Study recruitment occurs through clinician referral of interested patients and patient self-referral in response to informational study materials posted in patient care areas at the recruiting sites. Site clinicians receive information about the study and eligibility criteria through research staff presentations and study informational material provided at clinical staff meetings. Self- and clinician-referred individuals are screened by a study research assistant and, if eligible, invited to consent and complete a baseline assessment. Procedures are conducted in a quiet and private office space provided by the OTP clinic to the research team. The research assistant and the participant discuss the consent document, and potential participants are provided an opportunity to ask questions and time to consider their decision to participate. A comprehension quiz is given to ensure the participant has an adequate understanding of the study, and a copy of the consent form is given to the participant. After consent, the research assistant assigns a unique study ID code and administers baseline measures on a study laptop using the REDCap (Research Electronic Data Capture) software platform.

Randomization and Masking

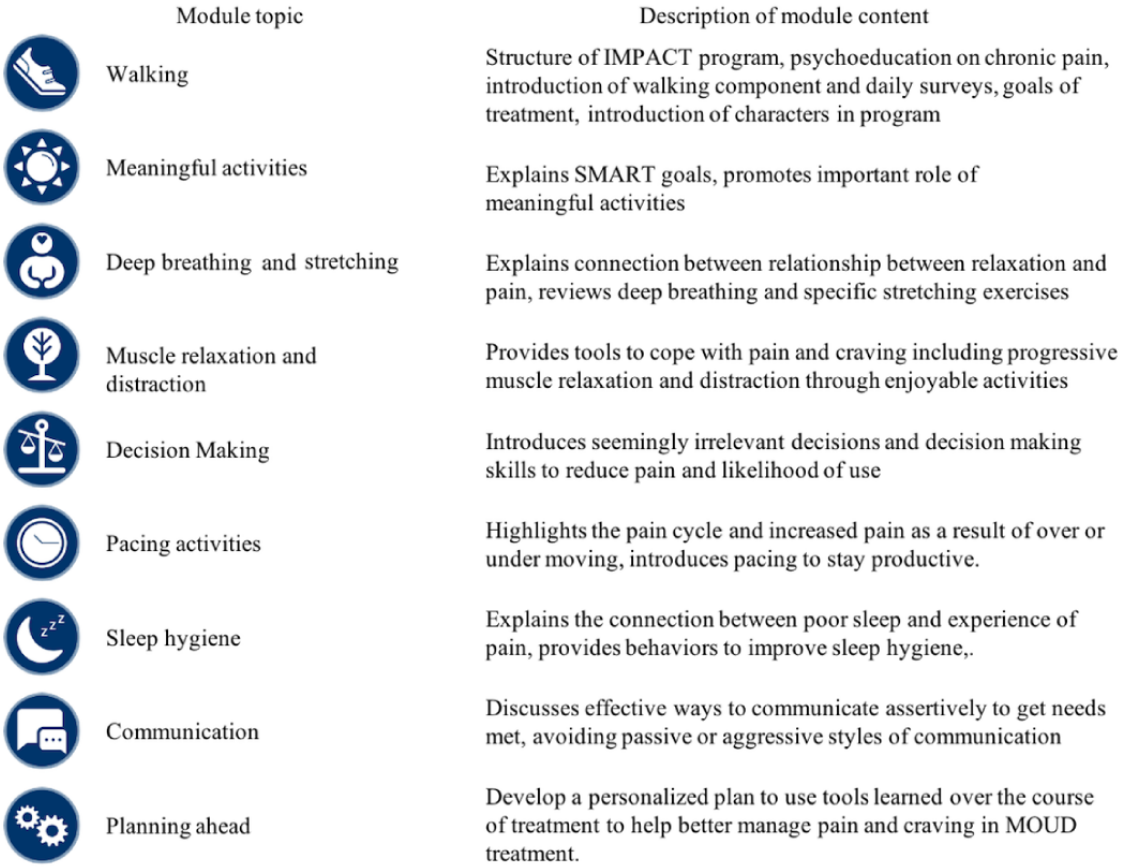
Following the baseline assessment, participants are randomized 1:1 to IMPACT+TAU or TAU (control) using urn randomization [54] balanced by demographic variables (self-reported gender identification and race or ethnicity [combination of ethnicity and racial identity]), as well as likely prognostic variables (severity of OUD as mild, moderate, or severe based on the DSM-5 [*Diagnostic and Statistical Manual of Mental Disorders* {Fifth Edition} OUD symptom count), buprenorphine versus methadone treatment, and length of MOUD treatment (<6 months, 6-12 months, and >12 months). Allocation is masked using a Microsoft Access (Microsoft Corp) program that our group has developed and implemented successfully in multiple previous trials [55-58]. Participants randomized to IMPACT+TAU are provided with a unique username and password to access the IMPACT website. To facilitate their participation in the walking portion of the treatment, participants are given a pedometer and a brief demonstration of its use. Study staff measure each participant's stride length and calibrate the pedometer accordingly. The research assistant then guides the participants through the first IMPACT module to ensure they are comfortable using the program and answer any questions they might have.

Interventions

IMPACT

Participants allocated to IMPACT+TAU receive standard MOUD treatment (ie, TAU) along with access to IMPACT for 12 weeks. IMPACT is a self-directed, 9-module digital treatment program with weekly personalized feedback messages from a trained masters- or doctoral-level coach under the supervision of a clinical psychologist. Participants are asked to complete 1 module per week using a study laptop that is available in the MOUD clinic or outside of the clinic using their own web-enabled device (eg, at home). We hope to maximize treatment adherence and engagement by providing multiple ways of accessing the IMPACT program [50]. The IMPACT program passively tracks individual behaviors to capture engagement (ie, number of logins, access to each module and component, time spent using the program, and digital survey completion). Module topics are shown in Figure 3. For each module, participants are asked to practice a specific skill that corresponds with the topic for that week. After indicating a baseline average number of steps during their first week of completing the daily survey, participants are provided with a daily step goal by their coach during the weekly feedback message. The goal is to increase their daily steps by 10% of the average daily step count reported in the previous week. All modules include a narrated introduction of the skill, video vignettes of characters in challenging situations and using skills, interactive practice exercises and weekly skill practice goals, and a quiz to evaluate the understanding of the module content. The IMPACT dashboard landing page displays personalized information for each participant, including a badge for each completed module, stars for completion of practice exercises, weekly averages of daily steps and step goals in graphical form, and a link to weekly coach messages.

Figure 3. Integrating the Management of Pain and Addiction via Collaborative Treatment (IMPACT) module topics and descriptions. MOUD: medications for opioid use disorder; SMART: specific, measurable, achievable, relevant, and time-bound.



Participants receive links to daily digital surveys through MMS text messages on their mobile phone at a participant-selected time for the duration of treatment. Surveys assess pain intensity, pain interference, pedometer-measured step counts, sleep quality, sleep duration, craving to use opioids, self-efficacy, MOUD adherence, and questions regarding the practice of the treatment skills. Based on our previous work, digital surveys are estimated to take no longer than 2 minutes to complete. Coaches review summaries of the daily survey data through a web portal that displays survey responses from the past week (as weekly averages or individual days). The coach records an audio message based on the participant-provided responses to the current week's surveys, as well as previous weeks, that is uploaded to the participant's IMPACT dashboard. The coach's message provides reinforcement of skill practice and goal attainment and highlights associations between participants' daily responses and trends in weekly averages over the course of treatment. Coaches receive training in message preparation and attend weekly supervision with a clinical psychologist. Participants are not able to directly respond to the coach's feedback through the program but are able to indirectly communicate with the coach by leaving a message with the research assistant during their weekly clinic visit, who can relay the message to the coaches.

TAU (Control)

Participants in both conditions receive TAU for the buprenorphine and methadone programs at participating MOUD clinics, which includes regular medication management by the clinic physician and regular individual and group counseling sessions delivered on-site by counselors employed at participating MOUD clinics. Participants randomized to IMPACT+TAU and TAU will receive MOUD dosing as indicated by their OTP clinician in conjunction with regular meetings as dictated by their treatment plan. Both groups are free to access any OTP clinic resources, including prescriptive services for mental health issues, group treatment, and individual counseling as offered at each recruitment site.

Assessment Visits

The study includes a baseline visit followed by brief weekly visits during treatment (up to 12 weeks) and a 3-, 6-, and 9-month postrandomization assessment visit. Neither participants nor research assistants are blinded to group assignments. However, outcome measures are obtained through self-report using REDCap digital assessments, and MOUD retention will be verified with MOUD clinic records, limiting the potential for bias. Participants complete the baseline, weekly visit, posttreatment, and follow-up measures at their outpatient MOUD clinic to facilitate the collection of a urine sample for urine toxicology analysis (Table 1). After baseline, if in-person attendance is not possible, study measures may be completed remotely. Remote participation is facilitated by the use of digital data collection, videoconferencing, or the telephone.

Table 1. Study measures.

IMPACT[g] engagement data (IMPACT+TAU[h] only)	None		✓		

[a]MOUD: medications for opioid use disorder.

[b]MINI: Mini-International Neuropsychiatric Interview.

[c]PROMIS: Patient Reported Outcomes Measurement Information System.

[d]Adherence will be assessed with the Timeline Followback for daily MOUD use for the previous week, clinic dispensing records, and urine toxicology screen for buprenorphine or methadone collected at each weekly assessment visit.

[e]NRS: Numerical Rating Scale.

[f]PHQ-4: Patient Health Questionnaire-4.

[g]IMPACT: Integrating the Management of Pain and Addiction via Collaborative Treatment.

[h]TAU: treatment as usual.

Primary Outcome Measure (Retention in MOUD)

Retention is defined as dichotomous enrollment in MOUD (ie, yes or no), with evidence of MOUD uptake in the week before the 3- (primary), 6-, and 9-month time points. Using data from the 7 days before the 3-month time point, dichotomous enrollment in MOUD services will be verified by clinic records and evidence of MOUD compliance will be assessed using clinic records and self-report. When these sources disagree, clinic records will be used to determine compliance. Retention will be a binary outcome, with 1=retained (conditions met) and 0=not retained.

Secondary Treatment Outcome Measures

We will also collect OUD (ie, MOUD adherence, craving, and substance use) and pain (ie, pain interference, physical functioning, pain intensity, sleep disturbance, pain catastrophizing, and pain self-efficacy) secondary outcome measures. These outcomes evaluate other important treatment effects that have an evidence base in OUD and chronic pain

treatment studies and will provide a more detailed assessment of possible treatment outcomes. Outcome measures are detailed in Table 1.

Other Measures

To better characterize other treatment effects, we will also evaluate general psychological symptoms, depression symptoms, anxiety symptoms, OTP treatment use and cost, cold pressor task (pain threshold), and digital treatment engagement (only participants randomized to IMPACT+TAU).

Data Sharing

Data collected during baseline, post treatment, and follow-up visits will be made available in compliance with the HEAL Public Access and Data Sharing policy. The study is registered in ClinicalTrials.gov and is in the process of being registered in the HEAL Data Platform. Once data collection is complete, 1 master data file will be created that includes all variables necessary to address the primary study aims and hypotheses. All analyses will be performed using the master data file. The final master data set will then be submitted to the appropriate HEAL-approved repository. All data will be deidentified before submission using procedures that are in compliance with the HIPAA (Health Insurance Portability and Accountability Act), the Yale Human Investigation Committee, and NIH standards.

Qualitative Interviews

Among those randomized to IMPACT+TAU, individual interviews (N=34) will be conducted at 3-month follow-up with a sample of completers (n=17) and noncompleters (n=17). This sample size should be sufficient to achieve saturation on interview themes; however, if saturation is not reached, additional participants will be interviewed until saturation is attained [72]. Completers will be defined as any participant that engages in 7-9 IMPACT modules. Noncompleters will be defined as any participant who completed between 1 and 4 IMPACT modules. Interviews will take place on the internet or in person, be digitally recorded, and be transcribed. All respondents will be asked a series of open-ended questions to probe participant experiences with IMPACT, including barriers or facilitators to engagement and how IMPACT influenced their ability to manage pain and OUD. Semistructured questions will elicit feedback on various features of the intervention, including the various module topics (Figure 3), the walking component, impressions of the weekly personalized feedback, the IMPACT platform, study outcomes, daily surveys, and combined emphasis on pain or OUD.

Data Analyses

Quantitative Data Analysis

Data will be reported for each treatment arm and overall at all time points in the study. Summary descriptions of recruitment rates, attrition, daily survey completion, and treatment outcomes will be calculated. The baseline demographic characteristics of both groups will be summarized.

We will perform a true intent-to-treat analysis of the primary MOUD retention outcome that will include all randomized participants and use logistic regression models to assess differences in MOUD retention by treatment condition at the 3-month time point. MOUD type (ie, buprenorphine or methadone) will be specified as a covariate. Similarly, the logistic regression model will be used to assess differences in MOUD retention by treatment condition at each follow-up time point (ie, 6 and 9 months post randomization).

In addition to retention, we will run secondary analyses to evaluate differences in several OUD (ie, MOUD adherence, craving, and substance use) and pain (ie, pain interference, physical functioning, pain intensity, sleep disturbance, pain catastrophizing, and pain self-efficacy) measures by treatment condition and by time using multilevel longitudinal models with MOUD type (ie, buprenorphine or methadone) specified as a between-person covariate.

Qualitative Data Analysis

Analysis of qualitative data will be conducted using Atlas.ti, a qualitative software program allowing fluid interaction of data across types or sources [73]. A qualitative-descriptive approach is suitable when information is needed to develop, summarize, or refine an intervention [74]. A constant comparative approach with sequential analysis will be used to reach a thematic consensus. Memos, field notes, and debriefing notes after each interview will also be incorporated into the analysis [75]. Each transcript will first be read in its entirety and then coded, proceeding from line-by-line in vivo codes to more broad codes and themes, comparing data across participants [75]. Coding will be completed independently by 2 researchers and compared, and final themes will be arrived at through consensus. Findings will be summarized and presented in tables. It is expected that the collected data will reflect mechanisms underlying engagement and participant perspectives of IMPACT.

Results

The funding for the clinical trial component of the study (phase 2) was obtained in June 2022, and the trial study protocol that included changes from phase 1 was approved by the institutional review board in January 2022. Enrollment began on July 15, 2022, at a single outpatient clinic; a second outpatient clinic was added on March 6, 2023; and a third site is expected in January 2024. Enrollment is expected to continue until June 2024. Final data are expected to be collected in March to May 2025, and the primary results of the study are expected to be published in March to May 2026.

Discussion

Summary of Study Significance

Given the prevalence of OUD and the increased mortality by overdose, the provision of MOUD and support for retention in MOUD are critical. Only a third of individuals receiving MOUD are retained in treatment after 6 months. Clearly, many people receiving MOUD require additional support to remain in treatment and attain its full benefit. Chronic pain, a common co-occurring condition among those receiving MOUD, interferes with MOUD retention and diminishes functioning and quality of life. An asynchronous digital integrated treatment for addiction and chronic pain, such as IMPACT, holds promise to increase access to evidence-based behavioral treatment in

MOUD clinical care. IMPACT is designed to be accessible, low-burden, and easily integrated into MOUD clinics despite their limited resources.

Benefits of Daily Surveys

Importantly, IMPACT collects individual responses through daily surveys that are used to generate weekly personalized feedback for participants. These data are the foundation of personalized coach feedback that may enhance engagement with treatment, which has been suggested in previous reviews [76] and yield relatively fine-grained data on patient reports of pain and pain interference, craving to use opioids, sleep problems, and physical activity for a comparatively large sample of individuals enrolled in MOUD. Daily ratings of pain and pain fluctuations in this population are unique, and the data generated will be critical in addressing key gaps in the literature, including understanding fluctuations in relationships between pain and pain interference, drug craving, treatment retention, sleep, and functioning in this population. These data may provide actionable information for further treatment refinement.

Benefit of Digital Interventions in the MOUD Setting

An integrated, digital intervention offers 2 particularly attractive benefits in the MOUD setting: a means to both (1) obtain treatment in a less stigmatizing manner and (2) provide treatment with high fidelity to evidence-based protocols without adding staff. Individuals receiving MOUD report high levels of stigma that can significantly impact the course of treatment [77-79]. Increased stigma is a primary barrier to engaging in MOUD treatment and is present even among addiction providers. In a recent qualitative study of MOUD providers, the perception of psychosocial interventions is mixed, with some providers suggesting that MOUD undermines the effectiveness of behavioral treatment while others argue that any provision of behavioral treatment is not a necessary component of MOUD treatment [80]. Furthermore, integrating evidence-based psychotherapies, such as CBT, into MOUD clinical care has been met with mixed results [81-83]. Some researchers have posited that the inconsistent findings are likely related to methodological flaws in previous research, including low fidelity and an inadequate control group [42]. IMPACT treatment materials can be delivered with a high degree of fidelity and consistency, effectively removing a lack of fidelity as a potential driver of outcomes in this study. The patient demands of MOUD clinical care often preclude trained providers from delivering behavioral treatment [84]. Technology-based and digital interventions, such as IMPACT, can address these barriers by offering treatment with high fidelity that can be completed outside the clinic, further reducing the possible stigma of discussing problems related to addiction and pain in MOUD settings.

Limitations

There are several limitations to the current protocol. First, as is common in behavioral intervention trials, participants will be unblinded to the condition once randomized. However, all participants and researchers will be blind to the condition when completing baseline structured interview measures. The primary outcome is based on objective measures and clinic attendance and, therefore, is less vulnerable to biases associated with being unblinded. Other treatment outcomes are collected through self-reported responses in REDCap, which also limits the potential for bias. There is also no attention control for IMPACT. We chose to use TAU as the control condition to maximize our ability to determine the efficacy of adding a digital treatment to the existing gold standard treatment (ie, MOUD). Next, participants randomized to IMPACT may not complete all daily surveys, resulting in missing data. While we expect that participants will miss surveys, completing the surveys benefits participants because they provide personalized feedback; and even 1-2 surveys per week can provide insight for weekly coach feedback. Additionally, previous research on COPES has shown high survey completion [85], which is consistent with findings from other asynchronous chronic pain interventions using daily surveys [86]. Finally, participants in both groups may receive other pain and addiction treatments both within and outside their MOUD clinic. We will inquire about additional treatment at weekly visits during treatment to account for any effects that could be attributed to other interventions.

Conclusions

Access to behavioral treatment for individuals with OUD and chronic pain is a critical gap in MOUD care. Offering access to a combined pain and addiction treatment may help retain individuals in MOUD while improving clinical outcomes for people who otherwise may not receive treatment. Digital treatments are especially well-suited to MOUD treatment settings because they reduce stigma and provide access to high fidelity, evidence-based behavioral treatment.

Acknowledgments

We would like to respectfully acknowledge the late Kathy M Carroll, PhD, for her contributions to the design of this study before her untimely passing in late 2020. Dr Carroll's brilliance was only surpassed by her unwavering commitment to increasing the accessibility of evidence-based treatment to improve the lives of individuals with substance use disorders. With this project, we continue her legacy with the same compassion and empathy that defined her professional and personal life. This research is supported by R61/33AT010619 (Heapy). The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health, the National Center for Complementary and Integrative Health, or the Department of Veterans Affairs.

Data Availability

Deidentified data sets generated during the course of this study will be made available on the Helping to End Addiction Long-Term (HEAL) Data Platform through a HEAL-approved repository.

Authors' Contributions

AAH, MAG, TLF, CN, WCB, SM, and MS contributed to the conceptualization of the study. AAH, RRM, BA, MAG, TLF, CN, SNE, WCB, SM, and MS contributed to the study design, development of the Integrating the Management of Pain and Addiction via Collaborative Treatment (IMPACT) program during the R61 phase, and clinical trial during the R33 phase. RRM wrote the initial draft, and AAH, SKS, JML, LB, MIPR, MAG, and MAD provided critical edits. All authors read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Referred to as the "silent killer," elevated blood pressure (BP) often goes unnoticed due to the absence of apparent symptoms, resulting in cumulative harm over time. Chronic stress has been consistently linked to increased BP. Prior studies have found that elevated BP often arises due to a stressful lifestyle, although the effect of exact stressors varies drastically between individuals. The heterogeneous nature of both the stress and BP response to a multitude of lifestyle decisions can make it difficult if not impossible to pinpoint the most deleterious behaviors using the traditional mechanism of clinical interviews.

Objective: The aim of this study is to leverage machine learning (ML) algorithms for real-time predictions of stress-induced BP spikes using consumer wearable devices such as Fitbit, providing actionable insights to both patients and clinicians to improve diagnostics and enable proactive health monitoring. This study also seeks to address the significant challenges in identifying specific deleterious behaviors associated with stress-induced hypertension through the development of personalized artificial intelligence models for individual patients, departing from the conventional approach of using generalized models.

Methods: The study proposes the development of ML algorithms to analyze biosignals obtained from these wearable devices, aiming to make real-time predictions about BP spikes. Given the longitudinal nature of the data set comprising time-series data from wearables (eg, Fitbit) and corresponding time-stamped labels representing stress levels from Ecological Momentary Assessment reports, the adoption of self-supervised learning for pretraining the network and using transformer models for fine-tuning the model on a personalized prediction task is proposed. Transformer models, with their self-attention mechanisms, dynamically weigh the importance of different time steps, enabling the model to focus on relevant temporal features and dependencies, facilitating accurate prediction.

Results: Supported as a pilot project from the Robert C Perry Fund of the Hawaii Community Foundation, the study team has developed the core study app, CardioMate. CardioMate not only reminds participants to initiate BP readings using an Omron HeartGuide wearable monitor but also prompts them multiple times a day to report stress levels. Additionally, it collects other useful information including medications, environmental conditions, and daily interactions. Through the app's messaging system, efficient contact and interaction between users and study admins ensure smooth progress.

Conclusions: Personalized ML when applied to biosignals offers the potential for real-time digital health interventions for chronic stress and its symptoms. The project's clinical use for Hawaiians with stress-induced high BP combined with its methodological innovation of personalized artificial intelligence models highlights its significance in advancing health care interventions. Through iterative refinement and optimization, the aim is to develop a personalized deep-learning framework capable of accurately predicting stress-induced BP spikes, thereby promoting individual well-being and health outcomes.

KEYWORDS

stress; hypertension; precision health; personalized artificial intelligence; wearables; ecological momentary assessments; passive sensing; mobile phone

Introduction

How This Research Benefits the People of Hawaii

According to the Department of Health Chronic Disease Prevention and Health Promotion Division, 1 in every 3 adults in Hawaii has been diagnosed with hypertension [1]. Mortality rates associated with heart disease are particularly high for Native Hawaiian and Other Pacific Islander populations, leading to 628 deaths per 100,000 residents as opposed to 154 deaths per 100,000 residents among Asian residents and 167 deaths per 100,000 among White residents in Hawaii [1].

A recent study conducted by researchers at the John A Burns School of Medicine found that Native Hawaiian and Other Pacific Islander individuals under a physician's care for hypertension experienced an 18.3 point drop in systolic blood pressure (BP) on average when participating in a 12-week hula program [2,3]. This study provides strong evidence that stress-reducing interventions can reduce hypertension in Native Hawaiian individuals. We hope to build upon this foundational research by leveraging consumer devices (ie, Fitbit) to detect moments of high stress and to provide just-in-time interventions that are culturally grounded. The first step of this long-term research plan is to develop the artificial intelligence (AI) that will power the digital intervention, and that first step is the focus of this grant proposal.

Clinical and Unmet Needs

Hypertension is an indirect cause of hundreds of thousands of annual deaths in the United States alone [4]. Known as the "silent killer"[5], elevated BP often remains unnoticed by affected individuals due to a lack of perceptible symptoms, resulting in accumulated harm over the years. While several causes of hypertension are related to an underlying health condition such as kidney disease, diabetes, sleep apnea, or hormone problems [6]; health condition; and medications combined only account for roughly 1 in 20 cases [7]. Chronic stress has been repeatedly documented to increase BP [8-10].

Prior studies have found that elevated BP often arises due to a stressful lifestyle, although the effect of exact stressors varies drastically between individuals. Due to the heterogeneous nature of both the stress and BP response to a multitude of lifestyle decisions, it can be difficult if not impossible to pinpoint the most deleterious behaviors in a personalized manner using the traditional mechanism of clinical interviews. Passive sensing technologies deployed on consumer devices have the potential to disrupt this status quo in a positive manner. By continuously monitoring a patient's lifestyle in naturalistic settings, digital technologies can provide clinicians and patients alike with actionable insights into their health trends with fine-grained precision.

We are interested in the use of wearable technologies to sense cardiovascular signals, as they are noninvasive and are already widely adopted. We will develop machine learning (ML) algorithms that analyze these biosignals to make real-time predictions about BP spikes. The resulting predictions could be used to alert, in real time, patients about unintentionally adverse behaviors as well as clinicians about the frequency of such behaviors. There is a critical opportunity and need to improve diagnostics for repeat health events to enable clinicians to monitor their patients and forecast future issues.

Innovation

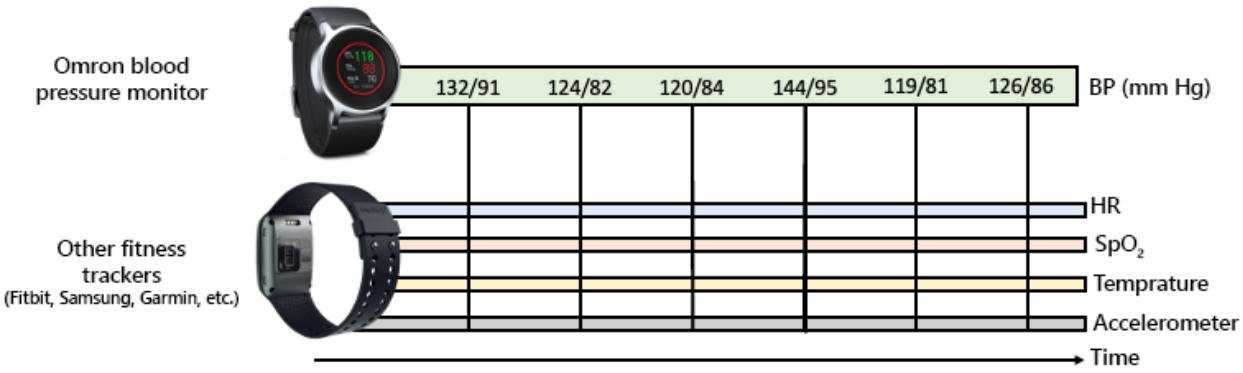
There are countless situations in health care and biomedicine where vast amounts of unlabeled data are collected from a single patient [11]. Annotations for the event of interest are frequently sparsely dispersed. The development of predictive supervised ML models is infeasible in such circumstances, as classical approaches cannot handle the complexity of the data and modern deep learning approaches require vast amounts of data [12]. For example, continuous readings from continuously worn glucose monitors can provide enough input data to train a model to make a prediction about patient energy based on glucose, but it is impracticable to require users to log their perceived energy at the same sampling frequency as a wearable device. Similar situations arise from data collected by consumer wearable health devices (eg, smart watches), smartphones, and other devices that measure biological signals.

To support AI development in these situations where vast longitudinal data are collected with minimal human-provided annotations, we propose the development of personalized ML models that are trained solely on an individual's unlabeled data to learn feature representations that are specific to their baseline temporal dynamics. We will train these models with a novel data set of Fitbit biosignals and corresponding BP readings (Figure 1). We are creating a novel method and framework, which has never been explored in health care, consisting of pretraining neural networks to learn the temporal dynamics of a patient's biosignals. This method will enable powerful, deep networks to be trained using relatively small data sets, which would not be possible without the self-supervised approach proposed here. From a usability standpoint, patients will only be required to provide tens of annotations tens of times to get a personalized predictive model.

While we propose to apply this new technological innovation toward the prediction of cardiac signals, multimodal time-series personalization can be applied to a variety of other biology and health problems where (1) multiple signals are emitted, (2) the baseline signal patterns are specific to each individual or organism, and (3) it is infeasible to acquire the vast amounts of labels required to train a supervised deep learning model from scratch. Examples of future apps of the proposed methodology include predictions stemming from nanopore signal data or multielectrode neuronal recordings. This method has the potential to dramatically advance the field of precision health care by enabling reliable ML predictions from massive but mostly unlabeled data sets which are trained in a self-supervised manner on data from a single user.

While this novel methodology could be applied to myriad domains within health and biology, a natural application is the prediction of cardiac events from wearable biosignals data. We will focus on high BP.

Figure 1. We will collect wearable biosignals from a Fitbit and use them to predict BP as measured by an Omron HeartGuide wearable BP monitor. We will use personalized self-supervised learning to enable the prediction of BP using minimal samples from the end user. BP: blood pressure; HR: heart rate.



Dissemination Plan

We plan to disseminate our research findings through a combination of (1) research publications in journals, (2) presentations at conferences, (3) as preliminary data for an National Institutes of Health (NIH) R01 application, and (4) as the basis of community-based participatory design sessions where we iteratively develop a culturally informed digital intervention using the AI created in this project. Target journals for submission include Nature Digital Medicine, Science Translational Medicine, Institute of Electrical and Electronics Engineers (IEEE) Transactions on Affective Computing, PLoS Digital Medicine, and Cell patterns. Target conferences include the American Medical Informatics Association (AMIA) Annual Symposium, the Pacific Symposium on Biocomputing (PSB), and the Conference for Computer-Human Interaction (CHI). There are several notices of special interest posted by the NIH that would support a large R01 grant application using the preliminary data from this work.

Specific Aims

We propose the following specific aims: (1) aim 1: create a novel data set of wearable sensor data and corresponding BP measurements, (2) aim 2: develop a personalized self-supervised pretraining procedure for time-series data using both contrastive learning and masked predictions, and (3) aim 3: develop a novel personalized pretraining procedure which exploits the multimodal nature of wearable time series-data.

Methods

Recruitment

We will recruit 40 carefully selected participants with diagnosed hypertension and self-reported stressful lifestyles to each participate in a 4-week remote data collection period. Each participant will wear an Omron HeartGuide BP wearable device and a Fitbit Sense 2 wearable watch during all waking hours for at least 15 hours each day. Apart from wearing the devices and periodically syncing the data to the cloud, participants will be asked to follow their normal routine for the duration of the study.

We will recruit adults aged 30 to 70 years in the state of Hawaii who have been diagnosed with hypertension and self-identify as living a high-stress lifestyle. Given the diversity of the population of Hawaii [13], we aim for the following demographic composition of our participants: 23% White, 37% Asian, 11% Native Hawaiian or Pacific Islander, 7% Black or African American, and 22% of 2 or more races. Approximately 9.5% of the recruited population will have Hispanic or Latino ethnicity.

PW has a network of clinical collaborators at the John A Burns School of Medicine at the University of Hawaii at Mānoa who also practice at local medical centers such as Queen's Medical Center and Kaiser Permanente's branch in Hawaii. We will recruit using the following sources: (1) direct recruitment from the Hawaii Pacific Health Center, which the collaborators at the Department of Psychiatry at the University of Hawaii are affiliated with and where they practice clinically; (2) via flyers and emails at the clinics which the Department of Psychiatry at the University of Hawaii regularly provides inpatient and outpatient psychiatric services and consultation at, including The Queen's Medical Center, Kapi olani Medical Center for Women and Children, and Hawaii State Hospital Community mental health centers on Hawaii Island, Moloka i, Maui, Kaua i, and Lāna i; (3) advertisements posted on the University of Hawaii campus and in public settings in Honolulu; and (4) targeted advertisements posted to social media websites. We will work with Anthony Guerrero, the chair of the Department of Psychiatry at the University of Hawaii, to ensure that the recruitment strategies and advertisement of the research program translate across cultures and to ensure effective recruitment as well as diverse and representative data.

We will exclude participants younger than 30 years and older than 70 years. We will require all potential participants to remotely complete the Perceived Stress Scale (PSS), a 10-item scale that is the most widely used psychological instrument for measuring the perception of stress [14]. We will exclude participants whose PSS score does not exceed 1 SD above the mean for at least one of their demographic brackets (age, gender, or race) as reported by Cohen et al [14]. We will also ask participants to self-report their BP. We will also exclude

participants who do not own a smartphone with continuous network connectivity. During the in-person study intake, we will measure the BP of potential study participants 3 times. We will exclude participants whose BP does not exceed 130/80 mm Hg for at least one of the measurements, as 130/80 mm Hg is the minimum cutoff for stage 1 hypertension.

Data Collection and Storage

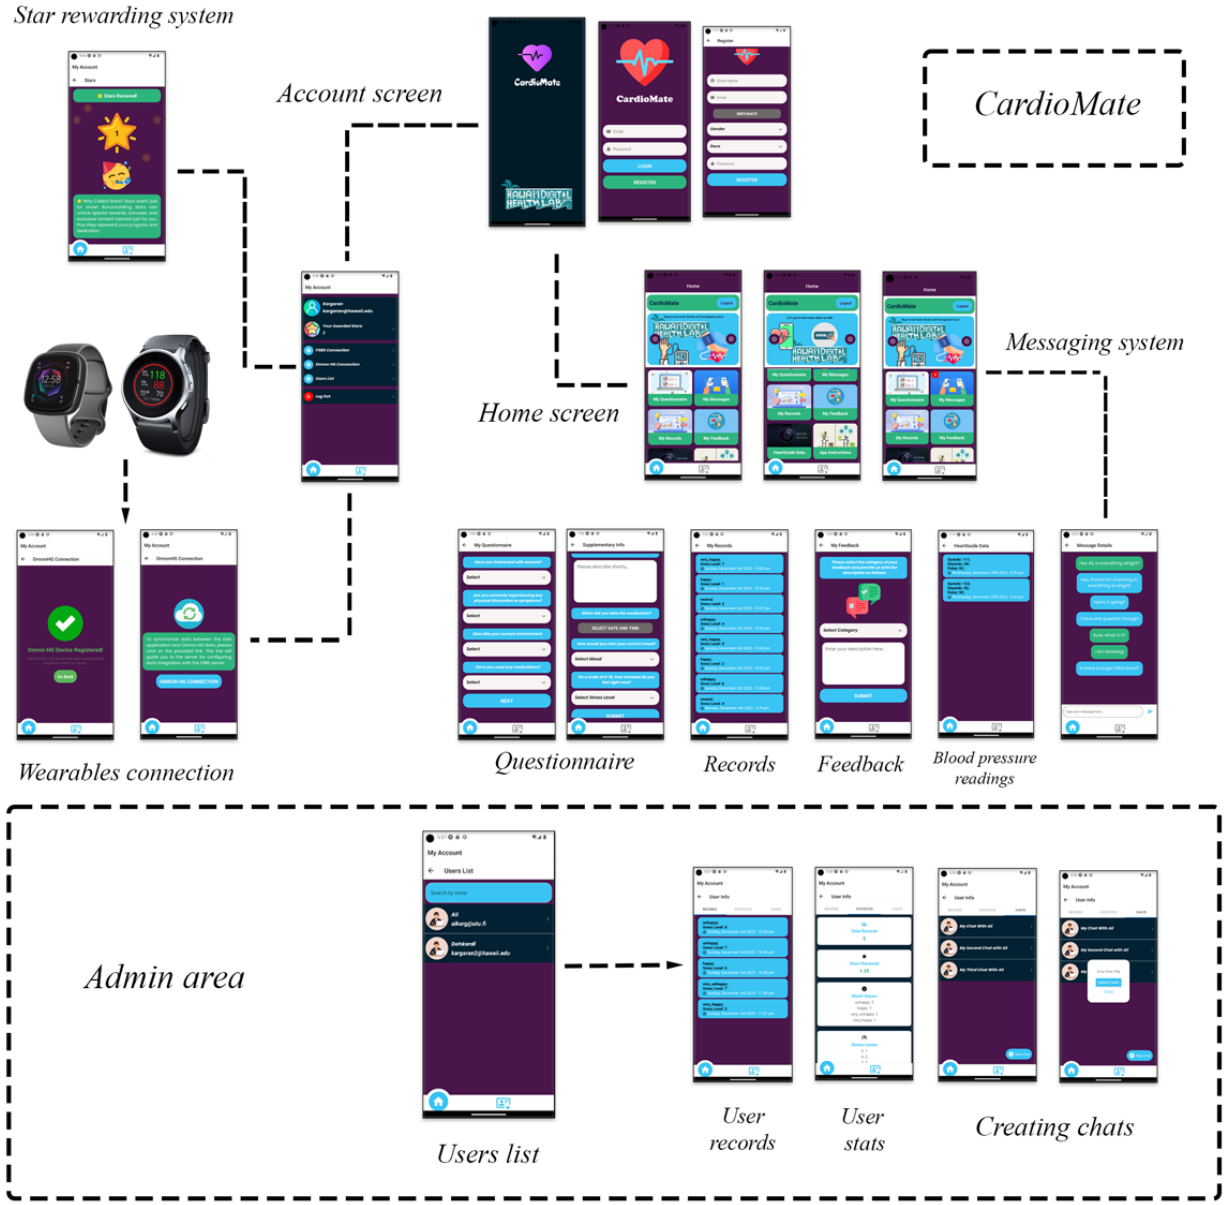
We will leverage the existing application programming interface (API) provided by both Omron and Fitbit to record the user's wearable sensor readings and upload the data to the cloud. Omron's health care API offers access to time-stamped BP readings as well as activity and sleep approximations. The Fitbit API provides access to sensor readings of heart rate (HR), gyroscope, accelerometer, breathing rate, blood oxygen levels (SpO_2), and skin temperature sensor readings. The data will be managed on each participant's smartphone devices through a mobile app, implemented for both iOS (Apple Inc) and Android, that we will develop. The study team will install the app on the user's smartphone and configure the Omron and Fitbit devices during study onboarding. The smartphone app will periodically trigger a notification reminding the participant to (1) measure their BP with the Omron wearable, (2) sync the Omron and Fitbit data to the app, and (3) connect to a network while the study app is open to allow the data to be uploaded to a centralized server.

We will store the curated data from each participant on a centralized server hosted on Amazon Web Services (AWS). Because Fitbit is owned by Google, participants' Fitbit data will be uploaded directly to Google's cloud servers, which use the same level of security as other Google products such as Gmail. Access to each participant's Fitbit data on Google's cloud servers is implemented through OAuth, which provides clients with secure delegated access to server resources on behalf of a resource owner (ie, the participants of this study). This mechanism is used by companies such as Amazon (Amazon.com, Inc), Google (Alphabet Inc), Facebook (Meta Platforms, Inc), Microsoft Corporation, and X (X Corp) to permit users to share information about their accounts with third-party applications or websites. In this case, the "third party" is the study team. The Fitbit data and BP readings will be preprocessed on an Elastic Cloud Compute instance on AWS, which is HIPAA (Health Insurance Portability and Accountability Act)-compliant. The Elastic Cloud Compute instance will store the data onto respective database tables using DynamoDB (Amazon.com). Each table will have columns for the child ID and the time-stamp. We will encrypt all server-side data and require secret access keys for data access. DynamoDB tables are automatically encrypted on the server side. To add an additional layer of security, we will implement client-side encryption on the mobile app, ensuring encrypted data transmission over HTTPS connection to move BP data between the devices and AWS. Data access will require a secret access key provided by the AWS administrators to any data analysis team. The data will not be accessible without this key. For further security, we will anonymize all user data on the server side by removing all protected health information from the DynamoDB tables.

We intend to release the curated data (Figure 2) as a publicly available data set for use in the evaluation of multimodal time-series ML models. Such data sets exist for activity and emotion recognition from wearable data, but the prediction of BP from these measurements will be a challenging task that other researchers can attempt with the release of our data set. This will be the first publicly available data set that includes at-home BP measurements alongside wearable sensors such as HR, SpO_2, and accelerometer readings. This fully anonymized data set will only be released to researchers who sign a Data Use Agreement, which will be approved by the University of Hawaii Data Governance Office.

The app comprises 2 primary screens, account and home. The account screen features user details, a star reward system for active participation in the study, and options to link 2 wearable devices (Fitbit and Omron Heartguide) for data synchronization with our secure and encrypted database. The home screen is divided into 6 sections, including questionnaires, messages, feedback, records, BP readings, and app instructions. Additionally, the CardioMate app includes an administrative area for study managers to view participant statistics and initiate personalized chats, complete with alarm and notification functions.

Figure 2. Workflow of the CardioMate app, comprising account and home screens with user details, study rewards, wearable device integration, and an administrative section for study managers.



Feasibility

The most difficult aspect of this aim will be maintaining participant engagement throughout the 4-week study period. The graduate research assistant funded by this project will dedicate some time each day toward running the study and interfacing with participants. We expect participants to open the smartphone app to sync and upload their data on a daily basis, which is a 1-minute time commitment per day.

While we expect no trouble recruiting 40 subjects for participants, we expect some participants to drop off during the study. Since we will have enough devices for 5 concurrent subjects, it will take 8 months to collect all data if no participants drop off. Our study timeline allocates 6 additional months of make-up time to collect data from new participants, accounting for >50% drop-off rate. Given the remote nature of the data collection procedures, we expect some participants to drop off from the study prematurely or to not comply with the study processes. We will therefore remotely monitor the upload progress and send an automated text and email notification to the participant if the data are not uploaded in a timely manner. If 3 consecutive days of participant noncompliance are detected, we will contact the participant for a device return.

Ethical Considerations

Under an expedited review procedure, this research project was approved on April 26, 2023, by the University of Hawaii Institutional Review Board (UHMUIF_2023-00130). The application qualified for expedited review under CFR 46.110 and 21 CFR 56.110, categories 1b, 4a, 4d, and 6. The informed consent process for this human subject research study involves participants completing an interview session where they receive comprehensive information about the research, including its purpose, procedures, and potential risks and benefits. Participants are assured of the voluntary nature of their participation and their right to refuse or withdraw at any time without penalty. For secondary analyses of research data, it is

clarified that the original informed consent allows for such analyses without additional consent, as approved by the institutional review board. Privacy and confidentiality protections are emphasized, with participant data anonymized and stored securely on HIPAA-compliant servers. Compensation for participation includes US $135 upon completion along with an additional US $15 for certain eligibility interview tasks, reflecting the time and effort required from participants while respecting the ethical standards. The consent form ensures that no identification of individual participants or users is possible in any images or supplementary materials without explicit consent, with researchers providing relevant consent forms or written communications to uphold participant privacy and consent.

AI Model Training

Self-supervised learning (SSL) is usually used to pretrain an entire data set with no explicit labeling by humans to guide the supervision task. We propose to redesign the SSL paradigm toward the task of model personalization. By pretraining a model only on the vast amounts of data curated from a single individual, the weights of the neural network will learn to make predictions using the inherent structure of each participant's biosignals. This is essential because the baseline HR, SpO_2, skin temperature, and movement patterns, regardless of stress, will vary drastically across individuals, limiting the performance of general-purpose ML models.

To train ML models that predict BP based on a user's wearable biometrics, we will develop and evaluate a series of both long short-term memory and transformer neural networks. The inputs to the models will consist of a separate 1D convolutional backbone for each biometric modality. The convolutional features will be fused upstream into a shared joint dense representation space and finally a dense prediction layer with linear activation for regression prediction. We will implement all models using Tensorflow (Google Brain) [15].

We will perform a series of self-supervised pretraining tasks to allow the networks to learn the baseline temporal dynamics of each individual's biosignals. As a pretraining task, we will develop contrastive learning methods to automatically learn embeddings that encode the structure of the signal. For each wearable sensor modality, we will run a sliding window to isolate short-time segments. We will apply signal-based data augmentation techniques to derive a new signal. We will perform contrastive learning to learn neural network embeddings that maximize the similarity between each original segment and its modified version while minimizing the similarity across segments.

We will develop a modified version of the SimCLR (simple framework for contrastive learning of visual representations) algorithm, which will be tuned for the task of personalization to a user's wearable signal readings. It is often the case that biosignals look highly similar, either due to temporal locality or relative homogeneity of the individual's activity. To account for this possibility of recurring signal patterns, we will weigh the attract and repel strength of SimCLR based on the temporal distance between two segments of a particular signal. We will run a grid search to tune this repel strength.

The data augmentation techniques that we apply to the signals will be domain-specific, keeping in mind the inherent nature of each sensor. For example, for accelerometer data, rotations simulate different sensor placements and cropping is used to diminish the dependency of event locations [16]. Across several modalities, sensor noise can be simulated through scaling, magnitude-warping, and jittering [16]. We will be careful to not apply augmentation strategies that might change the meaning of the underlying signal.

As another pretraining task, we will perform generative pretraining by masking the input signal and predicting the missing portion of the signal using a deep autoencoder architecture. Pretraining in this manner will teach the model to understand the dynamics of each time series signal independent of BP or any other labels.

We will train the model on the first 60% of data (by time), tune hyperparameters on the next 20% of data, and calculate the mean absolute error and mean squared error on the final 20%. This evaluation pattern mimics real-world use, where a model will be calibrated by a user prior to real-world deployment. It is important to emphasize that we will train and test a separate personalized ML model for each individual.

We will evaluate the models by comparing the performance with respect to the number of labeled examples used for supervised fine-tuning. A plot of this comparison will elucidate the number of BP measurements required for model calibration to a single individual. We will plot the mean squared error at 10, 20, 30, 40, 50, 75, 100, 125, and 150 BP annotations, as these are feasible amounts of labels that might be provided by a user in real-world use. To ensure a robust evaluation, we will bootstrap at least 20 random samples of BP annotation subsets for each point on the x-axis and will report the mean and 90% CI. Just as in the plain supervised learning condition, we will create a separate plot for each study participant, as the ML portion of this proposal is testing the personalization of ML models rather than a general-purpose one-size-fits-all ML model which is more typical in ML evaluations.

We will perform a similar style of analysis for other clinical outcomes using publicly available data sets such as the Wearable Stress and Affect Detection (WESAD) [17] data set, a multimodal sensor data set for stress detection of nurses in a hospital [18], and K-EmoCon, a multimodal sensor data set for continuous emotion recognition in naturalistic conversations [19]. Each of these data sets, as well as several other publicly available data sets, contains several hours of multimodal biosignal data that overlap with the signals that we propose to collect, such as skin temperature, accelerometer streams, and HR. These data sets also include time-stamped annotations of end points that are likely to be correlated with BP, including self-perceived stress.

In prior work by other researchers, SSL pretraining approaches have repeatedly demonstrated improved performance over pure supervised learning in a variety of contexts [20-23]. Our preliminary data (see Results section) support that self-supervised pretraining on data solely from each individual results in improved models over purely supervised learning. While unlikely given our preliminary data and prior SSL

publications, it is possible that minimal performance gains will be observed when applying the SSL strategies in a personalized manner. In such cases, the negative result would be a noteworthy finding due to prior successes of SSL.

Results

We have developed a smartphone app, CardioMate, that will prompt participants to measure their BP and log their stress (Figure 2). The app comprises 2 primary screens, account and home. The account screen features user details, a star reward system for active participation in the study, and options to link 2 wearable devices (Fitbit and Omron Heartguide) for data synchronization with our secure, encrypted database. The home screen is divided into 6 sections, including questionnaires, messages, feedback, records, BP readings, and app instructions. Additionally, the CardioMate app includes an administrative area for study managers to view participant statistics and initiate personalized chats, complete with alarm and notification functions.

Data collection commenced on February 15, 2024. As of the manuscript submission date of February 24, 2024, a total of 2 participants have been recruited. The data collection period for each participant spans 28 days. Upon completion of the data collection period for each participant, we will proceed with the personalized machine learning model development to predict stress-induced BP spikes in real time. We aim to recruit a total of at least 45 participants and complete the relevant data collection, data analysis, and personalized ML development for each participant by the end of December 2024.

Our initial sets of published experiments have demonstrated promise for personalized SSL of stress but with some caveats. Our experiments on the WESAD data set demonstrated that deep learning model performance improves drastically when using self-supervised personalization when compared to personalization without SSL when there are a small number of labeled data points for supervision [24]. This effect diminishes with increasing amounts of labeled data [25,26], aligning with prior work that demonstrates that SSL is only beneficial under low-label settings. We have also tried these methods on a particularly challenging data set, a multimodal sensor data set for stress detection of nurses in a hospital [18]. This data set consists of wearable biosignals measured from nurses who wore Empatica E4 wristbands while conducting their normal shifts. This data set is difficult because (1) the data were collected in the wild rather than in controlled laboratory settings and (2) individual nurses were not consistent about their labeling practices, leading to sparse, irregular, noisy, and otherwise messy labels. Consequently, we found that the difference in area under curve and the receiver operating characteristic curve scores for self-supervised models was only about 2.5% higher on average compared against an equivalent baseline model [27], and this increase is within the margin of error due to the limited sample size. This lack of improvement in noisy annotation settings highlights the need for HCI innovations to improve data labeling quality for personalized AI within naturalistic settings.

We have also observed improved performance when personalizing affect-related prediction tasks without personalization both using classical ML [28] and deep learning [29], as well as when only applying SSL without personalization [30]. When disentangling and comparing the effects of SSL and personalization separately, we find that SSL yields more benefit than individualization on nonaffective medical data with large time intervals between data points, suggesting that the sampling frequency and other data considerations must be considered [30]. Collectively, these preliminary results demonstrate promise for the core ML approach that we propose.

Discussion

The primary objective of this study is to leverage ML algorithms for real-time predictions of stress-induced BP spikes using consumer wearable devices such as Fitbit, providing actionable insights to both patients and clinicians to improve diagnostics and enable proactive health monitoring. Our study is motivated by recent research conducted at the John A Burns School of Medicine, which found that Native Hawaiian and other Pacific Islander individuals under a physician's care for hypertension experienced an average drop of 18.3 points in systolic BP after participating in a 12-week hula program [2,3]. This study provides strong evidence that stress-reducing interventions can reduce hypertension in Native Hawaiian individuals. We hope to build upon this foundational research by leveraging consumer devices, such as Fitbit, to detect moments of high stress and provide just-in-time interventions that are culturally grounded. The first phase of this long-term research plan involves developing the AI necessary to power the digital intervention, which is the primary focus of this proposal.

The successful development of ML algorithms tailored to individual participants signifies a significant advancement in personalized health care interventions. By using longitudinal data from Fitbit devices and corresponding stress level labels from Ecological Momentary Assessment reports, the study will be able to capture individual-specific patterns effectively, enabling accurate predictions of stress-induced BP spikes. This approach not only enhances the understanding of stress-related hypertension but also provides opportunities for targeted interventions and improved patient outcomes.

Furthermore, the findings of this study contribute to the growing body of literature on the use of wearable devices and ML in health care. The adoption of transformer models for personalized prediction tasks, coupled with SSL techniques for pretraining, represents a novel approach to leveraging advanced computational techniques for real-time health monitoring. By dynamically weighing the importance of different time steps and focusing on relevant temporal features and dependencies, transformer models offer a powerful tool for predicting complex physiological responses such as stress-induced BP spikes. These findings will add to the existing literature by highlighting the potential of ML in improving the accuracy and efficiency of health monitoring systems, particularly in the context of personalized interventions for stress-related hypertension.

It is essential to acknowledge the limitations of this study design. One limitation is the relatively small sample size, which may

limit the generalizability of the findings. Additionally, the study focuses primarily on predicting stress-induced BP spikes using wearable device data streams and may not capture other factors contributing to hypertension. Future research should aim to address these limitations by including larger and more diverse samples and exploring additional predictors of hypertension.

The findings of this study will demonstrate the feasibility and potential benefits of leveraging ML algorithms for real-time predictions of stress-induced BP spikes using consumer wearable devices. By developing personalized AI models based on individual biosignals, the study will provide valuable insights into the monitoring and management of stress-related hypertension. These findings will have broader implications for personalized health care interventions and underscore the importance of integrating advanced computational techniques into health care systems to improve patient outcomes. Through iterative refinement and optimization, we aim to develop a personalized deep-learning framework capable of accurately predicting stress-induced BP spikes, thereby promoting individual well-being and health outcomes.

Acknowledgments

This project received a grant (#MedRes_2023_00002689) from the Robert C Perry Fund of the Hawaii Community Foundation.

Data Availability

Upon the completion of the data collection phase, the data sets generated and analyzed during this study will be available in a public repository. The data citation should include a persistent identifier (eg, web URL or DOI) cited per journal style in the reference list. The amassed data will be fully anonymized and made accessible to the academic community. Subsequently, comprehensive guidelines, together with a designated link facilitating data retrieval and use, will be provided.

Abstract

Background: Alcohol and other substance use disorders usually begin with substance use in adolescence. Pediatric primary care offices, where most adolescents receive health care, are a promising venue for early identification of substance use and for brief intervention to prevent associated problems and the development of substance use disorder.

Objective: This study tests the effects of a computer-facilitated screening and brief intervention (cSBI) system (the *CRAFFT [Car, Relax, Alone, Forget, Family/Friends, Trouble] Interactive System* [CRAFFT-IS]) on heavy episodic drinking, riding with a driver who is substance impaired, or driving while substance impaired among adolescents aged 14 to 17 years presenting for a well visit at pediatric primary care practices.

Methods: We are conducting a cluster randomized controlled trial of the CRAFFT-IS versus usual care and recruiting up to 40 primary care clinicians at up to 20 pediatric primary care practices within the American Academy of Pediatrics (AAP) Pediatric Research in Office Settings network. Clinicians are randomized 1:1 within each practice to implement the CRAFFT-IS or usual care with a target sample size of 1300 adolescent patients aged 14 to 17 years. At study start, intervention clinicians complete web-based modules, trainer-led live sessions, and mock sessions to establish baseline competency with intervention counseling. Adolescents receive mailed recruitment materials that invite adolescents to complete an eligibility survey. Eligible and interested adolescents provide informed assent (parental permission requirement has been waived). Before their visit, enrolled adolescents seeing intervention clinicians complete a self-administered web-based CRAFFT screening questionnaire and view brief psychoeducational content illustrating substance use–associated health risks. During the visit, intervention clinicians access a computerized summary of the patient's screening results and a tailored counseling script to deliver a motivational interviewing–based brief intervention. All participants complete previsit, postvisit, and 12-month follow-up study assessments. Primary outcomes include past 90-day heavy episodic drinking and riding with a driver who is substance impaired at 3-, 6-, 9-, and 12-month follow-ups. Multiple logistic regression modeling with generalized estimating equations and mixed effects modeling will be used

in outcomes analyses. Exploratory aims include examining other substance use outcomes (eg, cannabis and nicotine vaping), potential mediators of intervention effect (eg, self-efficacy not to drink), and effect moderation by baseline risk level and sociodemographic characteristics.

Results: The AAP Institutional Review Board approved this study. The first practice and clinicians were enrolled in August 2022; as of July 2023, a total of 6 practices (23 clinicians) had enrolled. Recruitment is expected to continue until late 2024 or early 2025. Data collection will be completed in 2025 or 2026.

Conclusions: Findings from this study will inform the promotion of high-quality screening and brief intervention efforts in pediatric primary care with the aim of reducing alcohol-related morbidity and mortality during adolescence and beyond.

Introduction

Background and Rationale

Alcohol and other drugs are a major contributor to morbidity and mortality each year [1]. Most substance use disorders (SUDs) have a pediatric origin, and substance use remains among the most prevalent of adolescent risk behaviors [2-4]. In addition, motor vehicle crashes remain a leading cause of death among adolescents, and alcohol- or drug-impaired driving and riding with a driver who is substance impaired play a major role [5].

Pediatric primary care offices, where the majority of adolescents receive health care [6], are a promising venue for early identification of problematic substance use among adolescents and for brief intervention to prevent further problems. A substantial and increasing proportion of adolescents see a primary care clinician yearly [7] and have trusting, longitudinal relationships with their clinicians [8]. Primary care visits are opportunities for private conversations that support adolescents' autonomy and confidentiality while placing topics such as substance use in a nonpejorative health risk context.

The American Academy of Pediatrics (AAP) recommends alcohol, tobacco, and other drug use annual screening as part of routine care starting at age 11 years [9,10]. However, a national survey found that only approximately half of adolescents who had a past-year visit with a physician reported being asked about alcohol use [11,12]. Even when substance use screenings are performed, they can be of low quality if clinicians do not use a structured, validated screening tool or if they ask questions while caregivers are present [13,14]. Screenings also seldom include questions about substance-impaired driving or riding with a driver who is substance impaired [15]. Pediatric primary care clinicians also face barriers to brief intervention based on screen responses, including insufficient time during the appointment, a lack of familiarity with validated screening tools, and a lack of experience with managing care for patients who screen positive [16-18].

To overcome these barriers, digital technology can be applied to support consistent, effective screening and tailored intervention for adolescent substance use using evidence-based tools and approaches [19,20]. Clinicians may prefer to use technological tools such as tablet computers for previsit screening and electronic medical record–embedded decision support to enable brief intervention delivery [21]. Accordingly, we designed the CRAFFT (Car, Relax, Alone, Forget, Family/Friends, Trouble) Interactive System (CRAFFT-IS) to increase the frequency and quality of screenings in pediatric primary care, support a personalized response to results, and efficiently address alcohol and drug use and associated riding risks [22]. The CRAFFT-IS comprises a computer self-administered screening for patients (using the well-validated and widely used CRAFFT screening tool [23-25]), followed by psychoeducational content on the health risks of substance use, which adolescents complete before the clinician encounter. Clinicians access a computerized dashboard to view their patient's screening results and prompts for brief motivational interviewing (MI)–based counseling tailored to their patient's screening responses (clinician report).

CRAFFT-IS development was informed by the information-motivation-behavioral skills model [26], the health belief model [27,28], and social cognitive theory [29,30]. These models posit that individuals' health risk behaviors are predicted by their *attention* to the behavior, *knowledge* about its health impacts, perceived *severity* of the harms that could result, perceived *benefits* of avoiding the behavior, and perceived *self-efficacy* to avoid the behavior. The CRAFFT-IS uses an MI-based approach to alert patients' attention to the topic of alcohol use within a health context, enhance their awareness and perceived severity of the potential health harms of alcohol use, and boost their motivation and self-efficacy to avoid use.

We tested an initial version of the CRAFFT-IS among adolescent primary care patients at 9 practices in 3 New England states (Connecticut, Massachusetts, and Vermont) using a quasi-experimental design in which each office served as its own historical control (usual care [UC] phase followed by intervention phase; details reported elsewhere) [31-34]. Compared to UC patients, intervention patients reported double

the rate of receiving clinician advice about alcohol and, among those with prior drinking at baseline, had one-third lower drinking risk in the 3-month follow-up [31]. We also found a 22% lower risk for heavy episodic drinking (HED) among those with prior HED at baseline and a 30% lower risk for riding with a driver who is substance impaired [33].

We then enhanced the clinician advice to include brief MI strategies (eg, eliciting a patient's own reasons for avoiding use) while keeping the counseling brief enough for delivery by busy primary care clinicians. We pilot-tested this enhanced system compared to UC among adolescent patients seen for well visits at 5 Boston-area pediatric practices in a patient-randomized controlled trial. Intervention patients reported a 21% higher rate of receiving counseling about alcohol. Those reporting prior drinking at baseline (n=192) had a 34% lower risk for reporting HED during the 12-month follow-up [22]. Furthermore, those with riding risk at baseline (n=99) had a 42% lower risk of reporting riding with a driver who is substance impaired at the 12-month follow-up [35]. The CRAFFT-IS was also highly acceptable to the clinicians in the study, with 90% of the 49 clinicians agreeing that the system was useful, and 82% reporting that it increased their confidence in providing brief counseling [36].

To evaluate the replicability of these findings in a larger, more geographically diverse sample, we are now conducting a multisite effectiveness trial of the CRAFFT-IS among adolescent patients aged 14 to 17 years presenting for a well visit at practices within the national AAP Pediatric Research in Office Settings (PROS) network. This trial uses a clinician-randomized design, plans an adequately powered sample, and tests the intervention more broadly beyond New England. The CRAFFT-IS being tested in this study includes an updated version of the CRAFFT screen that includes nicotine vaping, now a leading form of substance use among adolescents [37]. It also includes updated psychoeducation material to reflect more current scientific knowledge and a revised brief counseling protocol to enhance alignment with MI-based counseling approaches.

Objectives

The primary objective of the Adolescent Substance Use Prevention and Intervention Research (ASPIRE) study is to test the effect of the CRAFFT-IS on past 90-day HED over 12 months' follow-up among adolescents who report past 12-month drinking at baseline. Our secondary objective is to test the effect of the CRAFFT-IS on riding with a driver who is substance impaired or driving while substance impaired (*riding or driving risk*) over 12 months' follow-up. Additional exploratory study objectives include evaluating (1) hypothesized effect mediators (eg, perceived risk of harm and refusal self-efficacy) and moderators (eg, baseline risk level and gender), (2) efficacy for reducing the use of other commonly used substances among adolescents (ie, nicotine and cannabis), and (3) efficacy for reducing the negative consequences of substance use.

Methods

Study Team

This study is being performed in the national AAP PROS network of pediatric primary care practices. The AAP PROS network consists of 67,000 pediatrician members whose guiding mission is to foster and conduct national collaborative practice-based research for improving child health. Boston Children's Hospital (BCH) investigators are conducting the study in collaboration with the AAP PROS team. BCH conducts patient recruitment; participant retention; and data collection, management, and analysis activities. BCH also provides training and fidelity monitoring for clinicians delivering the intervention and convenes the data safety and monitoring board (DSMB). The AAP PROS team leads practice and clinician recruitment and data collection activities and hosts 2 PROS-member pediatrician advisors who provide input on study decisions from the perspective of community-based pediatric primary care clinicians.

Ethical Considerations

The AAP Institutional Review Board (IRB) is the single IRB for the study. The AAP IRB initially approved this study on May 27, 2022, after full board review (#22 HA 01). Approval included a waiver of parental permission and a partial waiver of Health Insurance Portability and Accountability Act (HIPAA) authorization. We sought a partial waiver of HIPAA authorization because patient recruitment activities involve the exchange of patient health information from practices to the BCH study team. Furthermore, we sought a waiver of parental permission due to the minimal risk nature of the study, the developmental maturity of the target sample (adolescents aged 14-17 years), and the sensitivity of the substance-related topic. Our previous study on consent in adolescent substance use research showed that requiring parental permission resulted in a substantially higher study refusal rate (60% vs 20%) and a sample biased toward lower levels of substance use and substance-related problems [38]. Importantly, recruitment and assent materials state the voluntary nature of the study, emphasize that eligible adolescents *do not* have to have used alcohol or other substances to join the study, and encourage—but do not require—adolescents to discuss the study with their caregivers. The combination of these conditions supports parental involvement, preserves the privacy and confidentiality of adolescents who *do* use alcohol or other substances, and acknowledges adolescent autonomy to make an informed decision about participating.

The protocol version described in this paper was approved on June 21, 2023. Should there be modifications to the approved protocol or study materials, we will submit an amendment to the AAP IRB, and if applicable, the relying IRB at BCH. In addition, we will report scientific changes to the National Institute on Alcohol Abuse and Alcoholism (NIAAA) as needed or in the yearly progress report, at which point we will also update the trial registry on ClinicalTrials.gov.

In this trial, patient privacy and confidentiality protection is supported by executing a data transfer agreement between participating practices and BCH, assigning patients a numeric

study identifier and by storing identifiable data in secure and restricted-access network locations separate from survey data. This study operates under a National Institutes of Health certificate of confidentiality. Assent materials state that only deidentified data will be shared outside of the study team (refer to the Data Access and Dissemination subsection).

Participating clinicians and practice staff members are required to provide informed consent. AAP PROS staff will send study recruitment materials to the designated contact clinician at each potentially eligible practice. Practices that are interested in participating will have a designated lead clinician submit a practice intake survey to confirm study eligibility of the practice and its clinicians. If practices are eligible, the AAP PROS staff will obtain written informed consent from all participating clinicians (Multimedia Appendix 1) as well as designated practice staff members who will handle and exchange patient data, answer patient or family questions, and otherwise support study activities at their site. Each participating practice will be offered a US $1000 honorarium after concluding patient recruitment at their practice and be able to keep all intervention-related materials, including the tablet computers provided for CRAFFT-IS implementation. Clinicians will be offered lunch accommodations (up to US $25 per person) for attending study orientation training and debriefing focus groups. In addition, clinicians in both trial arms can receive up to 12 continuing medical education credits for completing study training activities (UC clinicians will be offered CRAFFT-IS training at study completion at their practice). Board-certified pediatricians in the intervention arm may also receive optional maintenance of Certification Part 4 (up to 25 points) for a quality improvement activity spanning at least 3 quarterly feedback cycles. To complete this certification, intervention clinicians receive their participating patients' aggregated postvisit data reporting receipt of counseling and compare their performance with a standardized benchmark. Intervention clinicians receive a US $5 electronic merchandise gift card for attending an optional *office hour* with the trainers by videoconference every 1 to 2 months and US $10 for completing a debriefing survey about their experience of, and views about, the CRAFFT-IS at study completion.

Adolescents must provide verbal informed assent to participate (Multimedia Appendix 2). On a regular schedule (eg, every 2 weeks), each practice will send a BCH research assistant (RA) a list of age-eligible adolescent patients with upcoming well visits in the next 2 to 6 weeks. The BCH RA will then mail a study invitation coaddressed to adolescents and their caregivers, which includes an informational letter on the practice's letterhead and a study flyer with a QR code that leads to the brief study eligibility survey. Recruitment materials emphasize that adolescents do not need to have used substances to join the study, just as those with riding risk do not need to have used a substance themselves. Within 2 weeks of an adolescent's scheduled visit, the RA will attempt to contact the adolescent by telephone to invite them to complete the eligibility survey, which the RA, based on the adolescent's preference, can administer verbally or send for self-completion using an electronic link by SMS text message or email. At any point, a caregiver or adolescent can opt out of being contacted further.

Eligible patients will be directed to an electronic information sheet and a 5-minute video brochure developed in collaboration with youth advisors. During a telephone call before the adolescent patients' visit, a BCH RA will summarize key information using a standard assent script. If willing to join the study and able to answer 6 questions assessing study understanding correctly, adolescents will have the option to discuss the study with a parent or guardian and may then provide their verbal assent to participate. Adolescents who turn 18 during the study period will be asked to consent as an adult on or near their 18th birthday.

In addition to obtaining study assent, we will ask adolescents whether they assent or decline to have their deidentified study data shared with the NIAAA Data Archive ($NIAAA_{DA}$), a national data repository to which NIAAA-funded investigators conducting human subjects research are expected to submit deidentified individual-level data [39]. This data sharing is not a condition of study participation and does not require parental permission. Adolescents can receive up to US $100 in small-value merchandise electronic gift cards for completion of study surveys (US $5, US $10, or US $15 for a survey, depending on its length).

Study Design and Randomization

The study is a cluster randomized controlled trial involving 2 arms, intervention (CRAFFT-IS) and control (UC), with prospective follow-up for 12 months. Clinician randomization occurs within practice and on a rolling basis as practices enroll into the study. Participating pediatric primary care clinicians (doctor of medicine [MD], doctor of osteopathic medicine [DO], nurse practitioner [NP], and physician assistant [PA]) are randomly assigned to 1 of the study arms in a 1:1 ratio. Randomization is performed using a computerized, adaptive biased coin minimization scheme, which minimizes imbalance on the following factors, ranked by priority: clinician type (MD or DO vs NP or PA) and years in practice (≥10 vs <10) [40,41]. Compared to permuted blocks, adaptive biased coin minimization randomization has superior efficiency for achieving balance across multiple factors in studies with small units of randomization.

Clinicians are assigned a unique numeric code for temporary blinding while being randomized. After randomization, clinician study arm assignments are unblinded and shared with the study team. Study arm assignments cannot be blinded because the study team needs to train clinicians according to group assignment.

Study Population, Sample Size, and Statistical Power

Practices and Clinicians

We will recruit up to 20 practices within the AAP PROS network, with up to 40 clinicians enrolled across these practices. To be eligible to participate, practices must (1) have at least 2 interested and eligible clinicians (clinician eligibility criteria are presented later in this subsection), (2) have a high-speed wireless internet connection available to ensure connectivity of study tablet computers, and (3) have an adolescent patient population that is primarily English speaking (the CRAFFT-IS has, to date, been tested only in English). Practices must not (1)

be a practice or continuity clinic where residents or medical students routinely provide adolescent care (because trainees may not be available for training, implementation, and data collection for the duration of the practice's participation in the study) or (2) have recently participated or be participating in other initiatives to improve adolescent substance use screening and brief intervention in their practice. Eligible clinicians (1) must be a clinician (MD, DO, NP, or PA) who sees patients for well visits and (2) must see ≥6 adolescents aged 14 to 17 years per week, on average, or approximately 300 adolescents per year, for well visits.

Adolescents

We aim to enroll a minimum of 1300 adolescent participants. Eligible adolescents must (1) present for an annual well visit with a participating clinician in either study arm, (2) be aged 14 to 17 years at the time of their well visit, (3) report past 12-month alcohol use or past 12-month riding risk, and (4) have a smartphone and be willing to share their mobile phone number with the study team. We chose the minimum age of 14 years because there is low prevalence of prior alcohol use among younger adolescents (<5% of adolescents aged 12-13 years in our prior studies reported past 12-month drinking [Harris SK, unpublished data, 2019]). In addition, to be considered fully enrolled, all adolescents must complete the previsit survey before seeing their clinician, as well as the CRAFFT screen for those scheduled to see a clinician in the intervention arm. Adolescents must be willing and able to complete monthly surveys for 12 months after their well visit.

Adolescent patients must not be (1) in foster care, (2) in college or trade school at the time of their well visit, (3) currently receiving counseling or treatment for a substance use concern from a specialty clinician, or (4) perceived by their clinician to be inappropriate for the study (eg, due to neurodevelopmental delays or another medical priority at the time of visit).

We calculated the adolescent patient sample size by applying recruitment and retention rates, alcohol use and riding risk prevalence rates, intervention effect sizes, a within-clinician clustering design effect (0.90), and the clinician intraclass correlation coefficient for HED (0.008) seen in our pilot study [22]. We estimated a 37% past 12-month drinking prevalence rate, 28% riding risk prevalence rate among adolescents with past 12-month drinking, and a 5.8% riding risk rate among those with no past 12-month drinking. The 37% past 12-month drinking prevalence rate is similar to the 36.1% prevalence rate found on the 2018 Monitoring the Future Survey [42]. We applied slightly more conservative rates of participation (80% vs 82%) and retention (70% vs 75%) than those found in our pilot study to ensure that we achieve a sample size with sufficient power. With α set at ≤.05 and β at ≥.80, our power calculation indicated that a minimum analysis sample size of 888 participants with 12-month follow-up data would provide 86% power to detect an effect size of ≥20% in our primary outcome measure of HED. Applying the conservative estimate of 70% retention at 12 months, we need to recruit a minimum of 1268 participants. Thus, we estimate needing approximately 4200 adolescents to complete the eligibility survey, with 1600 (40% of those screened) meeting eligibility criteria, and 1300 (80% of those eligible) enrolling. To enroll this sample, we anticipate enrolling an average of 40 patients per clinician among up to 40 clinicians completing the study.

Intervention

Overview

The CRAFFT-IS was developed to leverage the power of digital technology to provide a time-efficient and feasible way for busy pediatric practices to improve both the frequency and quality of adolescent substance use screening and counseling in primary care. To this end, the CRAFFT-IS consists of the following components: (1) previsit self-administered screen (CRAFFT version with extra questions that are related to nicotine vaping and tobacco use [CRAFFT 2.1+N]), immediately followed by (2) brief interactive psychoeducational content on substance use–related health risks, and (3) clinician delivery of brief MI-based counseling during the confidential portion of the well visit, guided by a computerized point-of-care decision support tool called the clinician report. In addition, as an intervention to reduce riding and driving risk, intervention clinicians provide all participating patients and their caregivers with the *Contract for Life* document [34,43]. These components are described in greater detail in the following subsections.

Previsit Screening

To complete the previsit self-administered substance use screening, adolescents will log in to a secure website via their smartphone (before or at visit) or a tablet computer (at visit only) and complete the CRAFFT 2.1+N, which assesses past 12-month substance use frequency, substance-related riding and driving, and signs of problematic use (eg, uses when alone) [44]. At a cut point of ≥2 *yes* answers, the CRAFFT is highly sensitive (91%) and specific (90%) for detecting SUD in adolescents [23]. The CRAFFT 2.1+N includes an item on past 12-month days of nicotine vaping and tobacco use and, if yes, an item on past 30-day use. Endorsement of past 30-day nicotine vaping or tobacco use is followed by the Hooked on Nicotine Checklist (HONC), a well-validated 10-item screen for detecting loss of autonomy over nicotine use in adolescents [45]. This study will use a modified HONC that incorporates nicotine vaping.

After completing the substance use screen, adolescents will be asked to choose up to 3 personal values from a prespecified list of 14 values (eg, creativity, family, honesty, and wealth), with the option to write in their own. The selected values are presented in the clinician report to support clinician-patient rapport building and patient-centered MI-based counseling.

Previsit Psychoeducation

Next, adolescents view brief interactive psychoeducational web pages on the health risks of substance use. These web pages illustrate the unique vulnerability of adolescents to the health harms of substance use through the presentation of scientific evidence and true-life stories of adolescents. We developed this content based on input from focus groups of youth who reported that this type of information was compelling [31]. For this study, the content was updated to include information about the health risks of nocotine vaping.

Clinician Report and Brief Counseling Protocol

The clinician report is a web-based dashboard designed to help clinicians efficiently view their adolescent patients' responses to the substance use screening and values items and deliver brief counseling tailored to the responses. On the basis of the screening responses, counseling guidance is tailored to 1 of three substance use profiles: (1) *recent use* (use of alcohol, cannabis, or another drug in the past 3 months or use of tobacco or nicotine in the past 30 days), (2) *distant use* (use of any substance in the past 12 months but not in the past 3 months or past 30 days for nicotine vaping and tobacco), and (3) *riding risk* (no past 12-month substance use but past 12-month riding in a vehicle with a driver who was substance impaired).

The brief counseling protocol is a modified form of the brief negotiated interview, a structured MI-based counseling intervention originally developed for use in emergency departments and found to be efficacious in reducing substance use in adolescents [46]. The counseling protocol is designed for delivery in 5 to 10 minutes, depending on the severity of risk. Counseling steps are summarized in Table 1.

Table 1. Overview of the Adolescent Substance Use Prevention Intervention Research (ASPIRE) multisite cluster randomized controlled trial's brief counseling protocol, which is delivered by intervention clinicians to participating adolescent patients who present for a well visit and report past 12-month alcohol use, past 12-month riding risk, or both.

Counseling protocol steps	Recent use[a]	Distant use[b]	Riding risk[c]
1. Engage and build rapport	✓	✓	✓
2. Review screening results and assess further	✓	✓	✓
3. Consider pros and cons of substance use (decisional balance)	✓		
4. Discuss health risks of substance use and riding risk	✓	✓	✓
5. Evaluate readiness to change substance use (readiness ruler [47]) and reasons for change	✓		
6. Elicit next steps toward behavior change and anticipate challenges	✓	✓	✓[d]
7. Wrap up by summarizing discussion and affirming autonomy and self-efficacy	✓[d]	✓[d]	✓

[a]Patient reports past 3-month substance use. Patient may or may not report past 12-month riding with a driver who was substance impaired.

[b]Patient reports past 12-month substance use but no past 3-month use. Patient may or may not report past 12-month riding with a driver who was substance impaired.

[c]Patient reports past 12-month riding with a driver who was substance impaired and no past 12-month substance use.

[d]Clinician provides patient with the *Contract for Life* [43].

Recent use counseling uses the MI style of communication to elicit the adolescent's reasons for and problems with substance use. The clinician discusses the adolescent's values, shares health information, explores the adolescent's reasons for and readiness to change their substance use behavior using a readiness ruler [47], and guides the adolescent through planning behavior change. The counseling concludes by summarizing the discussion and affirming the adolescent's autonomy and self-efficacy. *Distant use* counseling involves affirming and supporting the adolescent's continued nonuse, discussing health risks associated with past substance use, and anticipating and planning for challenges with maintaining abstinence. *Riding risk* counseling also includes affirmation and support of the adolescent's continued nonuse, discussion of health risks associated with riding with a driver who is substance impaired, and counseling to identify and plan safe transportation at all times. Both the *distant use* and *riding risk* counseling protocols are guided in a structured step-by-step manner similar to *recent use* counseling.

Near the end of the brief tailored counseling, intervention clinicians provide *all* participating patients with a paper or electronic version of the *Contract for Life*. Developed by Students Against Destructive Decisions, the *Contract for Life* asks youth and their caregivers to develop and commit to a plan to ensure that adolescents always have a safe ride home with a sober driver [43].

Intervention Training and Fidelity Monitoring

Two clinicians with expertise in MI train intervention clinicians to deliver the intervention counseling. Training was initially structured as 5 self-study modules on a web-based learning platform and 5 live sessions with expert trainers (approximately 7 total training hours). As scheduling the 5 live sessions was found to be challenging with the first practice, the study team restructured the training to include longer self-paced asynchronous modules to reduce scheduling challenges without changing the total number of training hours. The updated training schedule consists of 5 self-study modules with recorded lectures, 2 live counseling practice sessions, and 1 live technical training session to orient clinicians to the clinician report and tablet computers.

The self-study modules include video-recorded presentations on MI-based counseling principles, the counseling steps for each of the 3 risk categories, video-recorded mock counseling demonstrations with accompanying annotated transcripts, and self-assessment questions. In the 2 live sessions, the expert trainers guide clinicians through case-based practice of the counseling steps and provide feedback.

To establish baseline competency, each clinician completes the counseling steps with a standardized patient for each of the 3 risk categories in a single recorded videoconference session. The trainers and 2 research staff members review these recordings using a standardized rating form. The trainers then

meet with each clinician for individualized feedback and coaching. For fidelity monitoring, clinicians complete mock counseling sessions and receive feedback quarterly. In addition, the intervention trainers host optional live videoconference sessions (*office hours*) every 1 to 2 months for extra coaching.

Intervention Modification or Discontinuation

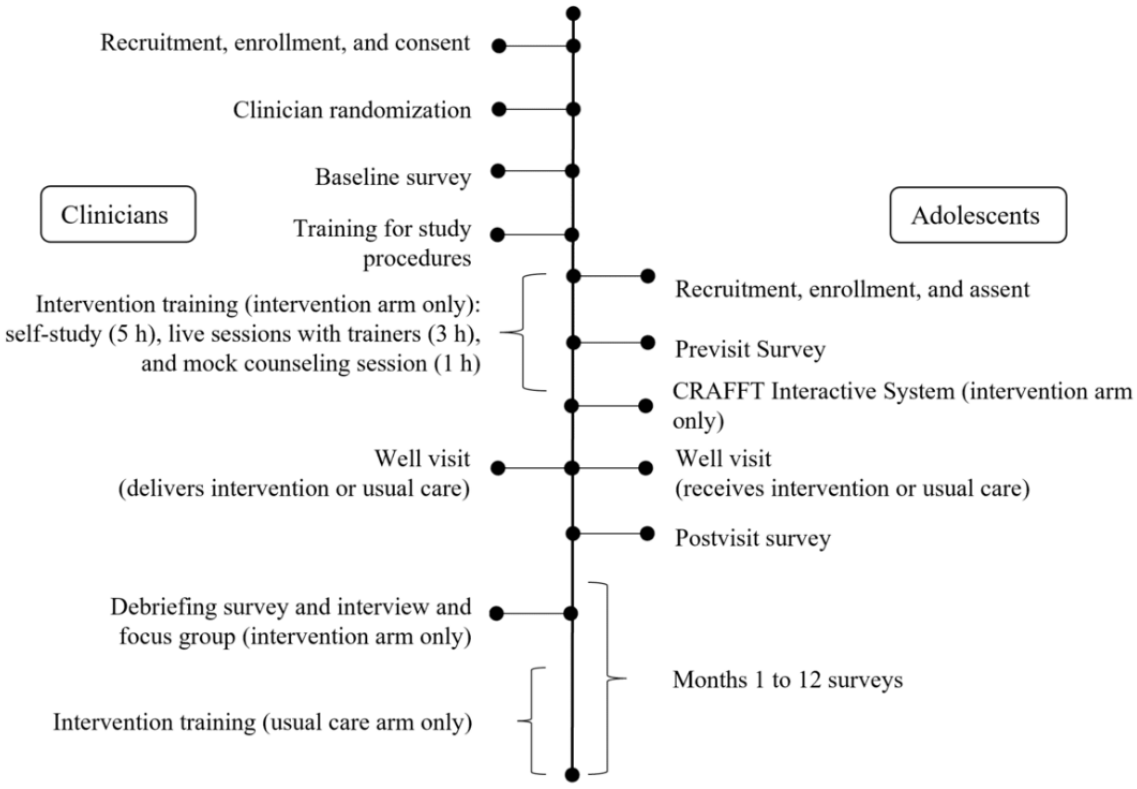
No concomitant care and interventions are prohibited during the trial beyond those defined in the practice inclusion criteria. We will withdraw a participant from the study if there is evidence to suggest that continuing in the study may be inappropriate (ie, there are intervening medical, mental health, or social circumstances that preclude or disrupt participation). Data collected from withdrawn participants will still be used in the analysis.

Outcomes and Measures

Study Activities and Assessment Timeline

Figure 1 illustrates the chronology of participating clinician and adolescent study activities.

Figure 1. Chronological overview of clinician and adolescent milestones during the Adolescent Substance Use Prevention Intervention Research (ASPIRE) multisite cluster randomized trial. CRAFFT: Car, Relax, Alone, Forget, Family/Friends, Trouble.



Outcome Measures

A detailed listing of study outcome measures, their reference sources where applicable, and time points of data collection is presented in Table 2, and thus they are only briefly described here. These measures are also reported in the ClinicalTrials.gov registry.

Our primary outcome measure is past 90-day HED, as reported by adolescents during the 12-month follow-up period, among adolescents who report past 12-month drinking at baseline. HED is defined using the age- and sex-specific cut points recommended by the NIAAA: ≥3 drinks on a single occasion for youth assigned female at birth who are aged 14 to 17 years, ≥4 drinks for youth assigned male at birth who are aged 14 to 15 years, and ≥5 drinks for youth assigned male at birth who are aged 16 to 17 years [68]. Our secondary outcome measure is any past 90-day riding with a driver who was substance impaired (who used alcohol, cannabis, or another drug) or driving while substance impaired. The exploratory outcomes of interest include past 90-day days of use of other commonly used substances among adolescents (ie, nicotine and cannabis) and experience of negative consequences associated with alcohol use (eg, missing school or work and getting into trouble at school, home, or work). In addition, we will explore the following intermediate outcome measures as hypothesized effect mediators: (1) report of readiness to reduce or stop alcohol use using a readiness ruler [47], (2) perceived risk of harm from use, and (3) self-efficacy to refuse alcohol.

[p]CHU9D: Child Health Utility–9 Dimensions.

[q]PATH: Population Assessment of Tobacco and Health.

[r]YRBS: Youth Risk Behavior Survey.

[s]MSPSS: Multidimensional Scale of Perceived Social Support.

Other Measures

We will explore potential intervention effect moderation by age group, sexual and gender identity and social determinants of health that enhance substance use risk for sexual and gender minority youth, baseline severity of substance use involvement, peer and family substance use, and patient-clinician relationship (number of prior visits the patient had with this clinician and perceived connectedness to their clinician).

We will also examine intervention implementation measures, including the time required to deliver the various CRAFFT-IS components and patient-reported receipt and quality of substance use counseling during their visit. Time information will be collected through computerized capture of patient clickstream times and clinician counseling start and stop times, as well as clinician report of average substance use–related counseling time and overall visit length on the clinician debriefing questionnaire completed at the end of patient recruitment at a practice. Adolescents complete an immediate postvisit questionnaire that includes items on the health topics discussed during the visit, ratings of counseling quality and the degree to which it reflected an MI-based counseling style, and whether they received the *Contract for Life*.

To assess the validity of the modified HONC for identifying risk for nicotine use disorder in adolescents, we will compare it to the 4-item Patient-Reported Outcomes Measurement Information System Nicotine Dependence Item Bank for Electronic Cigarettes (PROMIS-E) [60] administered in the previsit assessment. While the CRAFFT screening items are well validated [24], the modified HONC, which now includes nicotine vaping and is included in the CRAFFT-IS previsit screening for adolescents seeing intervention clinicians, needs validation.

Data Collection

Clinicians

Enrolled clinicians are assigned a unique numeric identifier for use in data collection throughout the study. A baseline survey assesses previous experience and training and UC practices around screening, brief intervention, and referral to treatment (10 min), as well as training on study procedures and human subjects protections (up to 90 min; all clinicians). Clinicians assigned to the intervention arm additionally complete brief (5 min each) postsession evaluation surveys after each live training session and a final summative evaluation after all training components have concluded. Clinician surveys and evaluations are completed on paper or by email or SMS text message link to an online survey per clinician preference. After adolescent recruitment and intervention delivery have concluded at a practice, intervention clinicians complete a 10-minute debriefing survey assessing experience using the CRAFFT-IS and seeking suggestions for improving the system, as well as participate in a 30- to 60-minute interview or focus group (along with participating staff) to offer feedback on their study experience.

Adolescents

All adolescent participants are assigned a unique numeric identifier at the time of recruitment for use in data collection, storage, and linkage throughout their study participation. Once assented, participants indicate their contact preferences. Adolescents who agree to have their data shared with the $NIAAA_{DA}$ are assigned a Global Unique Identifier using their first, middle, and last names; sex assigned at birth; and date and city of birth. Global Unique Identifiers are numeric codes that allow participant data to be submitted to the $NIAAA_{DA}$ without any personally identifiable information. All participants self-administer the confidential electronic previsit survey (approximately 20 min; refer to Table 2 for details on all surveys), and participants seeing an intervention clinician complete the screening and psychoeducational components of the CRAFFT-IS (5 min) before seeing their clinician. After their visit, all participants complete the immediate postvisit survey (approximately 10 min), and then, through the 12-month follow-up period, brief monthly surveys about their past 30-day substance use and longer surveys at 3, 6, 9, and 12 months (approximately 15 min each). Participants may choose to skip questions or entire surveys and still remain in the study.

All surveys can be completed electronically on smartphones and desktop or tablet computers through a link sent by SMS text message or email to participants' personal mobile phone numbers or email addresses, as preferred. Electronic surveys are protected by a password set by the adolescent. Adolescents can also complete a survey by mobile phone with a study RA. If the adolescent does not complete a survey after electronic reminders, a study RA will call the adolescent to encourage survey completion.

Data Management

Study data, including survey responses and internal study tracking data, will be collected and stored in Research Electronic Data Capture (REDCap), a HIPAA-compliant web-based data management and survey distribution tool hosted at BCH [69,70]. Data transmission among BCH, AAP PROS staff, and practices will occur securely via password-protected email or fax. Paper-based data (eg, faxes and verbally administered surveys) will be stored securely for 7 years and identifiable electronic data for 3 years. Deidentified data will be kept indefinitely.

Data Analysis Plan

Analysts will be blinded to treatment arm. We will evaluate randomization success and level of attrition bias by comparing baseline characteristics of adolescents by treatment arm and by those retained versus those lost to follow-up (ie, adolescent participants who stop completing study surveys during the 12 months after their well visit). Baseline variables meeting a P value of <.20 in randomized group comparisons will be entered as control variables in multivariable modeling of the intervention effect to yield adjusted estimates of effect. We will compare rates of counseling receipt and patient ratings of their visit between groups. We will also generate variables related to intervention *dose* (eg, receipt of clinician counseling and receipt of *Contract for Life*) for use in sensitivity analyses.

To assess intervention effects on our primary and secondary outcome measures (past 90-day HED and any past 90-day riding or driving risk) at each of the 3-, 6-, 9-, and 12-month follow-up time points, we will use multiple logistic regression modeling with generalized estimating equations to compute adjusted

relative risk ratios (CRAFFT-IS vs UC). Generalized estimating equations account for clustering of participants within practice and clinician. Furthermore, we will explore intervention effects on the number of days of drinking and of HED and on the number of times participants experienced alcohol-related negative consequences from baseline to each follow-up time point. As these variables are likely to have distributions that are highly skewed and overdispersed, we will specify a negative binomial distribution and log link in these regression models. We will also conduct longitudinal data analysis using mixed effects modeling to compare group outcomes trajectories through the entire 12-month follow-up period. We plan to explore intervention effect mediation by applying the product of coefficients test for mediation [71,72] and potential effect moderation by future-determined variables by testing the significance of interaction terms in regression models.

All intervention effect analyses will use intent-to-treat groups. We will transform continuous variables with skewed data and collapse categories as needed to preserve adequate cell sizes. To handle missing data, we will use multiple imputation based on regression modeling and compare the results of analyses using the imputed data set versus the original data set [73].

Safety and Monitoring

We define the following as nonemergency safety risks: drinking twice the NIAAA-defined HED amount for the adolescent's age and sex [68], daily use of alcohol or cannabis, use of other drugs on >6 days during the past 3 months, driving after use of substances >1 time in the past 3 months, and riding with a driver who is substance impaired >1 time in the past 3 months. When an adolescent's survey responses indicate any of these nonemergency risks, a BCH RA will notify the patient's clinician within 1 business day. If an adolescent spontaneously discloses an emergency safety risk (eg, abuse, suicide risk, or intentions to harm others), a BCH RA will immediately notify their clinician or appropriate contact person according to site-specific preferences.

This study has an independent DSMB that consists of 3 members: a child psychiatrist with expertise in adolescent SUD screening and treatment research (chair), a biostatistician with experience in clinical trial research, and an adolescent medicine primary care clinician. The DSMB will (1) review study procedures and progress, including recruitment, retention, and dropout; and (2) assess adverse events and unanticipated problems, if any, and their relationship to study participation. The full DSMB will meet annually to review overall study progress and will also convene as needed to review and address any adverse events or other study-related problems, should they arise. The DSMB is responsible for recommending whether to stop the study; no interim analyses are planned.

Given that this is a minimal risk study, we do not anticipate that participants will experience harm from study participation. However, we have planned for situations in which participants spontaneously report harms. Harms may consist of nonserious adverse events (eg, participant complaints or upset related to study activities and inadvertent disclosure of confidential information) or serious adverse events (eg, motor vehicle crashes and hospital visits). If we learn of an adverse event, we will consult with the DSMB chair and notify the AAP IRB and the patient's practice. The DSMB will determine whether a serious adverse event is related to study participation and recommend the appropriate response, including possible study withdrawal. Study data are protected by a certificate of confidentiality from the National Institutes of Health.

Results

Recruitment and Enrollment

The first practice enrolled in August 2022. As of July 2023, a total of 6 practices (23 clinicians) had enrolled in the study.

Adolescent recruitment began in December 2022 and is expected to continue until late 2024 or early 2025. Data collection is expected to conclude in 2025 or 2026, and data analysis will follow.

Data Access and Dissemination

The final trial deidentified data set will be provided to the study's biostatistician, the AAP PROS team, and any other interested investigators upon request. We will report results on ClinicalTrials.gov, and select deidentified data will be available to researchers worldwide via the $NIAAA_{DA}$.

In addition to this paper, we aim to publish at least 2 papers that disseminate study findings: 1 focused on our primary alcohol use–related outcomes and 1 focused on other substance use outcomes. We also anticipate submitting at least 2 abstracts to present at national conferences. Members of the study team will develop and write all publications resulting from this study. Authorship will be designated according to those who offer intellectual contribution to the design or preparation of a given publication and claim responsibility for its contents.

Discussion

The ASPIRE study aims to test the effectiveness of the CRAFFT-IS, compared to UC, in reducing alcohol use and substance use–related riding risk among adolescents aged 14 to 17 years presenting for well visits. Despite the AAP's recommendation for universal substance use screening in primary care beginning at age 11 years, the US Preventive Services Task Force gave primary care–based adolescent alcohol screening and brief behavioral counseling an "I" rating in its most recent review, indicating insufficient evidence for or against its recommendation [74]. The ASPIRE study builds on prior research supporting the promise of CRAFFT-IS as a feasible, acceptable, and efficacious approach to increasing high-quality screening and counseling.

Our study protocol has limitations. Although our virtual recruitment and enrollment approach allows the study team to contact a larger volume of individuals over an expanded time frame (eg, in comparison to in-person recruitment restricted to clinic operating hours), practices may not have up-to-date contact information for adolescent patients. Likewise, it is not guaranteed that adolescents will see or read the mailed recruitment invitation before their visit. Our approach also reduces burden on practice staff to conduct recruitment activities, but it may underuse pre-established connections

between practice staff and adolescent patients. Furthermore, the addition of the CRAFFT-IS to well visits may delay clinic flow. Further limitations to our study may emerge during the trial and will be reported in future outcomes manuscripts.

If the CRAFFT-IS is shown to be effective, we intend to scale, promote, and widely disseminate the instrument for use in pediatric practice, either as a tablet application or as a confidential add-on to existing electronic health record systems. We also envision this study informing future investigators interested in studying computer-facilitated screening and brief intervention for youth substance use, whether in primary care settings or elsewhere, with the aim of reducing alcohol-related morbidity and mortality during adolescence and beyond.

Acknowledgments

This research was supported by a grant from the National Institute on Alcohol Abuse and Alcoholism (NIAAA; R01AA027253; principal investigators: SKH and LAS; peer-review reports: Multimedia Appendix 3) and supplemental grants (3R01AA027253-03S1 and 3R01AA027253-03S2). In addition, infrastructure support was provided by the American Academy of Pediatrics and the Health Resources and Services Administration of the US Department of Health and Human Services (National Research Network to Improve Children's Health: UA6MC15585 and Pediatric Research Network Program: U5DMC39344). The contents are those of the authors and do not necessarily represent the official position or policy of, nor an endorsement by, the Health Resources and Services Administration, the US Department of Health and Human Services, or the US government. The NIAAA was not involved in any aspect of study design or implementation, nor in the preparation, review, or approval of this manuscript for publication. The authors would like to acknowledge the valuable contributions of youth advisors and interns who supported study activities and provided feedback on procedures and materials. The authors would like to thank Dr Jeremy Bray and Anna Goodall at the University of North Carolina Greensboro for their leadership in designing the cost-effectiveness analysis component of the study, which was not discussed in this manuscript. Finally, this research would not have been possible without the support of providers, practice staff, and patients in the American Academy of Pediatrics Pediatric Research in Office Settings network, to whom we owe the greatest thanks.

Data Availability

Data sharing is not applicable to this paper as no data sets were generated or analyzed.

Authors' Contributions

LAS and SKH conceptualized, designed, and obtained funding for the study. MMO and AT obtained ethics approval for the study, with oversight from LPS and AGF and assistance from JAP, JLM, NHM, and DH. LAS and PJB developed the intervention counseling. TF and MLM served as pediatrician advisors to the study. LS codeveloped and programmed the computer-facilitated screening and brief intervention. All authors contributed to the development of the protocol and approved the final manuscript.

Abstract

Background: In the United States, the proportion of criminal legal–involved (CLI) adults with a substance use disorder reaches 72%, and ~150,000 persons with HIV pass through a carceral setting annually, which represents 16% of the HIV-infected population nationally. Despite the high need for substance use treatment and HIV prevention services, few carceral settings successfully link CLI individuals to treatment upon release. Young adults represent 41.9% of the adults incarcerated in the United States and have the highest HIV incidence rates nationally. Peer patient navigation has successfully increased community-based care linkage for people living with HIV leaving jail; yet, peer-led navigation for HIV prevention among HIV-negative CLI populations is undeveloped and untested. eHealth approaches to substance use and HIV prevention services hold promise because they improve access to effective intervention services, particularly for younger people.

Objective: This paper describes a protocol for a pilot randomized controlled trial that aims to improve linkage to substance use treatment and HIV prevention services using peer navigation and a codeveloped eHealth technology adjunct.

Methods: The three aims of this study are to (1) adapt an existing evidence-based navigator model and incorporate codeveloped eHealth technology to refer and link young adults (18 to 29 years) surveilled by the criminal legal system to substance use and pre-exposure prophylaxis (PrEP) services; (2) refine and test the intervention with criminal legal–involved young adults (CLI-YAs); and (3) assess the feasibility, acceptability, and impact of the intervention. Data to inform the intervention will be collected via system partner interviews (n=4) and focus groups with CLI-YAs (n=24). Next, an open trial (n=10) will be conducted. The intervention will be refined via interviews with participants and facilitators, and a randomized pilot trial (n=75) will be conducted to assess the feasibility, acceptability, and preliminary impact of the eHealth-enhanced navigation on substance use and PrEP services linkage. Exit interviews conducted with a subsample of intervention participants (n=10), the navigator (n=1), and system partners (n=4) will assess intervention acceptability and suggestions for improvement. A community of practice, a group of system partners with an interest in working toward solutions to common problems, will inform each phase of the study.

Results: The project is currently ongoing. The project was funded in September 2022. Internal review board approval was received on March 21, 2022. The first results from early study aims are expected to be published in 2025.

Conclusions: This study provides an opportunity to reduce HIV acquisition and improve access to substance use treatment in a systemically marginalized group: young CLI-YAs. The results will contribute to the development and testing of a future multilevel randomized controlled trial.

KEYWORDS

substance use; HIV prevention; carceral system; intervention development; young adult

Introduction

In the United States, annually, individuals involved in the criminal legal (CL) system are at an increased risk of substance use disorders (SUDs) and HIV acquisition [1-4]. HIV rates among CL-involved (CLI) adults range from 3 to 15 times the rate among individuals not involved in the CL system [2]. Individuals involved in the CL system have high rates of lifetime and recent substance use: between 81% and 84% report lifetime substance use and between 63% and 83% test positive for substance use at the time of their arrest [3]. The proportion of CLI individuals with an SUD reaches 72% [3]. Despite the high need for treatment services, few correctional settings link CLI individuals to community-based substance use treatment upon release.

Young adults (YAs; ages 18-34 years) represent 41.9% of the adults impacted by the carceral system [5] and have the highest HIV incidence rates nationally; YAs aged 20 to 24 years and 25 to 29 years have the highest rates of HIV infections (27.9 and 32.6 per 100,000, respectively) [6]. YAs also disproportionately experience SUD, with 25.6% of those aged 18 to 25 years estimated to meet the Diagnostic and Statistical Manual of Mental Disorders criteria for SUD in the last year (as of 2021) compared to 16.1% of those over the age of 26 years [6]. Factors that increase the likelihood of substance misuse and SUD among YAs include an imbalance of brain maturity through the second decade of life as well as psychosocial factors like increased peer influence and substance use as part of identity exploration [7]. Notably, the criminalization of substance use can also shape vulnerability to HIV as periods of detention can disrupt health care access, employment, caregiving, and social networks [8].

Significant racial disparities exist among new HIV acquisitions for YAs; African American populations accounted for 45.7% of all new HIV infections among YAs, and Hispanic populations accounted for 28.8% [9]. Given the disproportionate number of racial and ethnic minoritized CLI-YAs [10], prioritizing interventions that reduce racial and ethnic disparities in HIV and SUD treatment engagement for CLI-YAs is essential [11,12]. Multiple negative outcomes are known to be associated with involvement with the carceral system itself, including increased prevalence of SUD and infectious diseases like hepatitis C and HIV, increased indicators of poor mental health, and high prevalence of traumatic experiences (physical, sexual, and emotional) that linked directly to carceral policies (eg, solitary confinement) [13,14]. In light of the fact that ~5 million adults pass through CL settings annually and one-third are YAs [10], it is critical to link CLI-YAs who misuse substances and are at risk for HIV with innovative prevention strategies (ie, pre-exposure prophylaxis [PrEP]) and substance use treatment.

PrEP, in the form of a fixed-dose combination of 2 antiretroviral drugs, has emerged as a powerful HIV prevention tool [15]. In addition to 2 oral PrEP medications available (ie, Truvada and Descovy), the US Food and Drug Administration recently approved long-acting injectable PrEP (ie, Apretude) as another PrEP administration tool [15]. Significant disparities exist both between PrEP eligibility and uptake. For example, there are significant racial disparities with low PrEP uptake for Black individuals compared to people with other racial identities [16]. Hispanic and Latinx populations face similar disparities in PrEP use; people assigned female at birth, transgender populations, and bisexual and heterosexual populations also experience lower odds of PrEP use compared to their counterparts despite their not insignificant HIV incidence rates [16]. A variety of factors impede efforts to increase PrEP and substance use treatment access among CLI populations including discrimination based on one's racial or ethnic identity, misinformation about HIV transmission and treatment, stigma related to an individual's intersecting identities (eg, CLI status, substance use, race, and ethnicity), distrust of the CL and medical systems, psychiatric symptoms, inability to pay for transportation, lack of familial and social support, and inconsistent access to health care [17-20]. Although PrEP has been found to be efficacious, its maximal impact depends on uptake among those at high risk, including CLI-YAs.

Peer navigation holds strong potential to address multifactorial and complex barriers to PrEP and substance use treatment linkage and uptake for CLI-YAs. Navigation uses a one-on-one relationship to promote the timely movement of an individual through a health care continuum by eliminating barriers [18]. One such intervention, The Navigator Project (NAV), found that navigation-enhanced case management supported linkage to care (<30 days) and consistent retention in care (<1 year) for persons with HIV leaving jail as compared to persons with HIV living in the community and not exposed to jail detention. Using a harm reduction framework, peer navigators use motivational interviewing and prevention care management to navigate reentry back into the community, including referrals for mental health treatment, substance use treatment and harm reduction support, housing, employment, legal aid, and social services [20]. While peer navigation has been successful in increasing connections to care for persons with HIV leaving jail settings [20,21], peer-led navigation for HIV prevention among HIV-negative CLI populations is nascent [22].

In tandem with patient navigation, eHealth has the potential to improve health care engagement for CLI-YAs [23,24]. eHealth-enhanced peer navigation for HIV-infected individuals released from jail has been shown to be effective in maintaining virologic suppression [21]. The private nature of eHealth makes it an appealing modality to deliver components of a navigation intervention and link individuals with stigmatized services (eg, HIV prevention and SUD treatment) [25-27]. Of YAs aged 18-29 years, nearly 100% own a mobile phone and 92% possess a smartphone, making eHealth health intervention approaches feasible [23]. eHealth interventions can improve attendance at health care appointments [28,29], medication adherence [30,31], and behavior changes [32], and can provide support in real time [33]. To our knowledge, however, eHealth-enhanced navigation is untested for integrated substance use treatment and HIV prevention service linkage for CLI-YAs who have returned to the community after incarceration or who are subject to community surveillance. This study aims to address this gap in the literature by examining the feasibility, acceptability, and impact of an eHealth-enhanced peer navigator-led SUD and HIV prevention referral and linkage intervention for CLI-YAs supervised in the community. This paper is intended to provide a thorough summary of this study protocol.

The objectives of this study are to (1) adapt an existing evidence-based navigator mode (NAV) and incorporate codeveloped eHealth technology to refer and link CLI-YAs (ages 18-29 years) to substance use treatment and HIV prevention (PrEP) services; (2) refine the adapted eHealth-enhanced navigator-led substance use treatment and HIV prevention (PrEP) linkage intervention for CLI-YAs and test for fidelity, appropriateness, and satisfaction; and (3) assess the feasibility, acceptability, and impact of the adapted eHealth-enhanced navigator program to refer and link CLI-YAs to substance use treatment and HIV prevention (PrEP) services.

Methods

Study Setting

Surveillance data from Allegheny County, Pennsylvania, the study location, indicate that YAs (aged 20-29 years) account for 43% of all new HIV infections [34]. Notably, most adults newly diagnosed with HIV in Allegheny County are from racial and ethnic minority groups (65.8% in 2020) [34], making research in this geographic area generalizable to other high HIV incidence US locales. As of 2020, 30% of individuals who died from drug overdoses in Allegheny County were involved with adult probation and 19% had been booked in a county jail in the prior year. Additionally, Black residents in Allegheny County were disproportionately represented in overdose deaths, with a rate more than 2 times that of White residents [35].

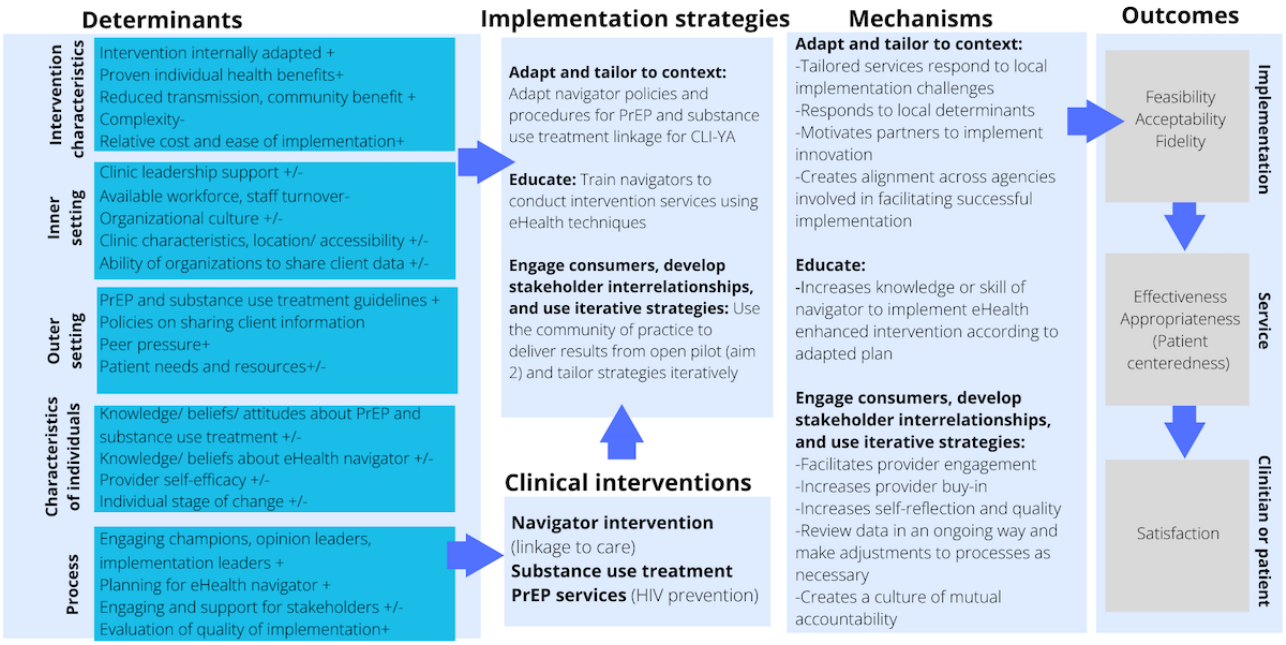
eHealth Enhancement

The proposed technology is a non-native web-based app that will facilitate resource linkage and communication between the navigator and participants. Expected functions of the eHealth technology include appointment scheduling and reminders, the provision of tailored resources (eg, substance use treatment information), motivational messages, and linkage to support persons. The partner for developing this technology is Chorus Innovations, Inc, which uses a participatory informatics approach that combines best practices from community-based participatory research (eg, equity and power sharing) [36] and user-centered design (eg, active user participation in design) to build technology products [37]. These practices ensure that the user participates in the design process [38], and there is a collaborative and equitable partnership in the research and design process, the process is iterative, and knowledge and action are mutually beneficial to all partners.

Implementation Research Logic Model

This study uses the CFIR (Consolidated Framework for Implementation Research) to identify key determinants [39], the “Expert Recommendations for Implementing Change” [40,41] to describe implementation strategies, and the Proctor Framework [42] to define implementation, service, and participant outcomes (Figure 1). The CFIR is organized into 5 domains based on context (intervention, outer setting, inner setting, individual, and process). We will use three implementation strategies from Expert Recommendations for Implementing Change [41] to (1) adapt and tailor to context for the eHealth enhancement protocol; (2) education to train navigators; and (3) engage consumers, develop stakeholder interrelationships, and use evaluative and iterative strategies achieved via the community of practice (CoP). This study focuses on feasibility, acceptability, fidelity (implementation outcomes), effectiveness, appropriateness (service outcomes), and satisfaction (clinical outcomes).

Figure 1. Intervention logic model for a 90-day randomized controlled trial designed to link young adults impacted by the criminal legal system to substance use and HIV prevention services in Allegheny County, PA, based on the CFIR (Consolidated Framework for Implementation Research), Expert Recommendations for Implementing Change (ERIC), and the Proctor Framework. +/- in the determinants column indicates directionality of impact. CLI-YA: criminal legal–involved young adult; PrEP: pre-exposure prophylaxis.



CoP

A CoP, originally conceptualized by anthropologists Lave and Wenger [43], is a community with a shared domain of interest or knowledge that provides support, resources, strategies, and best practices related to the shared domain. Our CoP will meet regularly throughout the intervention and be comprised of individuals from the public health and social service sectors with knowledge of substance use treatment and HIV prevention in CL settings, navigators with previous experience working with CLI-YAs, and YAs with a history of CLI. The CoP will be community experts who will participate in and support all 3 aims of the study including reviewing data collection tools and sampling frames, examining results from each aim, providing guidance on navigation structure and content, codeveloping the adaptation of the Chorus-supported navigation intervention in real time, and guiding research dissemination.

Aim 1: Development Phase

Participants

We present eligibility criteria by separate participant population. CLI-YAs (ages 18-29 years; n=24) will be eligible if they self-report recent CLI (past year); self-identify as HIV negative; endorse behaviors in the past 6 months indicating consideration of PrEP per the Center for Disease Control and Prevention's risk indices [44]; meet the Tobacco, Alcohol, Prescription medication, and other Substance use Tools' criteria for identifying the Diagnostic and Statistical Manual of Mental Disorders SUD (ie, ≥2 for tobacco, alcohol, and marijuana, and ≥1 for other substances) [45]; and are conversant in English. Exclusion criteria include being on PrEP, cognitive delays that would interfere with consent or participation, or inability to provide contact information for ≥2 locator individuals. CL system partners (n=2) will be in probation administration or frontline staff (eg, probation officers). Medical or public health system partners (n=2) will be involved in substance use treatment delivery and PrEP participant care in a setting where CLI participants are referred and will include individuals who have had experience navigating CLI to health services.

Recruitment

CLI-YAs will be recruited for participation in focus groups. To recruit focus groups, study staff are partnering with community-based carceral settings and community-based organizations serving CLI-YAs. Study staff will approach YAs for participation when they (1) come to meetings with their probation officers or (2) access services at community-based agencies serving CLI-YAs.

System partners will be recruited for individual interviews. Recruitment will be conducted using purposive sampling of community partners via email and phone outreach. We will identify initial contacts who work in CL and public health or health care spaces relevant to the study and use snowball sampling to include additional unknown system partners.

Data Collection

Overview

Focus groups and interviews will be held at times and locations convenient for participants (eg, for CLI-YAs, around probation visits, work schedules, or on weekends; for system partners, during lunch, or after work). Focus groups will be held via Zoom (Zoom Technologies Inc) or in a private room depending on participant preference and availability, while individual

interviews will be conducted by phone; both will be audio-recorded. A semistructured focus group and individual interview format will allow participants to respond freely and in an open-ended way [46].

Focus Groups

The research team will conduct 3 separate (75-90 minutes) focus groups with CLI-YAs (n=24). Focus groups will be informed by 2 domains of the CFIR relevant to CLI-YAs: characteristics of the intervention and individuals involved in the intervention. Sample content areas will assess the (1) knowledge about navigation as an effective approach to substance use treatment and HIV prevention service linkage, (2) perceptions of relevance of *NAV* content and gap areas, (3) strategies to support the likelihood of engaging with a navigator throughout the intervention period, and (4) attitudes toward and capabilities of using eHealth intervention enhancements of the CLI-YAs.

Interviews

As with the focus groups, individual interviews will be guided by several domains from the CFIR (eg, inner setting, intervention characteristics, and implementation process). Sample interview topics include (1) how a navigation intervention could be adopted, delivered, and sustained within the probation system; (2) perceptions of what YAs do or do not like to hear from them and what they might or might not like to have the navigator do on the topics of substance use, HIV risk, PrEP eligibility, and linkage; (3) identify intervention practices that might facilitate information sharing within and across probation and medical system while respecting participant privacy and confidentiality; and (4) areas of training relevant for navigators. At the end of the focus groups and individual interviews, study staff will administer a brief questionnaire to assess the sociodemographic characteristics of the sample.

Data Management and Analysis

We will conduct a content analysis, guided by CFIR domains, of notes collected as part of the CoP meetings occurring during this aim, focus groups, and individual interviews. Executive summaries, which provide data quickly, and evidence of whether theme redundancy is achieved, will be written within 48 hours of data collection. Digital recordings of all qualitative data will be transcribed verbatim. Following transcription and the completion of the executive summaries, data will be analyzed according to Inductive Thematic Analysis [47]. Inductive Thematic Analysis is often used to find solutions to real-world problems and provide program recommendations [48]. An initial codebook will be developed based on the focus group and individual interview guides and transcripts. To improve reliability and ensure adequate intercoder agreement, members of the research team will compare coding patterns, and the codebook will be refined until consensus is reached. Study team staff will generate memos to highlight connections between codes and subcodes. The team will meet weekly to discuss data as they are being collected and to come to a consensus on themes. To identify unique developmental, gender, and cultural perspectives, we will also examine data by race, ethnicity, sexual orientation, gender identity, and age or development (18-25 vs 26-29 years). NVivo (QSR International) will be used to facilitate analyses.

Outcomes

The primary outcome of aim 1's formative work is the adaptation of the existing navigator model (NAV) and the codevelopment of the proposed technology for eHealth enhancement. Both will be informed by the CoP and findings from focus groups with CLI-YAs and individual interviews with system partners. Both adaptation of the existing model and navigator training will be completed prior to the open pilot in aim 2.

Aim 2: Open Pilot Phase

Participants

To refine and test the adapted eHealth-enhanced intervention for CLI-YA, we will pilot the intervention with CLI-YAs (n=10). Final eligibility criteria for aims 2 and 3 will be determined from insights gained through the implementation and data collection of aim 1.

Recruitment

To recruit participants, study staff will be stationed in probation offices and community-based organizations working with individuals involved in the carceral system and will approach individuals to ask if they are interested in participating in the study screening. After consent, the study staff will refer participants to the navigator who will make contact within 24 hours.

Pilot Intervention Navigation Protocol

The navigation process will be informed by evidence-based practices from NAV, including harm reduction, peer navigation, motivational interviewing, and prevention care management to navigate reentry back into the community (eg, referrals for mental health treatment, substance use treatment, and social services) [20]. Navigation processes will be informed by 2 cascade frameworks: the *PrEP Continuum of Care* model [49] and the *JuvenileJusticeBehavioralHealth ServicesCascade* [50]. The PrEP continuum emphasizes identifying individuals at risk for HIV acquisition, increasing awareness of and willingness to take PrEP, ensuring linkage and access to PrEP, and adherence to PrEP medications. The *Juvenile Justice Behavioral Health Services Cascade* [50] was developed to move CLI youth from substance use screening and identification in CL settings to community-based treatment initiation and engagement; this cascade will be adapted to reflect processes specific to YAs.

Navigators will act as role models who can steer participants through the upstream steps of these cascades from screening to linkage with an exploratory look at engagement or initiation, adherence (PrEP specific), and continuing care (substance use treatment) or persistence (PrEP specific). We will test a 30-day intervention period (Textbox 1 for sample navigator visits, adapted from *NAV*). The first session (~75 minutes) will occur within 5 days of referral. In line with the *NAV* protocol, the navigator will initiate contact with the participant ≥3 times per week after the first session (the number of contacts may be higher, depending on the participant's needs and desires) [20]. Additional contacts could be made throughout the 30-day period in-person or with support via Chorus (eg, SMS text messages). Visits can occur via Zoom, telephonically, or in person based

on the participant's preferences. To maximize program retention, each navigation session will begin by updating the participant's contact information. If detention interrupts intervention delivery, we will "reset," where the participant left off to complete 30 days of exposure. Intervention "graduation" will be acknowledged and included in each participant's action plan (eg, certificate of completion).

Textbox 1. Sample navigator session content for a 90-day randomized controlled trial designed to link young adults impacted by the criminal legal system to substance use and HIV prevention services in Allegheny County, PA.

Session 1: Program orientation, relationship building, and needs assessment (~75 minutes)

- The navigator will build rapport by introducing themselves, their role, and the program. The navigator will identify significant contacts, and complete study documentation (eg, release of information forms). Finally, the navigator will conduct a comprehensive needs assessment of sexual health and substance use to develop an individual risk reduction plan. Relevant community resources will be presented to the participant.
- eHealth approaches identified in aim 1 (eg, SMS text messages, appointment reminders, motivational messages, and telehealth sessions) will be incorporated into session content.

Session 2: Substance use education and treatment cascade (~60 minutes)

- Provide psychosocial education on substance use (tailored to the client's behaviors and needs identified in session 1), provide participants with information on how patterns of substance use can affect their health, social, and legal outcomes and the Juvenile Justice Behavioral Health Services Cascade. The navigator will revisit the risk reduction plan (session l) and tailor it to any changes in the participant's life. Participants will be referred to local substance use treatment.
- eHealth approaches identified in aim 1 (eg, SMS text messages, appointment reminders, motivational messages, and telehealth sessions) will be incorporated into session content.

Session 3: HIV and Pre-exposure Prophylaxis knowledge and care cascade (~60 minutes)

- Provide psychosocial education on sexual health (tailored to the client's behaviors and needs identified in session 1) and can shape an individual's risk of sexually transmitted infections and HIV. Provide basic HIV (eg, transmission) and pre-exposure prophylaxis information, and outline the pre-exposure prophylaxis Care Continuum. The navigator will revisit the risk reduction plan (session 1) and tailor to any changes in the participant's life. Participants will be referred to local pre-exposure prophylaxis–related services.
- eHealth approaches identified in aim 1 (eg, SMS text messages, appointment reminders, motivational messages, and telehealth sessions) will be incorporated into session content.

Session 4. Substance use and Pre-exposure Prophylaxis care appointment scheduling and goal setting (~60 minutes)

- Provide follow-up information on where and how to access substance use and pre-exposure prophylaxis–related services. Develop a plan for substance use and pre-exposure prophylaxis linkage and maintenance to include planning for transportation to health care services, keeping appointment dates, obtaining medication (pre-exposure prophylaxis), formulating a medication schedule, and identifying motivation for appointment attendance and pre-exposure prophylaxis adherence.
- eHealth approaches identified in aim 1 (eg, SMS text messages, appointment reminders, motivational messages, and telehealth sessions) will be incorporated into session content.

Follow-up contacts (~30 minutes)

- Maintain regular contact between the navigator and the participant, provide guidance and support for goal setting, and ongoing emotional and psychosocial support.
- eHealth approaches identified in aim 1 (eg, SMS text messages and telehealth) will be incorporated to support follow-up contacts.

Navigator Training

The Navigator will receive a minimum of 7 days of training focused on relational service provisions (ie, emotional and psychosocial support), logistical service provisions (ie, assistance to overcome task-oriented barriers like scheduling and finding transportation to appointments), technology training, and population-specific training (eg, carceral system processes and harms perpetuated by the carceral system) [51]. Aim 1 system partner interviews will inform additional areas of training relevant to implementing a peer-led model, as well as preferred navigator characteristics (ie, peer navigators will share an age range and at least 1 intersecting identity or experience such as CLI, PrEP use, or substance use treatment with participants).

Intervention Fidelity

During the open pilot, navigators will audio record and complete a checklist documenting the delivery of session material [52]. Navigators will engage in weekly supervision with the principal investigator, and the principal investigator will periodically audit records and conduct field visits to observe sessions (required activities will be rated for completeness using a 4-point scale ranging from 0 "not at all" to 3 "completely").

Exit Interviews

The research team will collect qualitative feedback on the open pilot regarding intervention content, structure, and delivery (type of contact, ie, in-person or over the phone, eHealth [Chorus] enhancement acceptability, and a number of contacts) via individual interviews with CLI-YAs. We will also obtain

feedback from system partners regarding intervention recruitment, referral, delivery, and implementation. The navigator will be actively involved in the intervention pilot testing as well as in making further intervention manual revisions according to their lived experience of navigation delivery. Exit interview data will be analyzed using rapid qualitative analysis methods to reduce the time completing analysis to ensure timely results for use in aim 3; rapid analysis has been shown to have considerable overlapping findings with traditional qualitative analytic approaches [53,54].

Open Pilot Outcomes

In addition to completing a 7-day minimum navigator training, the open pilot's primary outcome is qualitative feedback to assess appropriateness and satisfaction. The results will be used to refine the intervention for pilot testing in aim 3.

Aim 3: Pilot Randomized Controlled Trial Phase

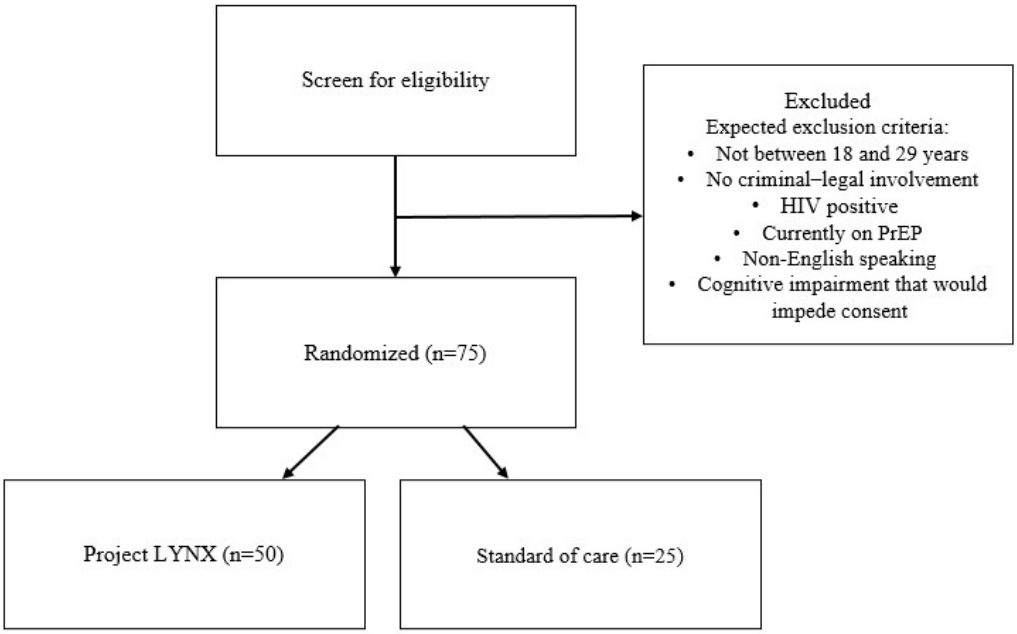
Participants

To assess the feasibility, acceptability, and impact of the adapted eHealth-enhanced intervention for CLI-YAs, we will test the intervention in a randomized pilot trial with CLI-YAs (n=75).

Recruitment and Randomization

Recruitment procedures will be informed by aim 2 results. Participants will be randomized either to the intervention group (n=50) or the standard of care (n=25) using a 2:1 randomization allocation scheme (Figure 2). Figure 3 provides a schematic of our study processes. Each participant will complete a baseline assessment immediately following the consent process. At the end of the baseline assessment, participants will be randomized to the intervention or control condition using a computerized algorithm programmed into REDCap (Research Electronic Data Capture; Vanderbilt University). Randomization will be blocked to avoid "runs" of assignment to the same.

Figure 2. Randomization protocol for aim 3, a 90-day randomized controlled trial designed to link young adults impacted by the criminal legal system to substance use and HIV prevention services in Allegheny County, PA. PrEP: pre-exposure prophylaxis.



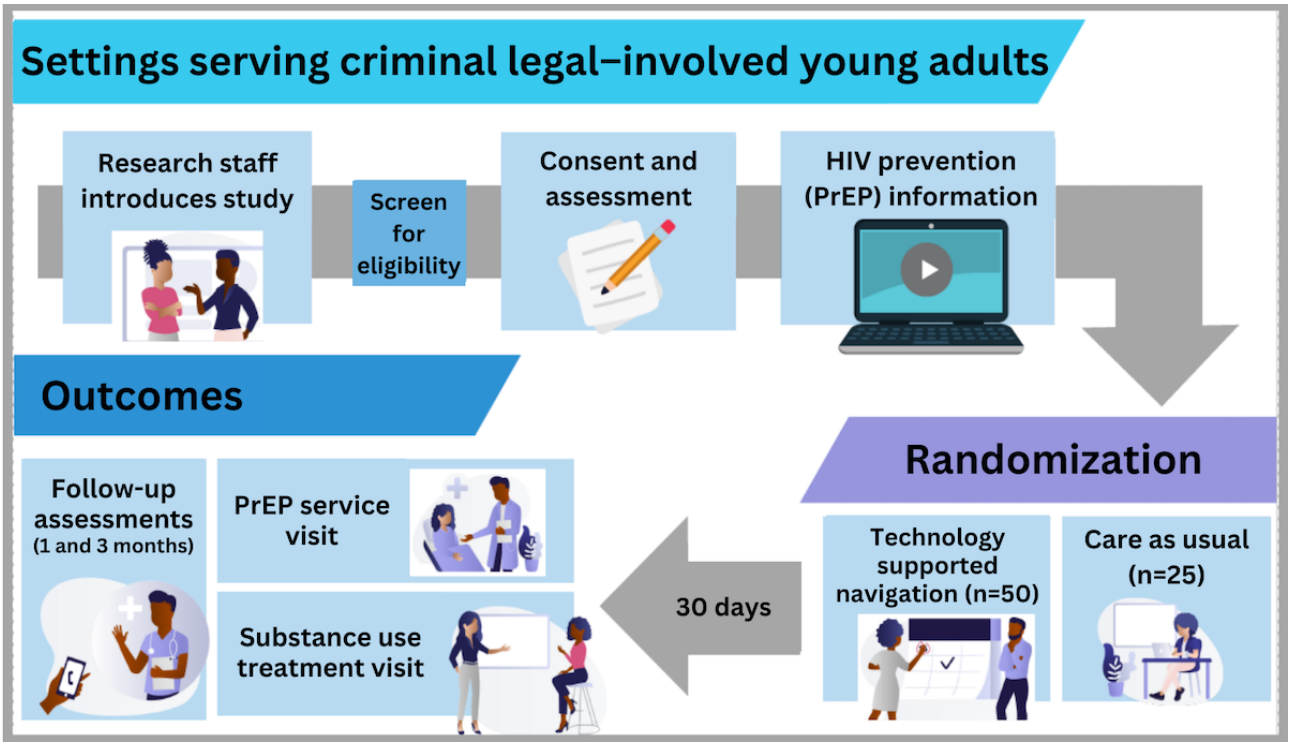
Standard of Care

The standard of care is a referral to substance use treatment and HIV prevention services from an individual's case worker.

Data Collection

The baseline assessment will occur immediately following participant consent, prior to randomization, and follow-up assessments will occur at 1 month and 3 months (Figure 3). Data will be collected via face-to-face one-on-one interviews in private locations to ensure confidentiality. If face-to-face interviews are not possible, a participant will be given the option of completing the assessment via a secure web-based survey link. Regardless of the method of interview administration, REDCap will be used to collect data (ie, in person on tablets or via a secure REDCap survey sent via email). If completing the assessment via a secure link, specific instructions will be provided to the participant to inform them about how to keep their data private.

Figure 3. Recruitment, randomization, and intervention practices for aim 3, a 90-day randomized controlled trial designed to link young adults impacted by the criminal legal system to substance use and HIV prevention services in Allegheny County, PA. PrEP: pre-exposure prophylaxis.



Pilot Trial Outcomes

Primary outcomes are linkage to substance use treatment and PrEP services. Because PrEP and substance use treatment health service linkage are a process and not a 1-time event, we will also explore prelinkage (eg, navigator satisfaction) and downstream outcomes (eg, PrEP initiation, adherence, and substance use treatment continuing of care) in an exploratory fashion [55]. The navigator will track these outcomes, but the primary outcomes of (1) PrEP linkage will be attendance at a PrEP services appointment, verified by medical records and (2) substance use treatment linkage will be attendance at a substance use treatment appointment, verified by the navigator and medical provider collateral (if the participant agrees). Other exploratory outcomes include time to health service linkage (substance use and PrEP) and data on HIV testing at the PrEP linkage appointment (uptake, result). Participants will be asked whether and for how long they have experienced hospitalization, residential treatment, and detention since the intervention to account for any system barriers to linkage. We will also assess preferred methods for communicating with the navigator as well as participant satisfaction with the intervention and navigator services. Table 1 provides additional detail on outcomes and correlates.

Table 1. Description and schedule of outcomes from a 90-day randomized controlled trial designed to link young adults impacted by the criminal legal system to substance use and HIV prevention services in Allegheny County, PA.

Primary outcomes	Baseline	30 days	90 days
PrEP[a] linkage: medical record		✓	✓
Substance use treatment linkage: self-report, medical provider collateral if the participant agrees		✓	✓
Secondary outcomes			
Navigator satisfaction: NAVSAT Pt 1		✓	
Client intervention satisfaction: Study Participant Feedback Questionnaire	✓	✓	✓
PrEP care continuum (accepted, initiated, and adhered): navigator report, medical record, and self-report		✓	✓
Substance use treatment continuum (accepted, initiated, and adhered): navigator report, medical record, and self-report		✓	✓
Linkage to other services: self-report and Navigator report		✓	✓
Sociodemographic, psychosocial, and behavioral correlates			
Demographic information (age in years, race or ethnicity, legal history, etc)	✓		✓
Health care use	✓		✓
Medical mistrust: Health Care System Distrust Scale	✓		✓
HIV knowledge or attitudes or risk: HIV-related knowledge scale, HIV-related attitudes scale, HIV stigma scale	✓		✓
PrEP knowledge or attitudes: willingness, intentions to use, barriers, stigma or conspiracy beliefs	✓		✓
Substance use: Alcohol use Disorders Identification Test, Texas Christian University Drug Screen V, Internalized Stigma of Substance Abuse	✓		✓
Psychiatric symptoms: Global Appraisal of Individual Needs-Short Screener	✓		✓

[a]PrEP: pre-exposure prophylaxis.

Data Management and Analysis

REDCap will facilitate routine data checking and exportation of data for analysis. Analyses will be conducted using SAS (version 9.4; SAS Institute). Preliminary analyses will include the examination of descriptive statistics, distributions, and internal consistency reliability of scaled measures. Logistic regression will be used to examine the relationship between the condition and the primary outcomes (services linkage, ie, PrEP, substance use treatment), and all other dichotomous outcomes (eg, acceptance of PrEP and substance use treatment referral). Dependent variables in initial analyses will be summary dichotomous indicators based on both month 1 and 3 assessments, reflecting whether the outcome ever occurred. Subsequent analyses will separately examine whether outcomes occurred by month 1 and by month 3. Generalized linear models will be used to examine variously distributed continuous outcomes (navigator contacts, time-to-service linkage, and satisfaction). Exploratory analyses will build on these models to preliminarily examine the impact of potential moderating variables including sociodemographic characteristics, HIV risk behaviors and perceptions, PrEP-related knowledge and attitudes, substance use treatment behaviors, psychiatric symptoms, social support, and substance use on primary and secondary outcomes.

Exit Interviews

We will conduct exit interviews with a subsample of intervention arm participants (n=10), the navigator (n=1), and partners from participating systems (n=4). Interviews will assess intervention acceptability and suggestions for improvement. To recruit for qualitative exit interviews, a member of the study team will contact intervention participants to invite them to a phone interview (~30 minutes). To ensure a range of responses, we will sample for (1) participants who connect or did not connect to the navigator and who linked or did not link to PrEP and substance use treatment services and (2) variation in characteristics that may impact the intervention (eg, psychiatric symptoms). We will seek to understand reasons why the intervention was or was not successful for a particular participant (via participant and navigator report). To analyze exit interview data, we will mirror aim 2's rapid qualitative analysis processes.

Ethical Considerations

Overview

This study was approved by the University of Pittsburgh internal review board (reference 22020053). As the intervention is refined, changes to the protocol will be submitted to the internal review board for further approval. Additional protections for participants are provided via a Certificate of Confidentiality through the National Institute of Health. This certificate allows the researchers to legally refuse to disclose information that may identify participants, even by a court subpoena, in any federal, state, or local civil, criminal, administrative, legislative, or other proceedings. To ensure confidentiality, all data will be deidentified and participants will be assigned a unique participant ID. Participant contact information will be stored

separately from any data that have been collected (eg, screening surveys, transcripts, and assessments).

Aim 1: Development Phase

CLI-YA

To determine eligibility, participants will undergo a confidential screening survey with study personnel. Following screening, participants will be compensated US $10 regardless of eligibility status. Eligible participants will undergo a verbal consent process with study personnel prior to participating in focus groups. The consent process will include (1) a review of the information sheet in detail, (2) an explanation of all study procedures in full detail, and (3) an opportunity for the participant to ask questions and have them answered. Potential participants will be asked to paraphrase the information sheet and will be asked basic questions to determine their understanding of key elements of the informed consent. Participants will be compensated US $40 following focus group participation.

System Partners

Prior to participating in interviews, system partners will undergo a verbal consent process that follows the same protocol as the focus group consent process outlined above. Participants will be compensated US $50 following completion of an individual interview.

Aim 2: Pilot Trial Phase

Prior to participation in the pilot trial, CLI-YAs will undergo a 2-step consent process. Potential participants will be given an information sheet and provide verbal informed consent for screening. Next, should individuals be interested in participating and eligible based on their HIV risk assessment and SUD screening, they will provide written informed consent to allow participation in the open pilot navigation intervention and exit interview. Participants will be compensated US $40 for participating in exit interviews.

Aim 3: Assessment Phase

The consent process for aim 3 follows the same 2-step process as outlined above for aim 2. Participants will be compensated US $40 for the baseline assessment, US $20 for the 1-month assessment, US $40 for the 3-month assessment, and US $30 for participating in exit interviews.

Results

The project was funded in September 2022. Internal review board approval was received on March 21, 2022. Data collection for aim 1 began on April 19, 2023, and is ongoing. At the time of publication, 5 system stakeholders and 16 CLI-YAs have been enrolled in aim 1 data collection activities. The first results from early study aims are expected to be published in 2025.

Discussion

Principal Findings

This study provides an opportunity to reduce HIV acquisition and improve access to substance use treatment in a systemically marginalized group of YAs. This emerging area of research has been rapidly amplified in the context of the ongoing coronavirus pandemic, for which empirical study of effective adjunctive technology tools to promote increased substance use and HIV prevention services access is greatly needed. The results will contribute to the development and testing of a future multilevel randomized controlled trial targeting CLI-YAs, CL system partners, and treatment providers.

Gaps in Literature and Comparisons With Prior Work

Previous studies leveraging peer navigation as a mechanism to link CLI individuals to HIV care have proved efficacious [19,20]. Patient navigation interventions led by individuals who share key personal characteristics, circumstances, or qualities with their participants (eg, ethnic background, culture, and membership in a subpopulation [formerly engaged in transactional sex or IDU]) or “peers” are ideal because they have demonstrated efficacy in building trust and reducing stigma and discrimination-related barriers to health care engagement, particularly among vulnerable populations [24,56]. The inclusion of eHealth technology in patient navigation is appealing because it provides a discrete platform for individuals to engage with potentially stigmatizing services (eg, substance use treatment and HIV prevention services). It also has the potential to facilitate frequent, meaningful communication between individuals and their peer navigators. Previous studies have found eHealth-enhanced peer navigation effective in maintaining viral suppression among people living with HIV [21]. However, there has been little research using this framework to link CLI-YAs to HIV prevention and substance use treatment services. This study will fill an important gap in the literature and provide insights that will inform future efforts to improve service linkage for CLI-YAs, a vulnerable and structurally precarious population [57].

Strengths and Limitations

A core tenet of this study is the codevelopment of the eHealth technology and navigation protocol. Including the perspectives of individuals who are a part of the population of focus, in addition to system partners, ensures the intervention will be reflective of the wants and needs of the community it will be serving. The inclusion of system partners and people with lived experience in the CoP is important but comes with challenges due to encounter challenges related to power dynamics between these groups. For example, individuals with lived experience may be hesitant to share their thoughts and opinions when they are in a room of service providers and system partners with whom they might already be familiar. The study team will begin each meeting with an overview of agreements and expectations and moderate the discussion to mitigate issues as they arise; however, we acknowledge the challenge that navigating these relationships might pose.

Additionally, the technology being developed will not be a native app. The benefit of this is that it will be accessible from a mobile device or a computer, which ensures that participants will be able to access the technology whether they have regular access to a mobile device. However, data will not be stored directly on a participant’s personal device, so it will not be accessible without an internet connection. This could be a

limiting factor for participants who have a phone but do not have regular internet access.

The inclusion of the eHealth portion of the study has the potential to expand access to linkage services for CLI-YAs. This is especially important because CLI-YAs experience structural and institutional obstacles that can hinder their ability to regularly engage in services [57]. However, there is no funding to distribute phones to participants if they do not have them. This may limit the eHealth functionalities available to participants who do not have phones (eg, SMS text messaging) and may make it difficult for them to engage in the intervention in the same way as participants with their personal devices. We will measure where and how participants are engaging with the technology to better examine the impact of technology access.

Conclusions

This study provides an opportunity to reduce HIV acquisition and improve access to substance use treatment in a vulnerable, underserved group of young adults (CLI-YAs) by adapting an evidence-based navigation intervention and incorporating eHealth technology. The need to further this line of research has been rapidly amplified in the context of the COVID-19 pandemic, for which empirical study of effective adjunctive technology tools that can promote access to substance use and HIV prevention services is greatly needed. The results will contribute to the development and testing of a future multilevel randomized controlled trial targeting CLI-YAs, CL system partners, and substance use treatment and PrEP providers.

Acknowledgments

With gratitude, the authors acknowledge the participants in previous studies whose pilot data contributed to this grant being funded. The funding for this study was provided by the National Institute on Drug Abuse (grant R34DA054853; EFD principal investigator).

Data Availability

The data sets generated in this study are available from the corresponding author upon reasonable request.

Authors' Contributions

SLC wrote the original draft and contributed to manuscript review and editing, and is assisting with project administration. SS and NM supported the writing of the original draft and contributed to manuscript review and editing, and is assisting with project administration including conducting data collection activities and supporting data analysis, and contributing to intervention refinement JJM, MS, and MTS contributed to project conceptualization and manuscript review and editing. EFD led the conceptualization of the project and the development of the proposed methodology, acquired project funding, supported the writing of the original draft and contributed to manuscript review and editing, and is leading the overall project administration.

Conflicts of Interest

None declared.

Abstract

Background: The use of naloxone, an opioid antagonist, is a critical component of the US response to fatal opioid-involved overdoses. The importance and utility of naloxone in preventing fatal overdoses have been widely declaimed by medical associations and government officials and are supported by strong research evidence. Still, there are gaps in the current US national strategy because many opioid-involved overdose fatalities have no evidence of naloxone administration. Improving the likelihood that naloxone will be used to prevent fatal overdoses is predicated on facilitating an environment wherein naloxone is available near each overdose and can be accessed by someone who is willing and able to use it. How to accomplish this on a national scale has been unclear. However, there exists a national network of >1 million cardiopulmonary resuscitation (CPR) layperson responders and 4800 emergency responder agencies linked through a mobile phone app called *PulsePoint Respond*. *PulsePoint* responders certify that they are trained to administer CPR and are willing to respond to possible cardiac events in public. When such an event occurs near their mobile phone's location, they receive an alert to respond. These motivated citizens are ideally positioned to carry naloxone and reverse overdoses that occur in public.

Objective: This randomized controlled trial will examine the feasibility of recruiting first responder agencies and layperson CPR responders who already use *PulsePoint* to obtain overdose education and carry naloxone.

Methods: This will be a 3-arm parallel-group randomized controlled trial. We will randomly select 180 first responder agencies from the population of agencies contracting with the PulsePoint Foundation. The 3 study arms will include a standard recruitment arm, a misperception-correction recruitment arm, and a control arm (1:1:1 allocation, with random allocation stratified by zip code designation [rural or nonrural]). We will study agency recruitment and, among the agencies we successfully recruit, responder certification of receiving overdose and naloxone education, carrying naloxone, or both. Hypothesis 1 contrasts agency recruitment success between arms 1 and 2, and hypothesis 2 contrasts the ratios of layperson certification across all 3 arms. The primary analyses will be a logistic regression comparing the recruitment rates among the arms, adjusting for rural or nonrural zip code designation.

Results: This study was reviewed by the Indiana University Institutional Review Board (20218 and 20219). This project was funded beginning September 14, 2023, by the National Institute on Drug Abuse.

Conclusions: The hypotheses in this study will test whether a specific type of messaging is particularly effective in recruiting agencies and layperson responders. Although we hypothesize that arm 2 will outperform the other arms, our intention is to use the best-performing approach in the next phase of this study if any of our approaches demonstrates feasibility.

Introduction

Background

In 2017, the US Acting Secretary of Health and Human Services formally declared that the opioid overdose crisis in the United States is a public health emergency [1]. Since that time, the prevalence of morbidity and mortality related to opioid overdoses has gotten substantively worse [2]. Beyond the prima facie impact of tens of thousands of overdose-involved deaths annually, the secondary impacts of the crisis strain the health care system across numerous axes; for example, even in 2013, when annual fatal prescription overdose incidence was "only" 16,235 persons, scientists at the Centers for Disease Control and Prevention found that these fatal cases accrued US $21.5 billion in costs [3]. The magnitude of the emergency is such that even in the midst of major global news on multiple fronts, news stories about fatal opioid overdoses are ubiquitous, often with calls from family members to build awareness and seek solutions [4]. Overdose and harm reduction strategies (including naloxone administration) have also received direct attention from the federal government, including as part of the 2023 State of the Union address [5].

Naloxone Is a Critical Part of the US Overdose Emergency Response

Naloxone (including Narcan, Kloxxado, Evzio, Zimhi, and other formulations) is an opioid antagonist that can be used to reverse an opioid overdose and restore breathing, converting a potentially fatal overdose into a nonfatal overdose [6,7]. Even before the formal declaration of a public health emergency around opioids, the Department of Health and Human Services included expanded use and distribution of naloxone in its 3 priority areas to address the overdose epidemic [8]. The importance and utility of naloxone have been widely declaimed, including by the American Medical Association ("should be available almost everywhere") [9], the American Society of Addiction Medicine ("remarkably effective, inexpensive and safe") [10], and the US Surgeon General ("Be Prepared. Get Naloxone. Save a Life.") [11]. Such statements are predicated on strong evidence of, and arguments for, naloxone's effectiveness and utility in reducing fatal opioid-involved overdoses [12-16].

Barriers Exist That Inhibit Proliferation of Expedient and Effective Overdose Responses

Data from 2019 indicate that in the majority of fatal opioid-involved overdoses, there is no evidence of naloxone administration [17]. Given the current evidence for the effectiveness of overdose education and naloxone distribution (OEND) programs [12-16], the national expansion of such programs [18,19], and simultaneous high rates of fatal opioid-involved overdoses without naloxone administration [17], we might reasonably conclude that there are one or more gaps in the current US national approach to opioid-involved overdose reversal.

For many years, the lack of availability of naloxone has been seen as a primary barrier. Most states have passed legislation intended to increase layperson access to naloxone and provide limited legal immunity to those who administer naloxone to persons experiencing an opioid-related overdose [10]. By 2021, a total of 47 states and Washington, District of Columbia, had enacted both Good Samaritan and naloxone access laws [20], and programs to facilitate distribution of naloxone to laypersons have steadily become more common [18], especially since 2010 [19]. Unfortunately, a 2018 study in Indiana and Arizona found that such policies did not always sufficiently facilitate layperson access [21]. The availability of naloxone *at cost* will likely increase in the United States in the next several years given a recent 19-0 US Food and Drug Administration advisory committee vote in favor of granting some naloxone products over-the-counter (OTC) status [22]. However, national data from a similar OTC change in Australia suggest that people may not automatically begin purchasing naloxone in response [23] (eg, other factors such as willingness may be salient).

More ubiquity in carrying and being willing to use naloxone is critical because, as described by Kim et al [24], the efficacy of naloxone is fundamentally time dependent. Brain injury from hypoxia is more likely the longer oxygen deprivation occurs [25]. In some cases, overdose death from heroin can be extremely rapid [26], and death typically occurs within 1 to 3 hours [27]. Overdoses from fentanyl and fentanyl analogs often present differently than other opioid overdoses and may be even more likely to rapidly result in fatality [28]. Thus, it is important that naloxone is *present at or near the scene* and *used as quickly as possible.* Unfortunately, despite a surge in OEND programs in the United States, relatively few people carry and are willing to use naloxone [29].

Misperceptions About Naloxone and Overdose May Inhibit OEND Programs

Evidence suggests that misperceptions about overdose and naloxone, as well as stigmatizing beliefs about people who use drugs, may affect both layperson and first responder willingness and interest in carrying and using naloxone [29-33]; for example, first responders may be ambivalent about "providing naloxone to those they deem undeserving" [34], and a review found that stigmatizing attitudes among first responders may reduce the likelihood of bystander response [35]. Some first responders have noted that laypersons in their communities may fear "real and perceived cultural opposition" to harm reduction strategies [36]. Such reticence and stigma may even persist after OEND training [29,37] and have been described as fundamentally hindering the US response to the opioid overdose crisis [38].

To the best of our knowledge, the prevalence of specific belief statements about naloxone and overdose that do not align with current scientific evidence had not been explored in depth until 2022 [39]. We conducted a study (using the Prolific platform) consisting of 702 respondents who were representative of the US adult population across race, ethnicity, gender, and age. Several misperceptions around naloxone and overdose were fairly common in our sample, and there was a surprisingly large minority of participants (approximately one-seventh of the sample) who believed that users could "get high on naloxone" [39]. We also observed potential evidence of cognitive dissonance about OEND; specifically, large latent profiles simultaneously believed, in the framed context of naloxone reversing an opioid overdose, that "if trained and provided with naloxone, bystanders can effectively prevent overdoses in the community" and "opioid users will use more opioids if they know they have access to naloxone" [39].

Our Proposed Study to Mitigate Barriers to Effective Overdose Response

Improving the likelihood that naloxone will be used to prevent fatal overdose is logically predicated on facilitating an environment wherein naloxone is available near each overdose and can be accessed by someone who is willing and able to use it. Conceptually, in a given community, the likelihood of an opioid overdose in the given community being reversed with naloxone is proportional to the likelihood that a trained person with access to naloxone is nearby, willing to administer it, and aware of the need. As noted, current approaches to OEND have not succeeded in reaching the threshold of sufficient coverage. With too few trained persons and sparse coverage, overdose survivability can be subject to the whims of chance, something implicitly recognized even in how lay news sometimes covers overdose reversals ("finds herself in the right place at the right time" [40]).

Recent, innovative pilot work demonstrated that a smartphone app (*UnityPhilly*) could support overdose reversal in a small group of volunteers [41]. Other innovative projects include multifaceted technology-based efforts by Brave Technology Co-Op [42]. In these cases, building to scale will take substantial time and investment. However, it may also be possible to integrate OEND within widespread but existing systems that perform other but similar services. Our particular interest is in a large, highly engaged system for cardiopulmonary resuscitation (CPR) that already exists nationally (*PulsePoint*), with >1,085,000 active monthly layperson users across approximately 4800 communities overseen by >755 agencies [43]. These individuals respond to unconscious and unresponsive persons within a prespecified radius of their smartphone based on alerts generated by local first responder agencies. While *PulsePoint* does not specifically generate alerts for an opioid overdose, the designation *unconscious and unresponsive* can refer to individuals possibly in need of CPR or those who may need overdose reversal; therefore, these laypersons are likely already responding to possible overdoses. However, they are neither systematically being encouraged to receive training around overdose and naloxone nor being reminded to carry naloxone.

We believe that the *PulsePoint* network may be an effective means of achieving widespread OEND coverage in the United States. With this preliminary study, our goal is to better understand whether and how it is feasible to recruit first responder organizations and *PulsePoint*-connected laypersons to broaden the scope of their voluntary service to include opioid overdose reversal.

Objectives

Overview

We will conduct a feasibility trial to assess whether, in a random sample of 180 agencies where *PulsePoint* is already active, revised procedures (hereinafter *PulsePoint-OD*) to facilitate OEND can successfully recruit first responder agencies and layperson responders. For this study, *agency* refers to a single implementation site where *PulsePoint* is active and that is bound by the service area or jurisdiction of the first responder agency collaborating with *PulsePoint* (we provide more detailed information about agencies in the *Methods* section).

Using a parallel-group randomized controlled trial design, we will randomize 180 agencies using a 1:1:1 allocation ratio within strata to 1 of 3 arms: arm 1 (*PulsePoint-OD*, which will include the recruitment of coordinating community first responder agencies; targeted recruitment, eg, push messages, aimed toward 100% of the active *PulsePoint* users in these communities; ongoing solicitation for training of these users; and naloxone facilitation), arm 2 (same as arm 1 but with stigma-focused misinformation-debunking messages embedded), or arm 3 (a control condition).

Hypotheses

We will test the following hypotheses:

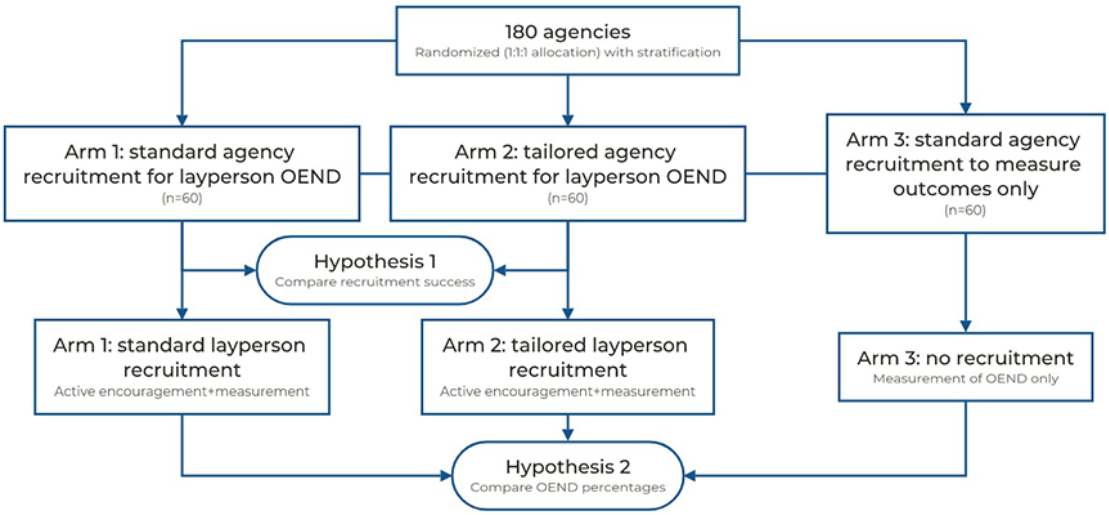
- H1: more first responder agencies will be successfully recruited by arm 2 than by arm 1.
- H2: more layperson responders will report engaging with OEND programming in arm 2 than in arms 1 or 3 and in arm 1 than in arm 3.

As an exploratory follow-up, we will conduct incentivized qualitative follow-up interviews with agencies to better understand barriers to participation and how to improve uptake feasibility.

Methods

As the participant types for H1 and H2 are different, we provide separate methodologies for each hypothesis. A conceptual diagram of the study and hypotheses is provided in Figure 1.

Figure 1. Conceptual diagram of the study and hypotheses. OEND: overdose education and naloxone distribution.



H1: First Responder Agencies

Parameters

The following parameters describe the interrelationships between communities and agencies for this study:

- The PulsePoint Foundation reports that approximately 4800 communities currently use the *PulsePoint* app.
- Community participation and the use of the *PulsePoint* app are supported by agency contract holders; there are >755 such contracts in place.
- A contract-holding agency can serve multiple communities (eg, a county 911 office can offer *PulsePoint* to 9 different communities in the county, such as townships). An agency can also serve a single community (eg, a city fire department can offer *PulsePoint* to that city only).
- Any number of *additional* first responder agencies (eg, fire or police departments, emergency medical services, 911 call centers, or related entities) can contribute to a community or cluster of communities covered by a single *PulsePoint* contract, but these agencies are not contract holders.

When *PulsePoint* is introduced to a community for layperson use, the PulsePoint Foundation neither directly recruits nor interfaces with individual lay responders. Instead, the contracted first responder agencies conduct local recruitment and have the ability to send *push messages* (app-driven notices and messages) to users. Therefore, to integrate OEND into the *PulsePoint* network (eg, *PulsePoint-OD*) and for our study team to directly contact the subset of active users within each study community, it is necessary that the contract-holding first responder agencies in each community agree to participate. This first phase of the overall study (and the first hypothesis) pertains to agency-level recruitment.

Participants, Eligibility, and Assignment

We will use the complete list of *PulsePoint* contracting agencies as constituted approximately 3 months before the study start date (to ensure sufficient experience with the *PulsePoint* program) as the population from which to draw a random sample. At present, this list includes >755 agencies, but the actual number will vary depending on the final start date and changes in *PulsePoint* membership.

All active agencies on the final list will be eligible for sampling and randomization, with 2 exceptions. First, an agency will be excluded (and a replacement resampled and assigned to the same study arm) if further communication identifies that it is not actually a *PulsePoint* subscriber. Second, we will exclude agencies a priori or a posteriori if we learn of a similar project being conducted, or having been conducted, with *PulsePoint* with the agency. Random sampling of communities will be accomplished by having a study statistician generate a random sequence of numbers, including all values between *1* and *X*, where *X* is the total number of eligible agencies. These numbers will be directly overlaid on the list of agencies, and agencies with the lowest 180 numbers will be selected. These numbers will also be carried forward to indicate the random arm assignment.

Agencies will be randomly assigned to a study arm using stratified allocation, with a 1:1:1 allocation ratio. Specifically, one-third of the rural agencies will be randomly assigned to each study arm, and separately, one-third of the nonrural agencies will be randomly assigned to each study arm. We will determine rural status using the definition from the US Office of Management and Budget (zip codes within metropolitan areas with an urban core of ≥50,000 people are not rural, and all other areas are rural [44]). In cases where agencies hold *PulsePoint* contracts that cover both rural and nonrural areas, we will assign a status based on the location of the numeric

majority of the population in the area. Arm assignment will be according to sequential numbers (from the simple random sample; therefore, this allocation approach is also by definition random) within each stratum (eg, if there are 60 rural agencies, the 20 rural agencies with the lowest random numbers will be assigned to arm 1). This procedure will ensure allocation concealment from the rest of the investigative team until the moment of assignment. Agencies will not be informed that they have been assigned to a specific trial arm; they will simply be contacted using the procedures developed for that arm. Thus, this can be considered a blinded trial.

Establishing Correspondence With Local PulsePoint Decision Makers

Although the PulsePoint Foundation will provide us with a list of participating agencies, its database does not include raw contact details (eg, telephone number and email address), and even these details may not link our study team with the people within the agency who manage the *PulsePoint* system. On the basis of discussions with the PulsePoint Foundation, the following examples describe cases that have occurred in the past:

- The point of contact on the agency list may be the accounting or billing representative for the agency, not the person who manages the program, especially among long-term subscribers.
- The decision makers for the agency may be different now than when the subscription to *PulsePoint* was purchased.

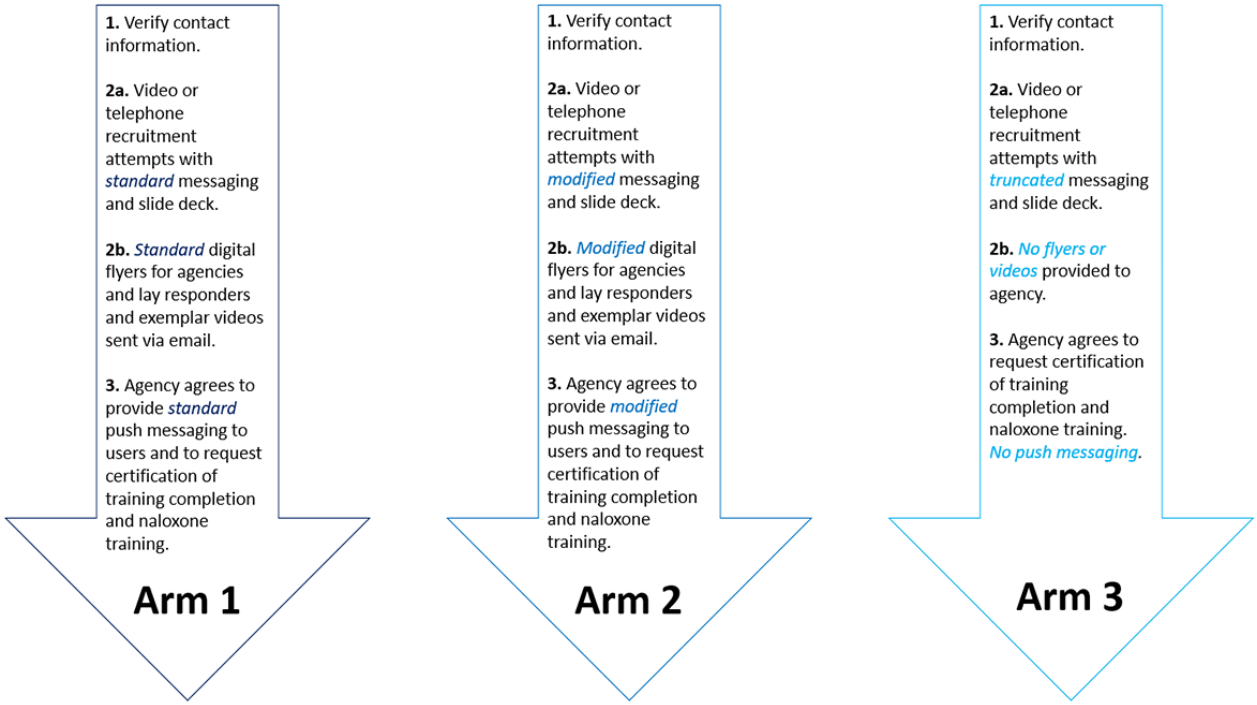
We will need to locate contact information for agencies and verify that the contact details link us with the person who manages the *PulsePoint* subscription, and if not, identify who in the agency does so and how to contact them. In other words, while our trial is intended to study recruitment strategies, we must first ensure that we can access the appropriate individuals at an agency. Once we have identified these points of contact, we can begin recruitment at the agency.

Intervention (Recruitment) Arm 1

Overview

The minimum goal of agency recruitment is to reach a memorandum of understanding (MOU) with agencies in which they agree to encourage their layperson *PulsePoint* responders to attend OEND programming and to carry naloxone (arms 1 and 2) and to indicate whether they have done so (arms 1, 2, and 3; Figure 2). The agencies will be asked to accomplish this using push messages prepared by our team and sent out by the agencies; the specific nature of these agency activities is outlined in the *H2: Layperson Responders* section.

Figure 2. Differing agency recruitment procedures for the PulsePoint-OD study by study arm.



Development

Our agency recruitment materials will be developed during the first phase of the study and provided in full when the study results are published. Oversight and review of marketing development will be provided by members of the study team and marketing consultants external to the study team. Review of all marketing materials will be granted to the PulsePoint Foundation (a not-for-profit 501[c][3] organization) to ensure consistency with the organization's branding. As a result of the development timeline, the exact phrases and examples used to illustrate components of the recruitment processes may change between the submission of this paper and the launch of the study.

Approaches

To be replicable at scale, recruitment will be conducted using a combination of video or telephone correspondence (preferably Zoom [Zoom Video Communications, Inc], but telephone where necessary), web links, and emails containing tangible materials. A full recruitment attempt with fidelity to our model will consist

of providing emailed materials and web links and attempting between 6 and 10 telephone contacts over approximately 6 months, based on best practice telephone recommendations from the American Association for Public Opinion Research [45]. Recruitment efforts will stop in the event that (1) an agency agrees to participate in the project, (2) an agency asks not to be contacted about the project again, (3) the aforementioned recruitment approaches clearly seem unlikely to yield a change in disposition, or (4) the recruitment timeline ends without the agency making a decision.

Materials

Members of our project staff will develop a short visual presentation to be used as a guideline for videoconference recruitment, along with a parallel set of core written or verbal statements reflecting the content of the presentation in cases where only telephone calls are possible. Drawing lessons from our previous successful agency and organization recruitment experiences [46-49], both the presentation and written statements will cover a limited list of important concepts that need to be imparted (eg, "Participating in this project will require very little time from your agency – we are only asking you to send out one push message each month."). While moving through these concepts, we will allow conversation to flow freely (eg, semistructured messaging) and also use live documentation of key concepts to ensure message fidelity.

The tangible documentation will consist of digital flyers based on the open-source marketing tools developed by the PulsePoint Foundation for general community agency recruitment, including the use of similar graphical assets and fonts. However, flyers will be differentiated sufficiently from the default *PulsePoint* flyers to make it clear that the organization itself is not conducting this project (eg, we will not use the *PulsePoint* logo). For reference, *PulsePoint*-branded recruitment flyers can be viewed by clicking on the hyperlink provided in the associated reference [50]. As community agencies have already committed to offering standard *PulsePoint* services, we expect that distributing these modified documents to agencies will be a high-leverage recruitment approach. Key messaging will be drawn from local demonstration projects by the study team (eg, "Be a Lifesaver" and "Citizen Opioid Responders") [51] as well as general marketing and recruitment principles.

As supplemental recruitment content, exemplar videos will be drawn from work produced by the Dearborn County Health Department in Lawrenceburg, Indiana, in collaboration with the study authors to create awareness of this type of initiative and will be included as web links to YouTube versions of the videos [51].

After Recruitment

When communities agree to participate, they will be asked to sign an MOU regarding their participation and to respond to a small set of readiness and implementation items, such as whether the organization is already involved in naloxone distribution and whether there are local laws pertaining to opioid overdose reversal. This information will be used to locally tailor piped text into messages used for H2 (layperson recruitment).

Intervention (Recruitment) Arm 2

The recruitment procedures for arm 2 will be similar to those outlined for arm 1. The primary difference will be that the messaging in arm 2 will proactively address several misperceptions or stigmatizing ideas about overdose and naloxone that our recent research has suggested may be prevalent [39]. In particular, content in the fact sheets and scripts for recruitment used in arm 2 will address and preempt the following scientifically unsupported ideas (potentially among others):

- "Naloxone causes risk compensation or presents a moral hazard": it is fairly well established that OEND is not associated with increased opioid use [52-55], nor is it associated with reduced risk perceptions for heroin use [56].
- "Repeated overdoses are inevitable and people who experience nonfatal overdoses will die of an overdose in the near future": while individuals who nonfatally overdose are at meaningfully increased risk, especially if they do not matriculate into a cascade of care, the substantive majority will not overdose again in the near future, and even fewer will die of a fatal overdose in the near future [57-60].
- "Individuals can get high from naloxone": while this is not possible [6], our study found that 14.2% of our nationally-representative sample still believed this claim [39] to some extent.

Though brief, our debunking content will follow specific procedures that recent research (particularly around COVID-19 misinformation and vaccine hesitancy) has found to improve the efficacy of debunking messaging. These include ensuring the credibility of the source of the factual correction [61] and including a sufficient level of detail and explanation for *why* the facts are correct and the misperceptions are not [62]. This level of detail will vary in extensiveness depending on the format of a given piece of communication. The use of such short-format corrections does not seem to result in a backfire effect [63]; for example, a statement made in the arm 1 recruitment flyer (standard) might be, "Overdoses involving opioids are a public health emergency in the United States (US). The US Surgeon General recommends: 'Be Prepared. Get Naloxone. Save a Life.'" The permutation for the arm 2 recruitment fact sheet (modified), in parallel, would be, "Rapid use of naloxone (Narcan) nasal spray is often an overdose victim's best chance for survival. Studies show that opioid use in a community does not increase when naloxone is widely available."

Inert Arm for H1 (Arm 3)

Arm 3 recruitment will mirror recruitment for arm 1, except that the stated goal for the agencies will be only to ask layperson respondents to indicate at 3 different time points whether they have attended OEND programming or carry naloxone (eg, no encouragement or messaging campaign will occur in this arm). This arm will not be actively analyzed when we test H1.

Outcome Variables and Measurement

In H1, we hypothesize that more community first responder agencies will agree to participate in the *PulsePoint-OD* program when contacted using procedures in arm 2 (tailored messaging)

compared to procedures in arm 1 (standard messaging) within 6 and 12 months of initial contact. Our primary outcome to test this hypothesis will be the number of agencies that agree to participate in the project as a percentage of the number of agencies with which we have been able to identify appropriate points of contact for recruitment. This metric *M* will be computed as follows:

- Each agency from the initial PulsePoint Foundation list that is randomized to participate in the study will be given a value *A* that is set at *0*, which indicates that we have not yet identified the appropriate point of contact at the agency.
- When we have identified a point of contact who can discuss *PulsePoint*, we will set the value for *A* at *1*.
- To define when a community first responder agency has agreed to participate, each agency will be assigned an ordinal value *R* ranging from *0* to *2*, where *0* will indicate nonparticipation or refusal, *1* will indicate that there is an agreement in principle to participate but that no formal MOU has been established, and *2* will indicate that a formal MOU has been put into place between the agency and the study team. For the purposes of hypothesis testing, we will aggregate values of *1* and *2*, but the data will be documented in ordinal form so that we can identify whether there is a concern with agencies failing to enter the MOU stage after agreeing in principle to participate.
- Next, the agency recruitment metric *M* for each arm will be the ratio of recruited agencies to total agencies with which active communication has been established: $M=(R_{R>0}/A_{A>0})$.

In addition to computation of the primary outcome metric, recruitment activities will be documented in a shared internal database, which will track, at a minimum, the nature, date, and outcome of each instance of correspondence with each community to inform our understanding of the uptake of *PulsePoint-OD* among *PulsePoint* communities and support ongoing mitigation of any issues with recruitment. Using this documentation, we will be able to estimate several secondary descriptive outcomes:

- An estimate of the dose-response uptake of the intervention (eg, mean number and types of correspondence associated with agreement to participate and completion of an MOU)
- An estimate of the average length of time between initial contact and agreement to participate

H1: Sample Size, Power, and Analysis

Although we plan for 180 agencies to compose the total sample size, only 120 (66.7%) will be allocated to arms 1 (n=60) and 2 (n=60), meaning that the sample size for this hypothesis is 120. With 60 agencies in each arm, we will have 80% power to detect significant differences (2-tailed α=.05) between arms 1 and 2 in the proportions of agencies that are successfully recruited if the difference in proportions is at least 0.25 (eg, 18/60, 30% recruited in arm 1 vs 33/60, 55% recruited in arm 2). The primary analysis will be conducted using logistic regression, comparing the recruitment rate between the arms. We will report exact P values and commit to a cautious interpretation of the findings, avoiding overreliance on P values as the single arbiter of meaning [64]. We do not expect any missing data in the outcome variable because the nature of its computation is such that missing data mean that either *A=0* or *R=0* and are therefore built into outcome variable *M*.

The primary study outcome (*M*) will be tested separately for the periods 6 and 12 months after initial recruitment correspondence. Analysis covariates are planned to include, but may not be limited to, community rurality and the community's percentage vote share for the Republican candidate in the 2020 presidential election (available for 2523 US counties and separable by zip code [65]), given that political orientation was 1 of 2 strongly predictive variables in our regression model examining misperceptions of OEND [39].

H2: Layperson Responders

Overview

Layperson responders who are part of the *PulsePoint* system register with a local first responder agency using their smartphone. Most layperson responders (eg, those who are not also off-duty first responders themselves) are only alerted to incidents in public spaces. No identifying information is collected from these users except the unique ID of the device.

The first responder agency in each community that manages the *PulsePoint* subscription can only determine the number of active users and, broadly, the type of smartphone being used (eg, Android smartphone or iPhone). Each time a first responder agency sends out a push notification, it is provided with an exact count of the number of unique devices, separated by type, that were active in the system and reached by the message.

It is important to note that we will have a count of unique active devices but not necessarily a count of unique active users (eg, it is unlikely but possible that someone will install the app on 2 different mobile phones at the same time). In correspondence with the PulsePoint Foundation, it is likely that the count of unique active devices serves as a very close approximation of unique active users. Furthermore, by virtue of randomization, the distribution of any unmeasured anomalies related to user-device mismatches should be evenly distributed across the arms.

Conceptualizing Recruitment for Layperson Responders

Currently, for a *PulsePoint* user to be officially recruited as a CPR responder and to be sent notifications regarding unconscious and unresponsive persons in public places, they need to affirmatively indicate that they are trained in CPR *and* are "willing to assist in case of an emergency." Individuals who so verify are sent push alerts and auditory alert tones, regardless of whether the app is open, whenever there is an unresponsive and unconscious person within a specific radius of their mobile phone (the radius is specified by the first responder agency for that community) [66].

For the purposes of this study, a layperson responder will be considered to have been recruited for *PulsePoint-OD* if they certify that they have received training on overdose and naloxone and that they currently carry naloxone on their person (both outcomes are of interest, which we describe later in the *Outcome Variables and Measurement* section). Once an MOU is in place with a first responder agency, it will send out a

customized baseline push message to all active users containing a link to a landing page. This page will contain brief introductory text explaining the importance of recognizing an overdose when responding to unconscious persons and the efficacy of naloxone, as well as 2 questions asking them to indicate, by pressing radio buttons, whether they have received training on recognizing an overdose and administering naloxone and whether they currently carry naloxone on their person. Additional push messages encouraging users to respond to the certification questions will be sent twice within the month to maximize the number of participants providing baseline data. A user's responses to these questions will not change their status within the app or the behavior of the app because all users are already alerted to unresponsive or unconscious persons who may have experienced an overdose. This certification procedure will be repeated twice (6 months and 12 months after the baseline certification requests are sent). These messages will emphasize that even users who have previously provided such information should do so again.

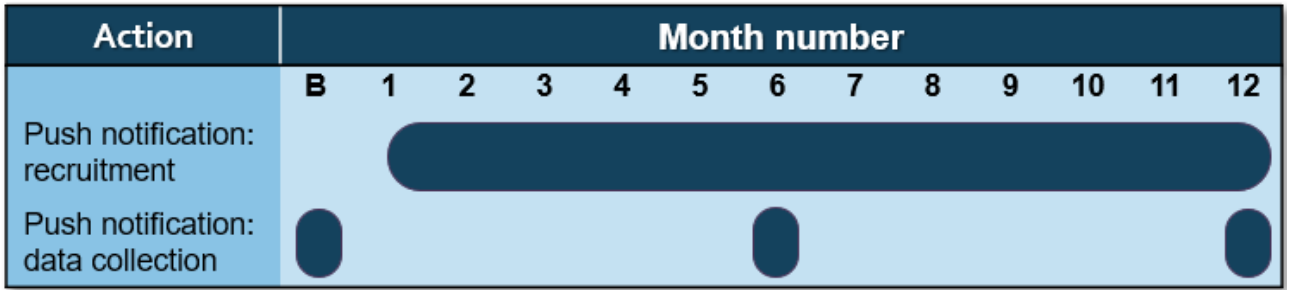
The *PulsePoint* app is structured in such a way that push notification hyperlinks can open an external web page in a web browser window inside the app. Using the style guides and templates from the PulsePoint Foundation, the certification web pages will be designed to be similar to the appearance of the app to avoid disrupting the user experience while avoiding cross-contamination of messaging between the study arms. Each web page will be accessible only via the hyperlink in its associated push notification, and users will not be able to navigate among web pages or access the web pages for other study arms.

As multiple data collection reminders will be sent each time (baseline, 6 months, and 12 months), we want to minimize the likelihood of an individual repeatedly certifying their involvement. This risk exists because of the completely anonymous way that individual *PulsePoint* users are managed by the system. Thus, the landing page will be configured to store a cookie [67] on the mobile device. Although cookies are typically perceived as tracking devices, this cookie will not *record anything except whether the user has previously responded to either question on the landing page* during the data collection cycle, and it will be programmed to delete itself after each data collection period (eg, 3 weeks). When users who have already completed the questions return to the landing page, the cookie will prevent the questions from being displayed, although we anticipate that some of the users may clear their smartphone browser cache or actively prevent the use of cookies.

Layperson Intervention (Recruitment) Arm 1

Users randomized to arm 1 will receive standard monthly recruitment push messages. These push messages will differ from the certification messages because they will contain language intended to foster engagement with OEND services (eg, to get trained and carry naloxone) alongside the link to a landing page (eg, "Are you trained to recognize an overdose? Be a community hero! Click here for more information!"). The messages will be developed based on best practice recruitment principles in cooperation with an external marketing team and then reviewed and finalized by the study team. Messages will be different each month. The monthly time frame was selected based on our need to balance contact with responders and research or expert opinions on push messaging saturation. In a hypothesis-driven objective measure study, increased push messaging frequency was associated with additional app uninstalls *and* lower push message opening rates [68]. This information is generally consistent with the much larger volume of layperson marketing gray literature on push notification optimization (eg, *how-to* blogs [69]). Figure 3 displays the planned timing of the recruitment and data collection messages.

Figure 3. Push notification types and timing relative to agency recruitment. B: baseline.



The landing page for recruitment will be updated to include a link to the Community Overdose Responder naloxone training [70], which has been designed specifically for laypersons and integrates elements of OEND programming and *PulsePoint*. Where provided by community first responder agencies, we will also include a list of ways to obtain free or reduced-cost naloxone locally as well as information about upcoming local OEND events. Separately, we note that accessing at-cost naloxone (ie, not free or subsidized) will be relatively easy, in principle, given its transition to OTC status [22].

Layperson Intervention (Recruitment) Arm 2

As in the case of the differentiation between agency recruitment in arm 1 and arm 2, the recruitment of layperson responders for arm 2 will follow the same procedures that are described for arm 1 but will use separate messaging. Specifically, the push messages and landing page will contain additional, brief messages that specifically provide factual information that counteracts misperceptions about overdose and naloxone [39]; for example, whereas an example message for arm 1 might be "Are you trained to recognize an overdose? Be a community hero! Click here for more information!" the permutation for arm 2 might be "Are you trained to recognize an overdose? Studies show that most people revived with naloxone will not overdose again within the next year! Click here for more information!"

Layperson Intervention (Control) Arm 3

Arm 3 functions as the control arm and will not receive any monthly recruitment messaging or encouragement, but laypersons will still be asked, using push notifications, to provide information at baseline and 6 and 12 months later to document whether they have been trained to recognize an overdose and administer naloxone and whether they currently carry naloxone on their person (eg, "Please let us know whether you have ever been trained to recognize an overdose or if you carry naloxone by clicking here."). The landing page will likewise contain the questions with radio button responses but will not link to training opportunities or contain additional information.

Outcome Variables and Measurement

In H2, we hypothesize that more layperson responders will indicate that they have received OEND programming and carry naloxone on their person within 6 and 12 months of initial contact using procedures in arm 2 (tailored messaging) compared to procedures in arm 1 (standard messaging) and using procedures in either arms 1 or 2 versus arm 3 (control). We will use several different data points to assess our hypothesis.

All push notifications sent out by first responder agencies already return information through the *PulsePoint* app indicating the total number of active devices, by type, that were messaged. As we explained previously, this is a strong proxy measure for the total number of active users messaged because most people use a single smartphone.

For purposes of computation, this total number of recipients of any push notification will be designated as *T*. Next, the total number of individuals who click on the pushed link will be represented by *O*, which will be a number between *0* and *T*. Importantly, the link will also be coded using HTML and CSS so that it sends additional data when clicked, indicating the originating community (cluster identity) and the data collection point (*D*, a value ranging from *0*, which is the initial push message cluster, to *2*, which is the final data collection message set at 12 months after baseline). Subsequently, the number of instances of an individual (ie, unique device) indicating that they have been trained on recognizing an overdose and administering naloxone (represented by *N*, a binary value of *0* or *1*) and whether they currently carry naloxone (represented by *C*, also a binary value of *0* or *1*) will be captured from the landing page itself.

This information will allow us to determine the following, separately by community:

- At baseline, we will calculate the ratio of persons certifying that they are trained (numeric count of *N*) compared to the total number of push message recipients (*T*), the ratio of persons certifying that they carry naloxone (numeric count of *C*) compared to the total number of push message recipients (*T*), and the ratio of individuals who clicked on the link (*O*) compared to the total number of push message recipients (*T*).
- Separately at 6- and 12-month follow-ups, the numbers of certifications of training and carrying naloxone (*N* and *C*, respectively) that were submitted compared to the numbers of push recipients (*T*) in each period (tracked by *D*) and the ratio of individuals who clicked on the link (*O*) each month compared to the number of total push message recipients (*T*).
- Our outcome variables are ratios: $X = (N / T)$ for each value of *D* (0, 1, or 2) and $Y = (C / T)$ for each value of *D*. The ratio $Z = (O / T)$ is a covariate representing engagement with push messages at each value of *D*.

Sample Size, Power, and Analysis

Our power analysis for H2 depends on the number of communities that agree to participate during the agency recruitment conducted as part of testing H1. To compare the average proportions of users who certify that they have received overdose education and personally carry naloxone, we sought 80% power to detect significant differences (2-tailed α=.05) among the 3 arms across 3 time points. Assuming a correlation of 0.5 in responses over time, we expect that we will be able to detect a medium effect size ranging from f=0.21 (if 50, 83% of the 60 communities participate in each arm on average) to f=0.34 (if 20, 33% of the 60 communities participate in each arm on average).

Our primary analyses will be metrics *X* and *Y* (as described previously), which will be analyzed separately. The primary analyses will be conducted using generalized linear mixed models, adjusting the *df* for the number of agencies. As with H1, we will report exact P values and commit to a cautious interpretation of the findings, avoiding overreliance on P values as the single arbiter of meaning [64]. In addition, as in the case of H1, we do not expect any missing data in the outcome variable because the nature of its computation is such that missing data mean that either *N=0* or *C=0* and are therefore built into outcome variables *X* and *Y*. Study covariates will include but may not be limited to variable *Z* to control for the conversion of push messages to clicks.

Exploratory Agency Follow-Up

We will conduct a set of intensive follow-up agency interviews with community first responder organizations with whom we have established active communication. We will prioritize qualitative recruitment of organizations and agencies that did not agree to be recruited after establishing correspondence because the elicitation of barriers to participation in the *PulsePoint-OD* program may be most informative when carried out with those who did not participate. This procedure will be similar in principle to, but more extensive than, our brief study of clinical providers who dropped out from a continuing medical education program [71]. However, we will not exclude participating agencies from the qualitative component of the project; instead, we will continue data collection until we have reached a point of theoretical inductive saturation, when new conversations and data no longer seem to add to our understanding of the topic [72]. Interviews will be guided by a semistructured interview guide to be developed during the agency recruitment process and will be coded using the general inductive approach to qualitative analysis [73], which does not make a priori assumptions about the data and allows themes to emerge organically based on repeated readings of the data.

Ethical Considerations

Ethics approval for the proposed work was determined to fall into 2 separate categories. Agency-level recruitment and interaction were determined not to constitute human participant research (Indiana University Institutional Review Board: 20218). The collection of information from layperson responders was approved under an expedited procedure (Indiana University Institutional Review Board: 20219). Data from layperson responders will be anonymous (no identifiers will be collected). Participation in the intensive follow-up agency interviews will be incentivized with an honorarium (US $500) to the organization to encourage participation.

Results

At the time of protocol submission, we had not engaged in any data collection or participant recruitment. This research was funded beginning September 14, 2023, by the National Institute on Drug Abuse of the National Institutes of Health (R34DA058162).

Discussion

Summary

The primary goal of this study is to understand the feasibility of recruiting current *PulsePoint* communities and layperson responders to complete overdose and naloxone training and to carry naloxone. Our hypotheses are intended to determine whether a specific type of correspondence targeting anticipated misunderstandings around opioid overdose and naloxone performs better when recruiting agencies and laypersons than standard messaging and whether active recruitment of laypersons using either message type performs better than the control.

At the same time, a separate consideration—regardless of the results of null hypothesis significance testing—is an overall sense of recruitment feasibility (eg, data on agency and responder uptake). Successful completion of this study is anticipated to improve the level of naloxone coverage in the United States, which remains insufficient [29]. We are also interested in examining elements that did and did not work and how we would ideally structure a similar recruitment process for a larger, outcomes-focused study (eg, comparing fatal overdose ratios in communities). Our exploratory discussions with agencies will be important to facilitate a better understanding of the mechanisms through which the proposed recruitment procedures did (or did not) work as intended.

Where possible, we have tried to control for anticipated limitations at the stage of study design. Owing to the nature of this real-world study, we still anticipate some limitations in the interpretation of the results. In particular, the degree to which agencies will agree to participate in arm 3 is uncertain because participation does not directly benefit those communities (unlike arms 1 and 2). This would not affect H1 (which only includes arms 1 and 2) but might affect the statistical power of H2. We expect that additional limitations may be uncovered in the process of conducting the study, and we plan to transparently note, and where possible mitigate, all such limitations, providing a comprehensive description of this information in subsequent documentation of the study.

Conclusions

If we successfully recruit agencies and laypersons and thereby facilitate training around overdose and naloxone and increase the numbers of layperson responders carrying naloxone, the next step will be to conduct a larger study examining opioid-involved overdose reversals using these procedures. This is predicated on current evidence for OEND, which allows us to hypothesize that our successful mobilization of layperson responders might reduce the prevalence of opioid-involved overdose [12-16], a theory that we will then prospectively test.

Acknowledgments

The authors would like to thank the PulsePoint Foundation for their encouragement of this project, with particular appreciation due to Kraig Erickson, vice president of community engagement.

Portions of this paper, including some verbatim text, will be presented as a 5-minute “lightning talk” and abstract at the 2024 American Academy of Health Behavior conference in Savannah, Georgia.

The research reported in this publication was supported by the National Institute on Drug Abuse of the National Institutes of Health (R34DA058162; JA). The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health or of the PulsePoint Foundation. Data Availability

Data sharing is not applicable to this paper because no data have been obtained or analyzed at this stage of the study.

Authors' Contributions

JA, CH, and DCS contributed to conceptualization. DT contributed to software development. JA contributed to visualization, supervision, and project administration. All authors contributed to methodology, resources, funding acquisition, and writing the original draft as well as reviewing and editing it.

Conflicts of Interest

JA, CH, MP, and DCS have received funding through their employer (Indiana University) to conduct various research projects pertaining to opioids, harm reduction, and naloxone from federal, state, and local government entities and nonprofit foundations. CH was co–principal investigator of a National Institute on Drug Abuse Small Business Innovation Research grant that facilitated the development of a web-based naloxone training (Community Overdose Responders) being provided as an option for layperson responders in this study, but their participation was as an Indiana University employee; therefore, they do not have any mechanisms in place (eg, trademarks, patents, and access agreements) that would result in any personal profit or financial benefits accruing from the use of the training. All other authors declare no other conflicts of interest.

Abstract

Background: Overweight and obesity pose a global public health challenge and have a multifactorial origin. One of these factors includes obesogenic environments, which promote ultraprocessed foods characterized by being high in calories, saturated fats, added sugars, and sodium. In Mexico, it has been estimated that 30% of the total energy consumed comes from processed foods. The Modification to the Official Mexican Standards introduces nutritional information through black octagonal seals that alert consumers about products with excessive amounts of some components for a better food selection in the population. However, the effects of warning labels on processed food selection and purchases among children remain unknown.

Objective: We aimed to evaluate the impact of a digital educational intervention focusing on front-of-package warning labels on the food selection and purchasing behavior of elementary schoolchildren and their caregivers.

Methods: Children from 4 elementary schools in Mexico City, 2 public and 2 private schools, will participate in a randomized controlled trial. The schools will be chosen by simple random sampling. Schools will be randomized into 2 groups: intervention and control. In the control group, the dyads (caregiver-schoolchildren) will receive general nutritional education, and in the intervention group, they will receive guidance on reading labels and raising awareness about the impact of consuming ultraprocessed products on health. The educational intervention will be conducted via a website. Baseline measurements will be taken for both groups at 3 and 6 months. All participants will have access to an online store through the website, allowing them to engage in exercises for selecting and purchasing food and beverages. In addition, other measures will include a brief 5-question exam to evaluate theoretical understanding, a 24-hour reminder, a survey on food habits and consumption, application of a food preference scale, anthropometric measurements, and recording of school lunch choices.

Results: Registration and funding were authorized in 2022, and we will begin data collection in September 2024. Recruitment has not yet taken place, but the status of data analysis and expected results will be published in April 2025.

Conclusions: The study is expected to contribute to evaluating whether reinforcing front-of-package warning labels with education enhances its effects and makes them more sustainable. Conducting this study will allow us to propose whether or not it is necessary to develop new intervention strategies related to front-of-package labeling for a better understanding of the population, improved food choices, and better health outcomes.

Introduction

Overweight and obesity pose a global public health challenge. In Mexico, data from the National Health and Nutrition Surveys from 2012, 2018, and 2020 show that the combined prevalence of overweight and obesity in children between the ages of 5 and 10 years has remained high (33.2%, 35.6%, and 38.2%, respectively) [1].

Obesity has a multifactorial etiology, involving genetic, environmental, and behavioral aspects. Obesogenic environments promote ultraprocessed foods, which are high in calories, saturated fats, added sugars, and sodium [2,3].

Therefore, public policies aimed at reducing the incidence and prevalence of childhood obesity must consider actions that modify the environment to improve nutrition. Labeling of ultraprocessed products has been a common strategy that governments worldwide use to improve people's diets [4].

In Mexico, it has been estimated that more than 30% of the total energy consumed comes from ultraprocessed foods, favoring the prevalence of overweight and obesity. The daily dietary guidelines by the Ministry of Economy and the Ministry of Health in Mexico were an effort for people to improve their food selection and purchasing; however, they did not show good results due to the complexity of interpreting them [5].

The Modification to the Official Mexican Standard (NOM-051-SCFI/SSA1-2010 [NOM 051]) was approved in 2020. This proposed a front labeling system for foods and beverages that consisted of nutritional information through black octagonal seals, with legends like "excess calories," "excess sodium," "excess saturated fat," "excess trans fat," "excess sugars," and other explanations, such as "contains caffeine, avoid for children" and "contains sweeteners, not recommended for children," to provide information to the consumers to help them make food selections [5,6].

Ultraprocessed products targeted at children are offered in all supermarkets and represent an important commercial income for the food industry [7,8]. At home, parents are primarily responsible for purchasing food and have a significant influence on their children's eating behaviors [7-10].

On the other hand, children also influence parents' purchasing decisions, especially when they want to choose unhealthy foods, which is why the influence of front labeling must be studied from both perspectives (ie, children's and parents') [11]. To reduce the purchase and consumption of ultraprocessed foods, various marketing strategies have been implemented, especially for products aimed at school children; however, the results have been varied and limited [12,13].

It is known that food packaging has an impact on how children perceive these products. For instance, the use of drawings and bright colors can make them associate the product with something suitable to eat, which is why changes have been made to packaging designs to discourage consumption, mainly by removing cartoon slogans or legends that promote their consumption [14].

Some types of front-of-package labeling guide the daily intake by indicating the proportion (%) of nutrients found in a serving according to the recommended daily intake for adults. This includes the traffic light system, which uses colors (green, yellow, and red) to indicate the amount of nutrients in a product, as well as warning labels, which are black octagonal symbols, which indicate the excess of nutrients, energy, and substances present in the product and are intended to discourage purchase and consumption [15].

Having identified the relationship between packaging and food consumption, it is expected that front-of-package nutritional labels will reduce the consumption of unhealthy foods [16].

Furthermore, it has been documented that another effective strategy to improve food selection is to enhance nutritional education to develop skills to distinguish healthy products from those that are not considered healthy [17].

Mobile nutritional interventions have been observed to reach a broader range of social and demographic groups and can facilitate the selection of healthy foods at the point of purchase, optimizing decision-making times [18].

In Mexico, it is estimated that 78.6% of the Mexican population aged 6 years and older has access to the internet, with 97% connecting through mobile devices. This is why various health institutions have implemented web portals, social networks, and the use of cell phone messages, telephone, and mobile apps for managing, preventing, and treating health-related activities [19-21].

The objective of this clinical trial is to evaluate the impact of a digital educational intervention focusing on front-of-package warning labels on the food selection and purchasing behavior of elementary school children and their caregivers [22].

Methods

Recruitment and Study Design

Third-, fourth-, and fifth-grade elementary school students and their caregivers from 4 primary schools—2 public and 2 private schools—in Mexico City will participate in the study. The schools will be chosen by simple random sampling. Schools will be randomized into 2 groups: intervention and control.

After approval from the directors of the primary schools, meetings will be held with parents to invite them to participate; they will be explained the intervention's objectives, activities, and duration. Parents and schoolchildren will be invited to sign a consent and informed assent, respectively, clarifying that their participation is voluntary, and they may choose to discontinue at any time without affecting their activities at school.

The main question this study aims to answer is the following: What is the effect of a digital educational intervention about front-of-package warning labels on food selection among children attending primary schools in Mexico City, compared to a control group?

Schools will be randomized into 2 groups. In the control group, the dyads (caregiver-schoolchildren), will receive general nutritional education, and in the intervention group, they will also receive guidance on reading labels, which raises awareness about the impact of consuming processed or ultraprocessed foods on health.

The intervention will be carried out via a website [23] (Figure 1) with audiovisual material, and all participants will also be asked to complete a multiple-choice evaluation (5 questions) to ensure a theoretical understanding of the topics. Other measures will include a lunch register, 24-hour dietary recall, a survey of food habits and consumption, a validated food preference questionnaire, anthropometric measurements (eg, weight, height, and waist circumference), a socioeconomic survey, as well as participation in a simulated web-based food and beverage selection and shopping activity. These measures will help assess if the digital educational intervention on front-of-package warning labeling for children and caregivers improves the selection and purchase of foods.

Figure 1. Website “Applicate por tu salud” (www.viviendo-saludable.org).

Inclusion Criteria

Inclusion criteria for children are as follows: students in third, fourth, and fifth grades (aged 8 to 12 years), of both sexes, enrolled in the selected primary schools, with normal weight, overweight, and obesity, who sign the written informed consent.

Inclusion criteria for caregivers are as follows: primary caregivers of any sex of children in the third, fourth, and fifth grades with normal weight, overweight and obesity, who sign the written informed consent.

Exclusion Criteria

Caregivers and children without internet access, computers, or mobile devices, as well as those participating in a weight reduction program with pharmacological treatment, will be excluded.

Nutritional Education Interventions

The control group and the intervention group in dyads (caregiver-schoolchildren) will receive general nutritional education, and only the intervention group will receive guidance on reading warning labels, which raises awareness about the impact of consuming processed and ultraprocessed foods on health.

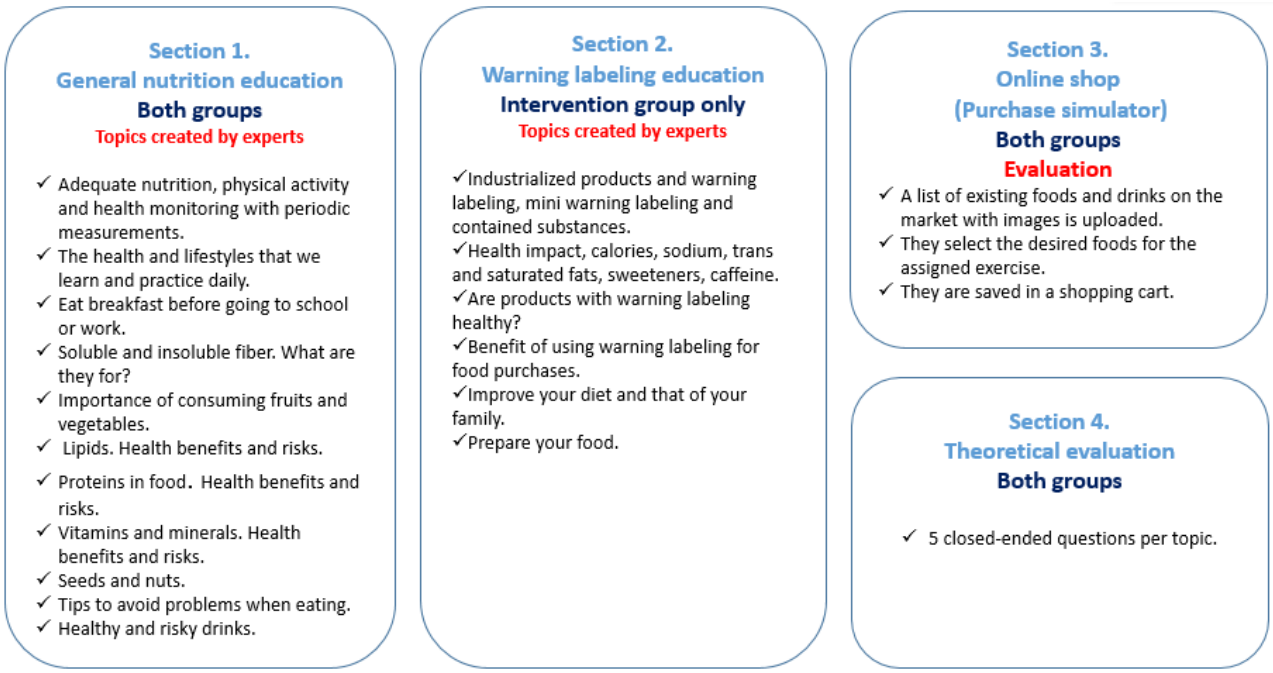
On the website, there will be 4 sections. Participants will receive an account and password to access the educational content corresponding to the group they belong, intervention or control group.

The intervention and control groups will have access to the first section, which contains general nutritional education topics. The second section will contain nutritional education topics related to warning labeling, and only the intervention group will have access to it.

Each topic will be presented through videos, released every 15 days, as well as weekly infographics and tips to the caregivers and children via the website. This material will also be sent to the participants’ mobile devices.

The third section will have the “Online shop,” which will be used as part of the food selection evaluation. The fourth section will evaluate theoretical understanding with 5 multiple-choice questions per topic (Figure 2).

Figure 2. Nutritional intervention topics by groups.



Primary Outcomes

Time Frame

The measurements will be carried out in 2 scenarios (in schools and through the website) at baseline (1 week before starting the educational interventions), at 3 months, and at 6 months after the intervention ends.

A socioeconomic survey will be used in the baseline measurement.

The following assessments will be conducted at 3 frame times (baseline, 3 months, and 6 months): a food preference questionnaire, a 24-hour dietary recall, lunch register, and a survey of food habits and consumption. Anthropometric measurements (eg, weight, height, and waist circumference) will only be performed at baseline and the end of the 6-month intervention.

Through the website, dyads will engage in food and beverage purchasing exercises in the online shop simulator at the 3 measurement points (baseline, 3 months, and 6 months), along with multiple-choice evaluation (5 questions).

Food and Drink Selection

The percentage of products purchased by each participant in the online store, whose content indicates “high in calories, sugar, fat, and sodium” and the average content of these nutrients in 100 g of each product will be measured.

Energy and Macronutrient Intake

The amount of kilocalories consumed as well as saturated fat, trans fat, sodium, and added sugar will be measured.

Statistical Analysis

Descriptive statistics will be used to characterize variables, and tables will be made with summary measures. Independent *t* tests and chi-square tests for categorical data will be used to compare baseline characteristics between the intervention and control groups. The Mann-Whitney *U* test will be used to evaluate differences between groups in case of nonnormal distribution.

Repeated measures ANOVA will be used to evaluate the change in the number of warning labels in nutrient consumption between groups and throughout the intervention. We will use a mixed-effects model to evaluate the effect of the intervention on changes in food and beverage selection, adjusting for confounding variables. Intention-to-treat analysis will be performed.

Ethical Considerations

The protocol has obtained ethics approval by the bioethics committees of the Hospital Infantil de México Federico Gómez (HIM/2022/054). This protocol has also been registered with ClinicalTrials.gov (NCT06102473).

The objectives and activities of the study will be explained to the caregivers and children. To participate, they must sign the informed consent and informed assent forms to give their authorization to participate, with confidentiality guaranteed.

The website will contain health education material and an online shop to simulate the selection and shopping of food and beverages. No personal or medical information will be uploaded to the website. The results will only be used for the study and will be stored by the research team on password-protected computers. In case of any changes to the protocol, the ethics committee will be informed.

Results

The protocol was registered in 2022 and was approved by the committees of the Federico Gómez Children's Hospital of Mexico, and they also obtained federal resources for the project. We expect to begin the study in schools in September 2024.

We are not recruiting yet. The results will be analyzed and published in April and May 2025.

Discussion

Expected Outcomes

This protocol aims to study a public health policy in Mexico, which seeks to contribute to improving the health of the Mexican population by facilitating the understanding of nutritional information about ultraprocessed foods and beverages using front-of-package warning labeling. Studying the effects of this intervention on the population is essential for continuing with the initiative, improving it, or considering other measures to achieve the expected health outcomes.

Some studies have been conducted around the world on different types of front labeling, exploring their effectiveness in selecting and purchasing healthier foods.

A study on adults [24] explored the effectiveness of different types of frontal labeling. Participants were given a brief educational session through a smartphone app before being exposed to 2 experimental shopping tasks. The study found that all types of front labeling, after the educational intervention, resulted in better food selection. In Mexico, a study [25] provided guidance on front labeling via video before participants engaged in online food selection, showing positive effects on food selection.

Another study [26] demonstrated that nutritional warning labels with stamps significantly reduced the percentage of participants who selected products with excessive content of at least one nutrient, compared to the control group (62% vs 85%), and a statistically significant difference was observed for participants who selected products with an excess of certain nutrients, such as sugar (P<.001), saturated fats (P<.001), and sodium (P=.01).

A study in the United States [27] targeting parents concluded that warning labels on sugary beverages reduced the purchase of these products for their children. Although the evidence indicates that front-of-package warning labels can improve the selection of foods and beverages, the effects of these labels on the pediatric population and how children influence the selection and purchase of foods in their homes are still unknown.

On the other hand, the guidance received by participants in the aforementioned studies is limited to ensuring understanding of reading the label.

One limitation of the study is that the exercise of food and beverage selection will be made in a simulated shopping scenario, which may differ from real-life situations of food and beverage purchasing and consumption; however, this study is important to determine whether a structured educational intervention on key nutrients and raising awareness about their implication in health enhances the effects of front-of-package warning labeling to reduce overweight and obesity as well as other chronic diseases, such as diabetes and hypertension.

Conclusions

It is expected that the study will contribute to evaluating whether reinforcing front-of-package warning labeling with education enhances its effects and makes them more sustainable. Carrying out this study will allow us to propose whether or not it is necessary to develop new intervention strategies related to front-of-package labeling for a better understanding of the population, improved food choices, and better health outcomes.

Acknowledgments

The authors would like to acknowledge the academic and administrative support provided by the Research Directorate of the Health Institute Hospital Infantil de México Federico Gómez and the Master's and Doctorate programs in Medical, Dental, and Health Sciences of the Universidad Autónoma de México for their interest in the subject and for providing the conditions required to conduct this study.

Data Availability

The data sets generated and analyzed during this study are not publicly available to comply with the ethical requirements and participants' confidentiality protection but are available from the corresponding author upon reasonable request.

Authors' Contributions

DAM, JVG, and MKK conceptualized the study and drafted the manuscript. ALML and LVL conceptualized the study and reviewed the manuscript.

Abstract

Background: Patients after kidney transplantation eventually face the risk of graft loss with the concomitant need for dialysis or retransplantation. Choosing the right kidney replacement therapy after graft loss is an important preference-sensitive decision for kidney transplant recipients. However, the rate of conversations about treatment options after kidney graft loss has been shown to be as low as 13% in previous studies. It is unknown whether the implementation of artificial intelligence (AI)–based risk prediction models can increase the number of conversations about treatment options after graft loss and how this might influence the associated shared decision-making (SDM).

Objective: This study aims to explore the impact of AI-based risk prediction for the risk of graft loss on the frequency of conversations about the treatment options after graft loss, as well as the associated SDM process.

Methods: This is a 2-year, prospective, randomized, 2-armed, parallel-group, single-center trial in a German kidney transplant center. All patients will receive the same routine post–kidney transplant care that usually includes follow-up visits every 3 months at the kidney transplant center. For patients in the intervention arm, physicians will be assisted by a validated and previously published AI-based risk prediction system that estimates the risk for graft loss in the next year, starting from 3 months after randomization until 24 months after randomization. The study population will consist of 122 kidney transplant recipients >12 months after transplantation, who are at least 18 years of age, are able to communicate in German, and have an estimated glomerular filtration rate <30 mL/min/1.73 m^2. Patients with multi-organ transplantation, or who are not able to communicate in German, as well as underage patients, cannot participate. For the primary end point, the proportion of patients who have had a conversation about their treatment options after graft loss is compared at 12 months after randomization. Additionally, 2 different assessment tools for SDM, the CollaboRATE mean score and the Control Preference Scale, are compared between the 2 groups at 12 months and 24 months after randomization. Furthermore, recordings of patient-physician conversations, as well as semistructured interviews with patients, support persons, and physicians, are performed to support the quantitative results.

Results: The enrollment for the study is ongoing. The first results are expected to be submitted for publication in 2025.

Conclusions: This is the first study to examine the influence of AI-based risk prediction on physician-patient interaction in the context of kidney transplantation. We use a mixed methods approach by combining a randomized design with a simple quantitative end point (frequency of conversations), different quantitative measurements for SDM, and several qualitative research methods

(eg, records of physician-patient conversations and semistructured interviews) to examine the implementation of AI-based risk prediction in the clinic.

KEYWORDS

shared decision-making; SDM; kidney transplantation; artificial intelligence; AI; decision-support system; DSS; qualitative research

Introduction

Shared decision-making (SDM) is increasingly important in health policy and clinical practice. Over the past decades, researchers, patient advocates, and policymakers all over the world have increased efforts to shift health care from a paternalistic to a patient-centered approach, focusing on the patient as a person [1,2]. Kidney transplantation is the most frequently performed solid organ transplantation and although the application of SDM prior to kidney transplantation has been discussed, little is known about how to improve SDM after transplantation [3]. This is surprising as there are numerous potentially preference-sensitive decisions that patients, support persons, and physicians have to make in this setting, for instance relating to the management of comorbidities, effects of treatment on fertility, use of immunosuppressant drugs, and resulting second cancers [4,5].

In patients with chronic kidney disease, choosing the right kidney replacement therapy and the optimal timing for kidney replacement therapy is an important preference-sensitive decision. Implementing SDM has been shown to leave more patients satisfied with their choice of dialysis modality [6]. Not only the modality itself but also details like the vascular access and the specific dialysis regimen are preference-sensitive and should be part of an SDM process that also considers age-dependent needs [7-9].

Since most patients after kidney transplantation eventually face the risk of graft loss with the concomitant need for dialysis or retransplantation, comparable considerations should be applied to kidney transplant recipients at risk for graft loss. However, the rate of conversations about treatment options after kidney graft loss is as low as 13% in conventional physician-centered care settings [10]. This leaves room for optimization with respect to the frequency of conversations as well as the associated SDM process. While care-based interventions have shown to be effective in increasing the frequency of conversations about treatment options after graft loss, it is unknown whether the implementation of artificial intelligence (AI)–based risk prediction models can have such influence on physician-patient interactions [10].

Different risk prediction models for graft loss using methods of statistics or AI have been introduced and show good predictive performance [11,12]. More importantly, they are more accurate than experienced physicians in predicting risks for graft loss [11,13]. Implementing such models into routine care could indicate patients at risk for graft loss and thereby increase the frequency of conversations about treatment options after graft loss. However, little is known about the impact of AI-based interventions on the interaction between patients, support persons, and physicians [14].

While there are several studies discussing the potential of AI to support SDM in the bioethical literature [15], there is a lack of empirical studies to systematically investigate the impact of AI on SDM [16].

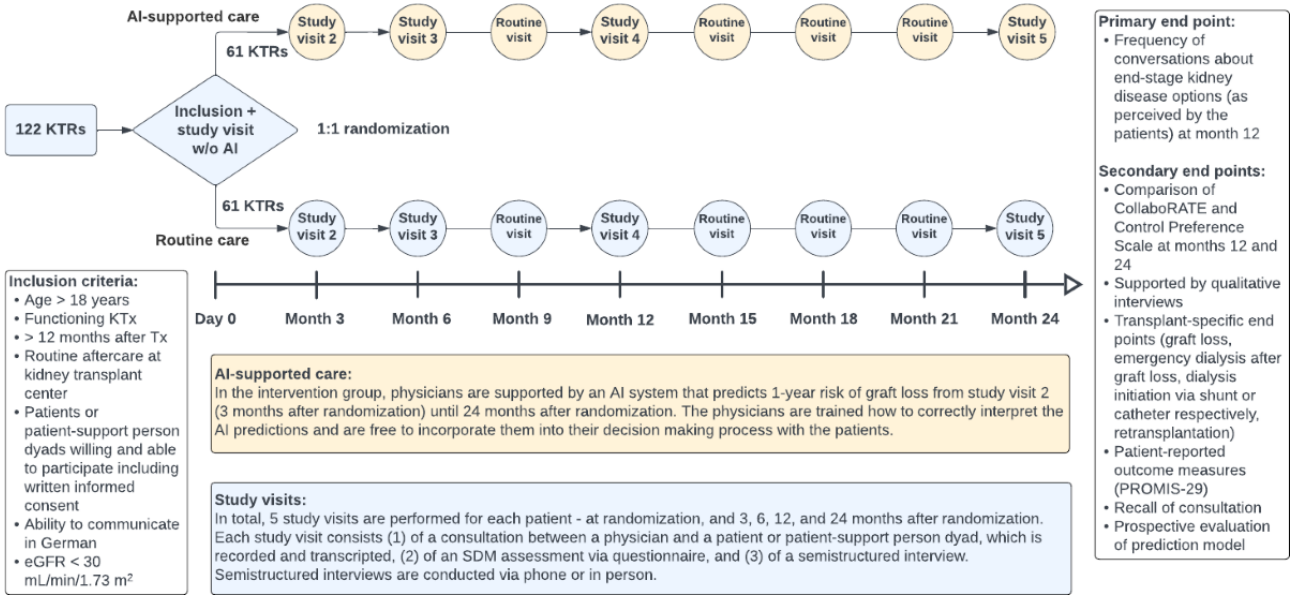
In this study, we aim to evaluate the influence of an AI-based risk prediction model for 1-year risk of graft loss on the frequency of conversations about treatment options after graft loss, as well as the associated SDM process, in patients who had kidney transplants with low estimated glomerular filtration rate (eGFR).

Methods

Study Design and Setting

The Prospectively investigating the Impact of AI on Shared Decision-Making in Post-Kidney Transplant Care (PRIMA-AI) trial is a 2-year, prospective, randomized, 2-armed, parallel-group, single-center trial in a German kidney transplant center (KTC). Patients more than 12 months after kidney transplantation with eGFR <30 mL/min/1.73 m^2 and support persons will be randomized to routine care or to AI-supported care in a 1:1 ratio. During the study, 5 study visits are planned at the KTC—at randomization, and 3, 6, 12, and 24 months after randomization (Figure 1). In both groups, routine care visits will be scheduled as needed, depending on the patient's medical condition and time posttransplant, which is usually every 3 months.

Figure 1. Study flowchart summarizing inclusion criteria, interventions, and end points. An estimated number of 122 KTRs will be recruited in the outpatient clinic of a tertiary care center and randomized 1:1 into routine care or AI-supported care and followed up over 24 months. AI: artificial intelligence; eGFR: estimated glomerular filtration rate; KTR: kidney transplant recipient; KTx: kidney transplantation; PROMIS-29: Patient Reported Outcomes Measurement Information System 29; SDM: shared decision-making; Tx: transplantation.



Recruitment Process

Patients after kidney transplantation regularly undergo routine follow-up at the KTC in an outpatient clinic. Patient data are available in a proprietary electronic health record that allows data extraction for research purposes [17]. Patients who are potentially eligible for the study based on their previous medical data will be contacted via telephone 1 week before their next scheduled appointment and will be asked if they are interested in study participation. If patients are potentially interested, they are provided detailed information about the study by trained study physicians and provide written informed consent after checking inclusion and exclusion criteria at the time of their next outpatient visit at the KTC. Recruitment will occur in the regular outpatient treatment at the KTC by designated study physicians who are not the treating physicians. After recruitment and randomization, the first study visit is performed. No study investigations are performed before written informed consent is obtained from the patients. The KTC is a tertiary care center specializing in kidney transplantation, where approximately 200 kidney transplantations per year are performed.

Participants

Participants may enter the trial if all the following apply: (1) they provide written informed consent, (2) they are patients with a functioning kidney allograft, (3) it has been at least 12 months after kidney transplantation, (4) they have an eGFR <30 mL/min/1.73 m^2 according to Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) 2021 formula, (5) they are aged at least 18 years, (6) they can communicate in German, and (7) they attend regular follow-ups at KTC. Participants may not enter the trial if any of the following apply: (1) they have undergone multi-organ transplantation, (2) it has been less than 12 months after kidney transplantation, (3) they have an eGFR >30 mL/min/1.73 m^2 according to CKD-EPI 2021 formula, (4) they are aged less than 18 years, (5) they cannot communicate in German, (6) they do not attend regular follow-ups at KTC, and (7) they enrolled in another interventional study less than 1 month before participation in this study. Additionally, support persons will be eligible if they are nominated by the patient as someone helping them cope with the consequences of their kidney transplant through support, encouragement, and communication. Support persons will be aged 18 years or older, German-speaking, and able to provide informed consent. Treating physicians who work at the participating clinics and use the AI-based decision-support system (DSS) will be eligible to participate in the study. Clinic staff will record the age and gender of nonconsenters who provided permission, which allows for the examination of consent bias.

Sample Size

The primary analysis will be performed based on the frequency of conversations about treatment options after graft loss as perceived by the patient, which is assessed in a questionnaire after the respective consultation. Based on the data from Bissonnette et al [10], we estimate that in the control group, 10%-15% of patients will have a conversation about therapy options at the end of graft function. Regarding the intervention studied herein, we estimate that this frequency can be increased to 40%-45%, which is half of the effect size achieved by Bissonnette et al [10]. Using a 2-sided χ^2 test, an α error of .05, and a power of 80%, 25-49 patients per group are needed. Estimating a dropout rate of 10% per year, this increases to 31-61 patients per group. Therefore, 61 patients per group were regarded as sufficient. In order to identify 122 participating patients, local study personnel will have to screen approximately 150 potentially eligible kidney transplant recipients over a period of 6 months.

Randomization

Randomization will be performed using a predefined variable block randomization scheme using a web-based randomization

service [18]. After screening for eligibility and assignment of the individual patient identifier, each patient-support person dyad can only be assigned once to 1 of the treatment arms. The sites will record the time of randomization.

Blinding

Blinding of participants and study staff is not possible given the nature of the intervention.

Intervention

Control Group: Routine Care

Routine care will be scheduled according to the current standard of care [19], which depends on the time after transplantation, medical condition, and other individual factors. Standard immunosuppression will be applied according to the international recommendations [20]. The prophylaxis and treatment of infections will follow the current standard of care as outlined in recent guidelines [21-26], for example, *Pneumocystis jirovecii* pneumonia prophylaxis for 4 to 6 months, cytomegalovirus prophylaxis according to the guidelines, and regular posttransplant BK virus monitoring according to guidelines [19]. Screenings for the antibodies against human leukocyte antigen once within the first 3 months, after 1 year, and every year thereafter, as well as in case of suspected rejection [27]. The overall medical treatment of kidney transplant recipients will be performed according to the Kidney Disease Improving Global Outcomes guidelines [19] and in patients with suspected rejection, a kidney biopsy should be performed and classified according to the most recent Banff criteria [28]. An integral part of the current routine aftercare is regular visits to the home nephrologist and KTC, where data are captured in an electronic health record [17]. Table 1 highlights the proposed schedule for posttransplant aftercare. The proposed schedule is adapted to the individual patient's needs.

Table 1. Frequency of routine visits in the outpatient clinic of the kidney transplant center (KTC) depending on time after transplantation.

Time after transplantation	Frequency of routine visits
Month 1	Once per week after discharge at the KTC
Month 2	Once per week
Month 3	Once per 2 weeks
Months 4 to 6	Once per 3 weeks
Months 6 to 12	Once per month
After 12 months	Once every 3 months

Intervention Group: AI-Supported Care

The kidney transplant recipients, who are randomized to the interventional arm, will receive identical routine posttransplant care as patients in the control group (see Table 1). In addition, the physicians in the KTC will be provided an AI-based decision support system making predictions for the risk of graft loss based on the patient's most recent clinical, laboratory, and histopathology data, beginning from the second visit. A previous version of the AI-based decision support system has been studied in silico and in a reader study [11]. The physicians are provided a recommendation on how to proceed in case of a high-risk score. Briefly, physicians are recommended to inform the patients about this risk and discuss the potential necessity of return to dialysis or retransplantation, as well as planning, which mode of renal replacement therapy is preferred by the patient (hemodialysis, peritoneal dialysis, or listing for retransplantation by living donation). Depending on the patient's preference, preparation for a smooth transition to dialysis or retransplantation should be performed.

Outcomes

Primary End Points

For the primary end point, the frequency of conversations about treatment options after graft loss as perceived by the patient will be compared between the 2 groups at 12 months after randomization.

Secondary End Points

As the main secondary end points, the 2 different assessment tools for SDM, the CollaboRATE mean score and the Control Preference Scale (CPS; adapted version as used in previous studies [29]), are compared between the 2 groups at 12 months after randomization. The CPS is widely used as a validated tool to assess involvement in SDM [29,30]. However, it has been suggested that CPS may be misleading in some contexts of medical decision-making since it does refer explicitly to a "decision," whereas, CollaboRATE is a brief process-orientated measure that recognizes that study participants may not always realize that a decision has been made or have difficulties focusing on 1 decision in the context of a complex care experience [31,32]. CollaboRATE has shown discriminative validity and interrater reliability. To supplement the quantitative outcome measures, qualitative data collection in the form of interviews will be performed and analyzed. All questionnaires and interview guides will be developed with the help of a multidisciplinary research group and pilot tested with patients and support persons to optimize acceptability and feasibility. Other secondary end points are summarized in Textbox 1.

Textbox 1. Secondary end points and time frame after which they are assessed

End points

- CollaboRATE mean score of all study visits from study inclusion until month 12 (values 0-9, higher values indicating better outcome)
- CollaboRATE mean score of all study visits from study inclusion until month 24 (values 0-9, higher values indicating better outcome)
- Mean Control Preferences Scale of all study visits from study inclusion until month 12 (values 1-5, higher values indicating better outcome)
- Mean Control Preferences Scale of all study visits from study inclusion until month 24 (values 1-5, higher values indicating better outcome)
- Frequency of kidney replacement therapy after graft loss at 12 months
- Frequency of kidney replacement therapy after graft loss at 24 months
- Frequency of emergency dialysis after graft loss at 12 months
- Frequency of emergency dialysis after graft loss at 24 months
- Frequency of dialysis initiation via arteriovenous-shunt after graft loss at 12 months
- Frequency of dialysis initiation via arteriovenous-shunt after graft loss at 24 months
- Frequency of dialysis initiation via permanent catheter after graft loss at 12 months
- Frequency of dialysis initiation via permanent catheter after graft loss at 24 months
- Frequency of retransplantation after graft loss at 12 months
- Frequency of retransplantation after graft loss at 24 months
- Qualitative analysis of semistructured interviews after at 24 months
- Qualitative analysis of physician-patient conversations after at 24 months
- Frequency of conversations about treatment options after graft loss as perceived by the patient will be compared between the 2 groups at 24 months

Procedures

Overview

The study plan is summarized in Table 2.

Table 2. Study plan including the data and time points at which these are assessed.

[g]AE: adverse event.

[h]SAE: serious adverse event.

Details of the AI-Based DSS and Recommended Procedures

An AI-based prediction model will be implemented to provide real-time predictions of the 1-year risk for graft loss based on the patient's clinical, laboratory, immunological, and histopathological data. A previous version of the prediction model has been described in detail before, and all substantial changes will be made publically available. The predictions are provided as regression scores from 0 to 100 with higher scores indicating higher risk. For ease of interpretability, each score is classified into low-, medium-, or high-risk categories, which are color-coded as green, yellow, and red. Along with the risk score and risk category over time, relevant risk factors are provided to increase interpretability for the latest risk assessment.

Physicians will undergo training, in which technical details of the underlying model (training cohort, inclusion and exclusion criteria, end point definition, and performance), and results of preclinical studies are presented [11]. Hereby, the physicians can gain familiarity with the AI-DSS and also discuss potential limitations with the developers and study physicians. These training sessions will be recorded and analyzed as part of the qualitative subproject.

During the study, the physicians are advised to use the AI-DSS as an additional source of information and be especially cautious in case of high risks detected by the AI-DSS. In any case, it will

be left to the physician's choice on how to include the system's information in the conversation with patients and support persons.

However, if the AI-DSS shows a high risk for graft loss, the physicians are free to discuss this with the patient and offer 1 procedure depending on their own assessment. First, physician—high risk for graft loss: if the physician agrees that there is a high risk of graft loss in a patient during the next year, the physician is advised to discuss this risk with the patient, when the situation is appropriate (enough time, no other major problems to be discussed, etc) or to discuss it during the next appointment. The physician should assess, whether the preferred renal replacement modality (hemodialysis, peritoneal dialysis, and retransplantation) of the patient is known and take measures to ensure a smooth transition without the need for emergency hospitalization (shunt planning, peritoneal dialysis catheter implantation, appointment for living donation, etc). Second, physician—low risk for graft loss: if the physician disagrees with the AI system and estimates a low risk for graft loss in a particular patient, the physician is advised to reconsider potential risk factors. The physician is free to incorporate or ignore the AI-DSS assessment into the SDM with patients and support persons.

Details on Qualitative Research Methodology

Overview

The physician-patient conversation will be recorded if physicians, patients, and support persons do not withdraw consent at randomization, as well as 3, 6, 12, and 24 months after randomization. Additionally, patients will be interviewed at randomization, as well as 3, 6, 12, and 24 months after randomization. Data collection at randomization, as well as 12 and 24 months after randomization will be conducted face-to-face, if possible and preferred by study participants. Data collection at 3 and 6 months after randomization will be conducted via telephone. This is to reduce the research-related burden on the participants. It has been suggested that telephone interviews produce similar quality data as face-to-face interviews [33-35]. Also, patients may appreciate being interviewed via telephone as they may feel more relaxed when being interviewed on the telephone and may find it easier to rearrange a telephone interview, rather than having to rearrange a face-to-face interview [36-39]. Participants will be encouraged to tell their views on how the AI-based DSS impacted physician-patient-support person communication and how treatment decisions were made, in the way they prefer, with as little interruption as possible from the interviewer. This narrative approach will help elicit the variety and interplay of potential factors related to treatment discussions [40]. The initial narrative will be followed by semistructured questions which will be developed based on a literature review and discussions among the research team which involves experts in the areas of medicine, communication and behavioral science, health services research, ethics, and medical informatics.

Influence of AI-Based Decision Support on the Normative Foundations of the Use of AI in SDM

Participants will be asked questions on their perceptions of concepts such as trust, agency, or transparency, for instance about how they evaluate the outputs of the tool and how these outputs relate to their physicians' judgments. Participants may also be asked to report on their views on the system's validity, effectiveness, and the perceived likelihood of errors, as well as on who is morally and legally liable for single treatment decisions.

Use of AI-Based Decision Support and Barriers and Enablers to its Implementation

Participants will be asked about their perceptions of acceptability, ease of use, agreement with specific components of the system's outputs, and self-efficacy (ie, the belief that one can understand and use the system's output). Participants will also be asked about further potential barriers to the use of AI in routine care, such as environmental factors like time pressure. These questions will be informed by the literature and discussions among the research team [41,42].

Sociodemographic and Disease Variables

Sociodemographic and disease variables obtained from patients and support persons will include gender, marital status, country of birth, postcode, highest level of education completed, income, and perceived health status. The support persons will also be asked to self-report their relationship to the patient and whether they are living with the patient. All sociodemographic and disease variables will be assessed at baseline and follow-ups to account for changes in participants' circumstances which may affect their views and experiences [43]. With patients' permission, information regarding diagnosis, disease stage, and treatments received will be obtained from patients' medical records to decrease the research-related burden on patients. At the end of the interview, participants will be given the option to provide additional comments.

Statistical Analysis

Preliminary analysis will involve computing descriptive statistics for all quantitative variables. For continuous variables, means, SDs, and quartiles will be estimated, while categorical variables will be summarized with counts and percentages in each category. Summaries will be performed by group and by assessment, as well as for the entire study group. Primary data analysis of the primary end point will involve comparing the frequencies of conversations about treatment options after graft loss between both groups using a 2-sided χ^2 test. Secondary data analysis will include a comparison in secondary outcomes between both groups using a χ^2 test. In general, test results will be described as significant if their P values are less than .05 without adjustments for multiple inferences. Multiple imputations will be used to deal with missing data.

Qualitative Research Analysis

Interviews will be transcribed verbatim. The interviews will be recorded for the purpose of transcription on provided devices and will be deleted after the end of the research process. Transcripts will be checked for accuracy by 1 researcher and

analyzed using framework analysis. This approach belongs to a broad family of qualitative data analysis methods often related to as "thematic analysis" or "qualitative content analysis" [44]. As suggested by these approaches, both manifest and latent content will be analyzed and descriptive and explanatory conclusions will be drawn from the data [45]. Each interview will serve as a unit of analysis. A journal of reasoning and additional ideas regarding data analysis will help ensure transparency in the coding process. This strategy has been extensively used to facilitate the reconstruction of the analysis and provide justification for the analytical steps undertaken [46,47]. Codes will frequently be compared with each other and parts of the material will be recoded, if necessary, as an intercoder agreement test and additional measure for reliability [48]. This method of qualitative data analysis will provide a systematic model for mapping and interpreting the data and is thus considered appropriate to develop a profound in-depth understanding of participants' communication experiences and preferences [46,49].

Data Management

Designated investigator staff must enter the information required by the protocol into the assigned database. Individual interviews, telephone interviews, and patient-physician conversations will be audio recorded, transcribed verbatim by a professional transcriptionist or a research team member, deidentified, and filed for data management and analysis. All qualitative data will be collected by a research team member with extensive experience in qualitative research.

Safety

Safety assessments will consist of monitoring and recording all adverse events (AEs) and serious AEs, the regular monitoring of blood chemistry and urine, and regular monitoring of vital signs, physical condition, and body weight. Appropriate sponsor personnel and investigators will monitor the safety of the participants throughout the conduct of the study. AEs mean "any untoward occurrence in a trial subject administered an investigational medicinal product and which does not necessarily have a causal relationship with this treatment" [50]. In the PRIMA-AI trial, subjects will not receive any investigational medicinal product, but physicians will be assisted by an AI-based decision support system. Thus, in this study, an AE can be any unfavorable and unintended sign, symptom, or disease (including concomitant illness), deterioration of a preexisting illness, accident, any suspected drug reaction, or a clinically relevant change of laboratory values whether or not considered to be related to the AI-based intervention. Adverse reactions (ARs) mean "all untoward and unintended responses to an investigational medicinal product unrelated to the dose administered" [50]. In PRIMA-AI, subjects will not receive any investigational medicinal product. Therefore, the definition of AR implies in this trial a reasonable possibility of a causal relationship between the event and the investigational AI-based intervention.

The period of observation for AEs extends from the baseline visit (month 0, visit 1) after informed consent was given until and including month 24 (visit 5). AEs have to be followed up until resolution or stabilization or until the subject's end-of-study visit (month 24, visit 5), whichever comes first. Preexisting conditions that do not worsen during the course of the study are not reportable as AE. To determine whether a condition has worsened, it is compared to the condition of the subject at baseline visit (month 0, visit 1). All AEs, whether volunteered by the patient, discovered by investigator questioning, or detected through physical examination, laboratory test, or other means will be assessed and recorded in detail in the subject's file and on the case report form, the AE report form. All AEs will be coded appropriately at the end of the clinical study using MeDRA or, in addition, on request by the study coordinator.

The following information must be recorded: (1) AE diagnosis (if possible) or main symptom; (2) date (and time, if relevant) of onset; (3) severity (maximum observed); (4) causal relationship (reasonable possibility or no reasonable possibility); (5) seriousness (yes or no); (6) outcome; (7) action taken with the study intervention; (8) AE leading to discontinuation of the study subject (yes or no); (9) treatment of AE; and (10) stop date (and time, if relevant). For the assessment of severity, the investigator should use grades from 1 to 5 as outlined in Textbox 2.

Textbox 2. Grades of assessments of severity for adverse events.

Grade 1

Mild or asymptomatic symptoms, clinical or diagnostic observations only, and intervention not indicated.

Grade 2

Moderate, minimal, local, or noninvasive intervention indicated, and limiting age-appropriate instrumental activities of daily living. Instrumental activities of daily living are activities such as preparing meals, shopping for groceries or clothes, using the telephone, managing money.

Grade 3

Severe or medically significant but not immediately life-threatening, hospitalization or prolongation of hospitalization indicated, disabling, and limiting self-care activities of daily living. Self-care activities of daily living are activities such as bathing, dressing and undressing, feeding oneself, using the toilet, taking medications, and not being bedridden.

Grade 4

Life-threatening consequences and urgent intervention indicated.

Grade 5

Death related to adverse event.

Ethical Considerations

Written informed consent will be collected from all study participants before performing any research activity by a research team member. To ensure the eligibility of a participate in the trial, the researcher will review the inclusion and exclusion criteria with potential participants prior to beginning the informed consent process. Prospective participants will be asked to personally sign and date the latest approved version of the informed consent forms before any trial procedure is performed. During the informed consent process, study participants will be informed of their right to withdraw from the study at any time without any impact on their treatment at the KTC. This study will be conducted in accordance with the tenets of the Declaration of Helsinki (1996). The ethics committee of Charité—Universitätsmedizin Berlin approved this study (EA1/177/23; August 08, 2023).

The trial results will be disseminated through a variety of strategies, including academic publications, research reports, infographics, media releases, and community events. Trial participants' anonymity and confidentiality will be protected during these activities by removing all identifiable information from the knowledge dissemination products.

Results

As of March 10, 2024, we enrolled 19 participants. The first results are expected to be submitted for publication in 2025.

Discussion

Principal Findings

This study is designed to investigate the influence of AI-based risk prediction on the frequency of conversations about treatment options after graft loss and the associated SDM process with a randomized design using a mixed methods approach. It is the first study in the context of kidney transplantation to analyze the potential effects of AI-based interventions on physician-patient interaction.

Despite tremendous enthusiasm surrounding the potential for AI to improve medical prognosis, diagnosis, and decision-making, only limited empirical data are available to help understand patients' and physicians' perspectives on how AI impacts their interactions, specifically SDM [16]. In the context of kidney transplantation, AI research has mostly focused on technical and medical challenges relating to robustness and implementation, excluding the sociotechnical environment into which such systems are embedded [12-14]. In the treatment of patients with cancer, an intervention that delivered machine learning mortality predictions with behavioral nudges to oncology clinicians significantly increased the rate of serious illness conversations [51,52]. While serious illness conversations are only in part comparable to conversations about graft loss, returning to dialysis after transplantation is also a life-changing event with serious effects on quality of life. We argue that increasing the frequency of conversation about treatment options after graft loss and improving SDM may improve patient satisfaction comparable to patients with chronic kidney disease without transplantation [6].

Strengths and Limitations

The main strength of this study is the mixed methods approach that will support the analysis of the primary end point with validated assessment tools for SDM and qualitative data from semistructured interviews. It is the first study in the context of kidney transplantation that investigates the impact of AI-based risk prediction on physician-patient interaction. While performed in a tertiary care setting, transplant nephrologists often serve as primary caregivers to kidney transplant recipients. Therefore, the results may generalize to a broader range of care settings as well. The randomized design enables to detect potential effects of the AI-based risk prediction on the conversation frequency about graft loss, which can improve patient information and patient care. It also provides us with a control group, in which SDM about treatment options after graft loss in kidney transplantation can be studied without any intervention, which has not been done so far. Another strength is the long observation time of 24 months, which enables to detect potential adaptations of physicians, patients, and support persons to the novel AI system and the emergence of a sociotechnical system in the recordings of patient-physician interactions as well as the semistructured interviews.

The main limitation is that potential effects of the AI intervention on SDM are indirect since no specific SDM intervention has been implemented and the AI system is not designed to improve SDM in particular, for example, by providing different scenarios or enabling input of patient preferences. Another potential limitation is that participation in the trial may influence physicians to talk about treatment options after graft loss, which may reduce the potential effect size of the AI intervention. Furthermore, the open-label design, which is unavoidable, introduces the possibility of bias, especially since the primary end point is not a medical end point.

Conclusions

In conclusion, this study will generate novel and important data about the impact of AI on physician-patient interaction and SDM in the context of kidney transplantation, which may be applicable to other disease contexts as well.

Abstract

Background: Sexual minority cisgender men and transgender (SMMT) individuals, particularly emerging adults (aged 18-34 years), often report hazardous drinking. Given that alcohol use increases the likelihood of HIV risk behaviors, and HIV disproportionately affects SMMT individuals, there is a need to test interventions that reduce hazardous alcohol use and subsequent HIV risk behaviors among this population. Ecological momentary interventions (EMIs), which use mobile phones to deliver risk reduction messages based on current location and behaviors, can help to address triggers that lead to drinking in real time.

Objective: This study will test an EMI that uses motivational interviewing (MI), smartphone surveys, mobile breathalyzers, and location tracking to provide real-time messaging that addresses triggers for drinking when SMMT individuals visit locations associated with hazardous alcohol use. In addition, the intervention will deliver harm reduction messaging if individuals report engaging in alcohol use.

Methods: We will conduct a 3-arm randomized controlled trial (N=405 HIV-negative SMMT individuals; n=135, 33% per arm) comparing the following conditions: (1) Tracking and Reducing Alcohol Consumption (a smartphone-delivered 4-session MI intervention), (2) Tracking and Reducing Alcohol Consumption and Environmental Risk (an EMI combining MI with real-time messaging based on geographic locations that are triggers to drinking), and (3) a smartphone-based alcohol monitoring–only control group. Breathalyzer results and daily self-reports will be used to assess the primary and secondary outcomes of drinking days, drinks per drinking day, binge drinking episodes, and HIV risk behaviors. Additional assessments at baseline, 3 months, 6 months, and 9 months will evaluate exploratory long-term outcomes.

Results: The study is part of a 5-year research project funded in August 2022 by the National Institute on Alcohol Abuse and Alcoholism. The first 1.5 years of the study will be dedicated to planning and development activities, including formative research, app design and testing, and message design and testing. The subsequent 3.5 years will see the study complete participant recruitment,

data collection, analyses, report writing, and dissemination. We expect to complete all study data collection in or before January 2027.

Conclusions: This study will provide novel evidence about the relative efficacy of using a smartphone-delivered MI intervention and real-time messaging to address triggers for hazardous alcohol use and sexual risk behaviors. The EMI approach, which incorporates location-based preventive messaging and behavior surveys, may help to better understand the complexity of daily stressors among SMMT individuals and their impact on hazardous alcohol use and HIV risk behaviors. The tailoring of this intervention toward SMMT individuals helps to address their underrepresentation in existing alcohol use research and will be promising for informing where structural alcohol use prevention and treatment interventions are needed to support SMMT individuals.

Introduction

Background

Those who identify as sexual and gender minority individuals (eg, gay, bisexual, transgender, or queer individuals) are more likely to report hazardous drinking, defined as "drinking behavior (such as per episode, daily, or weekly) that reflects meaningful increases in risk of negative alcohol-related outcomes" [1] and to have alcohol use disorders (AUDs) than their cisgender and heterosexual peers [2-5]. Similarly, emerging adult (aged 18-34 years) sexual and gender minority individuals are at increased odds of being diagnosed with AUDs compared to older adults, with up to 44% meeting AUD criteria [3,6]. An extensive body of research suggests that the increased use of alcohol among young sexual and gender minority populations is attributable to interlocking structural underpinnings of stigma, homophobia, transphobia, and other manifestations of violence against queer people [5,7-9]. These trends are concerning because multiple studies have found that alcohol use increases the likelihood of acquiring HIV through various behaviors [10-13] and that HIV disproportionately affects emerging adult sexual minority cisgender men and transgender (SMMT) individuals [14]. Consequently, individuals who have reported unhealthy levels of alcohol use also were likely to experience interference with their decision-making with regard to adhering to pre-exposure prophylaxis (PrEP) [15], which can prevent HIV. Thus, it is essential to test interventions for reducing alcohol use among SMMT individuals as a means of preventing HIV among these populations considered to be at high risk.

A recent systematic review found that motivational interviewing (MI) is a frequently used method for reducing alcohol use [16]. MI is a goal-oriented and patient-centered approach to motivating behavior change and increasing self-efficacy. While it has been effective for reducing alcohol use among gay and bisexual men [17-19], this review found only 1 alcohol-related MI intervention for transgender people [20], suggesting the need for more research with this population. Prior studies also suggest the effectiveness of MI being delivered through technology to support the reduction of alcohol use behaviors [21]. The Tracking and Reducing Alcohol Consumption (TRAC) intervention, recently tested among people with HIV and currently being tested (since July 2023) among young adult survivors of cancer, uses smartphones to deliver 4 to 8 weekly sessions of MI for reducing risky drinking. The sessions focus on identifying triggers for drinking and strategies for addressing these triggers. TRAC also incorporates daily smartphone-based alcohol monitoring (SAM) using mobile breathalyzers and surveys. While preliminary results are promising in terms of TRAC's effectiveness and acceptability [22], there is potential for enhancing it by reinforcing content in real-time situations where people are more likely to experience triggers to use alcohol.

Ecological momentary interventions (EMIs), which use smartphones to deliver messages to reduce alcohol use and related risk behaviors during or before drinking events, can help to address triggers in real time. GPS tracking can determine when individuals visit places where they have previously reported drinking or triggers to drink, and then EMI messages can be delivered upon arrival to *prevent* hazardous alcohol use. However, this GPS-based approach has rarely been studied to date and has generally targeted individuals with AUDs (as opposed to those who engage in hazardous drinking but do not have an AUD) [23,24]. We have developed a mobile app for a previous observational study that uses GPS tracking to determine when emerging adult SMMT individuals visit *riskylocations* and then delivers a survey asking about aspects of the location's social and geographic context that may relate to drinking and other risk behavior.

Objectives

The goal of the proposed study is to use this app to enhance TRAC by delivering messages that encourage participants to use strategies discussed during TRAC sessions when arriving at risky locations. When they leave these locations, they will complete a survey and a breathalyzer reading to collect event-level self-report and biological data on alcohol use and HIV risk. If their breathalyzer result indicates alcohol use, they will receive harm reduction messaging. It is expected that combining TRAC with EMI (Tracking and Reducing Alcohol

Consumption and Environmental Risk [TRAC-ER]) will increase effectiveness by reinforcing topics discussed during sessions, providing in-the-moment messaging to address triggers, and collecting real-time alcohol use data.

We will conduct a randomized controlled trial (RCT) of the TRAC and TRAC-ER interventions, examining their effects on alcohol use and HIV risk behaviors among SMMT individuals compared with a SAM-only control group. We will examine 2 aims.

- Aim 1: assess the effects of intervention conditions on drinking days (primary end point), drinks per drinking day, and binge drinking episodes (secondary end points).
  Hypothesis:
  TRAC and TRAC-ER will lead to significantly fewer drinking days compared with a SAM-only control group, with TRAC-ER having the strongest effects.
- Aim 2: assess the effects of intervention conditions on HIV risk behaviors (unprotected sex, number of partners, concurrent sex and substance use, and PrEP nonadherence).
  Hypothesis:
  TRAC and TRAC-ER will lead to significantly fewer HIV risk behaviors compared with a SAM-only control group, with TRAC-ER having the strongest effects.

Methods

Study Design

We will conduct a 3-arm RCT of TRAC and TRAC-ER (n=405 HIV-negative SMMT individuals; n=135, 33% per arm), with the following conditions: (1) SAM-only comparison group, (2) SAM+TRAC (no EMI messaging), and (3) SAM+TRAC-ER (participants receive EMI messaging when visiting risky locations).

Breathalyzer results and daily self-reports will be used to assess the primary and secondary outcomes of drinking days, drinks per drinking day, binge drinking episodes, and HIV risk behaviors. Additional assessments at baseline (T1), 3 months (T2), 6 months (T3), and 9 months (T4) will evaluate exploratory long-term outcomes, including diagnoses of HIV or other sexually transmitted infections (STIs).

Participants and Recruitment

Overview

Participants will be recruited using web-based and community-based recruitment, as well as through health clinics that serve SMMT individuals. A combination of venue-based and purposive sampling approaches appropriate for accessing populations considered to be hard to reach and at risk will be used to recruit participants [25-27]. Previous intervention studies with young adult SMMT populations have found 6-month dropout rates of 15% to 25% [28-30]. To reach our target final sample (n=324; refer to the Sample Size Justification subsection), we will recruit 405 individuals, accounting for an estimated 20% dropout rate based on prior literature.

Health Clinics

All patients presenting for appointments at participating clinics will be screened using a preprogrammed tablet computer to determine eligibility. The principal investigators will provide instruction to clinic staff regarding screening patients and distribute quick-reference study information sheets to keep in offices. The study coordinator will be available during business hours to help clinic staff as needed.

Web-Based and Community-Based Recruitment

Our previous studies have successfully used a variety of recruitment methods to reach SMMT individuals, which we will also leverage in the proposed study: flyer outreach (in locations frequented by SMMT individuals), social media recruitment (including paid and free posts on Instagram, Facebook, Reddit, and dating apps), a study website, and institutional collaborations. All advertisements will direct participants to the web-based screener. We will use a community advisory board, comprising members representing different subsets of the SMMT population, to obtain further guidance regarding ideal participant recruitment methods.

Inclusion and Exclusion Criteria

Participants will be eligible to participate if they meet the following inclusion criteria: (1) self-identify as a gender minority individual (eg, transgender man, transgender woman, nonbinary individual, agender individual, or gender fluid individual) or a sexual minority cisgender man (ie, assigned male sex at birth and identifies as a man with a sexual orientation other than heterosexual), (2) is aged between 18 and 35 years at the start of the study, (3) owns a smartphone, (4) is HIV-negative (confirmed through a test at baseline), (5) meets Centers for Disease Control and Prevention PrEP eligibility criteria (individuals will be eligible if they have had anal or vaginal sex in the past 6 months and have at least one of the following characteristics: a sexual partner with HIV, inconsistent condom and PrEP use, or a sexually transmitted disease diagnosis in the past 6 months; or if they inject drugs and have an injection partner with HIV or share needles, syringes, or other equipment to inject drugs) [31], and (6) screens positively for hazardous alcohol use. As most alcohol screening instruments rely on biological sex, we will use a combination of the Alcohol Use Disorders Identification Test–Concise (AUDIT-C), a validated 3-item screener for hazardous alcohol use [32], and a 1-item yes or no screening question to determine whether they engage in hazardous alcohol use (“Have you had 5 or more drinks on one occasion in the past year?”). This question was found to be a valid measure of hazardous alcohol use among gender-diverse individuals; despite it being a single item, this screening method performed better than the AUDIT-C for lower drink thresholds (eg, ≥4 drinks) in predicting hazardous alcohol use [33]. However, because this is still a new approach to assessing hazardous drinking and because we will also be enrolling cisgender individuals, we will consider AUDIT-C scores too; participants must also score ≥4 on the AUDIT-C to qualify [32].

Exclusion criteria include (1) not speaking English; (2) active psychosis or severe mental illness; (3) actively detoxifying from

substances and needing medical supervision; or (4) a score of ≥20 on the Alcohol Use Disorders Identification Test [32], which indicates that participants exhibit increased or higher risk drinking behaviors.

Regardless of the recruitment method used, all participants will complete a web-based screener. If participants are determined to be eligible according to the screener, they will be informed of their eligibility and invited to provide their contact information if they wish to learn more about the study.

Sample Size Justification

Sample size determination was based on the primary outcome variable: number of drinking days in the past month across the repeated visits corresponding to T1, T2, T3, and T4 for the 3 groups (SAM only, SAM+TRAC, and SAM+TRAC-ER). Data on effect sizes from previous alcohol use interventions [34,35] and our preliminary data (within-participant correlation of 0.69) were used to derive the mean number of days of alcohol use and their SDs. With a final sample size of n=324 (after accounting for a 20% dropout rate with a total n=405), 108 (33%) participants in each group will give us at least 90% power at 5% type I error rate to detect a significant difference among the groups for an effect size of 0.071 when comparing the groups over the study period. This effect size is smaller than a *small* effect as defined by Cohen et al [36].

We expect our sample to have the following characteristics: 48.1% (195/405) cisgender men, 24.9% (101/405) transgender men, 20% (81/405) transgender women, and 6.9% (28/405) nonbinary individuals. Our sample will likely have a higher proportion of transgender participants compared to the general population due to recruitment within health clinics that provide care for transgender patients; we view this as a strength of our study, given the underrepresentation of gender minority individuals in previous alcohol intervention and HIV prevention research.

Enrollment

If participants are determined to be eligible according to their responses to the web-based screener, they will be informed of their eligibility and invited to provide their contact information if they wish to learn more about the study. If participants are ineligible, they will be informed of this upon completion of the screener. A member of the study team will contact eligible participants via their preferred contact method to complete an interview confirming eligibility. This interview is conducted via Zoom (Zoom Video Communications, Inc) and is included as protection against spam or false screener responses.

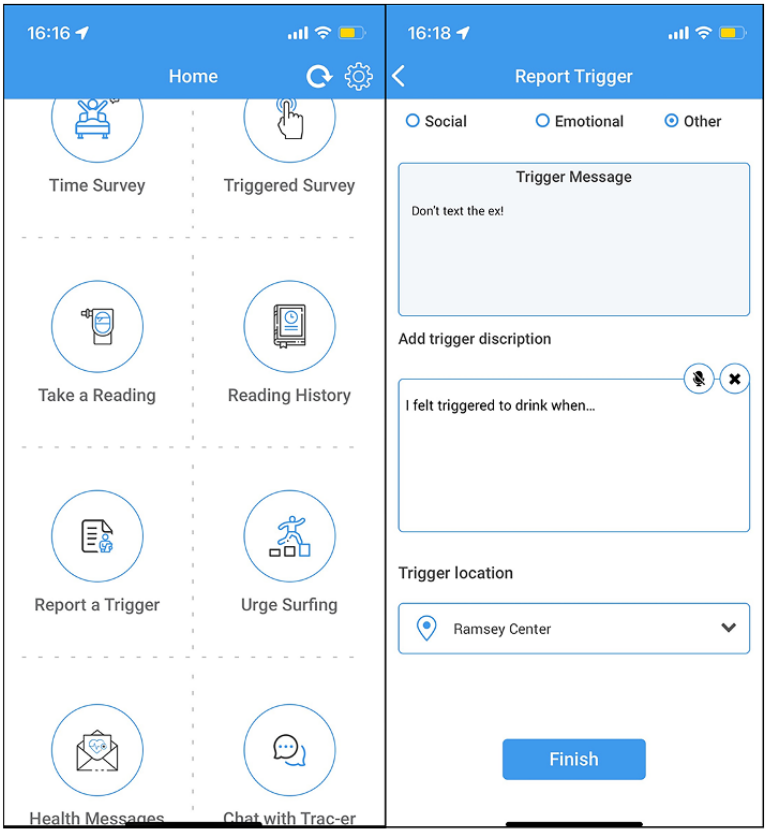
Study Interventions and Procedures

Description of TRAC-ER Study App

The app developed for this study has been designed to track participants' physical location through continuous GPS monitoring and to deliver assessments and messages at specific times of the day and in response to participants' physical location. At baseline, all participants will be asked to list the locations where they most frequently engage, or are triggered to engage, in alcohol use, unprotected sex, or other HIV risk behaviors as part of an activity space assessment. For each listed location, they will provide information regarding the types of alcohol triggers they experience (eg, social, situational, or emotional). These locations will then be programmed into the app and given a geofence (a distance around the location such that when participants break the geofence, intervention-specific actions such as surveys or messages are delivered). Before each follow-up monitoring period, participants will complete a short questionnaire that lists the locations they identified in the activity space assessment, as well as locations where they reported drinking via the random breathalyzer reading requests during prior monitoring periods. They will have the opportunity to revise the list of locations, which will ensure that the triggered surveys are being delivered for locations most relevant to the participants.

Every morning during the SAM periods, participants will receive a push notification asking them to report the number of drinks consumed in the previous day (if applicable), time spent drinking, alcohol withdrawal symptoms, and sexual risk behaviors. The app will also send requests for breathalyzer readings at least 2 times per day in response to visits to risky locations and through random requests. At the time of providing the breathalyzer reading, participants will also complete a brief mobile survey using the study app that includes questions related to their alcohol use. Participants can view a log of their breathalyzer readings in the app. Participants will have the option to report a trigger in the app and provide details about the trigger, including the location where the trigger was generated. Participants who are randomized to the TRAC-ER intervention will receive a harm reduction message based on the type of trigger (social, emotional, or other) they report. A guided breathing exercise and urge surfing exercise are included in the app for those in the TRAC and TRAC-ER conditions. Figure 1 presents a screenshot of the app. If, at any point during the monitoring periods, the app stops collecting GPS data, the study team will reach out to determine whether the participant accidentally turned off location tracking, lost their mobile phone, or is experiencing other technical difficulties.

Figure 1. Tracking and Reducing Alcohol Consumption and Environmental Risk (TRAC-ER) app screenshots (app developed by Vista IT Solutions, LLC).



Description of Study Arms

Overview

Participants will be enrolled in the study for 9 months, including the 2-month intervention period and multiple follow-up monitoring periods to assess long-term effects. All participants will begin with a 30-day monitoring period, which will establish baseline alcohol use through daily breathalyzer reading requests and surveys. After this 30-day period, they will complete additional baseline measures (T1) and then begin their assigned intervention, if applicable. After the interventions are delivered, participants will complete an additional self-report (T2). Subsequently, there will be 2 additional monitoring periods and assessments spread across the 9-month study period to assess long-term intervention effects, with some months involving no study activities. A depiction of the participation timeline is included in Figure 2, and details of study activities completed across the study timeline and RCT arms are provided in Table 1.

Figure 2. Participation timeline. STI: sexually transmitted infection; TRAC: Tracking and Reducing Alcohol Consumption; TRAC-ER: Tracking and Reducing Alcohol Consumption and Environmental Risk.

[a]TRAC: Tracking and Reducing Alcohol Consumption.

[b]TRAC-ER: Tracking and Reducing Alcohol Consumption and Environmental Risk.

SAM-Only Participants

Participants will complete alcohol self-monitoring tasks using the study app (daily surveys and breathalyzer readings) during months 1 to 3, month 6, and month 9. During these designated months, participants will receive prompts to complete morning surveys, random breathalyzer requests, and location surveys, as described in Table 1.

SAM-only participants will also complete the T1 to T4 assessments on the schedule illustrated in Figure 1.

TRAC Participants

TRAC participants will complete alcohol self-monitoring tasks and assessments following the schedule described for SAM-only participants. In addition, participants will receive the 4-session TRAC intervention. Individuals will meet for 30 minutes with an interventionist on a weekly basis via telephone or video chat, although the 6-week intervention period allows for some cancellations or rescheduling. Textbox 1 presents an overview of the 4-session TRAC intervention. Participants will be mailed a paper workbook to complete during the sessions. The SAM app will provide supplementary materials, including a triggers

diary, a guided breathing exercise, and a record of the participants' goals for reducing their drinking. After participants complete all intervention sessions, they will continue daily monitoring for the remainder of the 2-month intervention period. Participants will complete the T1 to T4 assessments following the schedule described for SAM-only participants.

Textbox 1. Session overview of the Tracking and Reducing Alcohol Consumption (TRAC) intervention.

Session 1

- Introduction (5-8 minutes)
- Alcohol and health factsheet (10 minutes)
- Review current alcohol use (15 minutes)
- Complete change plan (10 minutes)
- Diaphragmatic breathing (8 minutes)
- Wrap up and schedule next session (5 minutes)

Session 2

- Recap of past session, check-in, and agenda setting (5 minutes)
- Review weekly drinking data and change goals from last week (10 minutes)
- Review strategies for managing triggers (20 minutes)
- Urge surfing skill (10 minutes)
- Wrap up and schedule next session (5 minutes)

Session 3

- Recap of past session, check-in, and agenda setting (5 minutes)
- Review weekly drinking data and change goals from last week (10 minutes)
- Strategies for reducing alcohol-related harm (20 minutes)
  - Before known drinking occasions
  - While drinking alcohol
  - After drinking alcohol
- Wrap up and schedule next session (5 minutes)

Session 4

- Recap of past session, check-in, and agenda setting (5 minutes)
- Review weekly drinking data and change goals from last week (5-8 minutes)
- Review overall progress (5-8 minutes)
- Set goals and plan for going forward (10-15 minutes)
- Wrap up and give reminder of remaining study tasks (5 minutes)

TRAC-ER Participants

Overview

Participants will complete all aspects of the TRAC intervention condition. In addition to receiving triggered surveys when they leave a risky location, participants will also receive prevention messaging when they first arrive at a risky location. This messaging will be tailored based on the data collected regarding participants' risky locations and the strategies to address triggers discussed during the MI intervention sessions. In addition, if participants return a breathalyzer reading >0.00%, they will receive harm reduction messaging encouraging them to engage in protective behaviors. These messages will continue throughout the 2-month intervention period, including after the 4 TRAC sessions have been completed. Participants will complete the T1 to T4 assessments following the schedule described for SAM-only participants.

MI Interventionist Training and Fidelity Assessment

The full-time study interventionist, an individual with a master's degree in counseling, will receive refresher training from a supervisor who is a licensed clinical social worker regarding the principles of MI as they relate to substance use and the key components of the TRAC intervention through 12 hours of instruction and mock interviews. This supervisor will review the interventionist's first TRAC case (or additional cases, if needed). Fidelity ratings will be conducted using a combination of the Motivational Interviewing Treatment Integrity (MITI)

4.2.1 coding system and adherence checklists to be developed by the study team to code for the presence of specific skills and exercises included in the TRAC protocol. MITI is an established structured behavioral coding system that serves as a treatment fidelity measure for clinical trials of MI [37,38]. It provides a global impression of empathy and MI spirit, a reflection-to-question ratio, and summary scores for MI components based on behavior count ratios of complex reflections, open questions, and MI-adherent utterances. The interventionist will be *certified* as able to deliver the protocol with fidelity. Certification will involve meeting adherence of at least 80% of TRAC-specific skills and exercises and the recommended MI competency threshold on at least 80% of sessions for a given case. Until the interventionist is certified, the supervisor will review entire session recordings weekly to code TRAC adherence, and a randomly selected 20-minute segment will be coded with MITI. Individual feedback and training will be provided weekly. Overall trial fidelity ratings (adherence to TRAC skills and exercises and MI competency) will be determined via review of an additional randomly selected 20% of interviews (10% from each site), in line with recommendations for RCTs of MI [39], including double coding by the supervisor and a research assistant, both of whom will be certified in MITI coding.

Data Collection Procedures

Overview

As this study is examining both short- and long-term effects and comparing them among the groups, the primary end point of the number of past-month drinking days will be assessed based on SAM results collected before T1, throughout the intervention, and before T3 and T4. Secondary end points include drinks per drinking day and binge drinking episodes. All other variables measured, including those related to HIV risk behaviors, will be used to conduct exploratory analyses. The sources of data for this RCT include SAM data (including surveys and breathalyzer results, discussed in detail previously), baseline and follow-up self-report measures (T1-T4), HIV and STI testing, app-based process measures, and qualitative interviews.

Baseline and Follow-Up Measures

An assessment battery will be administered to all participants at T1, T2, T3, and T4. This will include several measures of alcohol use as well as more exploratory variables, including alcohol cravings, alcohol consequences, the use of alcohol treatment services, HIV risk behaviors, and experiences of discrimination related to participants' identity as sexual and gender minority individuals. Table 2 presents a description of the key study measures.

Table 2. Description of key study measures.

Construct and time	Measure	End point	Description
Drinking days, 2× daily	Breath alcohol content	Primary	BACtrack Mobile breathalyzer result sent via mobile app; measured 2× daily for 8 weeks during the intervention and for 1 month before T1[a], T3[b], and T4[c]; 2 negative readings per day=nondrinking day
Drinks per drinking day, daily	Self-reported alcohol use through app	Secondary	3 items: alcohol consumed (yes or no), number of drinks, and time spent drinking; measured daily during the intervention and for 1 month before T1, T3, and T4
Binge drinking episodes, daily	Self-reported alcohol use through app	Secondary	Occasions when participants had ≥5 drinks based on self-reported number of drinks; measured daily during the intervention and for 1 month before T1, T3, and T4
Alcohol withdrawal symptoms, daily	Single-item AWSC[d] [40]	Exploratory	1 item: alcohol withdrawal symptom severity on a scale of 0 to 9; those scoring ≥2 are asked to complete the 17-item AWSC, which assesses the severity of symptoms; measured daily during intervention and for 1 month before T1, T3, and T4
Sexual activity, daily	Self-reported through app	Exploratory	6 items: past-day sexual activity, number of partners, partner type, partner HIV status, type of sexual activity, condomless sex, and PrEP[e] use
Location characteristics, up to 2× daily	Self-reported through app	Exploratory	12 items assessing alcohol and substance use, sexual behaviors, peer use of alcohol or substances, and harassment or discrimination experienced
Alcohol use, T1, T2[f], T3, and T4	PROMIS[g] Short Form–Alcohol Use 7a [41]	Exploratory	7 items that assess general alcohol use and problem drinking in the past 30 days (eg, drank too much and drank heavily)
Alcohol consequences			
T1, T2, T3, and T4	PROMIS Short Form–Alcohol Use–Negative Consequences 7a [41]	Exploratory	7 items that assess the negative consequences of using alcohol in the previous 30 days (eg, unreliability, social problems, and judgment)
T1, T2, T3, and T4	PROMIS Short Form–Alcohol Use–Positive Consequences 7a [41]	Exploratory	7 items that assess the positive consequences of using alcohol in the previous 30 days (eg, self-esteem, confidence, and enjoyment)
Alcohol expectancies			
T1, T2, T3, and T4	PROMIS Short Form–Alcohol Use–Negative Expectancies 7a [41]	Exploratory	7 items that assess the negative expectancies of alcohol use (eg, making bad decisions and behaving rudely)
T1, T2, T3, and T4	PROMIS Short Form–Alcohol Use–Positive Expectancies 7a [41]	Exploratory	7 items that assess the positive expectancies of alcohol use (eg, improves mood and sociability)
Readiness to change drinking, T1, T2, T3, and T4	Readiness to Change Questionnaire [42]	Exploratory	12 items that assess the stage of change toward reducing alcohol use (precontemplation, contemplation, and action)
Drinking refusal self-efficacy, T1, T2, T3, and T4	Drinking Refusal Self-Efficacy Questionnaire–Revised [43]	Exploratory	19 items that assess individuals' belief in their ability to resist alcohol, with 3 subscales: social pressure drinking, emotional relief drinking, and opportunistic drinking
Sexual risk behaviors, T1, T2, T3, and T4	National HIV Behavioral Surveillance System [44]	Exploratory	≥6 items: number of partners in previous 12 (T1) or 3 (T2-T4) months; partner type (main vs casual); partner HIV status; frequency of condomless sex (anal, vaginal, or oral), transactional sex, and concurrent sex and drug or alcohol use; and PrEP use
Condom attitudes, T1, T2, T3, and T4	Multidimensional Condom Attitudes Scale [45]	Exploratory	16 items that measure attitudes toward condoms across 7 factors: reliability, effectiveness, pleasure, identity stigma, embarrassment about purchase, negotiation, and action maintenance
Perceived HIV risk, T1, T2, T3, and T4	Perceived Risk of HIV Scale [46]	Exploratory	8 items that assess likelihood estimates, intuitive judgments, and salience of HIV risk based on previous behaviors
Discrimination due to sexual or gender identity, T1, T2, T3, and T4	Heterosexist Harassment, Rejection, and Discrimination Scale [47]	Exploratory	12 items that assess harassment, rejection, and family discrimination related to LGBTQ[h] identities
Alcohol cravings, T1, T2, T3, and T4	Penn Alcohol Craving Scale [48]	Exploratory	5 items that assess alcohol-related cravings; higher scores indicate higher rates of alcohol cravings

Construct and time	Measure	End point	Description
Alcohol Use, T1, T2, T3, and T4	Alcohol Quantity Measures	Exploratory	7 items that assess alcohol use over the past 30 days

[a]T1: baseline assessment.

[b]T3: 6-month assessment.

[c]T4: 9-month assessment.

[d]AWSC: alcohol withdrawal symptom checklist.

[e]PrEP: pre-exposure prophylaxis.

[f]T2: 3-month assessment.

[g]PROMIS: Patient-Reported Outcomes Measurement Information System.

[h]LGBTQ: lesbian, gay, bisexual, transgender, and queer.

HIV and STI Testing

At T1 and T4, participants will receive HIV and 3-site gonorrhea and chlamydia testing. We will use myLAB Box, with whom we have worked successfully in prior research, to deliver home testing kits to participants. myLAB Box is a fully laboratory-certified company using College of American Pathologists– and Clinical Laboratory Improvement Amendments–certified testing organizations and a HIPAA (Health Insurance Portability and Accountability Act)–compliant web interface [49]. The home testing kits include written instructions for how to collect the samples; participants will complete a finger prick blood sample for the HIV test and collect swab and urine samples for the gonorrhea and chlamydia testing. The test kits will be mailed by the participants to myLAB Box using prepaid shipping boxes. Before completing testing, participants will complete a HIPAA release form giving permission for their results to be shared with the study team. In the case of a positive test, the participant will have the opportunity to complete a telehealth visit (free of charge) with one of myLAB Box's providers to discuss medications and linkage to care. The research team will also follow up with the participant to ensure that they have been connected to care and, in the case of a positive HIV test at T1, to communicate that they are no longer eligible to participate in the study.

Process Measures

We will assess several process measures related to the study app, including the number of opened and completed daily surveys, the number of messages opened, the length of time messages stayed open, the number of completed breathalyzer readings and location-based surveys, the frequency of missing GPS data, and the number of reported app issues. For each participant completing monitoring, we will generate a weekly report of these metrics to address any ongoing technical issues in a timely manner and to encourage the completion of surveys and breathalyzer readings if they are nonadherent. For the TRAC intervention, the interventionist will complete fidelity checklists after each session. We will also assess session attendance, dropout rates, and time spent in sessions. At the end of the intervention, we will conduct an overall fidelity assessment to aid in the interpretation of the intervention results. Overall, these process measures will inform future dissemination and implementation efforts.

Qualitative Intervention Assessment

At the T2 assessment, we will conduct a semistructured qualitative interview to obtain feedback on the SAM-only, and SAM+ TRAC, and SAM + TRAC-ER conditions. As applicable according to their intervention group, the interview will address the effects of the monitoring of alcohol use, attitudes toward MI intervention content, the impact of the EMI messages on drinking and HIV risk behavior, the impressions of intervention relevance and effects, challenges encountered during the intervention, and suggestions for improvement.

Participant Training

Participants in each condition will be trained to navigate the app and complete tasks, including completing location-based and daily assessments, reading messages, and providing breathalyzer readings. They will also be instructed on data safety and confidentiality procedures and how to remotely wipe their mobile phone data if it is lost or stolen. Wallet-size cards with information from the training and text reminders to carry the mobile phone and breathalyzers will be provided. A lack of response will be followed up with texts and telephone calls to ascertain the reason for noncompliance. If participants report problems, we will complete video calls to troubleshoot and further train participants, if needed.

Methods to Decrease Attrition and Missing Data

During the first 3 months of the study, participants will receive daily reminders to complete SAM, which will include information about potential incentives. Individuals in the SAM+TRAC and SAM+TRAC-ER arms will have weekly contact with research staff during the TRAC sessions and will receive reminders about upcoming appointments. We will contact participants 1 month before their follow-up monitoring periods to remind them about upcoming tasks and to ensure that contact information is up to date. The use of a novel smartphone app and a mobile breathalyzer, which has been highly rated by participants in past studies, will also help to ensure continued engagement with, and enthusiasm for, the study.

Ethical Considerations

All procedures were approved by the University of Kentucky Institutional Review Board (79109), with Yale University relying on the University of Kentucky for human participant oversight. All responses of participants will be held in confidence and kept secure. Only the researchers involved in this study and those responsible for the research oversight will have access to the information that may identify the participants.

All participants will complete informed consent before beginning research activities. All consenting procedures will be completed remotely and electronically using the REDCap (Research Electronic Data Capture; Vanderbilt University) *eConsent* framework. First, participants will be given basic information about the study. If they indicate interest in learning more and meet eligibility criteria after completing a brief screening survey, a member of the research team will contact them via their preferred contact method to confirm eligibility, provide more details about the research procedures, and obtain informed consent.

The research team will review all aspects of the study, including specific research procedures, the length of time participants will be enrolled in the study, and the associated risks and benefits of participation (eg, benefiting from free alcohol reduction counseling, which may impact overall health, and the risks of emotional distress from completing sessions and assessments and of a loss of confidentiality). Contact information for study staff, the principal investigators, the University of Kentucky's Office of Research Integrity, and Yale University's Human Research Protection Program will be provided, and the participant will be encouraged to contact any of the relevant individuals if they have questions or concerns regarding this research or to discuss their rights as a research participant.

If a participant chooses to sign up for the study after this conversation with the research team, they will complete consent by providing an electronic signature in REDCap. A copy of the consent form will be provided to the participant electronically and retained in REDCap's file repository for study records. By signing this form, participants agree to allow for future use, and sharing of, their deidentified study data with other researchers, without additional informed consent. No participant will begin research procedures without first providing signed informed consent.

To protect confidentiality, participants will be assigned a unique study ID number. Any identifying information will not be stored alongside survey responses and will be permanently deleted after the completion of data collection in accordance with the University of Kentucky Institutional Review Board policies.

The research team will take all precautions to prevent a loss of confidentiality, one of the primary risks of this study. Data collected and stored on mobile phones are inherently less secure than other storage methods; however, participants will be advised on how to protect data stored on mobile phones, and study staff will be trained on best practices for securing information on mobile phones.

Electronic data will be stored and managed in REDCap and will be accessible only to authorized study personnel. All data collected through the mobile app will be hosted on a secure private server at Yale University. myLAB Box uses a HIPAA-compliant web portal that encrypts all medical information, and all communications sent by the company will minimize personal details. Due to the sensitive nature of HIV and STI results, we will give the test results a unique ID in addition to the study ID and maintain them in a separate REDCap database without other identifying information. Access to these, and all other study data, will be permitted only to authorized personnel, who will be trained in the areas of ethics, clinical trials, confidentiality protection, and human participant protection.

Participants can earn up to US $825 (US $685 for monitoring tasks and US $140 for assessments). All participants will receive a US $1 compliance payment for each breathalyzer sample submitted within a 90-minute period. They will also receive a US $1 payment for submitting their daily morning surveys. Thus, those who complete all monitoring tasks (all breathalyzer readings and daily self-reports) during the whole study (4 weeks before T1, 8 weeks during the intervention, and 4 weeks before T3 and T4) will receive US $685. Participants will also receive US $35 for completing the T1 assessment (US $20 for the questionnaire and US $15 for HIV and STI testing), US $25 for T2, US $30 for T3, and US $50 for T4. Escalating payments will be used to discourage study attrition.

While the compensation amount is relatively high, it is for activities completed across a full 9 months of participation. Total time spent on study activities ranges from 45 hours (SAM-only participants) to 50 hours (SAM+TRAC and SAM+TRAC-ER participants) when considering daily monitoring, assessments, time spent on screening and enrollment, and time spent in MI sessions. This results in an average compensation of US $16-$18 per hour in exchange for participation in study activities.

We will pay participants with reloadable debit cards, administered using OnCore clinical trial software (Advarra). Funds will be added to these cards as payments are earned, which then become immediately available. This system will allow for frequent payments without the burden of office visits or the delays from mailing checks.

Data Analysis Plan

Analysis of Alcohol Use Outcomes

Descriptive statistics for breathalyzer reading data will be summarized overall, by group (SAM only, SAM+TRAC, and SAM+TRAC-ER) and across time periods (T1-T4). The primary outcome is the number of drinking days in the past month, which is defined as the days on which individuals did not report 2 negative breathalyzer results. The rate of drinking (incidence of drinking) is the number of drinking days observed within the past month. The secondary outcomes include the number of drinks per drinking day, the number of days with binge drinking episodes, and the number of days for which HIV risk behaviors occur. All these outcomes are count data. The goal of this analysis is 2-fold: first, short-term analysis at the end of the 2-month intervention period, and, second, long-term analysis at the end of 9 months. We will fit a generalized linear model [50], with a general formulation for count data as follows:

$$g(E(y_i)) = g(\mu_i) = x'_i\beta \quad (1)$$

where y_i is the outcome variable for (i=1,2,3,...,n), n is the total number of observations, μ_i=$E(y_i)$ is the expected count, g is the link function (a mathematical function connecting the counts with the explanatory variables), β is a vector of regression parameters to be estimated, and x_i is a vector of independent covariates to be included in the model. These covariates include

group, time, age (or age group), gender identity, sexual orientation, and site.

Short-Term Outcome Analyses

After 3 months, we will fit the aforementioned model to the data and compare the groups at T1 and T2 while adjusting for the covariates. The PROC GENMOD procedure in SAS (SAS Institute Inc) will be implemented to estimate the parameters of the model, where we specify a log-link function, Poisson distribution for the count data, an offset (which is a function of the total exposure), and the covariates. We will address overdispersion using negative binomial distribution. Overdispersion occurs when the expected count for the outcome variable is not the same as its variance. The generalized estimating equation procedure will be used to account for correlation induced by the repeated observations at T2.

Long-Term Outcome Analyses

At 9 months, the time variable will include observations at T1 to T4, and the procedure implemented for the short-term analysis will be repeated with the inclusion of additional covariates in the form of interaction terms among the groups and follow-up times (T1-T4). The interaction effect is central to the comparison of the groups over the study period. Generalized estimating equation fit criteria and quasi-likelihood under the independence model criterion value will be used to determine the adequacy of model fit. This modeling framework facilitates the easy computation of hypothesis tests and CIs for effects, which will form the basis of our inferential strategy in this project. Specifically, contrast statements will be used to test specific subgroup comparisons. Multiple imputation procedure will be implemented whenever necessary for missing data points. SAS (version 9.4 or higher) will be used for all analyses, and a standard 5% significance level will be used for all statistical tests.

Addressing Biological Variables

As this project is focused on SMMT individuals, rather than assessing the effects of biological sex, we will screen for the effects of gender identity and sexual orientation in the aforementioned modeling framework. This is accomplished by introducing indicator variables for these subgroups into the analyses and assessing statistical and practical significance. The stratified randomization procedure should prevent systematic differences at baseline among the groups. We will check for statistically significant differences after randomization and adjust for such differences in the analysis in the rare event that they manifest.

Qualitative Data Analysis

Audio files of postintervention interviews will be transcribed and imported into NVivo software (Lumivero). Each transcript will be examined and coded using a grounded thematic approach [51], drawing on observed themes regarding intervention attitudes, experiences, and effects. The research team will develop the coding scheme based on an initial review of the transcripts; next, 2 coders will independently code a random sample of 10% of the transcripts. Interrater reliability will be assessed, and the coding scheme will be refined if reliability is not acceptable (acceptable interrater agreement: >90%). Once interrater agreement is achieved, the coders will code the remaining transcripts and collect representative quotations.

Gender-Inclusive and Gender-Specific Approach to Analysis

As an analytic framing to examine inequities in alcohol behaviors within SMMT populations, we will use gender-inclusive and gender-specific approaches throughout the study's quantitative and qualitative analyses, following guidelines from Restar et al [52]. Given that there is epidemiological evidence that transgender and cisgender populations' health outcomes and behaviors, such as alcohol use, are dissimilar to each other and that the drivers of these inequities are contextually uniquely different [6,53-55], applying this approach to our analysis is appropriate. This approach allows our analytical modeling to examine and discern any potential shared versus differential intervention experiences and outcomes across gender groups (ie, between cisgender and transgender participants and within gender subgroups of transgender participants). On the basis of the findings, it will also allow us to provide future intervention recommendations for either the entire sample (ie, gender inclusive) or specific to each gender group (ie, gender specific).

Scientific Rigor

The proposed study uses a rigorous randomized comparative effectiveness trial design to assess intervention effects on alcohol use outcomes. The following characteristics add to the rigor of the study: (1) the use of a SAM-only control group so that all groups can be compared using daily-level alcohol use data, (2) the incorporation of breathalyzers to enhance the validity of self-reported alcohol use, (3) the inclusion of follow-up self-report and SAM data to assess long-term outcomes, (4) recruitment strategies that use in-person and web-based methods to enhance the diversity of the sample, (5) the inclusion of a dedicated biostatistician to provide rigorous outcome analyses, (6) support from app programmers to customize the app and address technical issues, and (7) the inclusion of a licensed social worker to ensure high-quality MI training and fidelity.

Results

The study is part of a 5-year National Institutes of Health research project that was funded in August 2022 by the National Institute on Alcohol Abuse and Alcoholism. The first 1.5 years of the study will be dedicated to planning and development activities, including formative research, app design and testing, and message design and testing. The subsequent 3.5 years will see the study complete participant recruitment, data collection, analyses, report writing, and dissemination. We expect to complete all study data collection in or before January 2027.

As of February 2024, we have published 1 manuscript, a systematic review exploring interventions for addressing alcohol use and sexual HIV risk–related behaviors [16]. We have also completed 2 rounds of focus groups to refine the intervention content and harm reduction messages delivered in TRAC-ER. Overall, 34 participants were enrolled in the first round of focus groups; however, 5 were excluded after further review showed they did not meet the eligibility criteria. This resulted in a final sample of 29 individuals for the first round of focus groups. We

enrolled 22 participants for the second round of focus groups. First, we conducted separate focus groups with participants of different gender identities (sexual minority cisgender men, nonbinary and gender nonconforming participants, transgender men, and transgender women) to obtain feedback on harm reduction content added to the intervention manual and to help us generate initial harm reduction messaging. Next, we conducted an additional blended focus group to help us further refine the messages and develop our final *library* of messages that will be programmed into the app. A manuscript describing this process and the results is forthcoming.

Discussion

Summary

This manuscript describes the protocol for a 3-arm RCT evaluating the efficacy of a mobile-based EMI for reducing alcohol use and HIV risk behaviors among emerging adult SMMT individuals (N=405). We will compare a monitoring-only control to TRAC, a mobile-based MI intervention, and to TRAC-ER, an intervention combining TRAC with in-the-moment messaging to prevent hazardous alcohol use and reduce harm when participants visit risky locations. Mobile breathalyzers and surveys will be used to collect frequent data on alcohol and HIV risk behaviors. We will assess outcomes immediately before and after the intervention, as well as at 6-month and 9-month follow-ups. The primary outcome is the number of drinking days. Formative development work for this RCT has been completed, with the trial to begin recruiting soon (as of February 2024).

This study will make significant contributions to the literature on alcohol use interventions for SMMT populations. It uses an innovative precision health approach that draws upon the frequent use of smartphone technologies by emerging adult populations and the high acceptability of mobile breathalyzers. Despite the proliferation of mobile devices in society, the field of EMIs remains understudied, with very few RCTs being conducted related to alcohol use. In addition, EMIs have shown initial promise in being paired with MI approaches [56-58]; therefore, the proposed study would help to add to the fledgling evidence base regarding the effectiveness of this approach. The use of mobile technology and remote delivery of the tested interventions means that once the ideal approach is identified in terms of efficacy, the intervention will be easily scalable to individuals across wide geographic areas.

Our study has promising strengths, but it must be considered in light of several limitations. While the use of ecological momentary assessment (EMA) provides advantageous opportunities for real-time trigger location data and convenience reporting through smartphones, prior EMA studies highlight the potential exhaustion that participants may experience, which may reduce the level of participation. This study may further explore convenient assessment windows to diminish the intensity of EMA sampling. In addition, as previously mentioned, SMMT communities experience unique sociostructural challenges, such as unemployment, homelessness, forced displacement, and community violence [59]. These systems of power may operate dynamically and render difficulties in participating fully and equitably in hazardous alcohol use prevention programs [60]. Finally, the real-time tracking of alcohol use behaviors of participants may give rise to reporting bias. In the context of alcohol-related stigma, social desirability biases may subject participants to aligning their responses to the expectations of societal norms around alcohol consumption; however, the use of breathalyzers will help to protect against self-report bias.

Prior studies have also reported concerns for temporal bias, where participants were reluctant to complete location- and time-based–triggered EMA surveys due to the inconvenient times at which the surveys were sent. Similarly, EMA studies related to substance use have mentioned challenges with the time frame for EMA sampling [61]. In this study, EMA assessments will occur between 11 AM and 11 PM to avoid disturbing participants. However, participants in prior studies have discussed that these hours may not be representative of the time frames when drinking occurs because alcohol use may occur later at night, along with variations in mood and social activities. Thus, we may explore the potential options for personalized hours of EMA sampling for participants. Breathalyzer device loss may also pose a challenge. However, unlike prior EMA studies that distributed mobile phones and experienced challenges with device loss [62], our study enables participants to use their existing smartphones to use the app, which will reduce instances of device loss or misplacement.

We plan to follow this study with dissemination and implementation research that takes the most effective approach identified here and distributes it to a wider population of SMMT individuals. Overall, by reducing hazardous alcohol use among emerging adult SMMT individuals, we hope to reduce the rates of alcohol-associated HIV transmission among this population considered to be at high risk.

Conclusions

This protocol describes an RCT of an innovative intervention for reducing alcohol use and HIV risk among SMMT individuals. This study will provide evidence about the relative efficacy of using a smartphone-delivered MI intervention and real-time messaging to address triggers for hazardous alcohol use and sexual risk behaviors. The study has potential implications for advancing science and improving public health for a subpopulation that is disproportionately stigmatized and disconnected from prevention research and services.

Abstract

Background: Concussion in children and adolescents is a significant public health concern, with 30% to 35% of patients at risk for prolonged emotional, cognitive, sleep, or physical symptoms. These symptoms negatively impact a child's quality of life while interfering with their participation in important neurodevelopmental activities such as schoolwork, socializing, and sports. Early psychological intervention following a concussion may improve the ability to regulate emotions and adapt to postinjury symptoms, resulting in the greater acceptance of change; reduced stress; and recovery of somatic, emotional, and cognitive symptoms.

Objective: The primary objective of this study is to assess the feasibility of conducting a parallel-group (1:1) randomized controlled trial (RCT) to evaluate a digital therapeutics (DTx) mindfulness-based intervention (MBI) in adolescents aged 12 to <18 years. The attention-matched comparator intervention (a math game also used in previous RCTs) will be delivered on the same DTx platform. Both groups will be provided with the standard of care guidelines. The secondary objective is to examine intervention trends for quality of life; resilience; self-efficacy; cognition such as attention, working memory, and executive functioning; symptom burden; and anxiety and depression scores at 4 weeks after concussion, which will inform a more definitive RCT. A subsample will be used to examine whether those randomized to the experimental intervention group have different brain-based imaging patterns compared with those randomized to the control group.

Methods: This study is a double-blind Health Canada–regulated trial. A total of 70 participants will be enrolled within 7 days of concussion and randomly assigned to receive the 4-week DTx MBI (experimental group) or comparator intervention. Feasibility will be assessed based on the recruitment rate, treatment adherence to both interventions, and retention. All outcome measures will be evaluated before the intervention (within 7 days after injury) and at 1, 2, and 4 weeks after the injury. A subset of 60 participants will undergo magnetic resonance imaging within 72 hours and at 4 weeks after recruitment to identify the neurophysiological mechanisms underlying the potential benefits from MBI training in adolescents following a concussion.

Results: The recruitment began in October 2022, and the data collection is expected to be completed by September 2024. Data collection and management is still in progress; therefore, data analysis is yet to be conducted.

Conclusions: This trial will confirm the feasibility and resolve uncertainties to inform a future definitive multicenter efficacy RCT. If proven effective, a smartphone-based MBI has the potential to be an accessible and low-risk preventive treatment for youth at risk of experiencing prolonged postconcussion symptoms and complications.

Introduction

Background and Rationale

Approximately 30% to 35% of the children and adolescents who experience a concussion are considered to have persisting symptoms after concussion (PSAC) [1,2], defined as the persistence of somatic (eg, headache, dizziness, and fatigue); cognitive (eg, memory, concentration, and confusion); and other physical, psychological, and behavioral changes lasting beyond 1 month [3]. PSAC may impair daily activities including schoolwork, socializing, and sports and thereby reduce the quality of life (QoL) [4]. Studies have demonstrated that both noninjury and injury factors predict PSAC following a concussion [2,5,6], with the contribution of injury factors to PSAC decreasing over time. However, premorbid conditions such as preinjury somatic symptoms [7], migraine [2], preinjury cognitive ability [8], preexisting attention and mood concerns [9], anxiety [10], and coping strategies [11] remain important predictors of symptom persistence over time [8,12]. Preventive, early rehabilitation programs such as interventions focusing on building psychological resiliency, emotional regulation, and self-efficacy might be key to managing concussions, reducing PSAC risk, and promoting neural recovery.

Mindfulness-based interventions (MBIs) are *present-centered* interventions that encourage acceptance of thoughts and emotions as they occur in the moment without judgment. MBIs have been demonstrated to improve attentional focus, cognitive flexibility, depression and anxiety symptoms, self-concept, resiliency, and academic achievements as well as reduce affective reactivity and fear in clinical youth samples [13]. In addition, in-person MBIs seem effective at treating preinjury predictors of PSAC, such as mood disorders [14-17], somatization-related illness [14,18,19], headache disorders [20], and chronic pain [21]. However, in-person interventions may not be suitable for adolescents with acute concussion owing to high cost and low accessibility [22,23] and require commitment from parents and children for in-person weekly meetings for periods varying from 8 to 16 weeks. Brief (as short as 3 days to 4 weeks) web-based MBIs with guided meditation have been shown to have positive effects on anxiety, negative mood, perceived stress, and attention in different clinical populations [24-27]. MBIs may foster adaptive coping, increase resiliency, and reduce the risk of PSAC following pediatric concussion. Smartphone, or mobile, apps may present a versatile and personalized platform for the delivery of a dedicated MBI for populations experiencing a concussion [28].

Health care digital therapeutics (DTx; smartphone app) have gained popularity in the past decade as a means of screening patients, monitoring symptoms, and delivering psychoeducation and interventions [28,29]. The efficacy of mobile apps in delivering psychological interventions has been demonstrated in mental health samples, particularly in the treatment of depression and anxiety. Randomized controlled trials (RCTs) have shown that app-based interventions can effectively improve depressive and anxiety symptoms compared with waiting list, alternative care, or control conditions [29-34]. Similarly, a recent meta-analysis of RCTs on app-based MBIs has demonstrated significant small-to-medium effects in improving perceived stress, symptoms of depression and anxiety, QoL, psychological well-being, and positive affects, compared with control conditions, waitlist, and alternative interventions [35]. However, the application of an app-based MBI in pediatric concussion has not yet been studied.

We partnered with Mobio Interactive Inc (Toronto, Ontario, Canada), the creator of a clinically validated platform called *AmDTx*, to create an app-based dedicated DTx MBI for pediatric concussion. We assessed the acceptability and usability of the DTx with a small open-label single-arm study (N=10) [36]. The participants reported high satisfaction and found the app easy to use and the treatment to be credible. They also developed a strong alliance with their MBI guides (ie, those who are leading the meditation and psychoeducation sessions) [37]. The primary aim of this study is to assess the feasibility of the 4-week planned RCT methods to determine whether we can advance

to an efficacy trial and, thereby, elevate our understanding of the optimal time points for collecting outcome measures. At 4 weeks, those randomized to the DTx MBI will have the opportunity to continue for another 4 weeks, that is, completing a total of 8 weeks of MBI. The goal of this additional 4-week intervention is to explore feasibility outcomes in an 8-week intervention. Finally, those who are part of the DTx control group (attention-matched comparator intervention) will have the opportunity to cross over to the DTx MBI group.

Primary Research Objective

The primary research objectives are to assess the feasibility of conducting a larger RCT by evaluating recruitment efficiency, adherence to treatment, credibility, and retention.

Secondary Research Objectives

The secondary research objectives were as follows:

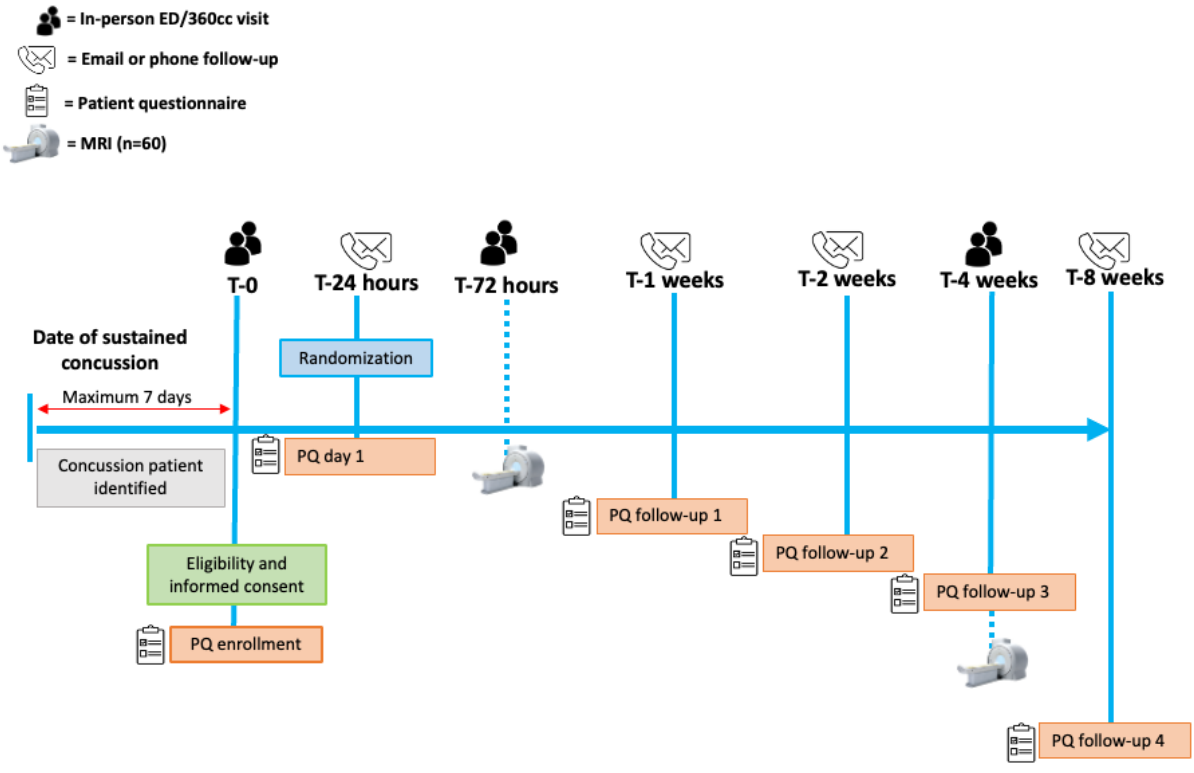
1. Establish the participants' expectancy toward both interventions.
2. Examine the participants' satisfaction with the interventions.
3. Generate estimates to inform sample size calculations for a future multicenter RCT.
4. Assess whether there is preliminary evidence of an efficacy signal for QoL, fatigue, symptoms, resiliency, self-efficacy, cognition, anxiety, depression, and mindfulness.
5. Examine the experimental group's baseline characteristics, adherence, and attrition rates in those who chose to continue for an additional 4 weeks compared with those who chose to complete the study at 4 weeks compared with those who were lost to follow-up.
6. Examine the control group's baseline characteristics, adherence, and attrition rates in those who chose to cross over to the experimental interventions at 4 weeks versus those who chose to complete the study at 4 week versus those who were lost to follow-up.
7. Examine whether the experimental intervention is associated with differential brain-based imaging patterns of functional connectivity, cerebral blood flow, and spectroscopy.
8. Examine safety by examining whether the experimental intervention has increased adverse events (ie, total number) relative to the control intervention.

Methods

Trial Design

The proposed study is a Health Canada–regulated parallel-group (1:1) RCT, where patients within 7 days of a concussion will be randomly assigned to one of the two groups: (1) experimental group (n=35), early introduction of the DTx MBI program and (2) control group (n=35), sham DTx attention-matched comparator intervention. The participants will start the intervention the next day after being enrolled in the study. After 4 weeks, those in the experimental group will be offered the MBI program with 4-week additional education modules. Those who are part of the control group will be offered to cross over to start the DTx MBI. Of the 70 participants enrolled, 60 (86%) consenting participants (n=30, 50% from the experimental group and n=30, 50% from the control group) will be enrolled in neuroimaging, which requires participation in a brain scanning session within 72 hours of enrollment and during week 4 of the study. For a schematic diagram of the trial design, procedures, and stages, refer to the study flow diagram in Figure 1.

Figure 1. Flowchart of the study procedures. 360cc: 360 Concussion Care; ED: emergency department; MRI: magnetic resonance imaging; PQ: patient questionnaire.



Study Setting

The study will be conducted at the Children's Hospital of Eastern Ontario (CHEO) and the 360 Concussion Care (360cc) clinic, a tertiary health care concussion clinic. The neuroimaging component of the study will be completed at the Royal Ottawa Mental Health Centre's Brain Imaging Centre on a 3-Tesla Siemens magnetic resonance-positron emission tomography system with a 32-channel head coil (Siemens Biograph mMR, Siemens).

Eligibility Criteria

Inclusion Criteria

Adolescents presenting to either CHEO's emergency department (ED) or 360cc after sustaining a direct or indirect mild traumatic brain injury (TBI) will be eligible to participate in this study if they (1) are aged 12 to <18 years; (2) have a diagnosed concussion (by a physician), (3) presented to the ED or 360cc within 7 days of TBI; (4) have a score >4 on the Predicting and Preventing Post-Concussive Problems in Pediatrics (5P) clinical risk score, a prediction rule to identify those at risk of poorer outcomes at 4 weeks postinjury [2]; and (5) are proficient in English [38]. To increase the probability of including adolescents with a true concussion, the adapted version of the American Congress of Rehabilitation Medicine [39] framework will be used [40]. Those with either 1 *highest level of certainty* symptom (dazed, confused, or trouble thinking within minutes after injury, difficulty remembering what happened just before or minutes after injury, and loss of consciousness) or 2 *higher level of certainty* symptoms (nausea or vomiting, headache, dizziness, clumsy or balance problems, blurred or double or change in vision, difficulty concentrating, and sensitivity to light or noise) immediately or within 1 hour of injury will be included.

Exclusion Criteria

Patients will be excluded if they present with TBIs with any of the following: (1) a Glasgow Coma Scale score of ≤13; (2) abnormality on standard neuroimaging studies [41], including positive head computed tomography findings (neuroimaging is not required, but may be performed if clinically indicated); (3) neurosurgical operative intervention, intubation, or intensive care required; (4) multisystem injuries with the treatment requiring hospital admission, operating room, or procedural sedation in ED (hospital admission for observation or management of ongoing concussion symptoms is not an exclusion criteria); (5) severe chronic neurological developmental delay resulting in communication difficulties; (6) intoxication to alcohol or drugs at the time of ED presentation as per clinician judgment; (7) no clear history of trauma as primary event to the concussion (eg, seizure, syncope, and migraine); (8) prior psychiatric hospitalization; (9) inability to obtain written informed consent or assent (eg, language barrier); (10) legal guardian not present (certain forms need to be completed by parents or legal guardians); (11) no internet and mobile or tablet access; and (12) currently in therapy.

In addition, patients will not be included in the magnetic resonance imaging (MRI) component if they present with the following: (1) previous neurological or neurodevelopmental disorder such as epilepsy, intellectual disability, or autism (history of attention-deficit or hyperactivity disorder or learning disability is not exclusionary); (2) previous stroke or transient ischemic attacks; (3) sedation medication (eg, propofol, ketamine, nitrous oxide, midazolam, benzodiazepines, and fentanyl) administered before or during ED visit; (4) inability to be present at the 72-hour (+48 or –48 hours) and 4-week (+5 or –5 days) MRI follow-up visits; and (5) medical contraindications to MRI (eg, claustrophobia, pregnancy, or presence of braces or spacers or other metal implants).

Randomization, Blinding, and Allocation

Sequence Generation

The CHEO Clinical Research Unit will provide data management services for this study and retain randomization codes. The randomization sequence will be created using R software (version 3.1.1; R Foundation for Statistical Computing) [42] and will be stratified by sex, with a 1:1 allocation using random blocks.

Allocation Concealment

A statistician at the CHEO CRU (not involved in the study) will maintain the master list.

Implementation

The day after enrollment and once all questionnaire data are complete, research assistants (RAs) will call participants over the phone, and RAs will log into REDCap (Research Electronic Data Capture; Vanderbilt University) to obtain the patient's group allocation. Only the RAs who randomized participants will be unblinded. The research team will be blinded to data acquisition. In case of a serious adverse event, the principal investigator and appropriate research staff will be unblinded to the participant's group.

Methods for Protecting Against Bias

The investigators, coaches, other research staff, data management staff, and biostatisticians will be blinded to the group assignment. Patients and families will be blinded to the purpose and expected results of the interventions and to the other treatment arm.

Intervention Description

Experimental Group Description: MBI Training

To be delivered via the *AmDTx* platform (Figure 2), the targeted DTx MBI training consists of a 4- to 8-week custom-made program (containing 8-modules) for adolescents with concussion, including setting intentions and check-ins on mood and stress, audio-recorded lectures, guided meditations such as focused attention exercises, and journaling events (Table 1). Each standardized psychoeducation or meditation practice will be unlocked as the participant progresses through the MBI program. Participants will be encouraged to participate in the DTx MBI activities for approximately 10 minutes every day, for a minimum of 4 days a week, over the 4- to-8-week period. Those who choose to end their therapy on the fourth week will be immediately directed to module 8 *Reviewing the program and how to maintain practice*. Those who choose to continue for an additional 4 weeks will move on to modules 5 through

8. The curriculum is based on previously validated *AmDTx* MBI app protocols [27,43] and team expertise in youth MBI (Sonia Roth, Craig Mackie, MC, and AAL) and was peer reviewed by experts in the field and parent engagement leaders (Ana Maria Vranceanu, Jonathan Greenberg, and Erin McCarthy). The intervention was piloted on 10 pediatric participants with concussion, and their feedback was integrated into the MBI and protocol [36]. We will track *meaningful* in-app use time, defined as the time spent engaging in meditation, psychoeducation, self-monitoring, and self-reflection, with a minimum threshold of 3 minutes per day. Any use time <3 minutes will not be counted toward the total weekly minutes spent using the *DTx*.

Figure 2. Adolescent concussion dedicated experimental and control interventions delivered through the AmDTx platform. (A) Initial loading screen of AmDTx; (B) main menu or home screen of AmDTx as seen by the participants randomized to the experimental intervention; (C) journey selection screen. Concussion Journey is shown; (D) main or menu page of the concussion MBI. Slices of the badge are awarded upon the completion of each module; (E) main or menu page of module 1; (F) stage 1 of module 1 play screen; (G) to complete the stage, the participant taps on the arrows at the top right; (H) main or menu page of module 3, with participant progression up to stage 5. (I, J and L) Before and after each the participant is prompted to complete the wellbeing measurements “Snapshot”; (K) stage 4 of module 2, “Body Scan” preplay screen with 2 meditation guide options; (L) snapshot ecological momentary assessment for stress and the open field box features; (M) journaling feature menu; (N) journaling feature input page relating to goal setting; (O) main menu or home screen of AmDTx as seen by the participants randomized to the control intervention. The feature “Concussion Recovery” is where the control math game is found; (P) main screen of the control task; (Q) to ensure as much similarity in the experience as possible and to collect valuable insights into the well-being of participants, the control is also book-ended with snapshots. Shown here is the mood circumplex feature; (R) control task midway through completion; (S) timer message prompting the participant to end their cognitive training for the day; (T) snapshot selfie scan feature after video has been captured; (U) the My Insights page where the participants randomized to either group can view how individual intervention stages or the control task impacted their well-being.

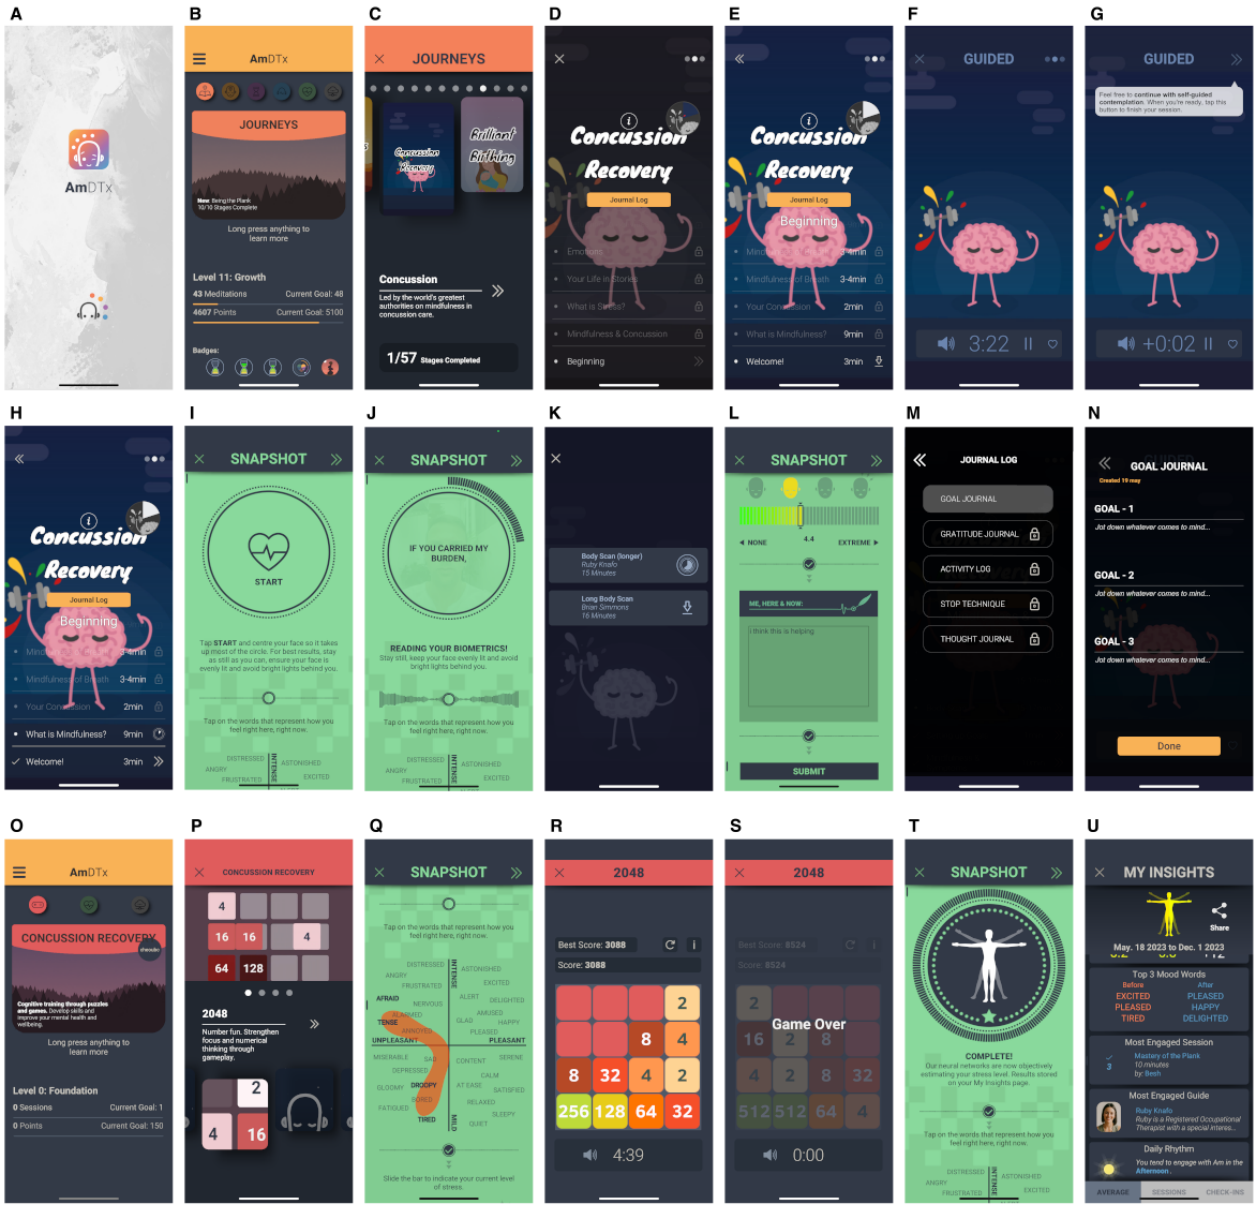


Table 1. Four- or 8-week experimental intervention consisting of a targeted digital therapeutics mindfulness-based intervention for adolescents with concussion that includes setting intentions and check-ins on mood and stress, audio-recorded lectures, guided meditations such as focused attention exercises, and journaling events.

Module	Course or focus	Meditation practices	Exercise
1	• What is mindfulness • Setting intentions • Belly breathing exercise • Introduction to body scan	• Body scan (short): 7 minutes × 2 • Belly breathing: 3 minutes × 2	• N/A[a]
2	• Mindful attitudes (nonjudgment and acceptance) • How to skillfully meet concussion symptoms	• Mindfulness of breath: 5 minutes × 2 • Body scan: 15 minutes × 2	• Setting goals • Positive event journal • Doing 1 daily routine mindfully
3	• Stress response • The biology of stress • Inner narrative and chronic stress • STOP technique	• Mindful of breath: 10 minutes × 2 • STOP technique • Mindful movement: 7 minutes × 2	• Symptoms of stress checklist and mapping stress on the body • Journal when you used the STOP technique
4	• Thoughts: the stories we tell ourselves • Reframing symptoms with thoughts and attitudes • Moving mindfully through your life	• Mindfulness of sound transitioning to thoughts: 10 minutes × 2 • Mindfulness movement: 10 minutes × 2	• Thought journal
5	• Pain and emotions • How to mindfully manage pain • Being mindful of your emotion • The Breathe-Calm-Okay-Observe-Love technique	• Body scan: 12 minutes × 2 • Practice sitting meditation with emphasis on emotion: 10 minutes × 2	• N/A
6	• How to return to activities • Gratitude—who or what has helped you in your recovery	• Mindful movement practice: 10 minutes × 2 • Loving-kindness and gratitude practice: 10 minutes × 2	• Thought journal
7	• Integrating mindfulness more fully into daily life • Barriers to practice	• Open awareness practice: 10 minutes × 2 • Users choice practice: 5-15 minutes × 2	• Thought journal
4 or 8	• Review of program, strategies for maintaining practice, and reflection on how mindfulness has helped cope with your concussion or otherwise	• Users choice practice: 5-15 minutes × 4	• Review treatment goals • Goal setting for the future

[a]N/A: not applicable.

Control Group Description: Sham App

To control for daily access to the *AmDTx* platform, expectation, and clinical attention bias, we created a sham DTx for the control group. The sham DTx will be delivered on the same main interface, within *AmDTx*; however, these participants will not have access to any of the MBI training or psychoeducational content. Their sham DTx will consist of playing an open-source math game called 2048 developed by Gabriele Cirulli [44]; this will be communicated to the control participants as *cognitive training*. The game requires participants to slide number tiles on a grid and combine them to create a tile with the number 2048. In a previous study, *AmDTx* was compared with 2048, revealing that 2048 did not reduce stress or improve psychological well-being in university students with anxiety [27]. Furthermore, 2048 was previously tested in a pediatric population with concussion, and the study found no evidence of harm or symptom improvement at 4 weeks [45]. It is expected that the control intervention will not bother individuals with sensitivity to light or high velocity motion because it lacks fast visuals or movement. The game is programmed to only be accessible for 10 minutes per day.

Coaching

All participants will be followed weekly by a coach through SMS text messaging. The coaches' role will be to ensure that the participants adhere to the intervention. All the participants will receive weekly text messages from a coach. These messages will be sent on the same day and time every week and will be limited to 160 characters. The coaches will use a standardized question and answer protocol developed by the team. Coaches will also remind the participants to complete their follow-up surveys.

Furthermore, both interventions are equipped with automated reminders (triggered by inactivity).

Standard of Care

All the participants will receive standard of care [46] instructions pamphlet provided by RAs in the ED or at 360cc. The standard of care indicates that the patient refrains from physical and cognitive activities for 24 to 48 hours after injury. After the rest period, it is recommended that low-to-moderate levels of physical and cognitive activity be gradually started, including screen time. The activities should be performed at a level that does not result in the recurrence or exacerbation of symptoms. Adolescents must refrain from any activities that increase the risk of reinjury (eg, contact sports or anything with risk of falls) until fully asymptomatic and cleared by their primary care or other medical providers.

Measures and Outcomes

Primary Outcomes

The prespecified thresholds (criteria for success), as outlined in Table 2 for the feasibility, are based on established benchmarks of previous feasibility trials [47,48] and our previous experience in recruiting pediatric patients with concussion from an ED [49]. We will use the *traffic light* system to determine whether proceeding to a full-scale trial is appropriate [50]. Progression can take place without any changes (green zone), with correctable adjustments (amber zone), or not occur because of issues that cannot be readily addressed (red zone). The decision to progress to a full-scale trial will be contingent on the criterion with the least favorable performance [50].

Table 3 provides an overview of all outcome measures collected and their specific end points.

Table 2. The criteria for success for progression to a full-scale efficacy trial.

Feasibility outcomes	Green zone (go)	Amber zone (amend)	Red zone (stop)
Eligibility	>40% of participants screened are eligible	20%-40% of participants screened are eligible	<20% of participants screened are eligible
Recruitment	>50% of eligible participants will be randomized [49]	30%-50% of eligible participants will be randomized	<30% of eligible participants will be randomized
Adherence	>70% of participants complete the minimum requirements, that is, approximately 10 minutes of activity 4 times a week	>50% of participants complete the minimum requirements, that is, approximately 10 minutes of activity 4 times a week	<50% of participants complete the minimum requirements, that is, approximately 10 minutes of activity 4 times a week
Credibility[a]	>70% of participants have score above the scale midpoint	>50% of participant have a score above the scale midpoint	<50% of participants have a score above the scale midpoint
Retention	>75% participants complete the follow-up assessment [49]	50%-75% participants complete the follow-up assessment	<50% participants complete the follow-up assessment

[a]Treatment credibility and expectancy will be assessed using the Credibility and Expectancy Questionnaire [51]. It is a 6-item questionnaire, scored using a Likert scale ranging from 1 to 9. The treatment will be considered credible (questions 1-3) if the participants scored above the midpoint. Furthermore, credibility and expectancy will be assessed to rule out the possibility of differential credibility as an explanation for the differences in therapy outcomes between the experimental and control groups. The credibility and expectancy of the intervention will be assessed at 1 week after enrollment.

Secondary Outcomes

Treatment Expectancy

Treatment expectancy will be assessed with the Credibility and Expectancy Questionnaire (questions 4 to 6) [51]. Expectancy will be considered good if the participants score above the midpoint on questions 4 to 6. Expectancy will be assessed at 1 week after the enrollment.

Intervention Satisfaction

Intervention satisfaction will be assessed with the modified version of the Client Satisfaction Questionnaire [52]. This is a validated, reliable, 8-item questionnaire used to measure client satisfaction with a particular program or service. In this case, the questionnaire has been modified to assess participant satisfaction with the digital intervention. The intervention will be deemed satisfactory if >70% of the participants score above the midpoint on the questionnaire [52]. Intervention satisfaction will be assessed at 4 weeks after the enrollment (end of the intervention).

Quality of Life

QoL will be measured using the Pediatric Quality of Life Inventory (PedsQL; version 4.0) [53,54]. The PedsQL is a reliable and valid measure of QoL in healthy children and adolescents and in those with acute or chronic health conditions [55]. It is a 23-item, 5-point Likert scale questionnaire yielding a total score (0-92) and 4 domain scores: physical, emotional, social, and school. QoL will be collected in the ED (for CHEO participants) or on day 1 (for 360cc participants) and at the 4- and 8-week follow-ups.

Fatigue

Fatigue will be measured using the Multidimensional Fatigue Scale PedsQL. This 18-item, 5-point Likert scale assessment comprises 3 scales: the General Fatigue Scale (6 items), Sleep-Rest Fatigue Scale (6 items), and Cognitive Fatigue Scale (6 items). The PedsQL Multidimensional Fatigue Scale has demonstrated excellent internal consistency, reliability, and validity [56-58]. The assessment will be collected in the ED (for CHEO participants) or on day 1 (for 360cc participants) and at the 4- and 8-week follow-ups.

Symptom Burden

Symptom burden will be measured in the ED or at 360cc (both retrospective and postinjury acute symptoms) and at 1, 2, 4, and 8 weeks after enrollment using the Health and Behavior Inventory (HBI) [3]. The HBI is a 20-item self-report questionnaire that uses a 4-point Likert scale, with a total range

0-60. It provides scores for cognitive and somatic symptom scales. Emotional symptoms and sleep disturbances will be assessed using the Post-Concussion Symptom Inventory (PCSI) [59-61]. The PCSI [59,60] is a validated, reliable, comprehensive, and self-administered instrument [59-61]. For the purpose of this study, the emotional and sleep domains of the PCSI adolescent scale version (20-item, 7-point Likert scale) will be used. The domains will be assessed in the ED or at 360cc and at 2, 4, and 8 weeks after enrollment.

Self-Efficacy

Self-efficacy will be measured using the Self-Efficacy Questionnaire for Children (SEQ-C). Self-efficacy is the individual's perceived and personal competence in their abilities to handle a situation. Self-efficacy reflects one's confidence in the ability to exert control over one's motivation, behavior, and social environment. Previous studies have demonstrated that at 12 weeks after the injury, children with a concussion lack confidence during physical activities at 12 weeks after a concussion as compared with that before the injury [62]. The SEQ-C is a valid and reliable assessment tool. It is a 24-item, 5-point Likert scale yielding a sum score (0-120) and emotional, social, and academic self-efficacy subscores [63]. The SEQ-C will be administered on day 1 and at 4 and 8 weeks after enrollment.

Attention, Working Memory, and Executive Function

Attention, working memory, and executive function will be assessed using the National Institutes of Health (NIH) Toolbox Cognitive Battery [64]. The NIH Toolbox is a validated and reliable computerized battery designed to measure executive function, attention, episodic memory, language, processing speed, working memory, and fluid cognition. Previous studies have demonstrated lower working memory, attention, and executive functioning scores after injury in pediatric samples with concussion [65-68]. Moreover, mindfulness has been shown to improve attention, working memory, and executive functioning [26,69,70]. The NIH Toolbox will be administered at the 4-week follow-up.

Resiliency

Resiliency will be measured using the Connor-Davidson Resilience Scale-10 (CD-RISC-10) [71]. The CD-RISC-10 is a 10-item questionnaire, scored on a 5-point Likert scale, that assesses an individual's perception of hardiness or perceived stress. Resiliency is defined as the ability to harbor interpersonal qualities, such as positive acceptance, to adapt or thrive in the face of adversity [71]. Previous research has shown that MBI increases resiliency in youth [13]. The CD-RISC-10 has been validated in an adolescent population with a concussion [72] and will be administered on day 1 and at 4 and 8 weeks after enrollment.

Anxiety and Depression

Anxiety and *depression* (mood) are frequently reported symptoms in pediatric concussion [73-75]. *Anxiety* will be measured using the Generalized Anxiety Disorder 7-item scale [73]. The Generalized Anxiety Disorder-7 is a validated, reliable, and sensitive to treatment-related changes tool that assesses anxiety symptoms in youth [76]. It is a 7-item, 3-point Likert scale that provides a sum score (0 to 21) of general anxiety symptoms. It will be administered in the ED (for CHEO participants) or on day 1 (for 360cc participants), capturing preinjury anxiety, and at 4- and 8-week intervals after enrollment to assess postenrollment anxiety.

Depression symptoms will be measured using the validated and reliable Center for Epidemiologic Studies Depression Scale for Children [74,75]. It is a 10-item, 4-point Likert scale that provides a total score (0-30). The Center for Epidemiologic Studies Depression Scale for Children will be administered in the ED (for CHEO participants) or on day 1 (for 360cc participants), capturing preinjury mood, and at 4- and 8-week intervals after enrollment to assess postenrollment mood.

Mindfulness

Mindfulness will be assessed using the validated Child and Adolescent Mindfulness Measure [77,78]. It is a 10-item, 5-point Likert scale. It will be administered in the ED (for CHEO participants) or on day 1 (for 360cc participants), capturing preintervention mindfulness, and at 4- and 8-week intervals after enrollment to assess postenrollment mindfulness.

Safety

Safety of the MBI will be determined by capturing and monitoring the worsening of symptoms and adverse events. Adverse events will be defined as an unscheduled visit to the ED or primary medical provider because of exacerbation of symptoms during or within 30 minutes after using the app. The participant will be asked about any possible adverse events at the 1-, 2-, 4-, and 8-week follow-ups.

Longitudinal Mental Well-Being

AmDTx contains 4 easy-to-use measurement features that together provide a longitudinal readout of patient well-being. First, psychological stress is objectively quantified via a 30-second *selfie* video that uses photoplethysmography to extract heart rate and 2 power bands of heart rate variability from biosignals inherent to the human face [79]. The amount of psychological stress is determined via a deep neural network trained on tens of thousands of selfie scans captured in parallel with a validated ecological momentary assessment of stress. The artificial intelligence output has reported 86% accuracy for determining an individual's stress as *very low*, *medium low*, *medium high*, or *very high* [80]. Second, emotional affect and arousal levels are obtained via a digital 4-quadrant emotion mapping board (circumplex) that lists feelings such as *afraid*, *droopy*, and at ease ranging on one axis from unpleasant to pleasant (valence axis) and along another axis from mild to intense (arousal axis). Each emotion listed is associated with a score that is not disclosed to the user and is used to calculate an implicit measure of mood. Third, subjective stress is obtained via a slider ranging from *none* to *extreme*. Fourth, personal notes are imputed using an open field text box. The outputs of the mood and stress slider ecological momentary assessments have been benchmarked to standard psychological surveys [27]. If a participant chooses to use the selfie camera to observe their biological stress levels, there will be no recording or storage of the generated video in the app or elsewhere. The AmDTx uses secure web authentication, data logging, and encryption that

ensure security and confidentiality of any personal identifiable information and in-app data. Personally identifiable information remains with the customer (ie, it is not downloaded by Mobio).

Imaging Measurements

Imaging measurements will be acquired within 72 hours of injury and during week 4 of the study on a subset of 60 participants. Each brain scanning session lasts 45 to 60 minutes and includes the following sequences: 3D T1-weighted anatomical scan to measure regional volumes and cortical thickness, resting-state functional MRI (rs-fMRI) to assess functional connectivity features or neural networks, arterial spin labeling to assess perfusion or cerebral blood flow, and magnetic proton spectroscopy in a single voxel in the anterior cingulate cortex to assess metabolite concentrations (ie, glutamate and gamma-aminobutyric acid). Table 3 lists the key imaging parameters.

Covariate Measurements

Information about injuries will be collected from medical records and medical personnel using a standardized case report form. Details regarding the injury and acute signs and symptoms of concussion (ie, loss of consciousness, Glasgow Coma Scale scores, mechanism of injury, neurological status, and other clinical features) will be collected by RAs, with clarification by physicians when necessary. The data will be verified by the site investigator. To calculate the 5P clinical risk score [2], balance will be evaluated by the RA using the balance error scoring system [81], a widely used instrument in the field of sports concussion [82] for objective assessment of postural stability. Pubertal status will be measured using a puberty questionnaire [83]. The questionnaire is a 5-item, self-administered rating scale for pubertal development without pictorial representations or interviews. Demographic data (ie, household annual income and parental education level) will be used as a proxy of socioeconomic status (SES). SES will be collected to assess whether randomization is equally distributed in both groups. If SES is not equally represented in the sample, it will be controlled for in our analysis.

Studies have shown that physical activity can reduce anxiety, improve mood, and help alleviate postconcussive symptoms [84]. We will evaluate physical activity to ensure balance between groups; physical activity levels will be assessed using the Godin-Shepard Leisure-Time Physical Activity Questionnaire [85] on day 1 and then at 2, 4, and 8 weeks after injury.

Procedures

Data Collection Methods

Recruitment will be conducted similar to the successful Pediatric Concussion Assessment of Rest and Exertion multicenter concussion study [86]. When an adolescent with a mechanism of injury and symptoms consistent with concussion presents to the ED, the nurse will triage the child as per the existing protocols. Once in the ED, a member of the ED clinical team (ie, an ED volunteer) will introduce the study to families of potentially eligible children to inquire whether they are interested in learning more about the study. If so, the electronic charts of potentially eligible participants will be flagged, and the research team will be notified. At 360cc, a health information custodian who is a part of the circle of care will mention to the family that there is a study on children who have head injuries and ask if they are interested in learning more about the study. In both the ED and 360cc, the RA will then approach the family to discuss the research study, and if they are interested, the RA will complete the screening form on an iPad.

During the screening procedure, we will evaluate the likelihood that the patients had a *definitive* or *probable* concussion based on the aforementioned inclusion criteria. Their 5P clinical risk score [2] will also be calculated with the following variables: age, sex, prior concussion and length of recovery, history of migraine, slow answers to questions, balance, headache, sensitivity to noise, and feeling fatigued. Only patients with a 5P score >4 will be eligible for the study. Patients who are ineligible based on the initial screening will be thanked for their time. Eligible and willing parents along with adolescents capable of consenting on their own behalf will be asked for written informed consent, and the adolescents who are unable to provide consent on their own behalf will be asked for assent.

Once enrolled in the study, the families will complete a series of questionnaires in an electronic survey format using a portable tablet computer on REDCap [87]. The survey includes questions regarding patient demographics, preinjury and injury characteristics, a symptoms checklist, and diagnostic history.

The day following the ED or 360cc visit, participants will receive a phone call from an RA to randomize the participants to either the experimental or the control group and give instructions to register an account on a study-dedicated landing page using a unique link for each participant. Following registration, participants will install *AmDTx* on the mobile device of their choice. After creating an account and logging in to *AmDTx*, each participant will be automatically directed to their assigned intervention (MBI or control).

During this phone call, an MRI appointment will be scheduled for the participants who have agreed to participate in that component of the study. Participants will complete the surveys or questionnaires for day 1 and MRI screener. They will have the option of completing the survey via phone or REDCap.

Follow-Up Procedures

The proposed duration of the app-based MBI is 4 to 8 weeks. After 4 weeks, all participants in the experimental group will be given the opportunity to pursue the MBI for an additional 4 weeks. At that time, participants in the control group will be offered to cross over and start the MBI intervention.

Participants will complete electronic follow-up questionnaires on REDCap at 1, 2, 4, and 8 weeks after enrollment and will have an in-person follow-up at 4 weeks for the cognitive assessment (and the MRI scan for a subset of participants). Cognitive testing will be conducted before brain scanning.

Neuroimaging Procedures

A subset of 60 participants (30 from each group) will undergo a 45-minute MRI scan at <72 hours and 4 weeks after injury. During the day 1 phone call, participants who have consented

to the MRI component of the study will complete the MRI screener and schedule their MRI appointment.

Each scanning session will be approximately 1 hour and will include a high-resolution structural scan, arterial spin labeling, rs-fMRI, and magnetic proton spectroscopy (Table 4).

Table 4. Magnetic resonance imaging acquisition.

Image type	Sequence name	Total time (minutes:seconds)	Resolution (mm×mm×mm)	Slices, n	FOV[a] (mm)	TR[b] (milliseconds)	TE[c] (milliseconds)	Other

[f]ASL: arterial spin labeling.

[g]MRS: magnetic resonance spectroscopy.

Data Management

The CHEO Clinical Research Unit Data Coordinating Centre will be used as a central location for data processing and management. Data will be kept private and secured to industry standards for both clinical and patient-sensitive data in Canada. Data for the study will be collected and managed using REDCap [88] tools hosted and supported by the CHEO Research Institute. REDCap is a secure, web-based application designed to support data capture for research studies. Only members of the research team will be granted access to the database. Users will be assigned to *Data Access Groups* that will restrict their rights to viewing and entering data. For monitoring purposes, the study coordinator will be able to view the data. Within the Data Access

Group, user privileges will be designated by the study coordinator to ensure that the research team members have only the minimum required rights to perform their duties. All identifying information that is collected will be flagged in the database and removed from data export unless the identifying information is required for statistical analysis (eg, date of birth).

Statistical Analysis

Primary Outcomes

Descriptive statistics will be used to summarize patient baseline characteristics and clinical information. The primary objective of this study is to assess the feasibility outcomes of the trial. This will be done by computing the observed points estimates for each criterion (eligibility, recruitment, adherence, credibility, and retention) and comparing them with our predefined red zone upper limits and green zone lower limits. The 3-tiered progression criteria will be used for each criterion (Textbox 1).

Textbox 1. Three-tiered progression criteria where E denotes the observed point estimate (ranging from 0 to 1 for proportions or percentages 0%-100%) [50].

Progression criteria

- Red (unacceptable): E≤red zone upper limit (*P* value nonsignificant, *P* value≥α)
- Amber (amend): red zone upper limit<E<green lower limit
- Green (acceptable): E≥G lower limit (*P* value significant, *P* value<α)

Secondary Outcomes

Mean and SDs will be computed for each collected measure. Pre-post correlations will be generated to assess preliminary evidence of *efficacy signal* for QoL, fatigue, symptoms, resiliency, self-efficacy, cognition, anxiety, depression, and mindfulness.

Neuroimaging Component: Nested Study

To acquire preliminary data on the association between the interventions and MRI metrics, per-protocol analyses will be conducted. A multivariable linear regression will be performed for each neuroimaging outcome, with age, sex, and handedness (for rs-fMRI) as covariates. If the groups differ at baseline on potentially confounding variables, such as attention-deficit or hyperactivity disorder, anxiety, medication, prior concussion, physical activity, and puberty, these variables will also be entered as covariates in the models. Per-protocol analyses will include only those participants who have adhered to the intervention.

Statistical Power

Feasibility Objective

The sample size calculations were informed on recommendations for feasibility trials using the *traffic light* system [50,89]. The significance cutoff points for each criterion, with green lower and red upper limits, were determined. Using Table 1 from the study by Lewis et al [50], to meet the individual >90% power requirements for each of the five criteria we would need the following: (1) for eligibility, the number of participants to be screened is 46; (2) for recruitment, the number of participants to be randomized is 54; (3) for adherence, the required number of participants to evaluate adherence is 55; (4) for credibility, the required number of participants is 55; and (5) for retention, the required number of participants is 34. To determine the overall sample size for the whole study, we based our decision on the criterion that requires the largest numbers (ie, adherence, n=55). Considering an approximately 20% rate of loss to follow-up and withdrawals, the required sample size for the adherence criteria is 70. We expect that 40% of the participants screened will be eligible and there will be a 50% recruitment uptake. Given these numbers, 350 children are expected to be screened: 350=[(1/0.4)×(1/0.5×70)]. Assuming that 70 of the 350 screened participants are randomized, criteria 1, 2, 3, 4, and 5 will have statistical powers of 100%, 99.9%, 95.8%, 95.8%, and 98.7%, respectively. This means that the null hypotheses can be rejected with a collective power of 90.5% if the alternative hypotheses (for acceptable feasibility outcomes) are true in each case.

Sample Size for the Nested Neuroimaging Component

As per Desmond and Glover [90], a liberal threshold of α=.05 requires 24 participants (12 per group) to achieve an 80% power for the single-voxel level for typical activations. To control the error rate when conducting multiple comparisons, it is suggested that the number of participants should be doubled to maintain this level of power. On the basis of our Pediatric Concussion Assessment of Rest and Exertion and MRI study, of the 89 participants with concussion who provided consent, 13 were lost to follow-up, 3 had incidental findings, and 5 had excessive motion [91]. Considering a 20% attrition, a total sample size of 60 participants (30 per group) will be recruited.

Data Safety and Monitoring

Data Safety Monitoring Board

The independent data safety monitoring board (DSMB) will consist of 1 independent pediatric ED physician, 1 neuropsychologist who specializes in pediatric concussion, and 1 statistician who is not involved in the research study. In keeping with the StaRChild Health guidelines [92], the DSMB will, in collaboration with the trial steering committee, establish safety outcomes and termination rules before the start of the study. The DSMB will be immediately advised of severe adverse events, and they will meet in case a serious adverse event occurs. The DSMB will meet annually to review enrollment, study procedures, form completion, data quality, loss to follow-up, and interim safety results. Given the low-risk intervention and

no intention to stop the trial for benefit or futility, only an annual meeting will be required. On the basis of negative data trends (increased symptoms) and adverse events, the DSMB may decide to meet earlier than planned and may request unblinding if deemed necessary.

Potential Harms

The safety outcomes include (1) severe worsening of symptoms identified on HBI reliable changes or (2) any symptoms requiring an unscheduled visit to the ED or primary care provider. If concussion symptoms worsen during the treatment to the degree that the participant requires an unscheduled visit to the ED or primary care provider, then symptoms will be considered as a possible adverse event. Symptoms could develop into an adverse event if they become unbearable and the patient needs immediate medical attention. Patients will report possible adverse events through REDCap reports, and their responses will be monitored by RAs. In the case of a possible adverse event, defined as the *worsening of symptoms requiring an unscheduled visit to the ED or primary care provider*, site investigators will be notified to determine if the event is linked to the treatment. If linked, the event will be monitored and the CHEO Research Ethics Board and DSMB will be notified.

Ethical Considerations

This study was approved by the Research Ethics Board (protocol number 20/72X) of the CHEO Research Institute in August 2020. Authorization from Health Canada was granted in July 2022. The study will be carried out according to the principles outlined in the Declaration of Helsinki [93] and Good Clinical Practices, within the laws and regulations of the Tri-Council Policy Statement, and the institutional policies of the CHEO REB.

Before consent is sought, the study will be introduced, and its purpose will be explained verbally. The consent form will also present the purpose of the research, the procedures, potential risks and benefits, and the use and security of the data. Informed written consent will be obtained from the parents and participants deemed capable of consenting. Informed assent will be obtained from the participants deemed by the RA to be cognitively unable to provide informed consent.

The participants will be remunerated with a CAD $20 (US $15) gift certificate (eg, Tango) for completing surveys. Participants will receive an additional CAD $20 (US $15) gift certificate for completing the MRIs. The gift certificate will be sent electronically to their email address. They will also receive a parking voucher or vouchers for in-person meeting or meetings and a letter attesting that they have completed 20 hours of volunteer work (5 hours per week completing the intervention).

Participant information will be coded using study identification numbers. Research personnel will take all appropriate and customary steps to ensure that data remain secure and that patient privacy and confidentiality are maintained.

Results

Project Initiation

This trial is funded by the Children's Hospital Academic Medical Organization Innovation Fund and the multidisciplinary team grant from the University of Ottawa Brain and Mind Research Institute. Recruitment began in October 2022, and data collection is expected to be completed by September 2024. Data collection and management is still in progress; therefore, data analysis is yet to be conducted.

Dissemination

The results will be disseminated at international conferences and in scientific manuscripts to peer-reviewed journals. The main manuscript presenting the results of the primary objective will be published in a high-impact peer-reviewed journal. Furthermore, separate manuscripts will be written on the secondary objectives of the protocol, and these will also be submitted for publication in peer-reviewed journals. We plan to engage key stakeholder groups (eg, families, Parachute, Canadian Concussion Network, and Mobio Interactive) to ensure mobilization and uptake of the findings to end users to progress to the next step, that is, the efficacy trial.

Discussion

First, we will use this study to examine the feasibility of our RCT methods, including delivering a DTx-containing MBI to participants who are acutely or subacutely concussed, and whether we can move to the efficacy trial. Second, to better inform our larger RCT, this study will allow us to estimate the effect sizes of QoL and the symptoms at 4 and 8 weeks after enrollment compared with those randomized to the control group (sham intervention). Third, we will use this study to assess whether MBI induces measurable brain-based effects, that is, examine whether the intervention modulates neuroimaging indicators such as functional connectivity. This trial will offer insight into a cost-effective way to manage pediatric concussion in the acute and subacute phases of injury. This study will help support the development of a future full-efficacy trial to assess the effectiveness of the intervention in increasing QoL and decreasing the concussion symptom burden.

The development of an intervention to increase adaptive interpersonal qualities in acute settings is important for reducing the risk of PSAC. Formal in-person MBIs such as mindfulness-based stress reduction have been shown to increase perceived self-efficacy and teach positive acceptance of change [13]. However, these interventions may not be suitable for a youth population with acute concussion as they are costly and not easily accessible. A brief web-based MBI with guided meditation had positive effects on anxiety, negative mood, perceived stress, and attention in different clinical populations [24-27]. Furthermore, a 3-week RCT using the DTx MBI within *AmDTx* increased stress resilience and attentional control in university students self-described as experiencing mild anxiety [27]. The customization of a novel MBI, designed in collaboration with MBI therapists, patients, and Mobio Interactive, will bring a required concussion treatment into the

homes of all patients, with the goal of increasing adaptive skills and cognitive performance, promoting neural recovery, and reducing the risk of PSAC. If found to be effective, DTx MBI holds promise as an accessible and low-risk preventative treatment for youth at risk for prolonged postconcussion symptoms and sequelae.

Acknowledgments

This study is funded by CHAMO Innovation grant, University of Ottawa Brain and Mind Research Institute, Martin Osmond Research Grant Award CHEORI and the Ontario Brain Institute NERD program.

Data Availability

Data sharing is not applicable to this paper as no data sets were generated or analyzed during this study.

Conflicts of Interest

AAL is one of the authors of the Mindfulness-Based Intervention for Concussion protocol used in this study, but she did not receive any financial benefit. AAL received funding from the Ontario Brain Institute Neurotech Early Research & Development Program for a separate component of the study. AAL has no other conflict of interest to disclose. RZ received financial support through competitively funded research grants from the Canadian Institutes of Health Research, Ontario Neurotrauma Foundation, Physician Services Incorporated Foundation, Children's Hospital of Eastern Ontario Foundation, University of Ottawa Brain and Mind Research Institute, Ontario Brain Institute, National Football League, Ontario Ministry of Health, Public Health Agency of Canada, Health Canada, Parachute Canada, and Ontario SPOR Support Unit. RZ was supported by a Tier 1 Clinical Research Chair in Pediatric Concussion from the University of Ottawa. All grant funding goes directly to the institution. RZ sits on the board of directors for the North American Brain Injury Society, which is a volunteer (unpaid) role. RZ is a founding partner and a minority shareholder of 360 Concussion Care (a learning health system and network of interdisciplinary concussion clinics in Ontario); no proceeds have been transferred to RZ. MC is one of the authors of the Mindfulness-Based Intervention for Concussion protocol used in this study, but she did not receive any financial benefit. ADH holds a Canada Research Chair in Magnetic Resonance Spectroscopy in Brain Injury and received funding from the Canadian Institutes of Health Research; Natural Sciences and Engineering Research Council of Canada; the New Frontiers in Research Fund; the Alberta Workers Compensation Board; The Arthritis Society; and both the Hotchkiss Brain Institute and the Alberta Children's Hospital Research Institute, University of Calgary. LW received an honorarium for a speaking engagement. BJS is a cofounder of Mobio Interactive Ptd Ltd, and at the time of submitting the manuscript, owned approximately 23% of the company's shares. NR holds a Canada Research Chair (Tier 2) in Pediatric Concussion and has received research funding from the Canadian Institutes of Health Research (CIHR), Social Sciences and Humanities Research Council (SSHRC), Ontario Neurotrauma Foundation (ONF), Public Health Agency of Canada (PHAC), Parachute Canada, Special Olympics Canada, Greater Toronto Hockey League, Dr. Tom Pashby Sport Safety Fund, Holland Bloorview Kids Rehabilitation Hospital and Scotiabank. NR is an Executive Board Member for the International Pediatric Brain Injury Society (IPIBS) which is an unpaid and volunteer role. All other authors declare no other conflicts of interest.

Abstract

Background: A medical student's career choice directly influences the physician workforce shortage and the misdistribution of resources. First, individual and contextual factors related to career choice have been evaluated separately, but their interaction over time is unclear. Second, actual career choice, reasons for this choice, and the influence of national political strategies are currently unknown in Switzerland.

Objective: The overall objective of this study is to better understand the process of Swiss medical students' career choice and to predict this choice. Our specific aims will be to examine the predominately static (ie, sociodemographic and personality traits) and predominately dynamic (ie, learning context perceptions, anxiety state, motivation, and motives for career choice) variables that predict the career choice of Swiss medical school students, as well as their interaction, and to examine the evolution of Swiss medical students' career choice and their ultimate career path, including an international comparison with French medical students.

Methods: The Swiss Medical Career Choice study is a national, multi-institution, and longitudinal study in which all medical students at all medical schools in Switzerland are eligible to participate. Data will be collected over 4 years for 4 cohorts of medical students using questionnaires in years 4 and 6. We will perform a follow-up during postgraduate training year 2 for medical graduates between 2018 and 2022. We will compare the different Swiss medical schools and a French medical school (the University of Strasbourg Faculty of Medicine). We will also examine the effect of new medical master's programs in terms of career choice and location of practice. For aim 2, in collaboration with the Swiss Institute for Medical Education, we will implement a national career choice tracking system and identify the final career choice of 2 cohorts of medical students who graduated from 4 Swiss medical schools from 2010 to 2012. We will also develop a model to predict their final career choice. Data analysis will be conducted using inferential statistics, and machine learning approaches will be used to refine the predictive model.

Results: This study was funded by the Swiss National Science Foundation in January 2023. Recruitment began in May 2023. Data analysis will begin after the completion of the first cohort data collection.
