Conclusions: Our research will inform national stakeholders and medical schools on the prediction of students' future career choice and on key aspects of physician workforce planning. We will identify targeted actions that may be implemented during medical school and may ultimately influence career choice and encourage the correct number of physicians in the right specialties to fulfill the needs of currently underserved regions.

Introduction

Background

The unbalanced distribution of medical staff is identified by the Global Health Workforce Alliance as the major public health challenge of the 21st century [1]. The equitable distribution of physicians in the appropriate specialties and in the appropriate regions challenges high-income countries that are currently dependent on foreign-trained physicians. The increasing pressure to supplement the physician workforce is because of the growing medical needs of an aging population coupled with an aging physician workforce [2,3]. A misdistribution of the physician workforce has been clearly predicted in recent statistics owing to increasing rates of part-time employment, difficulties in recruiting physicians to certain specialties, and growing gender gaps in certain specialties and places of practice [4,5].

This is particularly true in Switzerland, where life expectancy is high and 1 of 4 physicians is currently aged >60 years [2,3]. To increase the number of physicians, the federal and cantonal states have financed the creation of 4 new medical schools. However, there is little link, if any, between the physician and general population ratio and the distribution of the medical workforce; therefore, this strategy may be largely insufficient to meet the needs of the population [6,7].

Medical schools and postgraduate medical education policymaking bodies play a key role in this dynamic. They are responsible for the supply of an adequate medical workforce to meet demands for quality, quantity, and appropriate distribution of physicians among specialties and geographic areas [8-10]. The regulation of the Swiss medical postgraduate training system offers great flexibility to physician graduates regarding specialty selection, postgraduate program duration, and location. It is unique and differs from other systems in neighboring countries, where the specialty choice and training site are based on numerus clausus [2-4]. Beyond the regulation system, there is often an imbalance between students' wishes, the need for specialists, and the positions available, leading to shortages in some specialties and high levels of competition in others [11]. Furthermore, once specialization is achieved, concentrations in certain types of practice (private outpatient rather than hospital based) and in certain geographic areas (advantaged urban rather than rural or disadvantaged urban areas) are unbalanced [12]. Consequently, there is a growing effort to better understand what factors contribute to the physician workforce shortage and misdistribution.

These factors are impacted by the societal, political, and regulatory aspects of postgraduate medical training. The Bland-Meurer theoretical framework for medical career decision-making indicates that both specialty characteristics (eg, type of practice and person oriented) and students' career needs (eg, prestige and work-life balance) are shaped by students' individual static (eg, demographic) and dynamic (eg, motivation) features, by life experiences, and by the values and culture of the training institution [13,14]. Studies on predominately dynamic characteristics, such as motivational factors, show that students' specialty choice can be driven by internal motives ("intrinsic motivation"), such as personal abilities, interest in helping patients, intellectual challenge, and by external motives ("extrinsic motivation"), such as salary, status, and workload [15]. Their importance differs by specialty [16,17] and gender [18-21].

Various methods of artificial intelligence and machine learning have also been investigated to provide decision support for and predict individual career choice [22-28]. These career choice prediction and decision support studies have achieved some success at being able to predict career choice, with performance varying from 68% to 85% area under the receiver operating characteristic curve. To the best of our knowledge, only 1 study has used modern machine learning methods to predict a medical student's career choice [29]. To date, it remains unknown how these models perform in career choice analyses in which individual and contextual data are available. Moreover, how machine learning models perform in predictive scenarios for multiple medical career choices is yet to be explored.

Current State of Our Own Research

In our previous research, we explored the areas of intention to practice (urban and rural) of graduating students at 4 Swiss medical schools [30]. We found that 13.7% expressed an intention to practice in underserved areas (62.1% of whom intended to practice in rural areas) and 41.1% were undecided. These intentions varied from one school to another and were related to different motivational factors. Work variety and work conditions appear to be factors that might attract interested and undecided students to work in underserved areas. Among those who wished to practice in underserved areas, general practice (21.6%) was the most preferred specialty. Motivational factors influencing specialty choice were intellectual challenges, work variety, work conditions, and enthusiasm. In addition, using the same cohort at 4 Swiss medical schools, we analyzed the motivating factors that influence the choice of obstetrics and gynecology as career intentions. The results highlighted the

importance of "experiential factors" and gender in this specialty choice. These findings provide useful information for targeted interventions to promote obstetrics and gynecology during undergraduate and postgraduate training by providing more hands-on experiences and improving the integration of male students and residents [31]. We also explored the degree of motivation for general practice, surgery, radiology, and psychiatry throughout the preclinical years. We specifically focused on personal and motivational individual characteristics correlated with general practice and surgical career intention [32-35].

The Swiss Medical Career Choice study is the continuation of 2 preliminary studies [12,36]. We will explore the role of students' individual static and dynamic features as well as that of the educational organizational context and training institution culture on career choice, that is, specialty, type, and place of practice, from medical school to postgraduate training. Thus, the present proposal seeks to understand the process of Swiss medical student career choice and attempts to predict this choice. First, we will examine the static and dynamic variables that predict the career choice of Swiss medical school graduates and their interaction. Second, we will examine the evolution of Swiss medical students' career choice and their ultimate career path.

Study Objectives

Primary Objectives

The primary objectives are to determine the current career intentions of Swiss medical students (choice of specialty and type of practice) and to assess the personal and contextual factors that determine their choice.

Secondary Objectives

The secondary objectives are as follows:

- To assess the influence of static factors such as gender and socioeconomic status
- To assess the influence of dynamic factors such as student perceptions of medical specialties and motivation
- To examine the interactions between both types of factors
- To attempt to predict career choice based on static, dynamic, and motivational factors and to design and test data-driven methods (artificial intelligence) to predict medical students' career choice
- To determine how career choice intentions vary during medical school within and across different medical school sites and during postgraduate training
- To determine how career choice intentions of Swiss medical school graduates have evolved over the last decade, considering the political strategies that have been put into place
- To compare how career choice intentions differ from the final choice in the Swiss nonregulated system and the French regulated system

Methods

Study Design

The Swiss Medical Career Choice is a 24-month longitudinal prospective national investigation implemented over 4 years (2 data collection time points) for 4 cohorts of medical students across all Swiss medical schools as well as a follow-up during postgraduate training.

For comparison purposes, this study also includes (1) a follow-up of 2 previous cohorts of medical students from Western Switzerland during postgraduate training, (2) a follow-up of the final career choice of 2 previous cohorts of medical students from 4 Swiss medical schools, and (3) a follow-up of the final career choice of 2 cohorts of medical students from Strasbourg, France.

Participants

In Switzerland, medical school consists of a 6-year curriculum divided into 3 years of bachelor's (basic science training) and 3 years of master's (clinical training). For the national prospective study, eligible participants will be medical students entering year 4 (master's 1) between 2022 and 2024 and finishing year 6 (graduates) between 2023 and 2026. The total number of eligible participants is approximately 1440 per cohort. Participants who have completed the questionnaire either in year 4 or 6 and have a response rate of >90% on the structured scale will be eligible for the follow-up study in postgraduate training year 2.

Data Collection

Data will be collected through 4 different sources: (1) a questionnaire administered during undergraduate year 4 (master's 1) and year 6 (master's 2), (2) a short survey during postgraduate training year 2, (3) data extracted from the residents' logbook of the Swiss Institute for Medical Education (SIME), and (4) exogenous contextual data extracted from the Federal Offices of Public Health and Statistics and the Swiss Medical Association (FMH).

Undergraduate participants will be invited to complete the questionnaire (approximately 30 min) during a compulsory class at the beginning of year 4 and at the end of year 6. Data will be anonymized for confidentiality reasons and for data protection issues. Participants will provide their student ID for matching purposes for the duration of the study. During the postgraduate years, participants (residents) will be invited to complete the short questionnaire (approximately 10 min) by invitation from the SIME, and relevant data will be extracted from their logbook. Data matching between the 2 data sources (undergraduate survey and data collected during residency) will be performed for each participant based on their ID number.

Ethical Considerations

The Chair of the Cantonal Commission for Ethical Research designated this study as exempt from formal review (protocol BASEC 2020-00813) as the aim of the study aim is outside the scope of the Swiss law as defined in Article 2 of the Human Research Act (HRA).

To obtain informed consent for undergraduate data collection, eligible participants will receive an email 10 days before the survey to inform them about the research project's main goals, the content, and the testing conditions (confidential and voluntary participation). Students who agree to participate will confirm their informed consent by marking a box on the first page of the questionnaire. Comparison cohorts of medical students consented previously to this study.

Data matching will be performed by a technical administrator who is not involved in the data analysis and interpretation. Researchers will only have access to deidentified data. Anonymous responses will be collected and stored on the secure web-based server Evasys. Survey data will be extracted from Evasys and stored in a password-protected Excel (version 21; Microsoft Corporation) file that is accessible only to the central study team. The University of Geneva standards for data handling will be followed for all data management and record keeping.

Participants will not receive compensation for completing the questionnaire.

Measures

Main Outcomes

The intention of practice of the undergraduates will be assessed through a single-choice question among 6 possible options grouped into four categories: (1) hospital-based medicine (senior physician in a nonuniversity public hospital and academic and clinical career in a university hospital), (2) office-based medicine (private clinical practice in a solo practice and private clinical practice in a group practice), (3) research and teaching, and (4) undecided. The students' specialty intentions will be gathered through a single-choice question among the 46 federal specialist titles issued by the SIME plus geriatrics, emergency medicine, and an undecided option. Specialties will be further regrouped into seven categories of intentions: (1) surgical, (2) acute care, (3) diagnostic medicine, (4) preventive medicine, (5) medical subspecialties, (6) general practice, and (7) undecided. Categories 1, 2, and 3 will be grouped together in the supracategory of "technically oriented specialties." Categories 4, 5, and 6 will be grouped in the supracategory "person-centered specialties." Data collected during the postgraduate training and extracted from the SIME residents' logbook include the specialty in which the residents are currently registered, specialist title for which the resident is aiming, number of months completed in the desired specialty, and the number of months completed in different specialties. The index of change during medical school or residency will be calculated as follow: if the student does not change=0, if the student changes their intention in the same specialty category=0.5, and if the student changes for another supracategory=1. The frequency of changes will also be calculated.

Demographic Data

The demographic will include age, gender, nationality (Swiss, European, or other), medical school, high school diploma (scientific vs other), place of origin, marital status, mother tongue, and 2 indirect measures of students' socioeconomic level, that is, parents' highest educational achievement (primary, secondary, or tertiary), and parents' profession (elementary, employee, executive, or professional) [37,38].

Motivational Factors

A total of 5 global motivational factors identified in the scientific literature as influencing the choice of specialty, validated by Beaulieu et al [36], will be ranked by their importance. The degree of motivation to become a surgeon as well as a general practitioner will be measured on a 6-point Likert scale: 1=very unmotivated to 6=very motivated. The global motivational factors mentioned earlier will be broken down into 12 specific motivational factors [34] influencing the choice to become a surgeon and a general practitioner (measured on a 6-point Likert scale: 1=very dissuasive to 6=very attractive). In total, 2 single-choice questions will assess (1) students' intention to practice in medically underserved areas (yes, undecided, or no) and (2) if yes, they will be asked to specify the desired location of practice (rural, mountain, or urban areas). The desired percentage of employment will be measured as the percentage of full-time employment on a 10-point Likert scale (0=0% to 10=100%).

Individual Characteristics

The previous academic background will be identified through 2 items asking students to report the type of high school degree and the grade obtained. Personality traits will be measured through the NEO Five Factor Inventory, which is widely used to assess the major personality traits as described in the Big Five Model [39]. It consists of 60 items, 12 per trait, scored on 5-point Likert scales (0=strongly disagree to 4=strongly agree). Motivation will be measured through the Academic Motivation Scale, which is widely used to assess self-determinate motivation in educational settings [40]. It consists of 28 items scored on a 7-point Likert scale (1=strongly disagree to 7=strongly agree) assessing intrinsic motivation (12 items), extrinsic motivation (12 items), and amotivation (4 items). Students' anxiety will be measured through the State-Trait Anxiety Inventory Form Y-State. Notably, we will assess state anxiety using the state anxiety subscale [41]. It consists of 20 items scored on a 4-point Likert scale (1=yes to 4=no). The total score ranges from 20 to 80. Scores are categorized into a 3-point cutoff: below 55 (average anxiety), 56 to 65 (high anxiety), and above 65 (severe anxiety). Students' gender representation will be measured through 6 items assessing gender bias [42]. Single-item scores will be standardized into *t* scores, and a total score will be calculated.

Context Characteristics

Students' perception of learning context will be measured using a brief revised version of the students' perception of teachers in the Dundee Ready Educational Environment Measure 11-item subscale [43]. This revised version consists of 6 items scored from 0 (strongly disagree) to 4 (strongly agree) as in the original version (max score of 24). The selected questions will assess if students have identified a person they view as a role model (yes, during my medical school training; yes, but not during my medical school training; and no). If yes, 2 open-ended questions will assess (1) the function of this person and (2) in what context they met them. A total of 2 single-choice questions will assess

(1) if the actual program location is the desired one and (2), if not, which location is the desired one. In total, 2 6-point Likert scale questions will assess (3) the degree of importance of the language of instruction and (4) the degree of importance of the cultural context.

Exogenous data collected from the Federal Medical and Population Statistics and the FMH include population density and medical density (of area of origin and of medical schools), number of professionals per specialty, specialist density per region, average specialist salary, and average number of working hours.

Table 1 summarizes domains, constructs, and measures by time points of data collection.

[a]The questionnaires will be collected annually from 2023 to 2026 from all fourth-year and sixth-year medical students and residents of Switzerland.

[b]Master 1: fourth year of medical school.

[c]Master 3: sixth year of medical school.

[d]PGY: postgraduate year.

[e]Data collection for the associated variable at the time point.

[f]NEO-FFI: NEO Five Factor Inventory.

[g]AMS: Academic Motivation Scale.

[h]STAI-A: State-Trait Anxiety Inventory Form A.

[i]DREEM-R: Dundee Ready Educational Environment Measure.

In the postgraduate survey, the selected items of individual characteristic measures will be used, except for the State-Trait Anxiety Inventory Form A. Data collection for the Western Switzerland and French comparison cohorts is similar to that

for the prospective national cohort. For the Western Switzerland cohorts, we will conduct 2 cross-sectional data collections at 2 different time points. For all comparison cohorts, we will retrieve the career choice through the residents' logbook of the SIME and through the National Examination (Epreuves Nationales) and the National Classifying Examinations (Epreuves Classantes Nationales) official site in France.

Data Analysis

This study adheres to the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines for cohort studies [44].

Descriptive statistics will be applied to demographics, career intention, motivational factors, and individual and contextual characteristics. A chi-square test will be used to compare intentions by medical school as well as to compare previous cohorts with the national prospective cohorts. The type I error rate will be set at .05.

To examine specific motivational factors, a principal component analysis with varimax rotation will be run to aggregate the motives out of the 12, demonstrating a frequency of >10%. Data suitability will be confirmed using the Kaiser-Meyer-Olkin index of sampling adequacy. Combined criteria (ie, scree plot, eigenvalue >1.0, and interpretability) will be used to determine the number of factors [45]. The critical value for significant factor loading will be >0.40 [46]. Each factor obtained from the principal component analysis procedure will be labeled according to its content.

Appropriate statistical tests will be applied to measure changes in motivational factors, the Academic Motivation Scale, anxiety, and contextual characteristics between different time points, such as rank-order stability (Spearman correlation *r* coefficient), the Cohen *d* effect size magnitude ratios [47], and the Reliable Change Index [48].

To examine whether the demographic, motivational factors, and individual and contextual characteristics will correlate with our main outcomes, logistic regression (odds ratio and 95% CIs) and linear regression will be used. These statistical analyses will be performed using R (version 4 or above; R Foundation for Statistical Computing) and SPSS (version 27; IBM Corp).

Following a machine learning approach, the questionnaire data and exogenous contextual data from the Federal Medical and Population Statistics and the FMH will be combined in an attempt to obtain a comprehensive view of the different medical careers within the working environment. This combined data set will then be preprocessed according to the input format of the machine learning models and will link medical students and exogenous contextual data to their career intentions. To avoid issues of data bias being injected into the algorithms, data augmentation via downsampling and oversampling strategies will be assessed to reflect equal gender distribution in the training set. For the model design and experiments, different machine learning algorithms will be investigated, in particular extreme gradient boosting [49] and CatBoost [50], which provide state-of-the-art performance for categorical data, to learn career choice patterns from the collected data set. In our experiments, the data set will be randomly divided into training (60%), development (20%), and test (20%) sets to train the model parameters and hyperparameters and to evaluate the models' performance, respectively. Hyperparameter tuning and evaluation metrics will be computed using cross-fold validation to increase the robustness of the results. Standard classification evaluation metrics such as area under the receiver operating characteristic curve, F_1-score, precision, and recall will be reported. The comparison of models' predictive results will be measured using the McNemar statistical test. The type I error rate will be set at .05. The Shapley additive explanation method [51], a consistent, fast, and deterministic method for extracting feature contributions at the individual prediction level, will be used to identify factors impacting career choices.

Statistical Power

Regarding the planned analyses, all the main outcomes deal with the estimation of proportions (eg, specialty choice and practice in underserved areas). Considering the smallest subgroup population of the study (2 cohorts of residents, ie, approximately n=2880) and the proportion associated with the highest variability of the estimates (P=.50), a sample size of 864 (ie, 2×432; refer to Table 1) would allow to estimate any proportion with a precision of +2.790% to −2.790% (95% CIs derived from the hypergeometric distribution).

Results

The project has been peer reviewed and funded by the Swiss National Science Foundation in November 2022 with a start date of January 1, 2023, and an end date of December 31, 2026 (Multimedia Appendix 1). Data collection is currently underway, with the longitudinal cohort study having launched nationally on March 31, 2023. Because of organizational constraints, the postgraduate follow-up of historical cohorts will be launched from autumn 2023 to winter 2024. We expect to obtain preliminary results by mid-2024.

Discussion

Overview

This paper describes a longitudinal, prospective national investigation that will survey 4 cohorts of medical students across all Swiss medical schools as well as residents during their initial postgraduate training. The main objectives are to better understand the career choice process of Swiss medical students and to try to predict this choice.

This project will allow us to better understand the individual and contextual factors influencing Swiss medical students' career path, from students' intention at the end of medical school to postgraduate medical training and final specialization. This study will deepen preliminary findings on the relative influence and interaction of static and dynamic variables such as gender, work-life balance, and students' medical specialty perceptions [12,32-36]. The fact that the study is conducted in all Swiss medical schools will also pinpoint the differences between the various Swiss medical schools and, in particular, the effects of new medical master's programs regarding career choice and location of practice. This study will allow us to inform national stakeholders and medical schools both through prediction of

students' future choices and key aspects of physician workforce planning. Finally, by drawing comparisons with a regulated postgraduate training system such as France's, this study will also have potential benefits at the international level.

Strengths

To the best of our knowledge, this study is the first to investigate the personal characteristics and the evolution of students' career choices during their medical studies and postgraduate training at a national level. Similarly, there is a lack of data regarding the follow-up from the initial intention to the definitive choice. This information is essential because better monitoring and understanding of career choice paths could help promote the management of physician resources and direct undergraduate and postgraduate interventions aimed at a better distribution of these resources [8-10].

We will provide information and prediction tools to meet demands for quality, quantity, and appropriate distribution of physicians among specialties and among geographic areas.

Using both individual and contextual data from medical students, we should be able to improve the predictive performance of the machine learning models as compared with questionnaire-only data [29]. By enabling better estimates than standard past averages, we expect that the predictive models will provide more effective support to decision makers for capacity planning. Moreover, by identifying the factors impacting career choice, decision makers will have data-driven information to support mitigation actions against specialty shortage. Finally, the predictive models may also help medical students in their career choice.

Limitations

Difficulties in recruiting collaborators within each medical school and coordination for survey administration may hinder response rates from students and therefore impact the realization of the study's objectives. Finally, most of the variables are self-reported and therefore subject to personal bias. However, this study will use questionnaires with established evidence to support their validity. In addition, the project has received official support from the Joint Commission of Swiss Medical Schools. This allows us to include students from all medical schools and from multiple years of study. The partnership with the Swiss postgraduate governing body, SIME, is key to enabling data collection and follow-up of subjects during the postgraduate training years. The interdisciplinary research team brings together a psychologist, a statistician, a computer engineer, and 5 medical doctors, all involved in medical education at the undergraduate and postgraduate level and holding different specialty titles.

Conclusions

Exploring the individual and contextual factors associated with the career path of all medical students in Switzerland and the establishment of a follow-up system will provide important information for improving the quality of medical workforce planning.

We will identify targeted actions that may be implemented during medical school and may ultimately influence career choice and encourage the correct number of physicians in the right specialties to fulfill the needs of currently underserved regions. Potentially, these results could contribute to better management of the medical workforce by balancing future physician distribution and, in turn, increasing the efficiency of the health care system and meeting the needs of Swiss society.

Acknowledgments

This work is supported by the Swiss National Science Foundation (grant 100019_213172/1). The Swiss National Science Foundation played no role in the creation, review, or approval of this manuscript for publication. The authors would like to thank Zoya Horcik, Dr Philippe Conus, Dr David Gachoud, Dr Régis Marion-Veyron, Dr Julie Palix, and Dr Romano Regazzi of the University of Lausanne, Dr Michele Ghielmini, and Dr Marilu Guigli-Poretti of the University of Italian-speaking Switzerland, Dr Jean Sibilia and Dr Thierry Pelaccia of the University of Strasbourg, and Dr Raphael Bonvin and Dr Elke Bayha of the University of Fribourg for their support in the initial implementation of the study at their respective universities. The authors would like to thank Eva Hennel and Lukas Wyss for their help with the postgraduate aspect of their current collaboration with the Swiss Institute for Medical Education.

Data Availability

The data sets generated and/or analyzed in preparation for / prior to this study that underpin a publication are available from the corresponding author on reasonable request. The data sets generated and/or analyzed as part of this study that underpin a publication will be available in due course at the Yareta, University of Geneva data repository.

Authors' Contributions

MA, MRN, DVA, DT, GLS, and NMB contributed to the initial draft of the manuscript, whereas BC, MBM, and GAS reviewed, revised, and approved the final submission. GLS and NMB contributed equally to this manuscript.

Conflicts of Interest

None declared.

Abstract

Background: In Nigeria, similar to many leprosy-endemic countries, leprosy is highly stigmatized. High levels of stigma among community members as well as internalized stigma among persons affected by leprosy often result in negative psychosocial consequences for those affected. To break this vicious cycle, it is important to conduct context-specific behavioral change activities. Although written material has been successful in improving knowledge and perception, it is not suitable for populations with low educational levels. Audio-delivered interventions are likely to be more suitable for people who are illiterate. This study proposes to assess the impact of an audio-delivered intervention on the perception (knowledge, attitudes, and beliefs) of community members with regard to leprosy in Nigeria.

Objective: This study aims to assess the impact of audio-delivered and written health education on the perception of leprosy. Specific objectives are to (1) investigate the perception (local beliefs, knowledge, and attitudes) of community members toward leprosy and persons affected by leprosy; (2) investigate whether there is a difference in impact on perception between participants who have received audio-delivered health education and those who have received written health education, with specific reference to gender differences and differences between rural and urban areas; and (3) assess the impact of the participatory development of the audio-delivered and written interventions on empowerment and internalized stigma of persons affected by leprosy who developed the interventions. Additionally, we will translate and cross-culturally validate 4 study instruments measuring outcomes in 2 major Nigerian languages.

Methods: We will use a mixed methods, cross-sectional study design for the intervention development and a 3-arm cluster randomized controlled trial for its implementation and evaluation, comprising (1) baseline assessments of knowledge, attitudes, perceptions, and fears of community members, to develop the audio-delivered content and written material, and the self-esteem and internalized stigma of persons affected by leprosy; and (2) participatory development of the audio-delivered content and written material by persons affected by leprosy and the pilot and implementation of the interventions. This will be done among

different groups (selected using cluster randomization) that will be compared (control group, audio-intervention group, and written material group) to evaluate the intervention and the impact of developing the intervention on the persons affected.

Results: This study was funded in June 2022, and community member participant recruitment started in January 2023. Baseline data collection was completed by May 2023 (n=811). Participatory cocreation of the audio and written health education content began in July 2023, and the materials are currently under development. Study results are expected in September 2024.

Conclusions: Study findings will contribute to developing evidence-based, context-specific behavioral change interventions, which are critical to addressing stigma in many leprosy-endemic communities where leprosy is highly stigmatized, and contribute toward global triple zero leprosy efforts.

Introduction

Overview

Leprosy is an infectious disease caused by *Mycobacterium leprae* [1]. Leprosy has been stigmatized since ancient times [2]. Stigma refers to a negative social response from one group toward a low-power, stigmatized group [3]. Stigma is "a social process, experienced or anticipated, characterized by exclusion, rejection, blame, or devaluation that results from experience, perception, or reasonable anticipation of an adverse social judgment about a person or group" [4]. Stigma can occur at different levels, for example, at the intrapersonal, interpersonal, community, institutional, and structural levels [5]. Many people affected by leprosy experience the negative consequences of their condition [6,7]. Stigma can have a very negative effect on employment and education opportunities, social interaction, housing, and access to health care [8]. Stigma can also indirectly cause stress and negatively impact mental well-being, quality of life, and physical health [8]. Stigma can delay seeking treatment [9] and can also impede adherence to treatment [10]. Family members and friends may experience courtesy stigma (stigma by association) [11,12].

Perception, which refers to how individuals or groups "see" an object, person, event, or institution [13-15], is an important driver of stigma [4]. The origin of stigma lies in public perceptions about people who are stigmatized. Perception comprises knowledge, beliefs, and attitudes, which are in turn influenced by personal factors (eg, personality and experience) and environmental factors (eg, culture and religion) [13,14]. Leprosy-related stigma is mainly caused by fears of contagion, external manifestations, and disabilities; religious and cultural beliefs; misconceptions; and a lack of knowledge [2,16]. Personal characteristics such as age, gender, occupation, education, and living area have also been associated with leprosy-related community stigma [17-20]. Stigma reduction (which often consists of positively influencing the perception of leprosy and increasing knowledge of leprosy) is crucial to improving the lives of people affected by leprosy and to improving leprosy services. Several interventions have successfully reduced leprosy-related stigma [21-24]. Interventions that are culture-specific and contextualized tend to be more effective [25,26].

Nigeria is among 23 global priority countries identified by the World Health Organization (WHO). In 2019, a total of 2424 new patients with leprosy were detected in Nigeria, 15% of whom had Grade 2 disabilities (G2Ds) [27]. Nigeria is among the few countries that reported more cases of G2Ds in 2019 than in previous years [27]. G2D among new patients is used as an indicator of late detection of leprosy. In addition, G2Ds (visible impairments) often exacerbate stigma and discrimination [28,29]. Leprosy is a stigmatized disease in Nigeria [30,31]. In a study among persons affected by leprosy and community members in Western Nigeria, the stigmatization of leprosy was mainly linked to perceived infectivity and perceived immoral behavior [31].

Despite progress in the control of leprosy in the last decades, the disease remains highly stigmatized [7], especially in Nigeria [30,31]. High levels of community stigma as well as internalized stigma among persons affected by leprosy may result in delayed diagnosis and disabilities [32]. To break this vicious cycle, it is important that context-specific attitude and behavior change activities are carried out. From other studies, we know that changing perceptions and improving knowledge can lead to behavior change [18,33,34]. For example, between March and June 2020, several printed materials that aimed to improve the perception of leprosy and increase knowledge about leprosy were evaluated in Uttar Pradesh, India. These context-specific materials were developed as part of NLR International's Post-Exposure Prophylaxis project. Analysis revealed an association between the number of posters seen and a positive change in knowledge and stigma scores [35].

Access to appropriate health information is an essential step in the fight against stigma and discrimination. However, written materials are not suitable for populations with low educational levels [36]. To make health information accessible to people who are illiterate in many leprosy-endemic communities of the global south (especially women and girls), it is important to provide information through modalities other than printed materials. It is believed that audio-delivered interventions would be more suitable for people who are illiterate and low-literate.

Audio-delivered interventions, for example, radio, have been shown to be successful for different stigmatized conditions such as HIV, leprosy, and albinism [37-39].

This study aims to assess the impact of an audio-delivered intervention on the perception (knowledge, beliefs, and attitudes) of community members regarding leprosy by comparing an audio-delivered intervention with written health education. The study will be conducted in Nigeria.

Primary and Secondary Objectives

Our primary objective is to assess the impact of audio-delivered and written health education on the perception of leprosy in Nigeria. Additionally this study has the following secondary objectives: (1) to investigate the perception (local beliefs, knowledge, and attitudes) of community members toward leprosy and persons affected by leprosy; (2) to investigate whether there is a difference in impact on perception between participants who have received audio-delivered health education and those who have received written health education, with specific reference to gender differences and differences between rural and urban areas; and (3) to assess the impact of the participatory development of the audio and written interventions on empowerment and internalized stigma of persons affected by leprosy who developed the interventions.

Methods

Study Design

We will conduct a cross-sectional study (intervention development) and a 3-arm cluster randomized controlled trial (RCT; intervention implementation and evaluation). The three arms consist of (1) an intervention group who will receive the audio-delivered intervention, (2) an intervention group who will receive the written intervention (poster or flyer), and (3) a control group who will not receive any intervention.

Study Location and Setting

The study will be carried out in 6 local government areas (LGAs), 3 each in Cross River State (Boki, Calabar-South, and Obubra) and Taraba State (Jalingo, Yorro, and Zing). The 3 LGAs per area will be selected based on similarity in terms of literacy rate and prevalence of leprosy. Cross River is located in southern Nigeria, while Taraba is in the north. The total population of the study area is 940,540, estimated from the 2006 census, with 542,494 in Cross River and 398,046 in Taraba states. Both states have been selected because of the high prevalence of leprosy and G2D.

Cross River State notified a total of 106 new cases (17% with G2D) in 2019. The most common language spoken in Cross River State is Nigerian Pidgin. Over 90% of the people living in the selected LGAs in southern Nigeria speak Nigerian Pidgin. Other languages spoken in Cross River State include Efik, Ekoi, and Yala. The illiteracy rate (those with no schooling or primary or secondary education who cannot read at all) is 12.2% and 26.4% for male and female individuals, respectively. Occupations include farming, trading, and civil service employment. About 58% of women own mobile phones, compared with 71% among men [40]. Cross River State's poverty index is 0.146, and the poverty headcount rate is 36.3%. The case notification rate for leprosy is 2.76 per 100,000 people based on 2020 data.

Taraba is among the 15 high-burden states for leprosy in Nigeria; an average of 100 new cases were detected between 2013 and 2017, with an average of 6% and 5% of children and G2D cases, respectively. This figure is likely to be underreported, considering the significant presence of isolated populations such as nomadic pastoralists and internally displaced people in the state.

The most common language spoken in the selected LGAs in Taraba State is Hausa; 80% to 90% of the people living in the selected LGAs in Northern Nigeria speak Hausa. Other languages spoken in Taraba State include Mummuye and Fulfulde. The illiteracy rate is 30.1% and 64.9% in Taraba State for male and female individuals, respectively. Occupations in Taraba include farming, mainly crop production and cattle rearing, petty trading, and civil service employment. The majority of men (71%) own a mobile phone, while only 44.6% of women do. Taraba State's poverty index is 0.448, and the poverty headcount rate is 87.7%. The case notification rate for leprosy is 2.30 per 100,000 people.

Study Population

The following 2 groups of participants will be included in the study: persons affected by leprosy (for the participatory development of the interventions) and community members (the target group of the interventions).

Inclusion and Exclusion Criteria

Individuals aged 18 years or older will be included in this study. Individuals who do not speak Nigerian Pidgin or Hausa and who are unable or unwilling to give informed consent will be excluded from the study.

Study Duration and Sample Size Calculation

This study's duration will be 2 years. The sample size for the various components of the study is as follows. (1) A total of 200 community members (100 for each language per study area) will be included in the cross-cultural validation of the Explanatory Model Interview Catalogue Community Stigma Scale (EMIC-CSS) and Social Distance Scale (SDS), while 100 persons affected by leprosy (50 for each language per study area) will be included in the cross-cultural validation of the Internalized Stigma of Mental Illness (ISMI) scale and Rosenberg Self-Esteem Scale (RSES; see below). (2) A total of 770 community members will be included in the baseline and follow-up questionnaire interviews. This means a random sample of at least 385 persons in Taraba State (northern Nigeria) and at least 385 persons in Cross River State (southern Nigeria), which will consist of 114 in the audio intervention group, 114 in the written material intervention group, and 157 in the control group in each region.

This RCT will have three arms: (1) an audio-delivered intervention group, (2) a written material intervention group, and (3) a control group. The sample size calculation is based on 2 calculations. The intervention group calculation is based on an estimate of the difference in knowledge improvement

between the audio-delivered intervention and the written material intervention groups. We used data from a perception study in India. In this study, postintervention scores improved by 12.5% after a poster intervention and community meetings. We estimate that the effect of posters alone would be an increase of 10%. We want to be able to detect an improvement of at least 15% between the audio-delivered and the written material intervention groups. The sample size of the intervention group is therefore based on a proportion 1 of 10 (estimated percentage of improvement in knowledge of leprosy in the written intervention group) and a proportion 2 of 25 (ie, an improvement of 15% or more). With a power of 80%, a significance level of .05, and a 15% loss to follow-up, 114 participants are needed in each intervention group.

We expect an increase of 2% in the knowledge score in the control group. The control group calculation is therefore as follows: proportion 1:10, proportion 2:2, power 80%, significance .05, and 15% loss to follow-up, resulting in 157 participants.

A total of 25 people will be included in the participatory development of the material [41]. In each state, these will consist of 10 persons affected by leprosy and 2-3 community members. Semistructured interviews will be conducted until data saturation is reached.

Description of the Intervention

The interventions consist of (1) an audio-delivered intervention and (2) a written or printed intervention (such as posters or flyers) for education on leprosy, awareness-raising, and stigma reduction.

We will compare the effect of the interventions with a control group. The audio-delivered and written content will be developed based on local beliefs, misconceptions, and fears about leprosy identified in the baseline study. This will be done using participatory approaches. A group of persons affected by leprosy and a few members of the community will be formed, who will be guided by a researcher to develop the messages and materials (participatory development). The key messages of the audio-delivered and written interventions will be the same. The materials will be developed in the main languages spoken in the study areas: Nigerian Pidgin (Cross River State) and Hausa (Taraba State). The majority (>80%) of our target group speaks either Nigerian Pidgin or Hausa, which will hence be the language used for this study. The audio-delivered intervention will be incorporated into Audiopedia [42]. Audiopedia's website was designed to provide access to open knowledge foremost on health, livelihood, and well-being to both community-based organizations and nongovernmental organizations and individuals. Community-based organizations and nongovernmental organizations can benefit from using Audiopedia as part of their social and behavior change communication strategy, as it enables them to search, download, embed, and share audio files. Approximately 5000 audio clips, with a total runtime of 150 hours, are available in 11 languages. Audiopedia was optimized for search engines, thus making contents easy to find. Audiopedia also provides several technological solutions to make audio-based contents accessible to both literate and illiterate audiences, such as solar-powered audio players, mobile web applications for smart (feature) phones, and Wi-Fi hotspots that can stream audio-based contents without the need for internet connectivity, etc.

Participant Recruitment and Follow-Up

Persons affected by leprosy and community members will be selected based on purposive sampling. They will develop the content of the interventions. This is therefore, ideally, a diverse group of people who represent multiple perspectives. We will select participants based on purposive sampling to ensure adequate representation of age, gender, and villages.

The intervention will be implemented in North and South Nigeria, 2 areas that are very different. Therefore, we will cluster-randomize the interventions to ensure comparable groups are included in both areas. There are three different "groups" in each site (North and South): (1) the audio-delivered intervention, (2) the written materials intervention, and (3) no intervention (control group).

We will select 3 LGAs in North and South Nigeria (6 in total); each LGA will have either the audio-delivered or the written intervention or be a control group. The three LGAs per area will be selected based on their similarity in terms of literacy rate and endemicity of leprosy.

The interventions will be randomly allocated to clusters (LGAs) based on a random numbers list. This is a 2-stage random sampling. We will select a random sample of LGAs and a random sample of participants within each LGA. The participants in each LGA will be selected using the "spin the bottle" approach: a bottle will be spun in front of the most central place in the village (rural area) or neighborhood (urban area); the direction the bottle points at is the direction we start walking and counting. The first house to be included is selected by casting a die. Participant selection will be done by proportional sampling among the clusters. We will include the same participants at baseline and follow-up (a paired sample). This study protocol is reported in accordance with the SPIRIT statement (see checklist in Multimedia Appendix 1). The timeline schedule for participants during the study period is represented in Table 1, and a schematic description of the study flow chart is depicted in Figure 1.

Table 1. Study schedule for enrollment, intervention, and assessment.

Schedule	Study period and time point

[a]KAP: knowledge, attitudes, and practices.

[b]EMIC-CSS: Explanatory Model Interview Catalogue Community Stigma Scale.

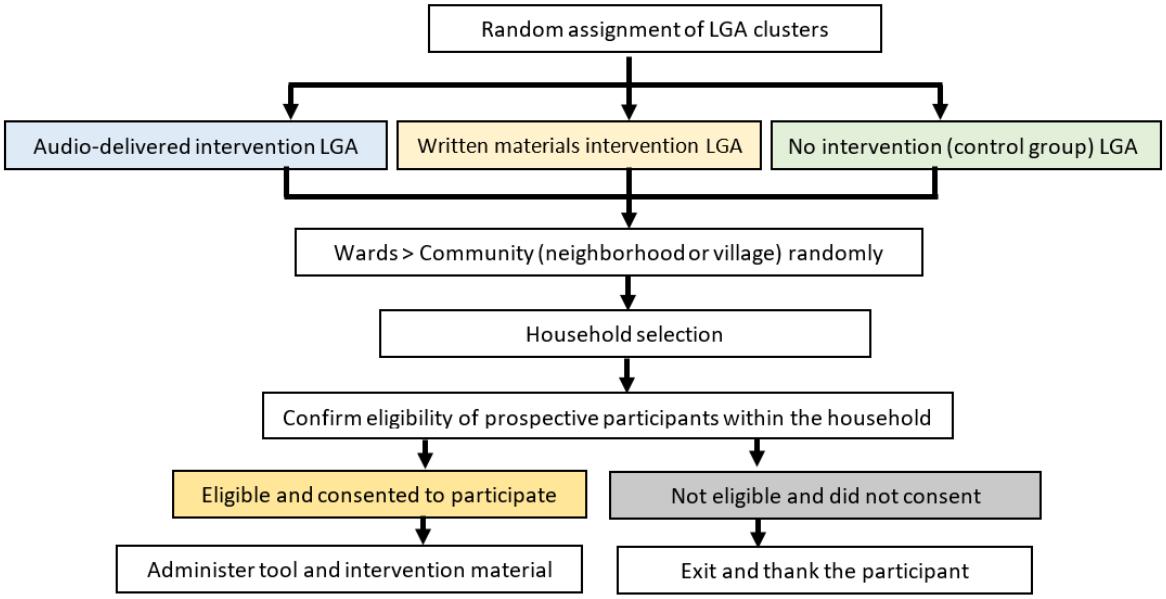
[c]SDS: Social Distance Scale.

[d]RSES: Rosenberg Self-Esteem Scale.

[e]L-ISMI: Leprosy-adapted Internalized Stigma of Mental Illness.

[F]CNA: Communication Needs Assessment.

Figure 1. Study flow chart. LGA: local government area.



Primary and Secondary End Points

The outputs of this study will be an audio-delivered intervention and written or printed health education material for education on leprosy, awareness-raising, and stigma reduction.

In addition, all 4 scales will be translated and cross-culturally validated in Nigerian Pidgin and Hausa languages as part of this study. The qualitative outcomes are knowledge and attitudes toward (persons affected by) leprosy (eg, local beliefs, fears, and misconceptions).

Outcome measures used to be assessed at baseline and follow-up are as follows:

- Demographic information: to disaggregate data by gender, the "knowledge, attitudes, and practices" (KAP) measure includes a form to collect demographic information.
- The KAP measure, as used in a study in India [16], covers 8 main topics: early symptoms, cause, mode of transmission, treatment, prevention, curability, contagiousness when on treatment, and prevention of disabilities. The KAP is a questionnaire and has not been formally validated as a scale (nor will it be used as a scale). We will translate and pilot test the KAP measure.
- Community stigma, using the EMIC-CSS (used in Nigeria but not validated in Nigerian Pidgin and Hausa yet [17]).
- Desired social distance toward persons affected by leprosy as a proxy for attitudes and fear, using the SDS (used among persons affected by leprosy in Nigeria but not validated in Nigerian Pidgin and Hausa yet [17]).
- Self-esteem and internalized stigma of persons affected by leprosy, using the RSES (used in Nigeria but not validated in Nigerian Pidgin and Hausa yet) and the leprosy-adapted ISMI (used among persons affected by leprosy and used in Nigeria but not formally validated yet [17]).

Data Collection

Overview

We will use a mixed methods approach and collect qualitative data (in-depth interviews and focus group discussions [FGDs]) and quantitative data (the KAP measure, EMIC-CSS, SDS, communication needs assessment, RSES, and ISMI). We will also collect demographic information (including literacy levels) from each participant.

This study consists of the steps and phases outlined in the following subsections.

Step 1

None of the tools listed in step 2 have been validated in Nigerian Pidgin and Hausa yet; therefore, they will be cross-culturally validated before use. We will assess conceptual, item, semantic, operational, and measurement equivalence using a framework for cross-cultural equivalence testing based on the work of Herdman et al [43], Terwee et al [44], and Stevelink and van Brakel [45]. In addition, the interview and group discussion guides (outlined in step 2) will be pilot tested among a small sample of participants before use. The KAP measure will be translated and pilot-tested.

Step 2

A baseline study to assess the perceptions of community members using mixed methods will be conducted, consisting of both in-depth interviews and FGD sessions and questionnaires (KAP, EMIC-CSS, and SDS). A communication needs assessment will be conducted as part of the baseline study to determine the most appropriate mode of delivery of the audio intervention and the most appropriate duration and frequency of the audio intervention. We will also conduct a baseline study among the persons affected by leprosy group who will be involved in the development of the interventions. Self-esteem and internalized stigma will be assessed using in-depth interviews, RSES, and ISMI.

Step 3

The participatory development of the audio-delivered and written content of the interventions is based on the knowledge gaps, beliefs, misconceptions, fears, and community attitudes identified in the baseline study. We will use the "6 steps in quality intervention development (6SQuID) framework [46], consisting of (1) defining and understanding the problem and its causes, (2) identifying which causal or contextual factors are modifiable: which have the greatest scope for change and who would benefit most, (3) deciding on the mechanisms of change, (4) clarifying how these will be delivered, (5) testing and adapting the intervention, and (6) collecting sufficient evidence of effectiveness to proceed to a rigorous evaluation. The final step of 6SQuID (step 6) is part of step 5 of this study—evaluation. The group of persons affected by leprosy who play a leading role in the development of the messages and materials (participatory development) will codetermine both the content of the materials (based on the knowledge gaps, beliefs, misconceptions, fears, and community attitudes identified in the baseline study) and the mode of delivery (based on the most appropriate means of communication determined by the communication needs assessment conducted as part of the baseline study).

Step 4

Implementation of the interventions in the study areas will be done in 2 groups: one intervention group will receive the audio-delivered intervention, and the other intervention group will receive the written intervention (poster or flyer). A control group will not receive any intervention. The groups will be cluster-randomized.

Step 5

Step 5 involves evaluating the impact of (1) the intervention on the community and (2) developing the intervention on persons affected, using the same mixed methods as the baseline studies (described in step 2). It should be noted that the in-depth interviews at baseline are mainly conducted to get insight into specific fears, local beliefs, and misconceptions about leprosy among community members, as well as insight into the self-esteem and internalized stigma of persons affected by leprosy. At follow-up, the communication needs questionnaire will not be administered anymore. In addition, FGDs will be held with community members at baseline and follow-up in the 6 LGAs and with the persons affected by leprosy group. In addition to further exploring themes that arose during the in-depth interviews, additional questions will be asked (at follow-up) to get insight into, among other things, awareness of, experiences with, and exposure or access to the audio and written interventions; thoughts about content; mode of delivery and frequency; and strengths and points of improvement.

Data Management and Data Analysis

Quantitative data collection will be done using electronic forms developed in the Open Data Kit, and all data will be securely stored in the cloud with access only to the research team. The recordings of the in-depth interviews and FGDs will be transcribed to the local languages, translated to English, and analyzed by 2 independent researchers using open, inductive coding and content analysis. Similar phrases with recurring themes will be coded in NVivo (QSR International). Quantitative data will be collected in the KoboCollect (Kobo Inc) mobile phone app. Data analysis will be done in the software package SPSS Statistics (SPSS Inc). Simple descriptive methods will be used to generate a demographic profile of the study sample. Differences between participants in the groups (audio, written materials, and control groups) will be evaluated using the Mann-Whitney *U* test or 1-tailed *t* test for continuous variables and the chi-square statistic for categorical variables. The mean (SD) or median (IQR), depending on the distribution of the data, of the total scores of the scales used will be calculated per intervention area. Stepwise multivariate regression with backward elimination will be done to examine what factors will have an independent effect on the outcomes. We will calculate the percentage change and corresponding 95% CI before and after the interventions are implemented and the statistical significance of this difference using a z test for differences between proportions. Effect sizes will also be calculated. If necessary, we will correct for differences in demographic information between study arms using quantile regression. We will compare the differences in follow-up assessment between the audio-delivered and written interventions. The knowledge gaps, beliefs, misconceptions, fears, etc identified in the baseline study will be summarized into a narrative review and will be used by the persons affected by leprosy group as input for the development of the content of the interventions. The most appropriate modes of delivery will be determined based on the communication needs assessment that will be conducted as part of the baseline study. The interventions will be developed using participatory methods.

Confidentiality and anonymity of data will be ensured in data collection, storage, analysis, and publication. Research assistants who will collect the data will be trained in data management, the maintenance of confidentiality, and ensuring privacy during data collection. Data will only be analyzed and shared with the Dutch and German researchers (outside of Nigeria) when they have been fully anonymized. The lead applicant will take full responsibility for ensuring the appropriate storage and security of data. Data will be kept for 5 years and destroyed after this time frame when no longer required.

Ethical Considerations

Ethical approval has been obtained from the Health Research and Ethics Committee of the University of Nigeria Teaching Hospital, Ituku-Ozalla, Enugu (NHREC/05/01/2008B-FWA00002458-1RB00002323). In addition, appropriate clearance was sought and obtained from the respective ethics committees of both the Taraba and Cross Rivers State Ministries of Health. The confidentiality of the study participants and the data collected from them will be ensured.

Written informed consent (Multimedia Appendix 2) will be obtained from the study participants. The questionnaire will be translated into the local languages included in this study and back-translated to ensure the soundness of the translation process. The consent form explicitly states the right of the participant to refuse giving consent or withdraw from the study

at any point. Also, he or she can decline to answer any question. Informed consent will be obtained from each participant before participation. Each participant will be given a copy of the participant information sheet and consent form to keep.

This RCT study was prospectively registered with and listed on the Pan African Clinical Trials Registry (PACTR202205543939385).

Results

This study was funded in June 2022, and community member participant recruitment started in January 2023. Baseline data collection was completed by May 2023, with a total of 811 respondents. Participatory cocreation of the audio and written health education content began in July 2023, and the materials are currently under development. Intervention will be administered after pilot-testing, and the follow-up period will last for 6 months. Neither the implementation of the study intervention nor the data analysis have commenced as of the time of submission. Study results are expected in September 2024.

Discussion

Principal Considerations

In this study, we will apply mixed methods to compare the impact of audio-delivered versus written health education intervention materials and a control group without any intervention on the perception (knowledge, beliefs, and attitudes) of community members regarding leprosy. Through a participatory cocreation process, we will develop the content of the intervention materials alongside persons affected by leprosy and implement a 3-arm cluster RCT to evaluate the effect of the intervention. The effect of the cocreation process on internalized stigma among the affected persons will also be evaluated.

Developing context-specific behavioral change intervention activities is critical to addressing stigma in many leprosy-endemic communities where leprosy is highly stigmatized. The outcome of this intervention is expected to influence knowledge and, hopefully, improve the attitudes of community members toward leprosy, as well as improve self-esteem among persons affected by leprosy. In the long run, early leprosy case finding will be boosted following stigma reduction. To the best of our knowledge, this is the first study of this kind in Nigeria. The generated educational materials (both the audio and written content) are reusable products that may be adopted or used by the national program. The audio-delivered educational content will be freely available on the Audiopedia platform, licensed under Creative Commons (CC BY).

Limitations

There are inherent limitations associated with cluster-randomized studies, such as cluster size variability. With the challenge of achieving uniform cluster sizes, variability in cluster size could impact the generalizability of the results. Additionally, there is a risk of contamination between clusters; however, this is minimal given the geographic distance between the study cluster locations.

The study sites were purposefully selected due to their similarity in having a high prevalence of leprosy and G2Ds; thus, the findings from this study may not be generalizable to the entire Nigerian populace.

Conclusion

Outputs from the research will offer policy makers, national and regional program managers, and partners reliable evidence for a new approach toward stigma reduction activities, thereby contributing toward global triple zero leprosy efforts. Content generated provides pragmatic and contextual evidence-based tools for effective health education campaigns and awareness creation, especially among populations with low literacy levels, both in Nigeria and other low- and middle-income countries.

Acknowledgments

This work is supported by the Leprosy Research Initiative Foundation (grant FP_22\15). The funding source had no role in the study design, collection, analysis, and interpretation of data; the writing of the report; or the decision to submit the article for publication.

The authors deeply appreciate the contributions of persons affected by leprosy and the kind support of the central unit of the National Tuberculosis, Leprosy, and Buruli Ulcer Control Programme, Federal Ministry of Health, Abuja, Nigeria, as well as the respective team members of both Cross River State and Taraba State Tuberculosis, Leprosy, and Buruli Ulcer Control Programme.

Data Availability

This is a study protocol manuscript. Deidentified research data that support the findings from this study will be made publicly available when the study is completed and published.

Authors' Contributions

AVTN and CG conceived the original research idea. AVTN, NMO, and JC contributed to fully conceptualizing the research proposal. AVTN, NMO, JC, CN, TD, SA, CG, UAO, AM, CE, OE, and NE all contributed to the design and planning of the study. NMO wrote the draft of the study protocol manuscript and the SPIRIT (Standard Protocol Items: Recommendations for

Interventional Trials) checklist. SA illustrated the study flow chart. All authors discussed the study protocol and contributed to the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: The increase in dengue cases can be attributed to social, demographic, environmental changes, or community-driven factors. In this regard, different strategies have been established in health education, using educational interventions as necessary tools for the reduction of the disease with the aim of reinforcing and stimulating the prevention and control of dengue.

Objective: This study aims to evaluate the effectiveness of a nursing educational intervention for dengue control.

Methods: A randomized controlled trial will be conducted with adults living in rural areas and participating in health promotion and disease prevention programs. We will enroll 116 adults. Adults will be randomized 1:1, with 58 adults assigned to the educational intervention group and 58 to the usual care group. Participants will receive 4 sessions over the course of a month, 1 week apart, and will be followed up for 1 month after the end of the educational intervention. Nursing Outcome Classification labels will be used to measure the outcomes: risk control (1902) and participation in health care decisions (1606).

Results: The participants in the intervention group are expected to achieve better dengue control behaviors than those in the usual care group.

Conclusions: Risk factors are fostered by the community, largely caused by artificial reservoirs or unprotected tanks in homes; also, the lack of information hinders the identification of symptomatology and the poor implementation of effective measures, and the development of standardized educational strategies can contribute to efficient and cost-effective control of the disease.

dengue; health education; health promotion; nursing care; prevention & control

Introduction

The World Health Organization, in a report for 2023, reported that between 100 and 400 million cases of dengue occur annually [1]. It also indicates that in the Americas for the year 2021, there was an incidence of 123 cases per 100,000 inhabitants, with a case fatality rate of 0.034% [2].

Dengue in general has a global annual cost of US $8.9 billion, with an average annual cost per case of US $151 in 2013 [3] and a global burden of 1.14 million disability-adjusted life years [4]. The main burden on affected countries is the enormous

number of hospitalizations and sick days, with older people being the most affected population [3,5]. For the economy, the negative effects are due to the high costs of controlling epidemics and absenteeism from work and school [6,7].

In addition, dengue generates indirect costs that are usually enormous. These costs are given by the consultations or medicines taken by the members of the family nucleus [8], or by the loss of income of the patients and their families due to hospitalizations and disabilities, which at the same time reflect a reduction in the supply of work from home [9,10], not to mention the distress that the patient and his family are exposed to, generated by the doubt, uncertainty, or disability that the disease can bring. Living in low socioeconomic strata in rural areas, urbanization, global warming, and increased human mobility may be factors contributing to the increased burden of the disease [11,12].

Studies in endemic countries, specifically in Latin America, reveal a low level of knowledge about dengue among the population [13]. In Peru, Gutiérrez and Montenegro-Idrogo [14] indicated that the population has a poor level of knowledge about dengue control and prevention. In Colombia, de Maria Cáceres-Manrique et al [15] reported that the knowledge of the participants about dengue is scarce, with favorable attitudes toward control but insufficient practices, and they also consider the disease to be something normal. Likewise, other studies reflect scarce knowledge about dengue, the adoption of risky practices that favor the development of the disease, and a lack of knowledge about ways to prevent dengue [16,17].

The increase of cases in these regions, apart from having behavioral and cognitive root components, such as the behavior and cultural patterns manifested by the population, essentially related to beliefs, customs, and traditions, which sometimes determine the circumstances in which the dengue virus vector lives, also presents factors that may favor the dynamics of the disease, such as socioeconomic (level of schooling, strata, overcrowding, and lack of public services), climatic, and political factors, where there is little participation of health institutions [18,19].

Research conducted in the study setting (Montería, Colombia) has related a lack of knowledge or inadequate knowledge, unfavorable attitudes, and inadequate behaviors in relation to dengue; in addition to this, people live in homes with characteristics that favor the development and multiplication of the vector, leading to recommendations for other interventions aimed at reducing contact with the vector, taking into account the conditions in which families live [20].

The presence or multiplication of dengue cases may be mostly preceded by the inadequate application of health behaviors in the management and control of the vector, having as a background the scarcity of knowledge for the appropriation and incorporation of sanitary measures in the different environments.

In view of the lack of knowledge and control measures for dengue, the literature points to several determining factors, such as sex [13], level of schooling, and socioeconomic level, since diseases such as dengue have a greater impact on low-income populations, where the conditions for the presence of vector breeding sites are more likely to occur. A low level of education generally coincides with a lack of knowledge of the disease. Other factors include residence in rural areas, occupation, overcrowding, and a lack of public services [19].

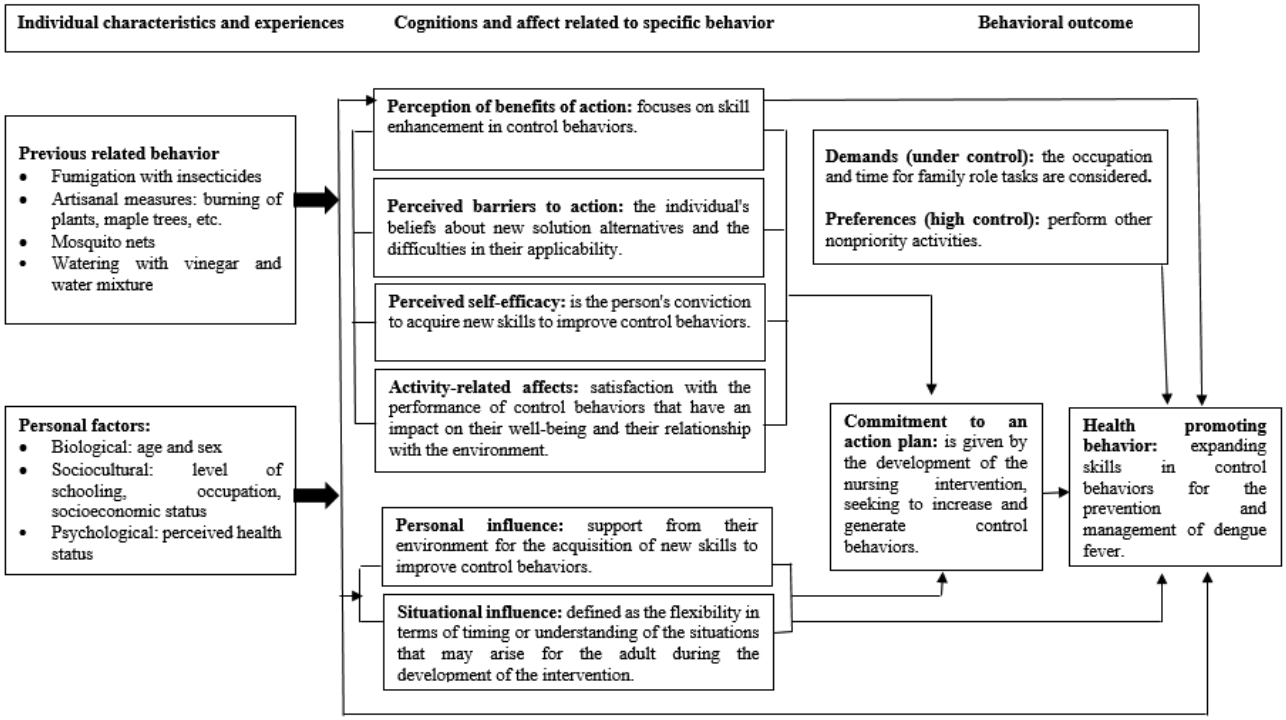
Other factors are lack of motivation and willingness, negative attitudes (low sense of belonging), inadequate habits or inappropriate cultural practices, lack of knowledge, difficult access to health services, lack of time, perception of risk, low involvement of health institutions, and limited economic and human resources allocated to public health infrastructures [21].

Thus, the evidence points to the increase in cases of dengue fever and cognitive and behavioral factors, which will be addressed in light of Nola Pender's Health Promotion Model (HPM). This model proposes that people interact with the environment, trying to achieve an adequate state of health, schematizing the nexus between personal characteristics and experiences, knowledge, beliefs, and situational aspects linked to the health behaviors or behaviors that are intended to be achieved [22], it raises dimensions and relationships that participate to generate or modify the health-promoting behavior [22], being the positive response that is expected to the actions carried out.

From the HPM perspective, the core concepts and subconcepts are used to achieve health-promoting behavior. Once the individual characteristics and experiences, cognitions, and affects related to the specific behavior are identified, the commitment to an action plan is expected, mediated in the research through the development of the nursing intervention that will generate a behavioral outcome, which is considered the expansion of skills in control behaviors in the prevention and management of dengue (Figure 1).

The objective of this study is to evaluate the effect of a nursing educational intervention to promote dengue control behaviors. We hypothesize that the participants in the intervention group will achieve better dengue control behaviors than participants in the usual care group.

Figure 1. Description of the conceptual elements for the study of health promoting behavior.



Methods

Study Design

A randomized controlled trial that follows the guidelines of SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) is used [23]. The study protocol was registered in ClinicalTrials.gov (NCT05321264).

Randomization and Blinding

Simple randomization into groups of equal size will be performed using the EPIDAT 4.2 program (Department of Health, Council of Galicia, Spain). Study participants will be randomized 1:1 to receive either the educational intervention or usual care. The randomization and allocation concealment will be carried out by the principal investigator. A centralized telephone randomization system will be used for masking [24]. With respect to blinding, the nurse who will perform the intervention will be blinded and will not know the outcome indicators of the study; the outcome assessors will be blinded and will not know to which group (intervention or control) the participants belong.

Participants, Setting, and Sample

The study participants are rural residents attending health promotion and disease prevention programs in a health care institution located in the municipality of Montería. It is a city in Colombia and capital of the department of Córdoba. It has 490,935 inhabitants and is considered a cattle-raising town.

Participants will be recruited during the opening hours established by the health institution. A sample size of 116 (58 participants for each group) was calculated according to the following parameters: effect size: an expected difference of 0.5 in the score of the nursing outcome labels between both groups [24], a statistical power of 90%, an α type error of 5%, a SD of the outcome scores of 1.0, an average correlation between the first and second evaluations of 0.3, an intervention/control ratio of 1:1, and a loss adjustment of 20%. Stata (version 16.0; StataCorp) software was used for this purpose.

Procedures

Eligibility Criteria

Persons older than 18 years of age, residing in a rural area of the municipality of Monteria in an endemic area with dengue or with exposure to dengue, attending health promotion and disease prevention programs of a health institution with an initial score ≤a 3.5 in the Nursing Outcome Labels (NOC) risk control (1902) and participation in health care decisions (1606), will be included in the study [25].

The Study Intervention

The educational nursing intervention in adults to promote dengue control behaviors, in terms of its structure, will follow the guidelines established by Sidani and Braden [26]. In addition, it will have as a theoretical reference Nola Pender's HPM, which is articulated for the phenomenon under study, to allow reaching a health-promoting behavior, which lies specifically in the expansion of skills in control behaviors in the face of dengue. The intervention contemplates 3 active ingredients that influence dengue control behavior: an educational component, behavioral support, and attitudinal support (Textbox 1).

Textbox 1. Content of the intervention.

Active ingredients and components

- Session 1: educational component

General information on dengue: definition of the disease, etiological agent, mosquito life cycle, modes of transmission, period of transmissibility, and personal and environmental risk factors (tanks, flower vases, pet drinkers, and plastic containers).

- Session 2: educational component

Dengue overview: health threats, clinical manifestations, diagnostic aids, treatment, prevention and control strategies, and barriers that may prevent the implementation of effective measures.

- Session 3: behavioral support

Commitment to the implementation of preventive strategies (personal, home, and environmental care), achievements obtained with the implementation of dengue strategies, self-control in dengue decision-making, and lifestyle changes.

- Session 4: attitudinal support

Main support networks that people can find in their environment: family, friends, health, and community resources. How to take advantage of available resources?

The intervention will consist of 4 face-to-face meetings with an interval of 1 week for 1 month, each lasting 45 minutes (Textbox 2). The first session will include an educational component and address issues related to dengue, etiological agents, transmission mechanisms, and personal and environmental risk factors. The second session will cover topics such as health threats, clinical manifestations, diagnostic aids, treatment, prevention and control strategies, and barriers that may prevent the application of effective measures against dengue, also belonging to the educational component. The third session will cover personal care practices, home and environment care, and lifestyle modification, which correspond to behavioral support. Final, the fourth session covers attitudinal support, which will review support networks and the use of resources.

Textbox 2. General characteristics of the intervention.

- Objective: increase knowledge and application of dengue control behaviors.
- Duration of the intervention: 1 month
- Number of sessions: 4 sessions
- Frequency: once a week for a period of 1 month.
- Environment: institution providing health services in rural areas (promotion and prevention program).
- Delivery strategies: individual, face-to-face, standardized educational material, and use of digital tools.
- Receiver: adult who meets inclusion criteria.
- Provider: qualified and trained nurse, with previous performance verification (does not work in health institution).
- Outcome measures: risk control and participation in health care decisions.

The intervention will be delivered in a personalized, face-to-face manner [27], and standardized educational material (booklet) will be used [28-30]. It also indicates that feedback, reviews of key points, and commitments will be made in each session that is held.

Intervention Fidelity

The intervention will be delivered to adults as it is designed, seeking to generate the desired changes in the results [26]. For this, it is necessary to develop methodological strategies to ensure the application of the active ingredients (delivery mode, doses, and activities) of the intervention, called fidelity. The fidelity of the intervention contemplates 2 fundamental levels: the theoretical level and the operational level, which are described in Table 1.

Table 1. Operationalization of intervention fidelity.

Levels and criteria	Objective	Strategies to ensure fidelity
Theoretical		
Study design control	Ensure that the intervention is consistent with the theoretical propositions of the Health Promoting Behavior.	The content of the study will be validated by experts to determine consistency between the active ingredients and the proposed theoretical component.
Operational		
Interventionist training	Ensure that the intervention is delivered in accordance with the protocol.	A course on dengue will be held and nurse training will be provided.
Delivery of the intervention	To reduce variability in the application of the intervention.	The intervention will be delivered by a trained nurse and performance will be verified. Development of the intervention protocol manual, with standardized educational material.
Treatment exposure	Ensure that all adults receive the intervention on equal terms.	Provide the intervention to all participants as defined in the intervention protocol manual: frequency, dosage, duration, delivery method, and sequence.
Treatment reception	Verify the appropriation and use of the active components of the intervention: educational, behavioral, and attitudinal support.	At the end of each session, there will be a space for feedback, review of key points, and commitments.
Follow-up of treatment compliance	Verify the implementation of health promoting behavior.	Face-to-face and telephone sessions will be held to provide feedback on the proposed objectives to achieve health-promoting behavior.

Data Collection and Measures

An intervention will be developed in 4 sessions with baseline, end line, and 2-month postintervention measures. The NOC labels chosen to evaluate the effect of the intervention are risk control (1902) and participation in health care decisions (1606).

To characterize the participants in both the intervention and control groups, a form containing variables such as age, sex, education level, marital status, actual occupation, health system affiliation, socioeconomic stratum, and dengue diagnosis will be filled out.

To evaluate the cognitive aspects or mental state of the adult, the mini mental test will be used, which is composed of 30 dichotomous items that evaluate 6 cognitive processes: temporal orientation, spatial orientation, fixation memory, evocation memory, attention and calculation, and language [31,32].

Outcomes

The outcomes of risk control and participation in health care decisions, which belong to the NOC classification, which is useful for analyzing and measuring the impact and quality of nursing interventions, will be evaluated.

Risk Control

Corresponding to code 1902, it consists of 21 indicators on a Likert-type scale with a score from 1 to 5 (1=never demonstrated, 2=rarely demonstrated, 3=sometimes demonstrated, 4=frequently demonstrated, and 5=always demonstrated) and is defined as personal actions to understand, avoid, eliminate, or reduce health threats that are modifiable [33]. It includes items that seek the implementation of behaviors by the adult.

Participation in Health Care Decisions

Defined as personal involvement in the selection and evaluation of health care options to achieve a desired outcome, it corresponds to code 1606 and consists of 15 indicators. It uses measurement scale 13, which is defined as the frequency of clarifying by report or behavior and has a score from 1 to 5 (1=never demonstrated, 2=rarely demonstrated, 3=sometimes demonstrated, 4=frequently demonstrated, and 5=always demonstrated) [33]. It contains several indicators that respond to some subconcepts of the theory, such as perceptions of benefits to action, perceptions of barriers to action, and preferences, which are the ones intended to be measured.

Follow-Up

Participants will be followed up 1 month after the end of the study intervention [34-36]. Individual and face-to-face follow-up is planned to assess the effect of the intervention over time.

Data Analysis

The information will be tabulated using the EpiData program, and the Stata software will be used for statistical analysis, following the principle of intention-to-treat analysis, which allows the patients to be analyzed as they were originally assigned or randomized [37]. Statistical hypothesis tests will be performed with an α level of 5%. A descriptive analysis of the baseline variables will be made to observe the behavior in each of the groups, using the student 2-tailed *t* test and the Fisher exact test. Categorical variables will be presented with absolute and relative frequencies. Quantitative variables with normal distribution will be presented with mean and SD, and for variables that do not comply with the principle of normal distribution, they will be presented with median and IQR (IQR=Q3–Q1). Normality will be assessed using the Kolmogorov-Smirnov test.

Baseline variables will be compared between the control group and the intervention group. The chi-square test will be used for categorical variables. The student *t* test will be used to compare the means in the 2 groups when the normality assumption is met, and otherwise, the nonparametric Mann-Whitney *U* test will be used.

To control for possible confounding variables, a statistical adjustment will be made through an analysis of covariance with their respective 95% CIs.

The effect of the intervention will be measured through analysis of covariance by means of the delta value or difference of the NOC label score between the 2 comparison groups.

Paired *t* tests will be performed to observe separately how each group fared before and after the intervention and at follow-up.

Ethical Considerations

The trial will be conducted taking into account the ethical guidelines established in the Declaration of Helsinki, the Belmont Report (1979), the Council for International Organizations of Medical Sciences (2002), and Resolution 8430 of 1993 (Ministry of Health, Colombia, 1993). Ethical approval was granted by the Research Ethics Committee of the Faculty of Nursing of the University of Antioquia (#2021-29). Adults willing to participate voluntarily in the study will be selected, applying the principle of fairness, and the information provided by them will be maintained under strict confidentiality. Alphanumeric codes will be used to record the information, and no names or any other personal identification data will be used. The participants in the control group at the end of the research will receive the same educational intervention as the intervention group.

Results

It is expected that participants in the nursing education intervention group will have better dengue control behaviors than those in the usual care group (effect size increase of at least 0.5 of the δ score in each of the NOC outcomes). The results are expected to be published in 2025.

Discussion

Principal Result

Dengue is linked to household sanitation. The existence of breeding sites is due to specific human behaviors that favor them, whether individual, community, or institutional [15]. Insufficient knowledge about the disease is one of the factors that precipitates the application of inadequate measures [38,39]. Research indicates that risk factors are fostered by the community, largely caused by artificial reservoirs or unprotected tanks in homes [40,41]; it also indicates that the lack of information hinders the identification of symptoms [38] and the poor application of effective measures.

In the study scenario, there is evidence of inadequate knowledge and practices regarding dengue [20], aspects that this study seeks to improve in order to generate favorable changes in the behavior of the population and, therefore, of the disease.

The results of the research may serve as a basis for the identification of lines of action that should be strengthened in the prevention and control of dengue, including the induction and reinduction of the human talent necessary for health care.

Likewise, the research is a window for theoretical-practical integration in health promotion scenarios, and at the same time, it is configured as an opportunity for the visibility of care and its standardization in the rural population. It is hoped that the results will serve to strengthen the role of nursing as an active member of health risk management.

Limitations

Length of follow-up, cointerventions, and attrition during the study are anticipated limitations. To reduce these limitations, the selection of participants will be controlled by random assignment to the intervention, specific eligibility criteria for entry into the study, and intention-to-treat analysis. Both the intervention and outcome assessors will receive appropriate training. Masking and adjustments to the statistical analysis will be performed as needed. Health care professionals will be sensitized to avoid cointervention in the study. The principal investigator will be the study supervisor and will not be involved in intervention delivery or outcome assessment.

Conclusion

The scarcity of studies with a high level of evidence, such as randomized clinical trials, provides an opportunity for the development of the present research, which has a quantitative approach and aims to generate new knowledge based on the best scientific evidence for the care of vector-borne diseases in rural populations.

With the evaluation of results through the NOC, the possibility of having measurement indicators for the discipline is opened, which allow making contributions based on evidence, given that the studies carried out show scarce application of the same, so they become important work elements for the development of care processes in favor of the less favored collectivities.

Conflicts of Interest

None declared.

Abstract

Background: Type 2 diabetes poses public health challenges for Māori and Pasifika communities in Australia. The women of these communities face a greater burden from type 2 diabetes–related mortality and comorbidities. Lifestyle modification behaviors through previous women's wellness programs have been shown to reduce the risk of developing complications in established type 2 diabetes. The Pasifika Women's Diabetes Wellness Program (PWDWP) pilot study, co-designed with Māori and Pasifika communities, was aimed at addressing late hospital presentations from diabetes-related complications.

Objective: This study (1) examines the efficacy of women with type 2 diabetes in the intervention group for improved glycated hemoglobin (HbA_{1c}) clinical levels and diabetes self-management compared with the control group from baseline (T_0) to week 12 (T_1) and week 24 (T_2; postintervention) and (2) assesses the cultural adaptability, acceptability, and feasibility of the pilot intervention for future studies.

Methods: This study uses a quasiexperimental design that involves a 24-week intervention. We recruited 50 Māori and Pasifika women with type 2 diabetes (25 in the intervention group from the south side of Brisbane and 25 in the control group from the north side of Brisbane) using participatory talanoa methodologies. The intervention group participated in face-to-face and virtual whānau education workshops (5 weeks) and had access to individual coaching and virtual support delivered by trained Māori and Pasifika health professionals and community health workers. The control group received usual care with their identified health provider. Both groups received copies of the PWDWP journal, fact sheets, and a health check passbook with tailored motivational text messages. An advisory committee was set up to oversee the program implementation, including protocols of engagement, health checks, and data collection in community settings. The quantitative data were collected at T_0, T_1, and T_2 with HbA_{1c} as the primary outcome measure. Secondary outcomes measured changes in diabetes self-care and body composition (eg, BMI, waist circumference). Qualitative data will ascertain the program's feasibility and cultural adaptability using talanoa focus groups.

Results: This pilot study was approved by the Queensland University of Technology Human Ethic Research Committee (5609) and began in January 2023 after participant recruitment between July 2022 and December 2022. The final data collection including the health check, focus group, and survey data was completed in November 2023, and data analysis and reporting are expected to conclude in 2024.

Conclusions: This study provides a blueprint for PWDWP. Collaborative partnerships with community organizations and stakeholders are crucial for program success and suggest a potential model for targeting diabetes management for Māori and Pasifika communities, emphasizing the need for culturally relevant interventions. The findings will have significant implications for policymakers and practitioners when developing and implementing public health initiatives, particularly for communities with unique cultural nuances.

Introduction

Background

The global prevalence of diabetes and its threat to public health continue to increase each year. Almost 90% of the estimated 537 million people currently living with diabetes worldwide have type 2 diabetes, despite it being largely preventable [1]. The Western Pacific region accounts for over one-third of the worldwide burden of diabetes, with 6 Pacific Island Countries and Territories (PICTs) among the top 10 globally with the highest prevalence of type 2 diabetes [1,2]. Additionally, PICTs face a higher prevalence of complications from debilitating diabetes as well as a higher prevalence of undiagnosed diabetes compared with other regions [2-5]. There are disparities in diabetes and diabetes-related conditions between people from PICTs and people from high-income countries, with similar disparities in Australia between Indigenous and non-Indigenous Australians [6]. As the prevalence of diabetes is positively associated with social and economic costs to individuals, families, and society, the severity and burden of type 2 diabetes are clearly highlighted [7-10].

Type 2 diabetes remains a major public health challenge for Māori and Pasifika peoples living in Queensland, which has the largest Pasifika diaspora after New Zealand [11]. Pasifika is a collective term used for Pacific peoples in Australia. Significant disparities in diabetes prevalence exist in these populations, who are 2 to 4 times more likely to be hospitalized and die from diabetes-related complications than non-Māori and Pasifika populations [12]. Evidence indicates that culturally and linguistically diverse women, in particular, face a greater burden of type 2 diabetes–related mortality and comorbidities including cardiovascular disease, kidney disease, vision impairment, and depression [12-15]. Diabetes care and support programs are less likely to be used by Māori and Pasifika women with diabetes due to low levels of health literacy, language barriers, and a strong cultural reluctance to seek help. Lack of culturally appropriate health and social services have resulted in an avoidance of engagement by Māori and Pasifika women [15]. Māori and Pasifika women carry significant cultural responsibility including expectations of acting as carers, leaders, and nurturers within their communities, often at the expense of their own chronic disease management [15]. This has significant implications for providing accessible, low-cost, and culturally appropriate diabetes care for Māori and Pasifika women with type 2 diabetes [15].

Encouraging healthier behaviors in Māori and Pasifika women with type 2 diabetes could potentially improve the health and well-being of women [15,16]. Modification of personal behaviors through women's wellness programs aimed at early intervention have been shown to reduce the risk of developing complications in established type 2 diabetes and may reduce hospitalization rates due to preventable complications [14]. A qualitative study of a multimodal behavioral intervention, the Women's Wellness with Type 2 Diabetes, found it to be effective at supporting women with developing strategies to improve their well-being and avoid complications associated with diabetes [16]. Another study with Māori and Pasifika women with type 2 diabetes in Queensland reported effective strategies to improve self-management through culturally appropriate interventions and educational resources [15,17]. Thus, the first culturally framed intervention, the Pasifika Women's Diabetes Wellness Program (PWDWP) emerged from these studies that informed the study's principles and processes, including recruitment strategies and co-design of the delivery format into a whaˉnau (family)-centered approach that harnesses digital technology [15,17]. The intervention was co-designed with Māori and Pasifika women living with type 2 diabetes in Queensland, underpinned by social cognitive theory and the Fonofale Pasifika Health Model that focuses on family, culture, community, and spirituality using talanoa, a Pacific form of dialogue, to promote sustainable self-management of type 2 diabetes [17-20]. This 24-week program is whānau-centered with 5 diabetes self-care behavior and wellness components (Figure 1) and delivered by trained Māori and Pasifika health professionals. The program takes into consideration the cultural shame associated with acknowledging the disease and tailors the interventions using talanoa as the key strategy to reach a shared meaning for behavioral changes [20].

Figure 1. The Pasifika Women's Diabetes Wellness Program and the "wellness" components.

The program team has previously ensured successful translation of interventions into practice through meaningful engagement with consumers, policymakers, health service managers, and clinicians [15,17,18,20-22]. This program will further consolidate collaborative partnerships between clinicians, health service providers, Māori and Pasifika communities and organizations, and consumer advocates. The study will evaluate the clinical benefits of the intervention and will target improvements in glycated hemoglobin (HbA_{1c}; measured using a point-of-care device [18]) and diabetes self-care including diet, physical activity, stress and medication management, and routine health checks of Māori and Pasifika women with type 2 diabetes from data collected via validated questionnaires using Qualtrics [24]. The study builds on a robust and systematic program of work, beginning with scoping studies, needs assessments, and early wellness trials with women [15-17].

Research Aim

The pilot study will evaluate the feasibility, acceptability, delivery, and effectiveness of PWDWP using mixed methods, in partnership with Māori and Pasifika community organizations and key stakeholders in southeast Queensland.

Objectives

The primary objective is to examine efficacy, defined as the women with type 2 diabetes in the intervention group having improved clinical HbA_{1c} levels from baseline (T_0) to week 12 (T_1) and week 24 (T_2) postintervention compared with the control group.

The secondary objective is to determine whether, compared with control participants, the intervention group achieves changes to bring body composition measurements closer to the recommended healthy range for specific cultural groups (eg, BMI ≤30 kg/m^2 and waist circumference <80 cm based on World Health Organization criteria) and improved diabetes self-care scores on diet, physical activity, routine health checks, and medication adherence assessed using the validated Summary of Diabetes Self-Care Activities scale [23,25-31].

In addition, we will assess the potential for success of the proposed intervention by examining accessibility, acceptability, uptake, and cultural adaptability of the intervention; sustainability of and adherence to the intervention over time; participants' perceptions of measurement burden; the effectiveness of the planned recruitment strategy and retention of participants; and documentation of women's experience with PWDWP through digital stories.

Hypotheses

H1 is that, compared with control participants, intervention participants who receive intensive wha¯nau face-to-face and virtual support for type 2 diabetes management will have improved HbA_{1c} levels at 12 weeks and 24 weeks (postintervention sustainability).

H2 is that, compared with control participants, intervention participants who receive intensive wha¯nau face-to-face and virtual support for type 2 diabetes management will have reduced waist circumference and BMI at 12 weeks and 24 weeks.

H3 is that, compared with control participants, intervention participants who receive intensive wha¯nau face-to-face and virtual support for type 2 diabetes management will have improved diabetes self-care at 12 weeks and 24 weeks.

Data collection occurred at 3 time points: T_0 (before the commencement of the pilot program, week 1), T_1 (postintervention, week 12), and T_2 (postintervention, week 24). Data on the feasibility, accessibility, and affordability of the PWDWP were collected via satisfaction surveys for the intervention group at the end of the workshop (week 5), week 12, and week 24. For the control group, satisfaction surveys were completed in week 12 and week 24.

Qualitative data obtained through talanoa focus groups with participants will determine measurement burden, acceptability, potential translation, and ease of intervention access. Feasibility covers how the participants were referred to the program, time taken to complete questionnaires, any strengths or weaknesses of the intervention, its cultural relevance, experience with accessing the intervention, perceptions of the digitally delivered coaching sessions and online virtual support sessions as well as the face-to-face intervention, and any suggested improvements to the study design or intervention.

Methods

Advisory Committee

An advisory committee (AC) was established to oversee the pilot study, including its setup, ongoing management, promotion, implementation, and evaluation with outcome deliverables including appropriate dissemination. The AC includes members of the Māori and Pasifika communities including the Pasifika Women's Alliance and Pacific Island Council of Queensland and key organizations such as the Good Start Program for Māori and Pacific Islander Peoples (Children's Health Queensland) and academia (eg, Queensland University of Technology [QUT] and University of Technology Sydney through the Women's Wellness Research Program). A series of group talanoa undertaken with AC community members ensures that the pilot study is implemented and evaluated within the talanoa cultural framework. The AC meets regularly every 4 months to review the study protocols including recruitment strategies, health checks, and data collection methods and approaches and how these are disseminated. The AC provides input on the trial progress, adherence to the protocol, participant safety, and consideration of new information as well as advice on the location and place of delivery (intervention and data collection) considered to be culturally acceptable to the participants.

Participatory Talanoa Methodologies

The research uses participatory action research using co-design and talanoa methods as the theoretical and cultural framework in the collection and analysis of data.

Talanoa is a way of communicating in a Pacific context. It has been described as the co-construction of knowledge through respectful, reciprocal conversation. It is a process enabling critical discussions and knowledge construction allowing for rich contextual and inter-related information to surface as co-constructed stories [19]. Vaioleti [19] uses the following metaphor of kakala:

- "Toli" is deciding on, selecting, and picking the flowers, equating to recognizing a problem, how participants are chosen, and which data are collected and analyzed [19].
- "Tui" is the process of making and weaving the kakala, in which the stories and emotions of deep talanoa encounters are integrated and synthesized. This involves deciding on the type and amount of data to use, how the data are arranged in relation to each other, and how they are presented.
- "Luva" is the giving away of the kakala, when the research is given for the benefit of the community, where solutions can be found.

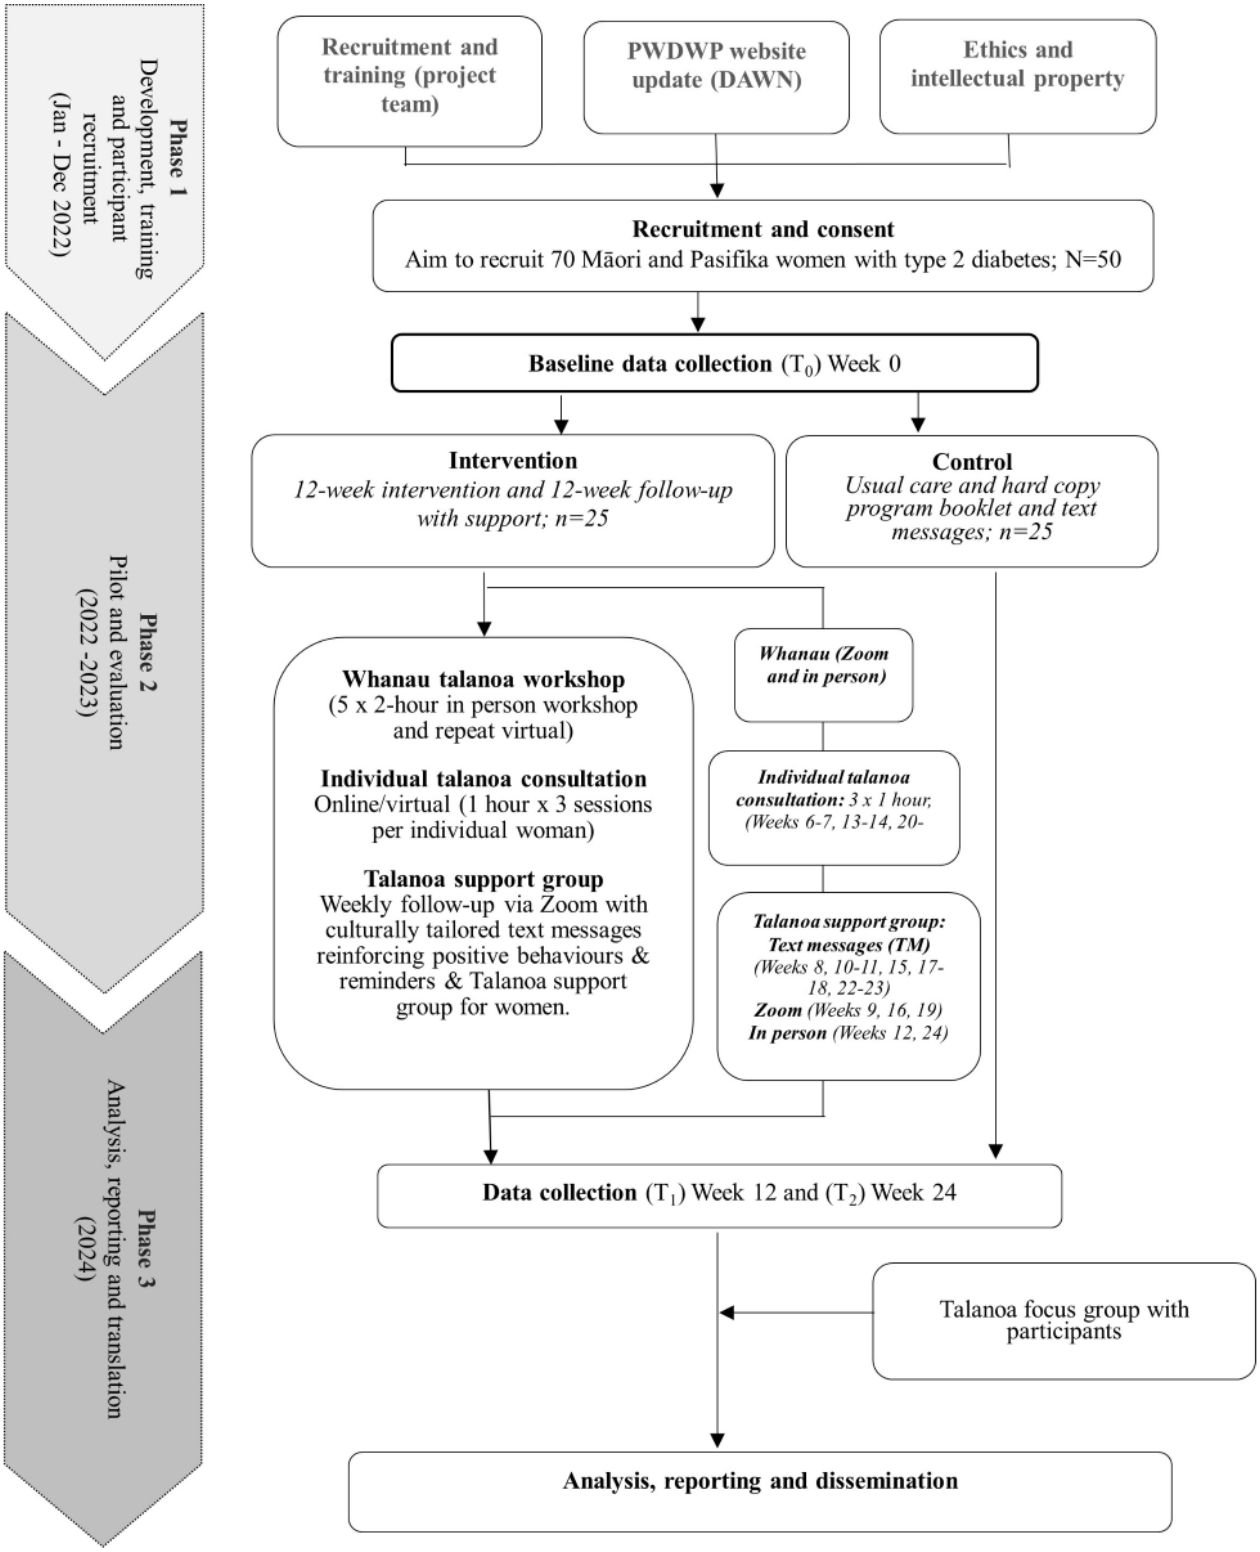
In this context, community engagement, including recruitment, data collection, and analysis processes, is a form of talanoa. All data are analyzed through talanoa with the AC and community researchers. In this context, talanoa is a method embedded within a participatory methodology [19] that informs the protocol of this study.

Study Design

This pilot study is a quasiexperimental design with 2 arms: an intervention (delivered in person and online for those who preferred virtual delivery) and an attention control arm (receiving written information and text messages). The study is being conducted to trial a 12-week intervention followed by a 12-week follow-up period (over 24 weeks) delivered by trained Māori and Pasifika health professionals (diabetes educator, clinicians, community health workers [CHWs], and community researchers). The study is conducted in southeast Queensland, Australia, with Māori and Pasifika women living with type 2 diabetes who were recruited through participatory community engagement with the Māori and Pasifika community leaders and organizations.

The study uses participatory talanoa methodologies using in-depth interviews and surveys and involves an in-person talanoa education workshop (5 weeks) as well as virtual workshops (5 weeks for those participants not in Brisbane and unable to attend in person), 3 online individual talanoa consultations (coaching) via Zoom, and an online virtual talanoa support group with motivational SMS text messages. The control participants received the usual care with their identified health professionals, a hard copy of the program materials (which includes a program journal, recipe book, fact sheets, and passbook), as well as general motivational SMS text messages. The process evaluation includes satisfaction surveys after the workshop sessions at week 5, week 12, and week 24 as well as a talanoa focus group with the participants after the intervention. Figure 2 is an overview of the PWDWP pilot study in southeast Queensland, Australia (2022-2024). The detailed intervention is described in the following sections.

Figure 2. Overview of the Pasifika Women's Diabetes Wellness Program (PWDWP) pilot study in southeast Queensland, Australia (2022-2024).



Intervention

The PWDWP intervention includes a whānau talanoa workshop, individual talanoa consultations, and a talanoa support group and text messages.

Whānau Talanoa Workshop

Five 2-hour sessions covered the wellness components. Whānau talanoa workshops provided interactive knowledge-based education on targeted health knowledge and behaviors with culturally specific tools to manage type 2 diabetes within family, community, and spiritual contexts (see Table 1).

Table 1. Whānau talanoa education workshops on diabetes wellness components delivered by a trained Pasifika diabetes educator and community health workers.

Education component	Content delivery	Weeks delivered
Becoming Healthy	This workshop provides practical information on type 2 diabetes and its symptoms, risk factors, diagnosis, treatment and management, medication, and self-care. This session also covers practical and cultural ways to deal with issues related to the shame and stigma of developing type 2 diabetes and the impact of denial.	1
Healthy Thinking & Feeling	This workshop provides information and tools to deal and cope with stress and barriers and ways to improve wellness that incorporate elements of Pasifika values, spirituality, and faith.	2
Healthy Eating	This workshop provides information and tools for healthy eating with a self-care healthy eating plan and strategies for managing cultural hospitality requirements without losing face.	3
Staying Active	This workshop covers ways to get moving, types of exercises to do with your family, and practical tips to remain motivated to stay active while managing family and community obligations.	4
Healthy Living	This workshop encourages, motivates, and maintains healthy living including looking after your bones, eyes, kidney, and heart; sleep; and menopause with spirituality, family, and community well-being.	5

Individual Talanoa Consultations

Three 1-hour, 1-on-1 sessions were conducted. The first session consisted of a routine check-up, appropriate screenings, and a discussion to facilitate tailored education, goal setting, and specialist advice to support individualized plans and goals for a healthy weight, diet, physical activity, stress management, sleep, and medications. The second session revisited goals set during session 1 and, if necessary, discusses prevention strategies and identification of barriers. The third session reviewed participant progress including barriers to self-management, reinforcement of positive behaviors, and setting future goals for maintenance.

Talanoa Support Group and Text Messages

A virtual peer support group facilitated by CHWs encouraged and supported women with targeted topics including stress management, barriers, understanding family situations, mindfulness, nutrition and diet, importance of health checks, regular visits to general practitioners and specialists, monitoring blood glucose levels, medication adherence, and maintenance. Motivational SMS text messages were sent regularly to reinforce key messages.

Cross-Intervention and Control Conditions

The intervention group received the complete intervention over the 24 weeks and had access to an interactive program journal (hard copy and electronic), a recipe book, a passbook for health check, and fact sheets as well as text messages with reinforcing positive motivational behaviors (Table 2). The participants also had access to a website that includes culturally developed resources (such as podcasts, digital stories, and information materials).

Table 2. The intervention component for the Māori and Pasifika women with type 2 diabetes from the south side of Brisbane, Queensland, Australia.

Intervention components	Weeks (1-24)
Whānau talanoa workshops (in person and virtual)	1-5[a]
Individual talanoa consultation (coaching via Zoom)	6-7, 13-14, 20-21
Motivational SMS text messaging	8, 10-11, 15, 17-18, 22-23
Talanoa support group (via Zoom)	9, 16, 19
Data collection (T_0, T_1, T_2; in person)	0 (baseline), 12, 24
Talanoa focus group (in person)	24

[a]Offered either (1) in person (face to face) with women or (2) online (virtual) for those who cannot attend in person.

The program provided all necessary health promotion content and supported participants with logging relevant health information in the journal (either hard copy or an electronic version). A weekly diet, physical activity, and diabetes self-care checklist encouraged participants to plan ahead. The interactive website aims to reinforce educational content, enabling home monitoring of measurable health indicators, and allowed participants to fill out questionnaires and other data. The website will also be adapted for all computing platforms, including mobile phones for future studies. Figure 3 illustrates the intervention participant journey of Māori and Pasifika women with type 2 diabetes from the south side of Brisbane over 24 weeks (January 2023 to November 2023).

Figure 3. Intervention participant journey of Māori and Pasifika women with type 2 diabetes from the south side of Brisbane, Queensland, over 24 weeks (January 2023 to November 2023), including five 2-hour education workshops (WS; either face to face or virtual), 3 individual talanoa (IT) consultations, and 3 virtual talanoa support group (VTSG) sessions with text messages (TM). DC: data collection.

The control group received their usual care with the hard copy of the program materials (ie, program journal, recipe book, fact sheets, and passbook) and SMS text messages (Table 3). At the completion of the intervention, control participants received a modified 1-day workshop covering talanoa education workshops. Figure 4 illustrates the control participant journey of the Māori and Pasifika women with type 2 diabetes from the north side of Brisbane over 24 weeks (January 2023 to November 2023).

Table 3. The control component for the Māori and Pasifika women with type 2 diabetes from the north side of Brisbane, Queensland, Australia.

Control components	Weeks (1-24)
Usual care with a hard copy program booklet (participants will be asked to document in the study journal [encouraged daily or weekly] but will be at their own discretion)	1-24
Motivational SMS text messaging	4, 8, 10-11, 15, 17-18, 22-23
Data collection (T_0, T_1, T_2; in person)	0 (baseline), 12, 24
Talanoa focus group (in person)	24

Figure 4. Control participant journey of Māori and Pasifika women with type 2 diabetes from the north side of Brisbane over 24 weeks (January 2023 to November 2023), including usual care with their preferred health provider and motivation text messages (TM). DC: data collection.

Inclusion and Exclusion Criteria

Inclusion criteria included Māori and Pasifika women with type 2 diabetes, aged ≥18 years, diagnosed with type 2 diabetes, and with access to the internet. Participants were excluded if they were pregnant and diagnosed with gestational diabetes, had a high-risk pregnancy, or were not diagnosed with type 2 diabetes.

Locations and Online Forums

Whānau Talanoa Intervention (Onsite)

The onsite face-to-face whānau talanoa sessions occurred in the community setting as recommended by the AC to ensure they were culturally acceptable to the participants in a whānau setting that is inclusive of the community.

Online Virtual Talanoa Intervention

The online sessions occurred via the Zoom platform over 5 weeks and covered the same content delivered in the face-to-face session. The Zoom setup was organized and managed through the secure QUT system, which enabled the project coordinator to host and manage each session and recordings. All the recordings and transcripts are stored with password protection and security in the QUT shared drive project folder, which can be accessed by the project team only (principal investigator and coordinator).

Individual Talanoa Consultation

The individual talanoa consultations (either via Zoom or telephone) were delivered by a trained CHW educator and managed through case notes that were uploaded (including

Zoom recordings) to a secure project folder within the QUT shared drive.

Study Population and Setting

Study Type

This is a participatory community-based study. Māori and Pasifika women living with type 2 diabetes were recruited from the Pasifika communities in southeast Queensland through a range of organizations, representing various sectors of the Māori and Pasifika communities in Queensland. The intervention and control groups were geographically distinct to minimize cross-communication, as members within the same community socialize, and this is the design the AC recommended as culturally appropriate.

Intervention Group

The intervention participants were recruited from the south side of Brisbane, including Logan, Ipswich, and Gold Coast, and geographically separated from the control group. Inclusion criteria for intervention participants were women aged ≥18 years from the south side of Brisbane, diagnosed with type 2 diabetes, and with access to the internet.

Control Group

The control participants were recruited from the north side of Brisbane, including the Sunshine Coast. Inclusion criteria for control participants were women aged ≥18 years from the north side of Brisbane who have been diagnosed with type 2 diabetes.

The exclusion criteria for intervention and control groups were pregnant women diagnosed with gestational diabetes or with a high risk of pregnancy. Women from each arm were also excluded depending on the location (eg, South side women were excluded from the control group and vice versa).

Sample Size

The sample size was calculated based on previous studies for detecting a difference of 1% reduction in HbA_{1c} (primary outcome) with a standard deviation of 1.4% in the intervention group. A significance level (α) of .05 was considered with a study power of 80% [32]. Based on this, a sample of 64 participants was needed (32 for the control group and 32 for the intervention group), with a target sample of 90 participants to compensate for a 40% attrition rate. Although the program received approximately 90 expression-of-interest responses, challenges with community engagement, complexities arising from COVID-19, and participant dropout resulted in a total of 50 participants, with 25 in the control group and 25 in the intervention group who enrolled and completed the pilot program.

Community Settings

The program for the intervention group was provided in community settings: Pasifika Te Haus in Runcorn and Adam Gould Community Centre in Logan on the south side of Brisbane. There is a large Māori and Pasifika population in southeast Queensland. For the control group, the first health checks and data collection occurred at a Pasifika Community Church, but for the follow-up visits, home visits were undertaken as requested by the participants. The community locations were recommended by the AC.

Recruitment Strategies

Recruitment for both intervention and control groups was multimodal and through distribution of study flyers, email invitations, and advertisements via social media (Facebook, websites); local ethnic radio stations; newsletters; and community networks including church groups, organizations, and Māori and Pasifika health workers. Recruitment also occurred through presentations and dialogue with community partners and organizations, including the Pasifika Women's Alliance Inc, Oceania Pacific Health Association, and Multicultural Communities Council Gold Coast, who have representatives on the AC, and they promoted the study through their networks and social media.

Ethical Considerations

The PWDWP was approved by the QUT Human Ethic Research Committee (5609). All data will be aggregated, with no individuals able to be identified. Collected data will be coded for analysis. The anonymity and privacy of all participants will be maintained through the use of fictional names, unique participant identification numbers, and secure data storage. All data will be stored securely on a password-protected research drive as per QUT's management of research data policy and the National Health and Medical Research Council guidelines for trials, with access restricted to only the principal investigator and co-investigator.

Potential participants were contacted to discuss the study and consent processes. Those who agreed received a "participant information pack" with an introduction letter detailing the program information, timelines, demographic questionnaires, and participant consent information. The project officer conducted 2 follow-up phone calls with each participant before the intervention to finalize details regarding the program; confirm the mode of preference for participating in part 1 (in person or online) of the intervention; and discuss issues or concerns with participation, access to their own GP, and dropout as well as any other issues that the women would like to discuss. Participants who consented to participate were asked to get a medical checkup prior to the start of the program and raise any concerns with the project officer. All participants (intervention and control) who consented were allocated a unique ID number and registered in a trial database. Any reasons for nonparticipation were recorded. The original informed consent for the primary data collection allows secondary analysis without additional consent.

Any cultural, spiritual, and personal concerns about disclosure in relation to cultural and religious beliefs especially around stigma associated with a diabetes diagnosis were discussed and clarified with participants before obtaining consent to disclose or use any sensitive information. Cultural sensitivity and respect form the underpinning guiding value in this research process especially when working with Māori or Pasifika families from various ethnic and religious backgrounds. This also included talanoa style of conversations to clearly explain the reason for choosing the 2 different locations (sites) for recruitment of

control and intervention participants and the benefits and risks with each group allocation.

Although we acknowledge that the Pasifika communities are well connected and share familial relationships, there was a possibility for the lack of confidentiality. One way this is addressed is by discussing with participants the importance of anonymity while at the same time acknowledging that this can be difficult in close-connected collective communities. This is a limitation to the study.

All participants, including control and intervention participants, were remunerated ("Koha") with gift vouchers (A$20 [US$13.05] for the health check and A$30 [US$19.57] for the talanoa focus group) to compensate for for their out-of-pocket expenses, travel time, and costs for participating at each data collection.

Data Collection and Analysis

Training of Community Health Workers, Community Researchers, and Research Team

Before the study commenced (July 2022 to December 2022), the Pasifika CHWs, health professionals, facilitators, and project team (including community researchers) received training on cultural protocols for engagement, community values, working with families across different Māori and Pasifika communities including the use of talanoa methods and approaches to coaching and delivering interventions within cultural Pasifika health model frameworks, and the protocols to be followed.

Training was undertaken by the principal investigator and diabetes educator in the form of role play, storytelling, and interactive activities using scenarios. The AC was invited to participate in the training as well as to contribute and share cultural experiences and advice in relation to working with Māori and Pasifika communities in a culturally safe and sensitive manner. All training was recorded, minutes were taken, and registration attendance was noted. The community researchers were also provided a step-by-step instruction manual on data collection.

Quantitative Outcomes

Quantitative data were collected through face-to-face or in-person sessions using online questionnaires at 3 time intervals (T_0, T_1, T_2) between January 2023 and December 2023 in a community-based location for both intervention and control participants. Data collected included anthropometric (height, weight, waist circumference, BMI), sociodemographic (age, marital status, employment status, income, post code, ethnicity), diabetes (self-care, self-efficacy), physical activity and dietary changes, and clinical (HbA_{1c} using the DVA Vantage point-of-care HbA_{1c} kit, Siemens) data [23,25-31]. The diabetes educator and CHWs collected anthropometric and clinical data, and the community researchers completed an online Qualtrics survey [24] using a tablet. Each participant was given a unique identifier.

Quantitative Data Analysis

Quantitative data analysis will be conducted in 2 steps. Raw data will be examined for missing entries, inconsistencies, and data entry errors. Any identified problems will be corrected by checking the data against the hard copy questionnaire. To further ensure reliability and accuracy of the data entry, the researcher will randomly re-enter 10% of the collected data and compare the 2 files [32].

Data are analyzed using SPSS 24 (IBM Corp), and missing data, outliers, normality, and multicollinearity will be examined using procedures outlined by Pallant [32,33]. Methods of data analysis will include descriptive, bivariate, and logistic regression analyses. The levels of statistical significance will be set at P=.49 to reduce the risk of type 1 errors [32]. The analyses will identify changes in the primary and secondary outcomes from baseline to week 12 and week 24 for Māori and Pasifika women with type 2 diabetes who completed the intervention. Descriptive statistics will examine participants' baseline measures and characteristics and will also explore trends in the data over time. Means (SDs) will be reported for continuous variables, and percentages and frequencies will be reported for categorical variables. Independent *t* tests will be used for continuous variables, and chi - square tests for categorical variables will be used to compare mean groups. Normality of the included variables will be evaluated using the Shapiro - Wilks normality test, and a nonparametric test (Mann - Whitney *U* test) will be used if data are not normally distributed to detect differences between groups. A 2 - sided P=.49 will be considered significant for all analyses [32,33].

The study will also provide initial parameter estimates for the primary endpoint, from which sample size calculations can be performed to determine sufficient power for the main trial. The primary endpoint between group differences at 12 and 24 weeks will be estimated using a linear mixed model with a treatment-time interaction. Although aiming for an intention-to-treat analysis, we recognize there were withdrawal from the study. A prespecified multiple imputation model will be used to obtain intention-to-treat estimates. Sensitivity analyses will explore the impact of nonignorable missing data. Analysis of secondary endpoints will follow the same approach in which changes will be compared between intervention and control groups using linear mixed models.

Process Evaluation

The process evaluation includes satisfaction surveys and a talanoa focus group involving the intervention and control participants to evaluate the feasibility of the program. This includes evaluating the training of Pasifika CHWs, community researchers, and the project team; types of delivery (in person and online or virtual for education sessions); whether core messages through text messaging reinforces a positive mindset and behaviors; the talanoa approach via online and in-person delivery of the intervention; shared understanding and core messages across the project team including CHWs, community researchers, and the workshop facilitator; and satisfaction with the program assessed at T_1 and T_2. In addition, we will capture where the participants heard about the program, if accessibility to the program was easy, some of the challenges with the program, and what the participants would change about the program.

Qualitative Outcomes

Qualitative data were collected using a talanoa focus group to gather information about the participants' experiences with the program and its acceptability, usefulness, barriers and enablers to participation, feasibility of time commitment, burden, and cultural relevance. Data gathered will explore time taken to complete data surveys, strengths and weaknesses of the intervention, perceptions of the digitally delivered sessions, and any suggested improvements to the study design or intervention as well as whether control participants had heard about the program, spoken to the intervention participants, and the influence of this on their participation.

Qualitative Data Analysis

Talanoa focus groups were conducted in a community setting, facilitated by community researchers and the principal researcher using a guide co-developed with the AC. The talanoa discussions, which lasted 90 minutes, were audio-recorded using a digital recorder and transcribed verbatim for analysis [20]. The trained community researcher took detailed notes using the guide. Immediately after the talanoa focus group session, the notetaker and community researcher summarized and prepared debrief notes that highlighted key points from the group. These were presented back to the focus group. The participants were also given the opportunity to read a copy of what they said and make any changes [20].

NVivo software will be used for data management and manual coding or identifying recurring keywords and phrases to ascertain measurement burden, acceptability, potential translation, and ease of intervention access. Co-analysis using inductive and deductive approaches will involve participatory talanoa processes with the Pasifika community researcher and participants iteratively [19,20]. The key themes from the co-analysis will be collated and presented to the AC for discussion. Patterns of meanings and interpretations during the analysis processes will be further deliberated by the AC to ensure community and cultural contexts are considered. Participants will be given progress feedback of the results and study outcomes. Giving feedback will be an integral part of the participatory research cycle in which the participants will have the opportunity to construct, reconstruct or retell, and reflect on the stories of their experience in the pilot program including both positive and negative feedback. A copy of the result findings and action outcomes will be disseminated to the participants, health providers, community organizations, and research team.

Results

Pilot Program

The pilot program began in February 2023 with 50 participants who were enrolled between January 2022 and January 2023. For the intervention group, 35 women were recruited, and there were 10 dropouts, resulting in 25 women in the intervention group. For the control group, 27 women were recruited, and there were 2 dropouts, resulting in 25 women in the control group.

Data were collected from January 2023 to December 2023. Methods of quantitative data analysis will include descriptive, bivariate, and logistic regression analyses. The focus group was conducted in November 2023, and the results are being analyzed using an inductive-deductive approach. Film and digital story production are underway and expected to be complete in April 2024. Data analysis is planned to occur from March 2024 to July 2024.

Importance of the Results

The study participants in the intervention and control groups are from diverse Pacific cultural backgrounds and include Fijians, Fiji Indians, Samoans, Māori, Tongans, Cook Islanders, and those who identify with more than one cultural group. The anticipated results from the quantitative and qualitative analyses would highlight the relevance that culturally co-designed programs could lead to improved diabetes self-care outcomes including clinical HbA_{1c} levels, positive changes in body composition measurements such as BMI and waist circumference, and enhanced diabetes self-care scores within the intervention group.

Dissemination Plan

Results are expected to be published as early as December 2024 and extend through July 2025. The study findings will be disseminated through presentations at state and national meetings (eg, Queensland Women's Health Forum, Australian Public Health), international meetings and conferences (eg, the International Diabetes Congress), and publication in peer-reviewed journals. In addition, we will work closely with Māori and Pasifika community partners to identify strategies to disseminate study findings in the community through community talanoa forums and meetings. Other social media network platforms and local community radio will be used to disseminate the study findings.

Discussion

Type 2 diabetes is a costly, rapidly growing, and largely preventable disease. Encouraging healthier lifestyles in Māori and Pasifika women with type 2 diabetes could potentially improve the health and well-being of women, prevent complications, and reduce health expenditure.

This paper describes the protocol of a quasiexperimental pilot study based on a culturally co-designed whānau-centered intervention for Māori and Pasifika women living with type 2 diabetes in Queensland, Australia [15]. The study consists of 2 arms (intervention and control) to trial a 12-week intervention followed by a 12-week follow up-period delivered by trained Māori and Pasifika health professionals and CHWs.

This study will report the clinical benefits of the intervention and will target improvements in HbA_{1c} and diabetes self-care including diet, physical activity, medication management, and routine health checks for Māori and Pasifika women with type 2 diabetes. Community-based interventions among Australian Samoans in Sydney, Australia, showed a reduction in HbA_{1c} [34], which would be promising for our study. Studies with Māori and Pasifika have shown that using community-based approaches and culturally tailored interventions are likely to

improve health behaviors [35,36]. The qualitative data from the focus groups will inform measurement burden, acceptability, potential translation, and ease of intervention access, which has not been evaluated in other community-based studies with Māori and Pasifika communities in Australia. The potential for success of the proposed intervention will be examined using accessibility, acceptability, uptake, sustainability, adherence, participants' perceptions of measurement burden, effectiveness of the recruitment strategy and retention, and the participants' overall experience, based on women's wellness resulting from type 2 diabetes programs [16]. This will inform the program's cultural adaptability, acceptability, and feasibility for future studies.

This study recruited 50 Māori and Pasifika women with type 2 diabetes through community-led participatory approaches and with the input from the AC to ensure that the protocols of engagement with the community, recruitment of participants, and implementation and evaluation of the program were community-driven and culturally appropriate [20-22] Interventions that are specifically co-designed with communities ensure cultural relevance, effectiveness, and sustainability for addressing chronic conditions such as type 2 diabetes [22,37]. Equally important is the community-led participatory approach that embeds Māori and Pasifika cultural values within program design and implementation, which is pivotal to engaging and empowering communities to successfully improve health behaviors, particularly when tackling type 2 diabetes [21,22,37]. Developing health and lifestyle programs within communities and partnering with stakeholders including health services, governmental and nongovernmental organizations, and academic institutions have been shown to be essential to empowering underserved populations, particularly as the programs aim to understand and support behavioral changes leading to better health and well-being outcomes [21,22,36,38]. This program supports the participants in developing knowledge and practical skills for preventing and managing type 2 diabetes as well as overcoming challenges that participants and their families may face in living a healthy life [21]. As a result, this has enabled the production of 5 digital stories of women from diverse Pasifika backgrounds in the intervention, documenting their experiences and journeys, which will be used as a health promotion resource for the program in future studies.

Despite these strengths, this pilot study has limitations. One inherent limitation is the potential for cross-communication. Due to the close nature of the included communities, it is likely that they will speak to each other regarding the program. For this reason, the intervention and control groups were allocated based on geographic location to attempt to minimize this. The sample size is too small to assess the extent to which the metabolic improvements are due to self-management (eg, lifestyle change) or clinical management and may also result in nonsignificant ($P<.05$) results for some of the measurement outcomes. In addition, community-based studies are difficult to conduct in a rigorous randomized controlled trial (RCT) design without significant funding, for which pilot data are important to inform study design, including power calculations [34]. However, this study was undertaken as a pilot study to provide a proof of concept prior to undertaking a stepped-wedge RCT or multicenter RCT. Regardless of this, the outcomes of this pilot study will provide valuable information regarding culturally appropriate implementation and evaluation. The lessons learned in this pilot trial will help us to plan the larger trial with regard to recruitment strategies, intervention implementation, and data collection. The evidence-based synthesis of findings with community participants and researchers, including dissemination of the pilot study outcomes, will have future applications aimed at leading to larger studies implementing a state or nation-wide program and undertaking translation research with the potential to develop innovative digital or virtual delivery of the program with a health data collection interphase, website platform for virtual delivery, and use of a mobile app.

In conclusion, this study provides a blueprint for PWDWP and proposes a model for evaluating intervention efficacy and effectiveness in partnership with Māori and Pasifika community organizations and key stakeholders in southeast Queensland, Australia. The study findings will have significant implications for policy makers and practitioners when implementing a diabetes management program for Māori and Pasifika communities, emphasizing the need for culturally relevant interventions. Collaboration with communities and stakeholders is crucial when developing diabetes management and lifestyle programs, particularly for communities with unique cultural nuances. The findings of this study may suggest a potential model for addressing health disparities in other culturally and linguistically diverse populations.

Acknowledgments

We would like to thank the Māori and Pasifika women with type 2 diabetes; the advisory committee members, many of whom are elders and leaders within their communities; and the Pasifika health workers for their dedication, time, and commitment to the design of this study protocol.

The research program was successful in securing funding through Diabetes Australia Research Program Grant (grant number Y22G-AKBH) and Australian Health Research Alliance (AHRA) Women's Health Research Translation Network (WHRTN) Early and Mid-Career Researcher Funded Award 2021. A progress interim report and final report with study findings and outcomes will be provided to the funders.

Data Availability

The data sets generated during and/or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

The authors fulfil the criteria for authorship by contributing to the planning, development, and writing of the protocol for this study. HA is the principal investigator, and DG is the co-investigator. HA and DG drafted the preliminary protocol, ethics application, and trial registry. HA, WN, and DG contributed to the design of the study protocol. HA and WN provided Pasifika cultural oversight. MC drafted the initial paper for publication with input and advice from HA. All authors contributed to the writing of the paper, and all have read and approved the final manuscript.

Conflicts of Interest

The authors declared the following potential conflicts of interest with respect to the research, authorship, and publication of this paper: DG is currently funded by the Queensland Children's Hospital Foundation via a philanthropic grant from Woolworths. All other authors have no conflicts of interest to declare.

Abstract

Background: Cognitive control training (CCT) has shown potential to reduce emotional vulnerability in adults and adolescents. However, there is scant literature testing the efficacy of CCT for the reduction of anxiety and transferring the effects to educational outcomes in children. Building on the evidence that a greater ability to suppress a prepotent response (inhibitory control) is associated with higher math achievement in children, it is plausible that training inhibitory processes using a CCT paradigm may be beneficial for reducing anxiety, improving inhibitory control, and in turn increasing math achievement.

Objective: This proof-of-concept study aims to investigate the efficacy of 15 sessions of inhibitory control training for reduction in anxiety and improvement in math achievement in primary school children.

Methods: We will use a 2 (group: CCT, adaptive Go/No-Go vs active control, low-load task) multiplied by 4 (time: pre- vs posttraining vs 1-month vs 3-month follow-up) randomized design in a nonselected sample of 100 children aged 8-10 years. Both groups will complete 10 minutes of daily training for 3 weeks at school. The dependent variables will be anxiety and correlates (Spence Children's Anxiety Scale, Penn State Worry Questionnaire for Children, Revised Children's Anxiety and Depression Scale, Child Response Style Questionnaire, and Modified Abbreviated Math Anxiety Scale), inhibitory control (Go/No-Go task), shifting (color-shape shifting task), updating (*n*-back task), and math achievement (Applied Problems, Calculation, and Math Facts Fluency subtests from the Woodcock-Johnson IV Tests of Achievement).

Results: We opened enrollment in September 2023. The initial results are expected to be published in late 2024. We predict that children in the CCT group will show a reduction in emotional symptoms; improvements in inhibition, shifting, and updating performance; and advances in math achievement from pre- to posttraining, and that these effects will be maintained at 1- and 3-month follow-ups, compared to children in the active control group.

Conclusions: The CCT paradigm used in our study will provide a greater understanding of the emotional and cognitive transfer effects on children and inform future work. Specifically, the findings will advance the knowledge of deploying inhibitory control training with children and provide valuable insights into its use for reducing anxiety and advancing math achievement.

KEYWORDS

cognitive control training; anxiety; inhibitory control; math achievement

Introduction

Overview

Anxiety is the most reported mental health problem in young people across and beyond the pandemic [1,2]. Childhood anxiety is associated with excessive worry, avoidance, physical symptoms, and severe social and academic problems [3]. Interventions for anxiety in children are typically expensive to administer (eg, 1:1 psychological therapy) with long waitlists to see providers in the public health system. Hence, there is a need for novel approaches to closing the treatment gap, that is, reducing the discrepancy between the percentage of children with mental health problems and the percentage who receive treatment [4]. The focus of this proof-of-concept study is treating childhood anxiety by targeting the modifiable cognitive processes that underpin emotional symptoms. We will deliver an intervention at school as part of regular classroom routines and examine its efficacy in reducing anxiety and improving cognitive and academic outcomes (more specifically, math achievement).

Research has shown that the ability to control the focus of one's attention (attentional control or cognitive control) is vital to learning and requires top-down cognitive processes to coordinate thoughts and behaviors to achieve a goal [5]. Attentional control theory [6] proposes that anxiety upsets the balance between the top-down (goal-driven) and bottom-up (stimulus-driven) attentional processes such that it is associated with increased activation of the stimulus-driven system (ie, attention to internal and external stimuli) and decreased influence of the goal-directed system (ie, attention to task demands). Furthermore, attentional control theory posits that highly anxious individuals direct their attention toward potentially threatening information (eg, worrisome thoughts) which in turn reduces the ability to perform ongoing tasks. The theory suggests that the cognitive processes or executive functions most affected by anxiety are inhibitory control, which requires inhibiting distractors and withholding a dominant response, shifting, which entails switching between tasks or demands of a task, and updating, which requires monitoring and updating information in working memory; see Miyake et al [7]. For example, an anxious child might direct their attention to emotional thoughts and be unable to inhibit distracting worries such as "this work is too hard" or "I might fail" and have difficulty shifting their focus back to the task at hand, and when new information is presented requiring them to update their working memory, the demands of controlling attention are borne out in poorer task performance.

There is growing empirical support for targeting or training the cognitive processes most vulnerable to anxiety (ie, inhibitory control, shifting, and updating) and reducing emotional symptoms in adults [8-12] and adolescents [13]. These paradigms are known by the umbrella term, cognitive control training (CCT) or if directly targeting the inhibitory control function, inhibitory control training. A small number of CCT studies have been conducted with children. Results from a systematic review [14] highlighted that of the 8 studies that showed promise for CCT to reduce anxiety only 2 were conducted with primary school-aged children (younger than 12 years of age). Bigorra et al [15] used commercial working memory training with children of 7-12 years with attention-deficit or hyperactivity disorder (ADHD) and behavioral difficulties and Shanok et al [16] used inhibitory control training with typically developing children aged 8-12 years. Both studies reported reduced anxiety in combination with improved cognitive performance (working memory and inhibitory control, respectively); however, neither study examined the transfer of these effects to educational outcomes.

Research in math achievement in school students supports the importance of cognitive control on executive functioning. For instance, Bull and Lee [17] suggest that during math problem-solving, inhibitory control is needed to suppress unwanted information or inappropriate strategies or prepotent number representations, shifting is required to switch math operations within and between more complex problems, and updating is vital for holding and monitoring information in working memory. However, age-related variances in the development of executive function need consideration, particularly as math skill requirements change across the school years [17]. Updating is associated with math achievement in preschoolers [18] and inhibitory control and shifting have also been implicated in early math skill variability [19]. In primary school children, nonetheless, inhibitory control has been shown to be vital for math achievement [20]. Given that the development of executive functioning increases rapidly in the early years of schooling [19,21] and attenuates in adolescence [22], it is plausible that targeting inhibitory control in children aged 8-10 years may serve to boost math performance at a critical time point. The focus of this study is to use a CCT paradigm to reduce anxiety, improve inhibitory control and in turn, math achievement.

This Study

This proof-of-concept study will examine the effect of inhibitory control training in typically developing children aged 8-10 years. We will compare emotional symptoms (indexed using self-reported scales of anxiety and correlates), inhibitory control, shifting and updating skills (assessed using computerized tasks), and math achievement (measured using standardized math tests) of children completing 15 sessions of daily inhibitory control training versus an active control task from pre- to posttraining and at 1- and 3-month follow-ups. The study will be conducted in year 4 and 5 classrooms. This study aims to determine whether 10 minutes of daily inhibitory control training for 3 weeks can reduce anxiety (and correlates) and improve math achievement and whether any changes are maintained 1 and 3 months after training.

Methods

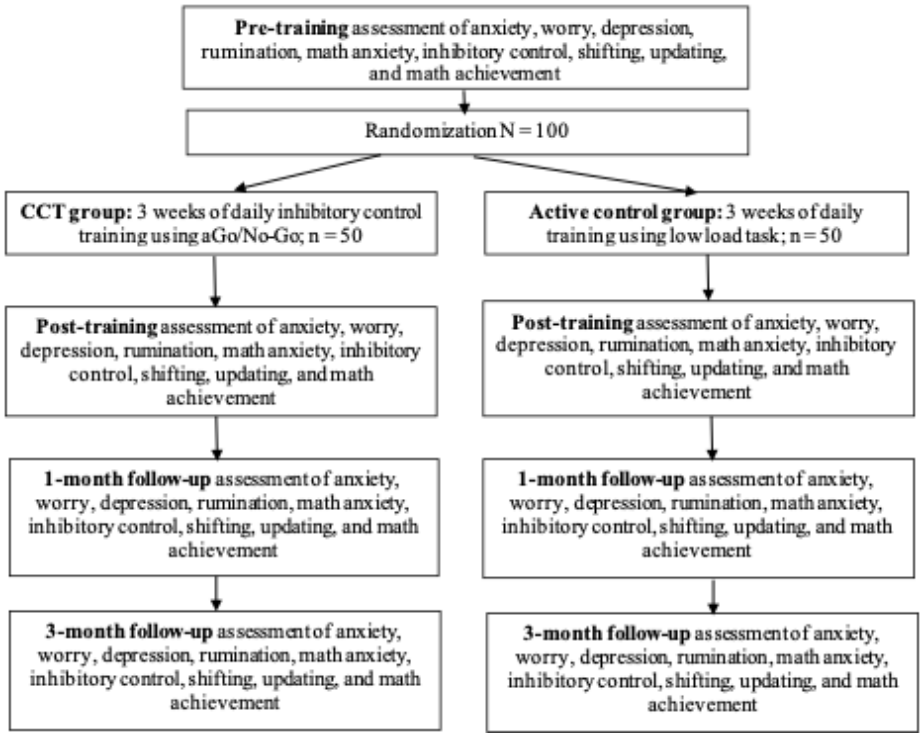
Ethical Considerations

The University of Queensland Human Research Ethics Committee provided approval to conduct this research (2023/HE000462). Gatekeeper approval was also received from participating education departments and schools. Parent consent and child assent will be gained prior to participation. The trial was registered on the Open Science Framework (ofs.io/de2qa).

Study Design

We will use a 2 (group: CCT, adaptive Go/No-Go vs active control, low-load task) multiplied by 4 (time: pre- vs posttraining vs 1-month vs 6-month follow-up) randomized design (see Figure 1). Children in both the CCT and active control groups will train for 10 minutes each day for 3 weeks (15 sessions) as part of their daily classroom routine. Changes in the dependent variables (anxiety, worry, depression, rumination, inhibitory control, shifting, updating, and math achievement) will be examined pre- to posttraining, and compared to 1- and 3-month follow-up.

Figure 1. Study flowchart.



Participants

A nonselect sample of children aged 8-10 years will be recruited from primary schools. An a priori power analysis revealed that 66 participants are required to detect small effects (d=0.20) approaching those reported by previous studies with 80% or greater power on primary outcome measures relative to controls [9,23,24]. To allow for approximately 30% attrition we will recruit 100 children proportionately balanced for sex and age across 8, 9, and 10 years. To incentivize enrollment and study completion, participating children will be compensated using monetary tokens redeemed at the end of the study; Aus $ 2.00 (US $1.31) for the completed questionnaires at each of 4 time points and Aus $ 2.00 (US $1.31) for each training session (~Aus $ 40.00; US $26.14 per participant). Given that teachers are required to supervise and monitor the daily training, they will be incentivized for their class's participation (minimum 20 students) at the rate of 1 teacher relief day for each data collection time point (pre- and posttraining and 1- and 3-month follow-ups).

Primary and P-12 schools, as well as private, independent, and Catholic schools, will be approached regarding participation in the study. A recruitment package of materials (including a university ethics approval letter, gatekeeper permission request, pamphlet, study protocol, participant information sheets for parents, teachers and children, consent forms, and an information sheet about children's anxiety and depression) will be sent to the school principal to determine interest in participation. Information sessions will be held face-to-face or using a video communications platform (eg, Zoom) for principals, teachers, and parents, as required.

Measures and Tasks

Anxiety

Anxiety will be measured using the Spence Children's Anxiety Scale [25], a self-report assessment of specific anxiety symptoms in children aged 8-11 years, categorized as social phobia (6 items), panic or agoraphobia (9 items), generalized anxiety (6 items), obsessive-compulsive (6 items), separation anxiety (6 items), and physical injury fears (5 items). Children respond using a 4-point Likert scale from 0=never to 3=always. Anxiety symptoms will be examined separately (eg, social phobia, and separation anxiety) in addition to the inspection of change in an overall anxiety score calculated by summing the 38 items. Higher scores represent higher symptoms of anxiety.

Worry

Worry will be assessed using the Penn State Worry Questionnaire for Children [26], a 14-item questionnaire that measures the tendency to engage in excessive, generalized, and uncontrollable worry in children aged 7-17 years. Items are rated on a 4-point Likert scale from 0=never to 3=always. Total worry scores are calculated (after reversing 3 items) by summing the scores on all items and range from 0 to 42; higher scores represent a greater tendency to worry.

Depression

Depression will be indexed by the Low Mood subscale from the Revised Children's Anxiety and Depression Scale [27], a self-report assessment of symptoms of major depressive disorder in children aged 8-18 years. The low mood subscale includes 10 items and children respond using a 4-point Likert scale from 0=never to 3=always. Total scores range from 0 to 30 with higher scores indicative of lower mood.

Rumination

The rumination subscale from the Child Response Style Questionnaire [28] will be used to capture repetitive negative thinking or rumination. Children respond to 13 items on a 4-point Likert scale from 0=almost never to 3=almost always. Total scores range from 0 to 39 with higher scores representing greater rumination.

Math Anxiety

The Modified Abbreviated Math Anxiety Scale [29] will be used to assess math anxiety. The 9-item self-report measure comprises 2 subscales, math evaluation anxiety (4 items), for example, thinking about a math test the day before you take it, and math learning anxiety (5 items), for example, starting a new topic in math. Children respond to statements asking how anxious they would feel during certain situations involving math using a 5-point Likert scale from 1=low anxiety to 5=high anxiety.

Inhibitory Control

A standard (ie, nonadaptive) Go/No-Go Task [30] will be used to measure inhibitory control. The Go/No-Go Task requires children to view visually presented stimuli and inhibit a dominant response based on instructions, for example, press the spacebar when they see a particular target (go) but do not press the spacebar when they see a different target (no-go). The task captures accuracy and reaction time (RT).

Shifting

The Color Shape-Shifting Task [31] will be used to assess shifting performance. In this task, children are presented with some colored shapes and are required to sort the stimuli by shape or color, as fast as they can. Children are given letter cues; for example, *S* for shape and *C* for color before each stimulus appears to indicate the characteristic to focus on. The task captures accuracy and RT.

Updating

The *n*-back Task [32] will be used to index updating performance. The task requires children to monitor letters presented in blocks of increasing difficulty (ie, *n*) and indicate when presented with a letter seen on the previous trial (1-back), after 1 intervening trial (2-back), or after 2 intervening trials (3-back). Difficulty increases with the number of intervening trials. Children indicate the same or different with a keyboard button press based on the letter 1-, 2-, or 3-back from this letter. The task captures accuracy and RT.

Math Achievement

A total of 3 subscales from the Woodcock-Johnson IV Tests of Achievement [33] will be used to assess math achievement, namely, Applied Problems, Calculation, and Math Fact Fluency. Administration and scoring will be consistent with the authors' manual. To avoid measurement error due to the practice effects, different test forms will be used at each data collection point.

Training Groups

We will randomly assign participants to 1 of the 2 training groups. Groups comprise an experimental CCT group that will train using an adaptive Go/No-Go Task (aGo/No-Go) targeting inhibitory control, and an active control group that will train using a low-load task. The active control task does not require the same cognitive load as the aGO/No-Go task; thus, we do not expect it to produce emotional or cognitive changes. Children in both groups will undertake 10 minutes of training per day for 3 weeks, allowing 15 sessions to be completed.

Inhibitory Control Training

The aGo/No-Go task requires participants to focus on desired cues related to a continuous stream of blended stimuli and press the spacebar when the desired cue appears and withhold a response when it does not appear (as per Go/No-Go). The adaptive nature of the task adjusts to the child's performance such that if the child is doing well, the task reduces the time for responding, whereas if the child is having difficulty the task allows more time for responding, thus positively reinforcing success.

Active Control Training

The low-load task presents children with a continuous stream of blended stimuli and requires them to identify target items.

Equipment and Procedure

All assessments and training will be completed on iPads (9th generation, iOS 16, 64GB; Apple Inc) specific to this project. Self-report symptom scales will be hosted on a computer-based survey platform (Qualtrics) such that the participating children can complete them under the supervision of their classroom teacher, during class time. Inquisit cognitive tasks will be deployed (retrieved from Millisecond Test Library). Math achievement tests will be administered 1:1 in a quiet room by the research team. Daily training of the aGo/No-Go and 1-back will be conducted using a computer-based experiment builder (Gorilla Experiment Builder) and include some minor gamification features to improve motivation and engagement. Training will be completed under the supervision of the classroom teacher.

Data Analytic Plan

Mixed between-within ANOVA will be used with Group (CCT, aGo/No-Go vs active control; low-load task) as the between-subjects factor and time (pre- vs posttraining vs 1- vs 3-month follow-up) as the within-subjects factor. Separate tests will be conducted with the emotional symptom scores, cognitive measures (ie, accuracy and RT), and math achievement scores as dependent variables. Intention-to-treat analyses will be used to account for missing data, as appropriate. Descriptive and inferential statistics will be performed using SPSS (IBM Corp). We will apply Bonferroni corrections to follow-up tests to control for type 1 error.

Results

Recruitment and testing opened in September 2023 and will continue for 12 months. We will begin analyzing our data on the completion of the data collection, and the publication of results is expected by the end of 2024.

Discussion

This study will examine the effect of inhibitory control training on anxiety and math achievement in children aged 8-10 years, relative to an active control condition. We predict children in the CCT group will report reduced emotional symptoms (anxiety, worry, depression, and rumination) and demonstrate improved inhibitory control, shifting, updating, and math achievement when comparing pre- to posttraining, 1-, and 3-month follow-up, relative to controls. Results will inform whether inhibitory control training affords promise as an intervention for anxiety in this age group and advance knowledge of factors affecting math achievement. These findings would provide a foundation for the development of a training app that has the capacity to reach those not well-served, be delivered on large scale for low cost, and afford the possibility of administration across a wide range of settings [4].

This research has several limitations worth noting. We realize using a small sample of children aged 8-10 years means we may not be able to generalize our findings to a larger population or a broader age group. However, pending our results, we aim to replicate our work using a larger cohort and a randomized control design. There are constructs outside the scope of this project. For example, our design will be unable to determine whether inhibitory control training affects other educational outcomes, especially language and reading, which are linked to math achievement. With these potential shortcomings in mind, we hope this work becomes the catalyst for other research using CCT paradigms with children.

Acknowledgments

We thank all participants for their valuable contribution. This study is funded by a Spencer Foundation Research Grants on Education: Small (2023-2024).

Abstract

Background: Globally, traumatic brain injury (TBI) is recognized as one of the most significant contributors to mortality and disability. Most of the patients who have experienced TBI will be discharged home and reunited with their families or primary caregivers. The degree of severity of their reliance on caregivers varies. Therefore, the task of delivering essential care to the patients becomes demanding for the caregivers. A significant proportion of caregivers expressed considerable burden, distress, and discontentment with their lives. Therefore, it is critical to comprehend the dynamic of TBI and caregivers to optimize patient care, rehabilitation, and administration. The effectiveness of the Brain Injury Family Intervention (BIFI) program tailored for caregivers of patients with TBI has been widely proven in Western countries. However, the impact is less clear among caregivers of patients with TBI in Malaysia.

Objective: This study aims to assess the effectiveness of BIFI in reducing emotional distress and burden of care, fulfilling the needs, and increasing the life satisfaction of caregivers of patients with TBI at government hospitals in Malaysia.

Methods: This is a 2-arm, single-blinded, randomized controlled trial. It will be conducted at Hospital Rehabilitasi Cheras and Hospital Sungai Buloh. In total, 100 caregivers of patients with TBI attending the neurorehabilitation unit will be randomized equally to the intervention and control groups. The intervention group will undergo the BIFI program, whereas the control group will receive standard treatment. Caregivers aged ≥18 years, caring for patients who have completed >3 months after the injury, are eligible to participate. The BIFI program will be scheduled for 5 sessions as recommended by the developer of the module. Each session will take approximately 90 to 120 minutes. The participants are required to attend all 5 sessions. A total of 5 weeks is needed for each group to complete the program. Self-reported questionnaires (ie, Beck Depression Inventory, Positive and Negative Affect Schedule, Caregiver Strain Index, Satisfaction With Life Scale, and Family Needs Questionnaire) will be collected at baseline, immediately after the intervention program, at 3-month follow-up, and at 6-month follow-up. The primary end point is the caregivers' emotional distress.

Results: The participant recruitment process began in January 2019 and was completed in December 2020. In total, 100 participants were enrolled in this study, of whom 70 (70%) caregivers are women and 30 (30%) are men. We are currently at the final stage of data analysis. The results of this study are expected to be published in 2024. Ethics approval has been obtained.

Conclusions: It is expected that the psychological well-being of the intervention group will be better compared with that of the control group after the intervention at 3-month follow-up and at 6-month follow-up.

traumatic brain injury; TBI; caregiver; randomized controlled trial; psychological well-being; Malaysia

Introduction

Background and Rationale

Traumatic brain injury (TBI) is defined as any injury sustained by the head as a result of blunt or penetrating trauma, acceleration or deceleration forces [1]. It remains as a leading cause of mortality and morbidity worldwide [2]. In Malaysia, despite investment in various preventive efforts, the incidence of TBI continues to increase yearly [3]. In 2009, as many as 166,768 trauma cases were recorded in 8 hospitals in Malaysia, most cases (76.8%) being road traffic accidents [4]. A recent study reported an extremely high cost of treatment for patients with TBI in Malaysia. The estimated annual cost of treatment for 49 patients with TBI was as high as MYR 1.5 million (US $313840) [5]. In the long term, this would lead to an adverse impact on the social and economic development of the country.

The effects of TBI depend largely on the severity and location of the injury and the age and personality of the patient [1]. TBI will affect their self-care ability, employment capacity, and social functioning. Upon discharge from hospitals, most patients with moderate to severe levels of TBI would need to move back in with their families to receive the care they need [6,7]. Patients with severe TBI are unlikely to return to their previous employment as they require a significant amount of care [8]. As most of the patients with TBI are highly dependent, their caregivers are tasked with providing the necessary physical care for them. The caregivers are also constantly involved in any ongoing rehabilitation of the patients, for example, encouraging them to perform physiotherapy exercises and reminding them to take medication. Moreover, the caregivers need to deal with difficult behaviors and challenging emotional states of patients with TBI [9-12]. These extra demands can be unfavorable to the health and well-being of the caregivers.

Many studies have highlighted the importance of understanding the dynamics of TBI on caregivers. There is an extensive body of research on the effect of TBI on caregivers globally [13-22]. However, local data are scarce, as only a few studies have been conducted to assess the effects of TBI on Malaysian caregivers [23-25]. The available studies have found that most TBI caregivers in Malaysia reported high burden and poor life satisfaction as a result of caregiving activities [25]. Similarly, there is also a lack of information regarding the needs of caregivers of patients with TBI in developing countries. It was suggested that caregivers of patients with TBI should be provided a postdischarge rehabilitation program to reduce their burden as caregivers [25]. A systematic review has suggested that caregivers of patients with TBI should be prioritized in TBI rehabilitation [26], as evidence abounds on the benefits of intervention programs tailored for caregivers toward patients with TBI [27-30].

In Malaysia, there is a lack of specific or structured intervention programs focusing on the psychological well-being of caregivers of patients with TBI. Identifying caregivers at an increased risk of burden is important for preventing emotional distress and caregiver burden to improve care for both patients and caregivers. Therefore, it is important to design a proper intervention plan to improve the quality of life of caregivers of patients with TBI. Ultimately, this will result in better care and management of patients with TBI.

Conceptual Framework

This study is based on 2 major theories, namely, the Family System Theory (FST) and Cognitive Behavior Therapy (CBT) [31].

The first theory, FST, assumes that the whole family is interconnected to one another [32]. For instance, if a family member is affected by TBI, the whole family system will also be affected [31]. Patients with TBI would most likely depend on their family members for activities of daily living, routine follow-up, rehabilitation, and financial support. This would increase the burden on the caregivers. Family members would also need to look for coping resources to overcome their problems [13,33,34]. As a result of the sudden changes in the family's functioning, family members often reported a lack of coping skills, in addition to high levels of burden, anxiety, and emotional distress [17,33,35-40], thus resulting in a decrease in psychological well-being [19,41-43]. Therefore, Brain Injury Family Intervention (BIFI) incorporates family therapy techniques such as normalization and validation to assist patients with TBI and their families.

The second theory, CBT, is widely known for its use in treating various types of psychological disorders [44]. Several studies have applied CBT to provide psychological interventions to patients with TBI and their caregivers [28,45-50]. A systematic review revealed that CBT has a significant impact on improving the psychological well-being of TBI caregivers [32,45]. CBT would equip caregivers of patients with TBI with strategies to deal with psychological problems such as depression and anxiety [44]. A specific component of CBT would also be implemented in BIFI that covers important aspects such as psychoeducation, problem-solving skills, management of emotions, setting of realistic goals and expectations, and stress management.

Aims of This Study

This study aims to assess the effectiveness of BIFI in reducing emotional distress and burden of care, besides fulfilling the needs and increasing the life satisfaction of caregivers of patients with TBI in selected hospitals.

The hypotheses of this study are as follows:

1. There is a significant association between the sociodemographic and clinical characteristics of patients with TBI and the emotional distress, burden of care, needs, and life satisfaction of caregivers of patients with TBI.

2. There is a significant difference in the mean scores of caregivers' emotional distress, burden of care, needs, and life satisfaction between the intervention and control groups before the intervention, after the intervention, at 3-month follow-up, and at 6-month follow-up.
3. The sociodemographic and clinical characteristics of the patients are predictors of the intervention outcomes.

Methods

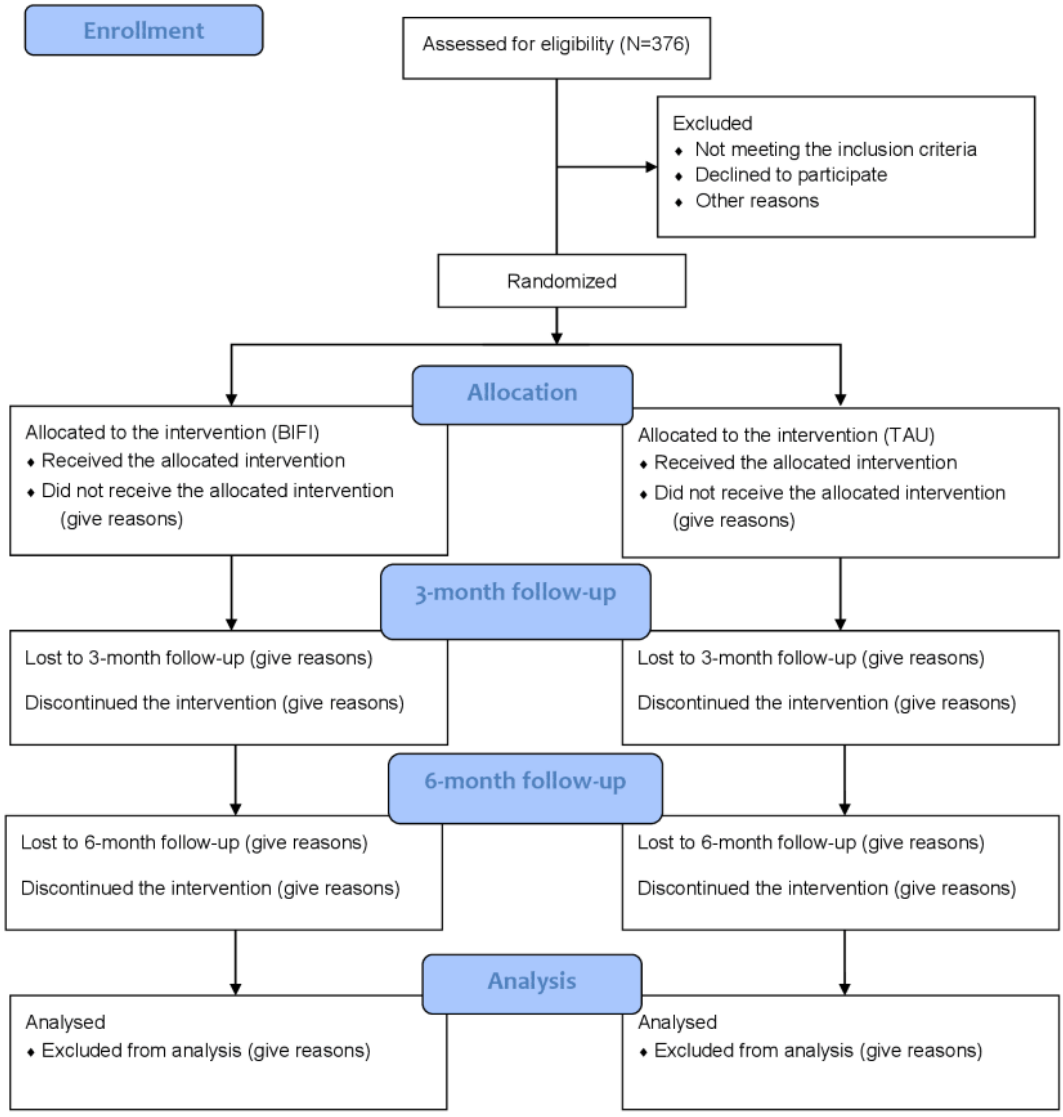
Study Design

This is a 2-arm, single-blinded, randomized controlled trial (RCT). All participants will be randomly assigned to the intervention group or control group. Only the investigators will be aware of the treatment allocation.

Study Setting

This study will be conducted at Hospital Rehabilitasi Cheras (HRC) and Hospital Sungai Buloh (HSB). These hospitals are the main referral hospitals for patients with TBI. A specific room in each site will be used for data collection. Figure 1 outlines the study flow according to CONSORT (Consolidated Standards of Reporting Trials) 2010.

Figure 1. Research flowchart. BIFI: Brain Injury Family Intervention; TAU: treatment as usual.



Participants

A total of 100 participants were recruited for this study. Of the 100 participants, 50 (50%) were randomly assigned to the intervention and control groups, respectively. All caregivers of patients with TBI who attend follow-up with patients with TBI at the Neuro Rehabilitation outpatient clinic of HRC and HSB were screened for eligibility to participate in this study.

Inclusion and Exclusion Criteria

To be eligible, caregivers of patients with TBI must be citizens or permanent residents of Malaysia and be aged ≥18 years, regardless of their race, ethnicity, and sex. The participants must be able to read or write in Bahasa Malaysia or English. The caregivers can be the parents, spouses, siblings, sons or daughters, or relatives of the patients with TBI. Only 1 caregiver per patient with TBI can be recruited for the program. Time

since injury for the patient with TBI must be >3 months and time spent on caring for the patients must be at least 2 hours per day. All types of injury severity were included. However, paid caregivers were excluded.

Withdrawal Criteria

The participants may choose to withdraw at any point of time without any penalty. The participants may be withdrawn if the investigator believes that it is harmful or risky for the participants to continue.

Sample Size Estimation

Sample size estimation is based on the formula for clinical superiority trial [51]:

$$N=2x\ (Z_{1-\alpha} + Z_{1-\beta})^2 \times S^2 / (\delta-\delta_0).$$

The sample size is calculated with 80% power ($Z_{1-\beta}$=0.845) at a significance level (α) of .05, with 95% CI ($Z_{1-\alpha}$=1.96), 25% dropout rate, and medium size effect of 0.60. The parameters used in the formula will be based on a previous study [45], including δ^2=9.355 (pooled SD) and depression (Beck Depression Inventory [BDI] score) $\delta-\delta_0$=5.86 (mean difference). According to the calculation, a total of 50 participants per arm will be needed for this study.

The parameter used to compute the prevalence of caregivers of patients with TBI was taken from the paper titled "Life satisfaction and strain among informal caregivers of patients with traumatic brain injury in Malaysia" [25].

Sample Size Calculation for Prevalence Studies

In this formula, n=sample size, z=z statistic for the level of confidence, P=expected prevalence, and d^2=allowable error. This formula assumes that P and d^2 are decimal values but would also hold true if they are percentages, except that the term, 1–P, in the numerator would become 100–P [52]:

$$N=Z^2P\ (1–P) / d^2$$

Percentage of caregiver's burden=57.4%, level of significance=5%, power=80%, and d=0.05:

$$N=(1.96)^2\ 0.574\ (1 – 0.574) / 0.05^2$$

$$N=376$$

This study aimed to assess eligibility for at least 376 caregivers of patients with TBI.

Allocation

Allocation Sequence Generation

Methods of random allocation are used to ensure that all study participants have the same chance of allocation to the treatment or control group. Caregivers of patients with TBI who are eligible and consent to participate will be number coded before randomization. A simple random sampling method using computer-generated random sampling will be used to assign participants to the intervention group or control group. The procedure would be performed by following the 1:1 allocation format. Randomization will be performed by the principal investigator. All participants will have equal chance of being assigned to the intervention or control group.

Contamination Bias

To minimize contamination bias, the intervention program will be conducted outside their follow-up clinic time. The intervention program will be conducted at the seminar room of the designated hospitals. Participants are strongly encouraged not to disclose the program materials or discuss them with other caregivers of patients with TBI outside the program.

Blinding

The method of blinding in RCT is used to ensure that there are no differences in the way in which each group is assessed or managed and therefore minimize bias. In this study, only the principal investigator is aware of the treatment allocated to the participants.

Statistical Analysis

Data analysis will be performed using SPSS software (version 24.0; IBM Corp). Descriptive statistics will be used to describe the characteristics of participants. Continuous data will be reported as means and SDs or as medians and IQRs. Categorical data will be reported as percentages and frequencies. The comparison of the means between the 2 groups will be performed using a paired samples 2-tailed *t* test. In addition, 1-way ANOVA and repeated measure ANOVA will be conducted to identify any significant differences in mean scores of emotional distress (BDI), caregiver's needs (Family Needs Questionnaire [FNQ]), burden of care (Caregiver Strain Index [CSI]), and life satisfaction (Satisfaction With Life Scale [SWLS]) before the intervention, after the intervention, at 3-month follow-up, and at 6-month follow-up between the intervention and control groups. Multivariate regression analysis will be used to determine the predictors of intervention outcomes.

The intention-to-treat analysis will be performed accordingly. Assumptions of normality and homogeneity of variance will be conducted and adjusted where necessary.

Program Assessment and Translation

The BIFI manual has undergone several stages of thorough forward and backward translation, content review, and revision by a panel of local experts. The expert panel included 2 clinical psychologists, 1 certified translator (psychology content translator), and 2 rehabilitation physicians. All the panels had experience with working in the related fields for >5 years.

On the basis of the experts' feedback and comments, a few changes were made to the module. The first change was the use of a more simple Malay language. The second change was related to the pictures used in the material. The experts suggested changing to universal pictures, so that they can be adapted locally.

The final product of the manual was revised to match the local population and to ensure the intervention's fidelity.

Pilot Study

A pilot study was conducted to assess the feasibility of the BIFI program among caregivers of patients with TBI in Malaysia. In total, 10 caregivers of patients with TBI participated, and only 8 (80%) managed to complete all 5 sessions. A caregiver withdrew owing to work commitments and another withdrew owing to personal issues. Challenges included (1) punctuality of the participants, (2) duration of the sessions, and (3) homework material.

Overall, participants were satisfied with the content and delivery of the program. Some suggested to increase the duration of the sessions and to reduce the amount of homework given. All feedback was taken into consideration, and slight alterations were performed to accommodate the participants and the program.

Intervention

BIFI will be the main intervention tool. It is a structured intervention module specifically for patients with TBI and their caregivers, developed by Professor Dr Jeffry Kreutzer and colleagues from Virginia Commonwealth University, United States. This module is based on CBT [44] and FST [53].

This module consists of several objectives: (1) providing patients and caregivers with fundamental information about brain injury, (2) helping caregivers to better understand the effects of brain injury, (3) teaching patients and caregivers about problem-solving skills, (4) teaching coping strategies, (5) recognizing progress and personal strengths and helping them to access community and professional resources, and (6) teaching effective communication skills.

BIFI was designed to be implemented in 5 sessions, with 90 to 120 minutes for each session. In total, 2 or 3 topics will be covered in each session. Using a standardized and family-focused intervention, BIFI was found to be beneficial for caregivers of patients with TBI both immediately and at 3 months after the intervention [31,54,55]. Furthermore, another study also showed that patients with TBI and caregivers reported high ratings of helpfulness, goal attainment, and satisfaction regarding the BIFI program [55].

Several measures will be taken to ensure that all participants comply with the intervention program. The program would also be conducted during weekends to accommodate the schedule of caregivers of patients with TBI. They are also allowed to choose any day during weekends at their convenience. However, they are required to complete all 5 sessions within the stipulated time frame.

Control Group

The control group or treatment-as-usual group will not receive any additional treatment during the study period. Participants in the control group will receive the usual treatment at their respective hospitals. According to the Malaysian Clinical Practice Guidelines for early management of head injury, all patients who have been discharged are recommended to attend follow-up sessions at the hospital [56]. It is recommended that patients with moderate and severe head injuries are scheduled for routine clinic follow-up. However, patients with a mild head injury can be followed up via clinic visits or telephone calls. Apart from the routine follow-up, other programs tailored for patients with TBI and their caregivers are also considered as treatment as usual in this RCT. For example, the Acquired Brain Injury Rehabilitation Unit in HRC would offer a program known as “Return to Work” for suitable patients and caregivers. A similar program is also available in HSB.

Outcomes

Overview

The outcomes of this study will be assessed using self-report questionnaires at four periods: (1) baseline, (2) 5 weeks (after the treatment), (3) 3-month follow-up, and (4) 6-month follow-up. The schedule of enrollment, interventions, and assessments are presented in Table 1.

Table 1. Schedule of enrollment, interventions, and assessments.

[a]BIFI: Brain Injury Family Intervention.

[b]TAU: treatment as usual.

[c]BDI: Beck Depression Inventory.

[d]PANAS: Positive and Negative Affect Schedule.

[e]CSI: Caregiver Strain Index.

[f]FNQ: Family Needs Questionnaire.

Primary Outcomes

The primary outcome for this study is the TBI caregiver's emotional distress, which will be measured using two scales: (1) BDI and (2) Positive and Negative Affect Schedule (PANAS). The measures are described in the Methods section.

Secondary Outcomes

The secondary outcomes will include (1) burden (CSI), (2) life satisfaction (SWLS), and (3) caregiver's needs (FNQ). The measures are described in the Methods section.

Data Collection and Time Frame

Recruitment for potential participants was conducted by the rehabilitation physicians at both hospitals, who are also the coinvestigators of the study. They screened for potential participants among the caregivers of patients with TBI who attend regular rehabilitation therapy and follow-up at their clinics. These caregivers were then invited to participate in this study. If the caregiver was interested in learning more about the study, they were led to another room, where the investigator explained the study in great detail and answered any questions that the caregivers had. At this stage, a patient information sheet about the nature of the study was provided to the potential participants.

The investigator then left the room for 10 to 15 minutes to allow the caregiver to read the information and to think about whether they would like to participate in the study. If they expressed interest in participating, they were asked to sign the consent form before completing the questionnaire. The same questionnaire used at baseline will be distributed immediately after the intervention, at 3-month follow-up, and at 6-month follow-up. The questionnaire will take approximately 30 to 40 minutes to complete. Data collection was performed between December 2018 and December 2020.

Measures

BDI Questionnaire

The original version of BDI is a self-reporting questionnaire consisting of 21 items on a 4-point scale. It is assessed using a Likert scale ranging from 0 (symptom not present) to 3 (symptom very intense). The total score can range from 0 to 63. BDI is used to measure the main symptoms of depression such as mood, pessimism, sense of failure, self-dissatisfaction, guilt, punishment, self-dislike, self-accusation, suicidal ideas, crying, irritability, social withdrawal, indecisiveness, body image change, work difficulty, insomnia, fatigability, loss of appetite, weight loss, somatic preoccupation, and loss of libido [57]. Respondents who scored between 0 and 9 are considered negative for depression. In contrast, those who score >9 are screened positive for depression, whereby a score between 10

and 18 indicates mild to moderate depression, score between 19 and 29 indicates moderate to severe depression, and score between 30 and 63 indicates severe depression (60). The BDI test is widely used globally, and its content, concurrent, and construct validity have been tested. High concurrent validity ratings are detected between BDI and other depression instruments such as the Minnesota Multiphasic Personality Inventory and the Hamilton Depression Scale. Correlation rating of 0.77 was obtained between the inventory and psychiatric ratings. BDI also showed high construct validity with the medical symptoms it measures. The study by Beck and Steer [58] reported a coefficient α rating of 0.92 for patients at outpatient clinics and 0.93 for college students. BDI has been translated into the Malay language and validated for use among the Malaysian population. Internal consistency (Cronbach α) ranged from 0.71 to 0.91, and the validity of BDI-Malay was deemed as satisfactory [59].

PANAS Questionnaire

PANAS comprises 2 mood scales that measure the positive affect (PA) and negative affect (NA), respectively. PANAS is used to assess the relationship between positive and negative effects on personality traits. Each of the PA and NA scales consists of 10 items that define their meanings. Respondents need to answer 20 items on a 5-point scale that ranges from 1 (very slightly or not at all) to 5 (extremely). The total score generated will range between 10 and 50, with low scores indicating low (positive or negative) affect and high scores indicating high (positive or negative) affect. The reliability and validity of PANAS were moderately good [60]. For the PA scale, the Cronbach α coefficient was between 0.86 and 0.90, and for the NA scale, it was between 0.84 and 0.87. Over 8 weeks, the test-retest correlations were between 0.47 and 0.68 for PA and between 0.39 and 0.71 for NA. PANAS also had strong validity with other measures of general distress and dysfunction, depression, and anxiety [61]. The Malay-translated version of PANAS had Cronbach α coefficient of 0.73 [62].

CSI Questionnaire

CSI is a self-rated, 13-item questionnaire that measures strain related to care provision. It consists of 5 major domains related to employment, financial, social, time, and physical aspects. The items can be answered as yes (score=1) or no (score=0). The maximum score for the questionnaire is 13. A score >7 is categorized as “having strain,” whereas a score <7 is defined as “no strain.” There is no age limit for the individuals who could be assessed with the tool**.** CSI has been translated into the Malay language, and the Cronbach α coefficient for the 13-item CSI-Malay was 0.79, indicating good internal consistency reliability of the scale [63].

SWLS Questionnaire

SWLS evaluates the respondents’ agreement with 5 statements on overall satisfaction with life (eg, in most ways, my life is close to my ideal). It uses a 7-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree), giving rise to a range of scores between 5 and 35. A score of 20 is considered the neutral point of the scale. Scores between 5 and 9 indicate that the respondent is extremely dissatisfied with life. In contrast, scores between 31 and 35 show that the respondent is extremely satisfied. SWLS is reported as having excellent internal consistency (Cronbach α=0.88) and good test-retest reliability (r=0.68). SWLS has been translated into the Malay language and validated among the Malaysian population [64,65]. The Malay SWLS has been found to have good internal consistency (Cronbach α=0.83).

FNQ Questionnaire

FNQ is a self-administered questionnaire consisting of 37 items. It was designed to determine the family needs of patients with TBI. The family members will rate the importance of each need on a scale ranging from 1 (not important) to 4 (very important). FNQ is divided into 6 areas, namely, health information, emotional support, instrumental support, professional support, community support network, and involvement with care. It has been proven to have good content and construct validity and good internal consistency Spearman-Brown split-half reliability at 0.75 [66].

Study Procedure

All the screening procedures to identify the participants based on inclusion and exclusion criteria were performed before the intervention program by rehabilitation physicians in the respective hospitals. The recruitment started in November 2018 and was continued until the required sample size was achieved. The BIFI program will be conducted in the Malay or English language depending on the needs of the caregivers. The participants in the intervention group will be divided into smaller groups of 10 people each. Each group will receive a scheduled time and date to attend the program at the hospital. The program will be conducted by the principal investigator, who is also a clinical psychologist. The clinical psychologist must at least have 5 years of experience.

At the baseline of the program (T1), all participants are required to complete the questionnaires (BDI, CSI, PANAS, FNQ, and SWLS). The same questionnaire will be distributed immediately after the intervention program (T2), at 3-month follow-up (T3), and at 6-month follow-up (T4). The average time needed to complete the questionnaire is 30 to 40 minutes. The follow-up sessions (T3 and T4) will be scheduled by the coinvestigators. The session will be conducted at the respective hospitals by the coinvestigators to prevent any bias during follow-up. The participants were also encouraged not to share the intervention materials with other caregivers until data collection is completed.

The intervention group will undergo the BIFI program. The BIFI program will be scheduled for 5 sessions as recommended by the developer of the module. Each session will take approximately 90 to 120 minutes. The participants are required to attend all 5 sessions. A total of 5 weeks is needed for each group to complete the program, and 2 groups will be scheduled every week. All the sessions will start with an overview of the topic and end with the summary and homework assignments. Participants will be required to complete the homework given according to the module. This homework will then be reviewed by the principal investigator in the subsequent session.

For the control group that receives the usual standard treatment, the caregivers will need to complete the questionnaires at similar time points as the intervention group.

Patient Involvement

Patients were involved during the early stage of cultural adaptation of the intervention program. The patients were invited to give their comments and feedback and review all the materials. Their valuable feedback was taken into account to ensure this program is suitable to the current culture and population.

Ethical Considerations

Approval

This study has been reviewed by the Medical Research and Ethics Committee Malaysia, Ministry of Health Malaysia (NMRR 18-2253-42951). Ethics approval has been obtained from the National Medical Research Register (NMRR-18-2253-42951-IIR) for the study to be conducted at the Ministry of Health settings. Please refer to Multimedia Appendices 1 and 2 for further details of Research Ethics comments and review. The approval letter was received on December 19, 2018. The recruitment period started in December 2018 and was completed on December 18, 2020.

Compensation

All the participants in the intervention group will be given incentives for attending the intervention program and completing the questionnaires. All participants are compensated with a travel token at the baseline (MYR 25), immediately after the program (MYR 25), at 3-month follow-up (MYR 25), and at 6-month follow-up (MYR 25).

Consent

The investigator will explain the potential risks and benefits of involvement to the participants using an information leaflet before they determine whether to participate in the study. They might ask the researcher any questions they may have regarding the study before deciding whether to participate. Once the investigator is confident that they have understood the potential risks and benefits of participating, the participant will be asked to sign a consent form. The consent forms are obtained in the written format during primary data collection and secondary data analysis is allowed to proceed without additional informed consent.

Data Management

Consent forms and paper copies of the questionnaire will be stored separately in a locked filing cabinet at University Teknologi MARA. After data collection is complete, they will be transferred to a locked filing cabinet. They will be maintained by the principal investigator for 10 years according to university regulations. Data will be accessible to the researchers and anyone authorized by Universiti Teknologi MARA to conduct a research audit.

Electronic copies of the data will be maintained by the principal investigator. These electronic files will not contain any personal identifying information and will not contain the identifying code that links the paper copies of the questionnaires with the consent forms. They will be stored only on password-protected electronic devices. Once the thesis submission and other publications are completed, these files will be destroyed. The files will be accessible to the principal investigator, the research team, and anyone authorized by Universiti Teknologi MARA to conduct a research audit.

No personal identifying details, such as names and contact details, will be recorded on the questionnaire; they will appear only on the consent form. The questionnaires will be linked to the consent forms by a unique code appearing on both documents. No digital record of the personal identifying details will be maintained, and these details will not be included in the data file. The report of the findings will also not include any such details.

Dissemination Plan

The findings of this study will be published in an academic or medical journal, and they will be presented at academic conferences. Only the research team has access to the data. As with any anonymously obtained data, the participants will not be named in any of the study's reports or publications. Permission from the Medical Research and Ethics Commission will be sought before publication.

Results

The participant recruitment process began in January 2019 and was completed in December 2020. A total of 100 participants were enrolled in this study, of whom 70 (70%) caregivers are women and 30 (30%) are men. We are currently at the final stage of data analysis. The result of this study is expected to be published in 2024.

Discussion

Anticipated Findings

In this study, we will be evaluating the effectiveness of BIFI in reducing the emotional distress and burden of care, fulfilling the needs, and increasing the life satisfaction of caregivers of patients with TBI. A total of 100 caregivers were recruited in this study. Most of the caregivers are women (70/100, 70%) and the remaining are men (30/100, 30%). The age range of the caregivers was between 22 and 55 years, with a mean age of 39.85 (SD 8.184) years. Most caregivers were Malay (65/100, 65%), followed by Chinese (21/100, 21%), Indians (12/100, 12%), and other races (2/100, 2%). Initial analysis showed promising result where there was significant reduction in emotional distress among caregivers (intervention group) immediately after the program and at the 3-month follow-up as compared with the control group.

Limitations

This study also has limitations. It was observed that during the implementation of the program, most participants (90/100, 90%) requested the program to be conducted during the weekends, whereas others wanted it to be conducted during the weekdays. This was because some of them needed to arrange for the patient's care if they were to attend the program. Hence, the program was conducted during weekends and weekdays to

accommodate their request. The participants were allowed to choose when they wanted to attend the program. Owing to this issue, the intervention program took a long period to complete.

It is also important to address that data collection was conducted during the COVID-19 pandemic. The intervention program was halted for several months owing to Movement Control Order by the Malaysian Government. Therefore, participants were hesitant to visit the research site owing to fear of contracting COVID-19; the social distancing policy exacerbated this difficulty. It is hoped that future studies might to consider implementing intervention programs over the web to ease the participants. Web-based intervention program is another emerging approach and is more suited to current trends. However, web-based intervention versus physical intervention is still debated, and more studies are needed to answer this question.

Conclusions

To the best of our knowledge, this study would be among the first to use RCT methods to assess the effectiveness of BIFI in improving the psychological functioning of caregivers of patients with TBI in Malaysia. Perhaps, this module could be incorporated into the *Return to Work* program as standard clinical care and be made available to all. It is hoped that the results will provide more knowledge and scientific evidence to improve the rehabilitation services for patients with TBI and their caregivers.

Acknowledgments

This study was supported partially by Universiti Teknologi MARA (grant number 600-IRMI/MyRA 5/3/ LESTARI [036/2017]). The authors acknowledge the contribution of the Ministry of Health Malaysia and Universiti Teknologi MARA for aiding and support throughout the study. The authors also thank Professor Dr Jeffrey S Kreutzer and Dr Emilie Godwin, developers of Brain Injury Family Intervention therapy, Virginia Commonwealth University, Richmond, Virginia, United States, for their assistance.

Data Availability

The data of this study are available upon request from the corresponding author, and it is subject to approval from the Ministry of Health Malaysia and Universiti Teknologi MARA.

Authors' Contributions

SAO is the principal investigator of this study and drafted the manuscript. FM and NSZ contributed to review of the paper and content development. All authors provided written review and feedback and revised and approved the final paper.

Conflicts of Interest

None declared.

Abstract

Background: Interventions that promote adaptive emotion regulation (ER) skills reduce pain in patients with chronic pain; however, whether the effects of yoga practice on chronic low back pain (CLBP) are due to improvements in ER remains to be examined.

Objective: This study will test whether the effects of yoga on CLBP (improved pain severity and interference) are mediated by improved ER, the extent to which effects are related to specific aspects of ER, and the role of pain sensitization as a mediator or moderator of effects. In this study, pain sensitization will be assessed by quantitative sensory testing and gene expression profiles to examine whether pain sensitization moderates yoga's effects on pain or whether yoga and ER abilities reduce pain sensitization, leading to decreased pain severity and interference.

Methods: For this 2-arm parallel group blinded randomized controlled trial, we will enroll 204 adults with CLBP who will be randomized to receive the yoga (n=102) or a control stretching and strengthening (n=102) intervention, which are delivered via web-based synchronous biweekly 75-minute sessions over 12 weeks. Participants are encouraged to practice postures or exercises for 25 minutes on other days using accessible prerecorded practice videos that are sent to participants digitally. Participants will be assessed at 5 time points: baseline, midintervention (6 weeks), postintervention (12 weeks), and 3- and 6-month follow-ups. Assessments of ER, pain severity and interference, pain sensitivity including somatosensory and gene expression profiles, and physical strength and flexibility will be conducted at each visit. The fidelity of the interventions is assessed using a manualized checklist to evaluate recorded group sessions to ensure consistent instructor delivery.

Results: The primary outcome will be the mean change in pain severity as measured by the Brief Pain Inventory-Short Form at 12 weeks. The primary mechanism of action is ER measured by change in the Difficulties in Emotion Regulation Scale total score. Secondary outcomes include pain sensitivity, physical strength and flexibility, pain interference, and quality of life. A mediation path analysis and series of moderated mediation path analyses will be conducted to test the study hypotheses. As of January 2024, we have enrolled 138 participants. We expect the study to be completed by May 2025.

Conclusions: The study will provide important data for evaluating whether improvements in ER are responsible for reduced pain perception and pain sensitivity as well as increased quality of life in the context of chronic pain. The study findings have important implications for determining the mechanism of action for yoga and possibly other mind-body interventions as nonpharmacological therapies for pain management. The results of the study will inform the content, delivery, and measures for intervention trials involving yoga as a modality for relieving pain and improving function.

Introduction

Background

Yoga has been shown to reduce pain and improve function in populations with chronic low back pain (CLBP) in multiple randomized controlled trials (RCTs) [1,2]. However, results vary, and effects are generally modest [3]. This variation is perhaps due to differences in the specific neurobiological mechanisms through which yoga exerts clinical improvements on pain that are affected by different yoga interventions. These mechanisms, which have been only minimally identified, could potentially be harnessed to achieve more consistent and optimal outcomes from yoga interventions. A study that examined mediators of yoga's effects on pain lacked strong theoretical bases for assessment of the mechanisms involved [4]. Using a comprehensive theoretical emotion regulation (ER) model of yoga [5], we will conduct the first test of ER as a primary mechanism of yoga's effects on CLBP. We will also test the role of pain sensitization using somatosensory and gene expression profiles in this model [6] and examine the specific aspects of ER.

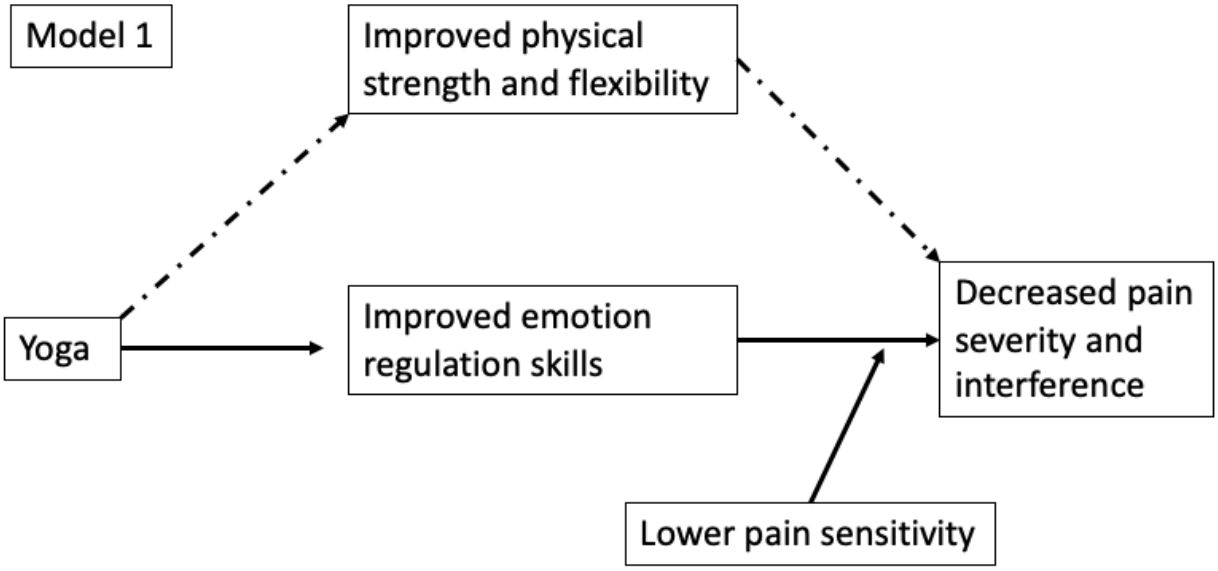
ER refers to "extrinsic and intrinsic processes responsible for monitoring, evaluating, and modifying emotional reactions, especially their intensive and temporal features, to accomplish one's goals" [7]. Emotions strongly influence perceptions of pain intensity and predict disability [8], particularly among individuals with CLBP [9,10]. Interventions that promote adaptive ER skills reduce pain in patients with chronic pain [11]. Increasing evidence demonstrates that consistent yoga practice can promote improved ER [12,13], but research has not yet tested whether the effects of yoga practice on CLBP are due to improvements in ER.

Integrative Model of Yoga's Effects on ER

Given the importance of ER in managing chronic pain and yoga's demonstrated promotion of improved ER, we developed an integrative model of yoga's effects on CLBP that highlights the key role of ER. Previous work by our team [14,15] and others [16] demonstrated that yoga simultaneously comprises multiple components and that physical activity (poses and transitions between poses), breathwork, and meditation are all important therapeutic elements. Thus, although physical activity interventions alone have demonstrated salutary effects on negative emotion [17] and ER [18,19], yoga's inclusion of breathwork and meditation along with physical activity may more potently improve ER [5].

Yoga provides myriad opportunities to develop ER skills helpful to people managing chronic pain. Practitioners can learn how to experience sensation without negative evaluative judgments, cultivating nonreactivity. Due to cognitive priming and reinforcement during movement, yoga provides simultaneous input to cognitive, motor, and sensory pathways, which may allow practitioners to consciously influence their interpretation of sensation or pain and manage its affective dimensions. Given the myriad components of yoga that can facilitate developing ER skills, we posit that ER is a key mechanism by which yoga exerts effects on individuals with CLBP. The few studies examining links among yoga, ER, and pain support our model (Figure 1). For example, yoga practitioners were better able to tolerate experimentally induced pain compared to nonpractitioners, with corresponding greater left intrainsular white matter connectivity [20]. Further, the yoga practitioners reported coping with the pain stimulus using (adaptive) ER strategies such as relaxation, nonjudgmental focusing, and reappraisal. Thus, the ability to minimize the affective dimensions of pain may dampen physiological responses to negative emotions such as anxiety, which have been associated with the perception of pain [21,22].

Figure 1. Model of primary and alternative mechanisms of action. Model 1 proposes that pain sensitization moderates yoga's effects on pain, in that chronic low back pain patients with higher sensitization may benefit less given that their pain is more centralized.



Pain Sensitivity May Influence the Effects of Yoga and ER on CLBP via Moderation or Mediation

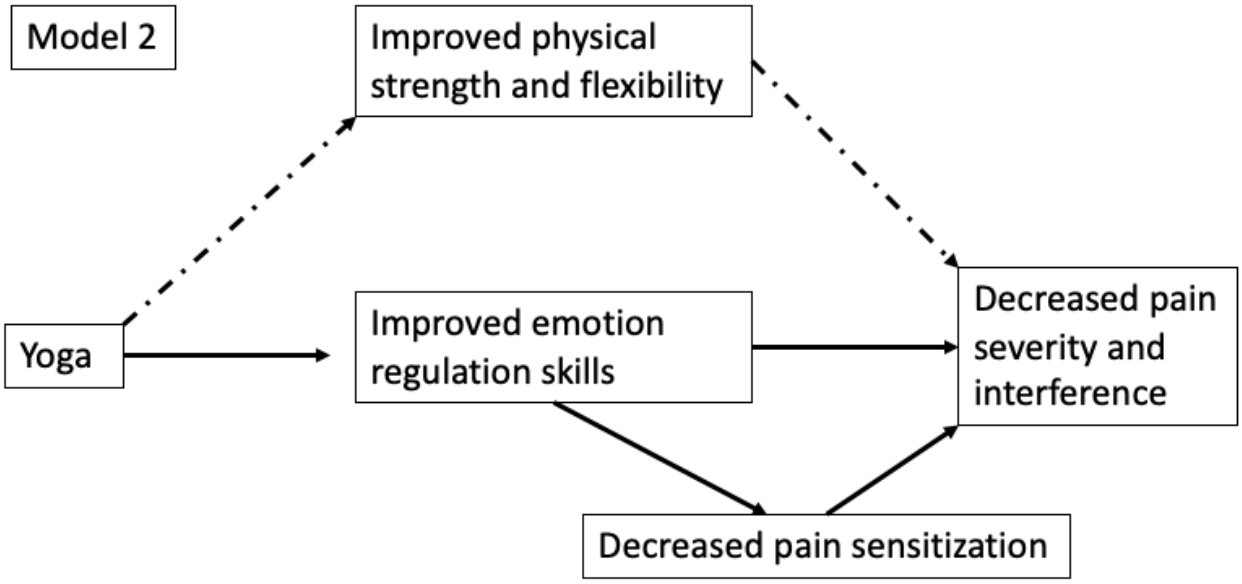
Recent studies document that patients with CLBP demonstrate sensory and functional alterations reflecting peripheral and central nervous system sensitization associated with enhanced pain sensitivity [23-25]. Enhanced pain sensitivity as a mechanism of CLBP includes sensitization of nociceptors and neuronal circuits [26] and increased pain signaling through membrane excitability and synaptic efficacy [27], which are conferred through altered expression of pain sensitivity (and immune-related) genes [6,28]. The somatosensory changes associated with enhanced pain sensitivity in CLBP involve decreased thermal and mechanical pain thresholds at the site of pain and remote areas [25,26].

Preliminary research suggests that negative emotion is an important determinant of pain sensitivity [29,30], predicting up to 23% of the variance in CLBP-related disability [31,32]. For instance, greater pain catastrophizing and anxiety are associated with lower standardized values of heat pain threshold and tolerance in patients with chronic pain [33]. In turn, negative emotions and inability to tolerate stress have been shown to activate inflammatory pathways through the release of proinflammatory cytokines and substance P [34,35]. To date, only 2 small studies have examined whether yoga specifically influences pain sensitivity. However, in a systematic review of 15 RCTs, yoga was associated with decreases in interleukin-1β, interleukin-6, and tumor necrosis factor-α [36]. In addition, specific components of yoga (meditation, relaxation, and breathing) have been shown to alter gene expression profiles and levels of inflammatory mediators [37-39].

As shown in Figure 1, we propose that pain sensitization moderates yoga's effects on pain, where patients with CLBP with higher sensitization may benefit less [40,41], given that their pain is more centralized [42,43]. This is a fairly novel hypothesis with some supportive evidence [44,45]. We will also explore the possibility that yoga and improved ER abilities might actually *improve* sensitization and thus decrease pain (Figure 2).

Little research has demonstrated that treatments for pain, including behavioral interventions, modify sensitization once it has occurred [46,47], although a reversal of central sensitization was observed in patients with structural pain–related pathology who underwent corrective surgery [48] as well as patients with migraine and chronic pancreatitis [49,50]. We considered alternative strategies to test these linkages. For example, a systematic review of 1037 individuals with CLBP provided moderate evidence that structural brain differences in specific cortical and subcortical areas of the brain and altered functional connectivity in pain-related areas following painful stimulation differentiate chronic pain from pain-free individuals [51]. While brain imaging provides 1 way to examine changes in pain sensitivity, we assert that identifying specific cellular mechanisms through which ER affects pain sensitivity will generate greater translational capacity for the clinical care of individuals with CLBP.

Figure 2. Moderated mediation model of emotion regulation. Model 2 will explore the possibility that yoga and improved emotion regulation abilities might actually improve sensitization and thus decrease pain.



Controlling for Improvements in Physical Strength and Flexibility

To be comprehensive, our model includes improved strength and flexibility, given that improvements in these domains are common in yoga intervention trials. In fact, yoga typically shows the effects on strength, flexibility, and other physical outcomes that are as substantial as those of physical therapy or stretching-strengthening exercise groups [52,53]. Sherman et al [4] demonstrated that strength and flexibility may mediate some of yoga's effects on pain. Overall, accumulating evidence demonstrates moderate but varied effects of yoga for reducing CLBP pain and disability; much remains to be learned about *how* yoga exerts these effects and why its effects vary. Understanding the proposed mechanism of actions (MOAs) of yoga will provide not only a more solid scientific basis to assure clinicians of the value of yoga to patients with CLBP and other conditions but also important targets for intervention modification and optimization.

Objectives

To address this gap, we will test the impact of a yoga intervention on ER and pain severity and functioning compared to a general stretching or strengthening intervention. This design allows us to isolate the additional effects of yoga above and beyond more general movement practices, thereby testing ER as a key MOA underlying the clinical effects of yoga on CLBP. Specifically, we will test whether yoga's effects on CLBP (improved pain severity and interference) are mediated by improved ER, the extent to which effects are related to specific aspects of ER, and the role of pain sensitization as a mediator or moderator of effects.

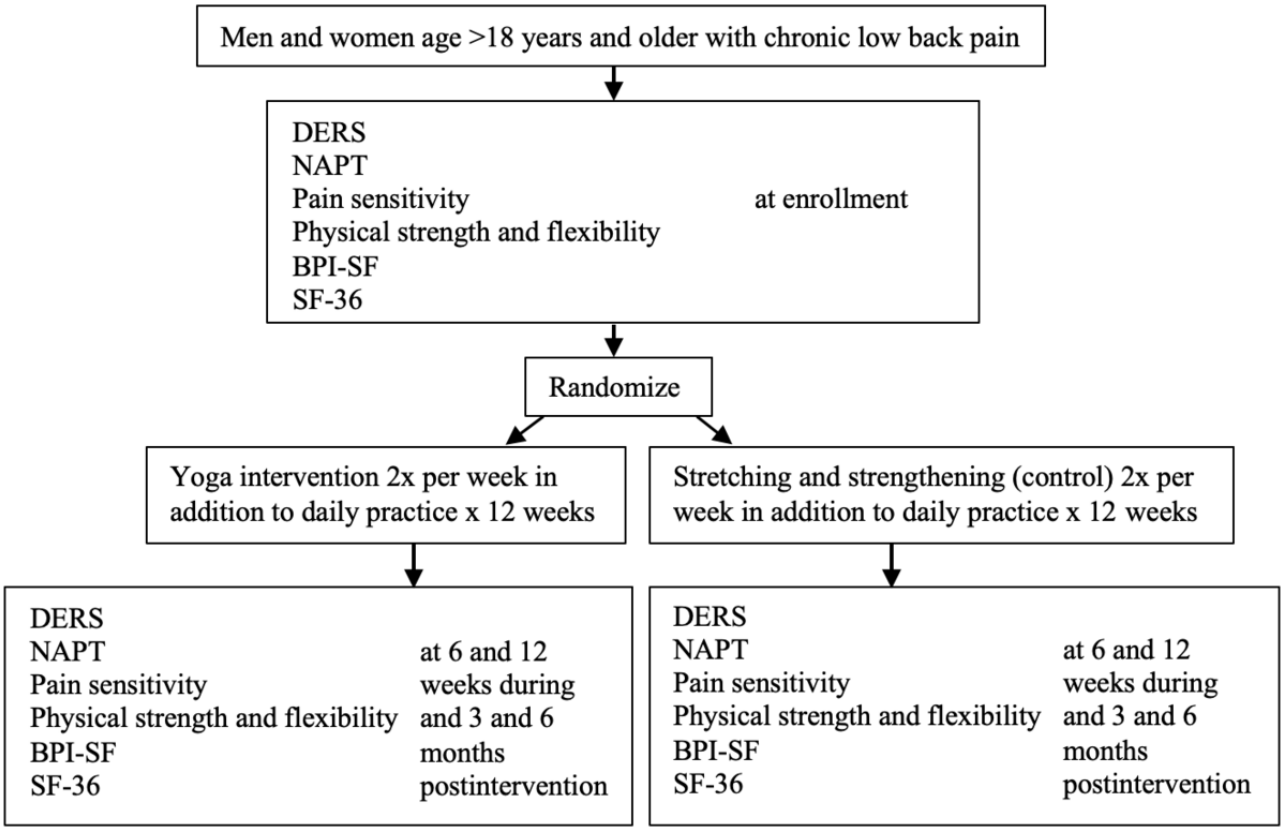
For the active comparison intervention, we chose to use stretching and strengthening exercises, given that we are interested in determining not only whether yoga influences ER but also the extent to which these effects are due to aspects of yoga above and beyond nonspecific factors (eg, expectancies, time, attention, and effort) [13] as well as improvements in strength and flexibility [4]. The 2 intervention groups will be similar in many aspects, but only yoga will incorporate aspects that we hypothesize will facilitate ER (eg, breathwork, mindfulness, and relaxation). We selected the hypothesized MOA based on our extensive work regarding the therapeutic characteristics of yoga and mechanisms of CLBP [5,14]. Our 3-month and 6-month follow-ups will allow us to examine whether the effects of yoga emerge later or persist. The study is highly innovative in its approach to testing the MOA of yoga for alleviating CLBP. By identifying the specific mechanisms through which yoga may influence pain, these results will facilitate optimizing interventions to improve therapeutic accuracy for prescribing and using yoga for CLBP, a highly prevalent and costly health condition in the United States and worldwide.

Methods

Design

This study is a 2-arm parallel group blinded RCT to examine ER as a MOA of yoga in individuals with CLBP (Figure 3). In total, 204 people with CLBP will be randomized to receive yoga or the stretching and strengthening intervention with assessments of pain severity and interference; ER; pain sensitivity; physical strength and flexibility; and quality of life at baseline, 6 weeks (midway through the intervention), 12 weeks (after completion of the intervention), and 3 and 6 months after the completion of the intervention. Both groups will be instructed to continue the use of any other strategies or treatments that they have been using to manage their CLBP throughout the study.

Figure 3. Study overview. BPI-SF: Brief Pain Inventory Short-form; DERS: Difficulties with Emotion Regulation Scale; NAPT: Negative Affective Priming Task; Pain sensitivity measured by quantitative sensory testing and blood drawn for gene expression profile; SF-36: 36-item Short Form Health Survey.



Participants

We will enroll 204 men and women aged 18 years and older with nonspecific CLBP who meet eligibility (Textbox 1). Nonspecific CLBP is defined as pain without a specific cause or need for surgical intervention that is anywhere in the region of the low back bound superiorly by the thoracolumbar junction and inferiorly by the lumbosacral junction, which has been present for more than 3 months out of the prior 6 months and is currently rated at a level of ≥2 on the numeric rating scale. Eligibility will be determined by asking the following screening questions [54]: (1) How long has back pain been an ongoing problem for you? (2) How often has low-back pain been an ongoing problem for you over the past 6 months? Responses of greater than 3 months to question 1 and "at least half the days in the past 6 months" to question 2 will define CLBP.

Textbox 1. Inclusion and exclusion criteria to determine eligibility for study participation.

Inclusion criteria

- Aged 18 years and older
- Report low back pain for more than 3 months out of 6 months
- Willing to attend 12 weeks of yoga or stretching (twice per week)
- Willing to complete 5 assessments
- English literacy
- No changes in pain treatments in the past month
- Willing to not change pain treatments during the study unless medically necessary
- Have not practiced yoga more than 2 times in the last 3 months

Exclusion criteria

- Back surgery within the last 1 year
- Back pain due to specific systemic problem (eg, lupus)
- Lower extremity weakness (motor strength four-fifths of the quads, glutes, hamstrings, and extensor hallucis longus)
- Sciatica or (+) straight leg raise
- Coexisting chronic pain problem (migraine headaches and fibromyalgia)
- Serious or unstable psychiatric illness (eg, psychosis, mania, and history of suicide attempt) and current suicidal ideation
- Major coexisting medical illness (eg, cancer, chronic obstructive pulmonary disease, and morbid obesity)
- Positive Romberg test (with or without sensory neuropathy)

Recruitment and Retention Strategies

Active and passive recruitment strategies will be used to recruit individuals with CLBP include (1) contacting CLBP participants enrolled in an institutional review board (IRB)–approved pain registry, (2) advertisements on social media (Instagram, Facebook, Twitter, Reddit, and Craigslist), (3) placing printed advertisements in public transportation vehicles and local newspapers, and (4) distributing flyers at local outpatient clinical sites and local universities. We will recruit continuously and start a new cohort every 6 months, so that there will be cohorts in both interventions and follow-up phases throughout the study. This approach will help control for seasonal effects and other potential confounds. All participants will receive a yoga or exercise mat, block, and strap prior to their first session, and US $70 following the baseline, 6- and 12-week postintervention, and 3- and 6-month follow-up assessments with an additional US $50 for those who complete all data collection sessions.

Interested volunteers are asked to complete a web-based screening questionnaire via REDCap (Research Electronic Data Capture; Vanderbilt University), which includes questions to ensure they meet inclusion and exclusion criteria and can participate safely. Volunteers who are deemed eligible to participate are contacted by study staff to schedule their baseline appointment.

Ethical Considerations

The study was approved by the University of Connecticut IRB (#H19-191). Prior to completing any study procedures, all participants provide written informed consent on a form that was approved by the IRB at the University of Connecticut (IRB#H19-191). All study procedures are in accordance with the ethical standards described by the Helsinki Declaration. Study participants are assigned an identification number, allowing all stored records to be deidentified. Deidentified data are kept in locked file room or stored in a password-protected database on a password-protected computer. All participants are monetarily compensated for their participation up to US $400 for completing all study visits. Participants can withdraw from the study at any time.

Procedures

Randomization and Blinding

Eligible volunteers are scheduled to meet with a study staff member who will follow all informed consent procedures. After written consent is obtained, participants are randomized to the yoga or stretching and strengthening group using a stratified randomization scheme based on biological sex to ensure balance between groups, and the assigned group is known only by the study staff managing the participant and instructor schedules.

We will use blinding whenever possible. Assessments, evaluations, and data analysis will be conducted without the knowledge of participants' assigned group. We will blind the study personnel to the assigned condition of subjects when conducting data collection by using unique study identification numbers, by following a strict script to refrain from discussing participant activities, and by using different members of the study team to coordinate assigned condition activities and collect data. Deidentified data with codes for assigned condition will facilitate blinded data analysis.

Data Collection Visits

At each study visit, venous blood samples (15 mL) will be collected in one 10-mL PAXgene vacutainer and one 6-mL K2 ethylenediaminetetraacetic acid vacutainer by a research team member experienced in venipuncture. The samples will be immediately placed in a biohazard container and transported to the laboratory where they will be processed and stored in a –80 °C freezer for bulk processing of genetic and protein measures. Physiological and quantitative sensory measurements will be conducted by a trained research assistant. Participants will be asked to complete all study questionnaires via REDCap after completion of the laboratory data collection.

Interventions

All yoga and stretching and strengthening sessions will take place on a secure web-based platform. This delivery modality will provide more inclusive participation and reduce barriers such as participant transportation and parking. For both study arms, 75-minute classes will be offered 3 times per week for 12 weeks. Participants will be asked to attend at least 2 out of 3 of the offered classes per week. The importance of attending 2 sessions per week is emphasized during the first session and throughout all subsequent sessions. Participants who repeatedly miss sessions without notifying the study personnel will be contacted to check on the reason for nonattendance and to encourage resuming participation as soon as possible. Participants are encouraged to consult with the instructor individually before or after class about problems or difficulties they are encountering at home or in the formal sessions.

Participants are asked to practice exercises at home on days they do not attend formal synchronous sessions to maximize the benefit of the intervention. Participants will be emailed daily links to prerecorded practice videos that are approximately 25 minutes in length and asked to record the amount of time they spent on the practice videos.

Yoga Intervention

Overview

The yoga intervention will be led by certified 500-hour registered yoga teachers trained in working with patients with back pain. The yoga for CLBP protocol [55] consists of classical hatha yoga with influences from vinyasa and Iyengar yoga. These yoga styles are those most commonly offered in clinical and community settings and emphasize the importance of modifications and adaptations including the use of props such as straps and blocks to minimize the risk of injury and make the poses accessible to people with health problems and limitations [56]. The manual developed to standardize the yoga classes offered in the intervention contains pictures and a description of how to perform each pose. The manual also includes suggested instructor dialogue, which may be paraphrased or varied slightly yet promotes consistent delivery, which enhances the replicability and generalization of results. The intervention includes some poses that could aggravate back conditions in some people if they are not modified; therefore, multiple modifications are suggested, and many poses are only worked up to after weeks of practice and individual attention from the instructor. The more challenging poses are never included in the home practice videos.

For each yoga class in the protocol, the instructor leads participants through a series of 23 yoga poses (32 total variations) at a slow-moderate pace. During the formal sessions, participants are instructed to take slow deep breaths, timing their inhales and their exhales with specific phases of poses. Participants are encouraged to emulate optimal alignment as demonstrated by the instructor and to focus on a goal or positive direction for their yoga practice. Yoga classes are constructed to allow optimal flow from one pose to another. Each session begins with a few minutes of deep breathing and mindfulness or meditation followed by 15 minutes of basic postures (poses 1-8) to warm up muscles by increasing circulation to provide increased flexibility as the class progresses. Most poses are conducted once per side. After the warm up, the instructor leads participants through a series of standing poses (poses 9-14) for 15 minutes. After the standing poses, the class moves into floor poses (poses 15-23) for 20 minutes. Sessions end with 5-7 minutes of complete relaxation in the standard ending pose “savasana,” during which additional positive affirmations are provided.

Stretching and Strengthening Control Intervention

This intervention is designed to require a similar amount of physical exertion (stretching and strengthening exercises only, with no extreme movement). Classes will be led by physical therapists or other skilled therapeutic exercise instructors and involve conventional exercises appropriate for patients with CLBP, including a comprehensive set of exercises that stretch all the major muscle groups, with an emphasis on the trunk and legs. The intervention will include 12 stretching exercises used in the exercise arm of previous studies that have successfully compared exercise to yoga [57,58] (ie, gastrocnemius, soleus, quadriceps, posterior and inferior shoulder, upper trapezius, hip flexor, back extension, back rotation, hamstrings, hip external rotators, and back flexion). It will also include 3 additional stretches (hip internal rotators, hip adductors, and hip flexion). Each stretch will be held for approximately 60 seconds and repeated once. In addition to a complete set of full-body stretches, the class will begin with a 5-minute warm up period consisting of basic aerobics steps (ie, 1 minute each of walking in place, marching, lateral shuffling, turning and reaching, and box step) and will also include 4 exercises that strengthen the back, abdomen, and hips (ie, squats, crunches, oblique crunches, and back extensions). Over the 12 weeks, the repetitions of each strength exercise are increased from 8 to 30. Specific strength exercises are practiced in separate sets of 5 to 10 repetitions.

Treatment Fidelity

All sessions will be recorded, and instructor fidelity to the yoga intervention or stretching intervention manuals will be evaluated using video-recordings of sessions. Instructors and participants will be aware of and consent to the recordings. We will select 1 session per week from each condition for rating by trained research assistants, who will review sessions using a manual checklist for instructor adherence to the manuals, using a 0-10 rating scale for each procedure or instruction. If the rating is

less than 100% adherent, we will meet with the instructor to discuss the places in the session that were not adherent.

Measures

The assessments of pain intensity, pain interference, ER, and other parameters will be taken at baseline, 6 and 12 weeks, and 3 and 6 months post intervention.

Primary Outcome: Primary MOA

Pain severity will be measured with the Brief Pain Inventory-Short Form (BPI-SF) [59] at 12 weeks. The BPI-SF has been validated with CLBP and has shown good reliability [60].

ER as the primary MOA will be measured using the Difficulties in Emotion Regulation Scale (DERS) score at 12 weeks. The DERS is the gold standard self-report measure of individuals' abilities to respond to emotional experiences in a goal-oriented manner [60]. The 36-item DERS taps aspects of difficulties with ER, which we anticipate will lessen with yoga practice [61]. Participants rate the extent to which each of 36 statements currently applies to them, and the measure yields a total score comprising summed subscales. The DERS is sensitive to change over time in ER, and internal consistency reliability is high [60].

The Negative Affective Priming Task [62] will also be used to capture individual differences in emotional attention, reactivity and appraisal, and ability to inhibit negative emotion and purposefully shift attention to more positive aspects of daily life. Participants are exposed to neutral and affective words with a strong positive and negative valence in consecutive paired trials, one word serving as the "target" and the other as a "distractor." Participants are instructed to ignore the distractor and to attend to the target in both control and negative priming conditions, with "inhibition ability" operationalized as a difference score between response latencies in control and negative priming conditions. The stronger one's inhibition abilities, the longer the latency in the negative priming condition compared to the control condition (scored in milliseconds). Individuals with chronic depression and greater tendency to engage in maladaptive rumination demonstrate reduced ability to inhibit negative, as opposed to neutral, words with no difference in the ability to inhibit positive words [63,64].

Secondary Outcomes

Overview

There are 4 secondary outcomes for this study: pain sensitivity, physical strength and flexibility, pain interference, and quality of life.

Pain Sensitivity: Peripheral and Central Sensitivity

We will use a comprehensive quantitative sensory testing (QST) battery of mechanical and thermal stimuli [65]: (1) cutaneous mechanical pain sensitivity, involving measures of tolerance, threshold, temporal summation, and after sensations; (2) heat and cold pain sensitivity, involving threshold, tolerance, and ratings of suprathreshold stimuli; and (3) pressure pain thresholds. Interrater reliability of the QST protocol has been reported in several clinical trials, with each individual test achieving a CI of 0.87-0.94 [66,67].

In addition to the QST battery, we will isolate total RNA from whole blood for sequencing at each time point. We will prepare libraries per Illumina standard protocols and sequence RNA on the Illumina HiSeq2500 System (Illumina Inc) to obtain 150 base pair paired-end reads. We will examine how changes in the expression of pain sensitivity genes, as well as the entire transcriptome, differ between the experimental and control group (those with complete data from yoga vs stretching) × sex using statistical modeling and construct a database of gene expression profiles to generate a profile of change in ER, as well as identify novel therapeutic targets for better pain management. We will use a candidate approach to examine genes identified from our preliminary studies, and a hypothesis-generating approach to identify differentially expressed genes.

Physical Strength and Flexibility

Physical measures include grip strength and core stabilization and strength. Grip strength will be measured using 2 trials for each hand with a hydraulic dynamometer. The best performance is selected for each side, and the average of the left and right hand is used for analysis. Painful or injured hands or wrists are not tested, and the result of the good hand is used. Good reliability and predictive validity have been shown [68]. Core stabilization and strength will be assessed using prone and supine bridge positions [69]. Participants begin on their elbows in the prone position with shoulders, hips, and ankles aligned. The supine position is tested next, with knees flexed 90° and pelvis raised from the floor with shoulders, hips, and knees aligned. Assessors record the length of time (120 seconds maximum) that each position is held in proper form.

Pain Interference

Interference of function due to pain will be measured with the Brief Pain Inventory [60]. The pain interference score is the mean of the 7 interference items.

Quality of Life

The 36-item Short Form Health Survey [70] will be administered at each time point to gain a deeper understanding of the psychological, physical, and social limitations that participants experience as a result of pain. Subscales characterize participants' physical functioning, role functioning as impacted by physical and emotional health, energy or fatigue, emotional well-being, social functioning, pain, and general health. The 36-item Short Form Health Survey demonstrates excellent strong psychometric properties and predictive validity in a variety of diverse samples, including those experiencing chronic pain [71].

Exploratory Variables

Demographics, class attendance or home practice, expectancies, and substance use will be measured to examine the impact on the primary and secondary outcomes. A brief questionnaire (minimum data set as recommended by the National Institutes of Health Taskforce on Research Standards for CLBP) [54] will assess demographics (age, gender, race or ethnicity, education, and employment status) and medical or psychiatric history (comorbidities, medication usage, and ongoing treatments). Attendance at yoga or stretching sessions will be assessed using attendance data from the session recordings. The Essential

Properties of Yoga Questionnaire [72] will be used to rate both interventions (yoga and stretching or strengthening) and measures the extent to which 14 different dimensions are emphasized in a mind-body intervention (eg, physical challenge, breathwork, restorative postures, and mindfulness). The Credibility Expectancy Questionnaire [73], a 6-item self-report instrument, will be used to assess treatment credibility and patient expectancy for improvement [74]. In order to assess participants' use of tobacco, alcohol, prescription medicines, cannabis, and other nonprescribed substances, the Alcohol, Smoking, and Substance Involvement Screening Test [75] will be administered by study staff at each time point.

Statistical Analysis

The primary aim of this study will test the null hypothesis that the 2 population means are equal between the yoga and stretching and strengthening groups on the primary outcome, pain severity as measured by the BPI-SF, as well as the primary MOA, ER as assessed by the DERS. Power calculations incorporated prior effect sizes from works by others. A proposed sample size of 102 per group, which adjusted for attrition, was calculated to detect statistically significant results with 80% power (estimated d=0.50). In consideration of our secondary aims, we also powered the detection of paths a and b within pain interference mediation models. This was done using simulation in R (R Foundation for Statistical Computing; N=5000). Following simulation methods (N=5000) presented in Fritz and MacKinnon [76], sample size was determined by increasing simulation sample size until 90% of simulations significantly detected both paths a and b with estimated effect size magnitudes of d=0.39 (path a) and d=0.26 (path b) at α=.05. A proposed sample size of 116 was calculated, which was already reached when powering our primary aim.

Data Analysis

All analyses will be performed in SPSS (version 29; IBM Corp). A P value of .05 or less will be considered statistically significant. The primary outcome is pain severity (BPI-SF) and the primary MOA is ER (DERS). We will examine baseline demographics and study variables descriptively and test for differences between yoga and stretching and strengthening groups. If assumptions are met, a series of 2-sided t tests, mixed effects models, and path analyses will test our hypotheses. A mediation path analysis will be conducted examining the indirect path of group and change in ER from baseline to 6 weeks (path a), and change in ER from baseline to 6 weeks and pain severity (BPI-SF) at 12 weeks (path b) controlling for baseline pain severity. The magnitude of indirect path b will be assessed controlling for path a and the direct path between group and change in pain severity at 12 weeks (path c) to test if changes in ER predict subsequent changes in pain severity. Identical models will be created with change in ER from baseline to 12 weeks and pain severity at 3- and 6-month follow-ups. The magnitude of indirect path b will be compared between groups to test if the path between ER and pain severity is greater in the yoga group than in the stretching and strengthening group. If 95% CIs of path estimates do not contain 0, they will be considered meaningful. Finally, a series of moderated mediation path analyses will be conducted, examining the measures of baseline pain sensitivity (QST scores and normalized gene expression values), strength and flexibility, pain interference, and quality of life as moderators of the identical mediation model. All analyses will also be adjusted for important covariates including, but not limited to demographics (eg, biological sex, race, and sex), cohort, instructor, and intervention components (Essential Properties of Yoga Questionnaire) and credibility or perception of success (Credibility Expectancy Questionnaire). Sensitivity analyses will examine whether treatment responders and nonresponders differ significantly in baseline ER abilities. Baseline DERS scores will also be examined as a continuous moderator in main study analyses to establish whether some individuals may enjoy greater benefit from this intervention more than others.

Results

This project is funded by the National Center for Complementary and Integrative Health and reviewed by the University of Connecticut's IRB. Recruitment began in September 2020. As of January 2024, we have enrolled 138 participants. We expect the study to be completed by May 2025. No interim analyses are planned for evaluation of the primary and secondary outcomes. Analyses will be conducted following final data collection using a mediation path analysis and series of moderated mediation path analyses to examine the mechanisms through which yoga reduces pain.

Discussion

Yoga has been shown to decrease pain severity in individuals with CLBP. This study aims to determine whether ER is a mechanism of yoga through which a significant reduction in pain can be achieved. We will also determine whether yoga can lead to improvements in pain sensitivity, physical strength and flexibility, pain interference, and quality of life.

This will be the first study to assess ER as an MOA of yoga and interrogate plausible biological and psychological pathways that impact the contribution of ER on pain relief. The study results will provide empirical data on the role of ER as a MOA for yoga interventions and inform future studies on whether ER could be bolstered as a component of yoga or other mind-body interventions to improve pain outcomes.

Limitations of the study include that it will be performed at 1 site within the United States, and the interventions are only delivered in English. As a first step to determine whether ER is a MOA of yoga, the study may support evaluating or targeting ER in yoga interventions among more diverse populations, with delivery in other languages, and with other chronic pain conditions.

This 2-arm parallel group blinded RCT will examine ER as the MOA of yoga in individuals with CLBP. The study will provide important data for evaluating whether improvements in ER are responsible for reduced pain, whether pain sensitization moderates yoga's effects on pain, or if yoga and improved ER abilities reduce pain sensitivity and thereby relieves pain. The study findings have important implications for future yoga

research studies, as well as other mind-body modalities designed to improve pain management.

Acknowledgments

This work was supported by the National Institutes of Health (grants R01AT010555, MPI: Park/Starkweather; and F31AT012315, Gnall).

Data Availability

Data sharing is not applicable to this article as no data sets were generated or analyzed during this study.

Authors' Contributions

ARS and CP wrote the initial manuscript, designed the tables and figures, and acquired funding. EJG designed and helped to modify the yoga intervention. All authors contributed to revisions and reviewed the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Low levels of physical activity are associated with numerous adverse health outcomes, yet sedentary lifestyles are common among both children and adults. Physical activity levels tend to decline steeply among children aged between 8 and 12 years, even though children's behavioral patterns are largely governed by familial structures. Similarly, parents' activity levels have been generally reported as lower than those of nonparents of comparable age. For this reason, family-based physical activity promotion interventions are a potentially valuable and relatively underresearched method for mitigating physical activity declines as children develop into adolescents and for increasing physical activity in parents.

Objective: This study aims to assess the efficacy, feasibility, and acceptability of a novel theory-based web-based physical activity promotion intervention among parent-child dyads in Finland who do not meet physical activity recommendations at baseline.

Methods: Participants (target N=254) will be recruited from the general population using a panel company and advertisements on social media and randomly assigned to either an immediate intervention group or a waitlist control group. The intervention consists of 4 web-based group workshops over the course of 10 weeks, web-based tasks and resources, and a social support chat group. Data on physical activity behavior and constructs from the integrated behavior change model will be collected through self-report surveys assessing physical activity, autonomy support, autonomous motivation, attitude, subjective norm, perceived behavioral control, intention, self-monitoring, habit, and accelerometer measurements at baseline, post intervention, and 3 months post intervention. Exit interviews with participants will assess the feasibility and acceptability of the intervention procedures.

Results: This study will reveal whether the intervention changes leisure-time physical activity among intervention participants relative to the control group and will examine the intervention's effects on important theoretical predictors of physical activity. It will also yield data that can be used to refine intervention materials and inform further implementation. Trial recruitment commenced in September 2023, and data collection should be completed by December 2024.

Conclusions: The planned intervention has potential implications for both theory and practice. Practically, the use of an entirely web-based intervention may have scalable future uses for improving physical activity in 2 key populations, while also potentially informing on the value of dyadic, family-based strategies for encouraging an active lifestyle as an alternative to strategies that target either parents or children independently. Further, by assessing change in psychological constructs alongside potential change in behavior, the intervention also allows for important tests of theory regarding which constructs are most linked to favorable behavior change outcomes.

Introduction

Overview

Low levels of physical activity in adult and youth populations are associated with an increased risk of physical and mental health conditions and a reduced quality of life. Conversely, regular physical activity participation is associated with reduced chronic disease risk and better psychological health and well-being [1]. Accordingly, the World Health Organization has published evidence-based guideline levels of physical activity required to realize these health benefits. The guidelines recommend that adults aged between 18 and 64 years participate in at least 75 minutes of vigorous physical activity, 150 minutes of moderate physical activity, or an equivalent combination of both per week, while children aged between 7 and 17 years are recommended to participate in at least 60 minutes of physical activity per day. Studies indicate that most people do not achieve these guideline levels of physical activity [2]. Further, studies have observed a sharp drop in physical activity participation in child and adolescent populations, followed by generally low participation levels into and throughout adulthood [3].

Given the steep decline in activity levels, as children transition into adolescence, the development and implementation of behavioral interventions to encourage an active lifestyle is a key target area for health promotion research. One strategy proposed to enhance the efficacy of behavior change strategies for children's activity levels is to target the family unit rather than children themselves. Specifically, parents of preteen children retain a strong influence on their child's behavior, both through their own activity levels [4,5] and through the opportunity to provide support for and foster motivation toward leisure-time physical activity behaviors [6,7]. Further, evidence indicates that children likely influence physical activity behaviors and beliefs in their parents, as parents tend to be less active than nonparents [8], often citing their children's lack of motivation or support as a barrier to being physically active [9]. This evidence of within-family effects indicates the potential utility of dyadic interventions for both parents and children [10], using theory-driven, group-based behavior change strategies to bolster social support, foster motivation, and reduce the perceived barriers to behavior in both the parent and child. Yet, despite evidence for the potential utility of these strategies, few physical activity interventions have been applied for parent-child dyads, and those that have tend not to have a strong basis in behavioral theory and are seldom evaluated systematically [11], inhibiting meaningful conclusions on their efficacy. In response to the relative scarcity of theory-driven, family-based physical activity intervention programs, we aim to develop and test an intervention to promote physical activity in low-active parents and their children based on the integrated behavior change model, an approach that outlines the multiple determinants and potential targets for intervention derived from multiple theoretical perspectives [12].

The Integrated Behavior Change Model

The integrated behavior change model draws from several well-established behavioral theories: self-determination theory [13], the theory of planned behavior [14], the health action process approach [15], and the reflective impulsive model [16]. Central to the model is that individuals' quality of motivation, which reflects whether their behavior is consistent with the self-endorsed reasons, is highly influential in individuals' intentions to perform physical activity and physical activity participation. This premise is derived from self-determination theory, which makes the distinction between autonomous and controlled forms of motivation. Autonomous motivation reflects an individual's performing physical activity consistent with their own interests, choices, needs, and sense of personal involvement [13,17]. By contrast, controlled motivation reflects performing activities for externally referenced reasons, such as for rewards or out of obligation to others. Of critical importance when it comes to performing physical activity, individuals who perform physical activities for autonomous motives are more likely to form intentions to perform physical activity in the future and are more likely to develop routines and habits, which can translate to long-term physical activity persistence [18]. This is because those citing autonomous reasons for performing physical activity are likely to persist because their motivation emanates from themselves, while those whose motives are controlled will only persist as long as the external contingencies

(eg, rewards and demands from others) persist. A key tenant of self-determination theory [17,19], is that autonomous motivation for physical activity can be fostered through the support of salient others, such as parents or teachers. For example, parents who display behaviors that indicate support for children's autonomy and competence toward physical activity and demonstrate a sense of unconditional relatedness with their children for physical activities, are more likely to foster autonomous motives in their children toward performing physical activity in the future [6,7,20]. As such, enabling parents to display autonomy-supportive behaviors with respect to presenting, discussing, and performing physical activity with their children is likely an important strategy to promote physical activity participation in children and may be particularly valuable in family-based interventions aimed at promoting physical activity. It is also likely to be useful in parent-child dyads, where both parent and child can be encouraged to display behaviors that support each other's autonomous motivation. This is supported in empirical data, where autonomy-supportive parenting has been associated with autonomous motivation in children as well as positive behavioral outcomes [21], including enhanced physical activity [6].

The integrated behavior change model also specifies the processes by which autonomous motivation leads to intention toward, and actual participation in, physical activity in the future. Specifically, individuals who are autonomously motivated toward a behavior are proposed to be more likely to form adaptive beliefs in favor of performing that behavior in the future [12,22-24] and, as a consequence, form an intention to perform physical activity in the future. Such beliefs are represented in the model by the belief-based attitude, subjective norm, and perceived behavioral control constructs from the theory of planned behavior [14], a prototypical theory that identifies the antecedents of intentional behaviors such as physical activity. The theory stipulates intention is the salient predictor of subsequent behavior, and intentions themselves are a function of attitudes (beliefs about the perceived likely affective or instrumental outcomes of engaging in a behavior), subjective norms (beliefs about where important others in one's life would want them to engage in a behavior or not), and perceived behavioral control (beliefs about whether engaging in a behavior is under one's own control or within their abilities). Research has demonstrated that these beliefs tend to be reliably related to physical activity intentions and participation, signaling their potential as modifiable constructs that could be targeted in intervention strategies aimed at promoting positive intentions toward, and actual participation in, physical activity. Accordingly, interventions based on the theory and targeting the belief-based constructs have shown efficacy in changing intentions and behavior [25]. For example, interventions presenting persuasive messages that highlight the advantages of behavior and downplay the disadvantages, targeting attitude change, or prompting practice that assists individuals in successfully mastering the target behavior and overcoming obstacles, targeting perceived behavior control change, have been shown to be effective in promoting intention and behavior change in physical activity contexts [26].

While there is evidence for the utility of interventions based on the recommendations of self-determination theory (eg, use of strategies like fostering autonomy support in influential others) or the theory of planned behavior (eg, providing persuasive communications targeting belief change), the integrated behavior change model also acknowledges that these strategies are often more efficacious in changing motivation or intention than changing behavior [27]. Recognizing the shortfall in the association between motivation and behavior, such as relatively modest intention-behavior relations observed in physical activity [28-32], other strategies that bolster intentions may be useful. For example, researchers adopting action control frameworks have suggested that leveraging [28,33] intervention strategies such as planning and self-monitoring may strengthen the intention-behavior relationship and increase the likelihood that individuals act on their good intentions when performing physical activity [15,34].

Study Overview Objectives

Given the need for interventions to help children maintain physical activity levels as they transition into adolescence and to help parents become more physically active, our group used the integrated model as a starting point to develop a novel, remotely delivered dyadic physical activity promotion intervention. By applying the integrated behavior change model to a parent-child intervention, we aim to use and strengthen within-family dynamics to foster autonomous motivation and encourage physical activity in both parents and preteen children. In this protocol, we describe a planned randomized controlled trial for testing the effects of this intervention in a sample of insufficiently active Finnish-speaking parents and children.

Methods

Trial Design

The trial will adopt a randomized waitlist control design in which parent-child dyads are the unit of randomization. Families will be randomized on sign-up to either an intervention group that receives the intervention immediately after baseline data collection or to a waitlist control group that will receive the intervention after all outcome data have been collected.

Participant Recruitment and Eligibility

Parent-child dyads will be recruited from the general Finnish population through direct contact with a panel company, through social media advertisements, and through posts on parenting discussion boards and forums. Individuals who responded to the advertisements were directed to a screening survey hosted on the Webropol platform. To be eligible for inclusion, dyads must consist of a parent or guardian aged >18 years and a child aged 8-12 years, and both dyad members need to be considered sedentary. Parents are considered sedentary if they were not active for at least 30 minutes a day on 5 or more days in the past week, and children are considered sedentary if they were not active for at least 60 minutes per day in the past week. Dyads will be excluded if either the parent or child reported having a medical condition or injury likely to prevent them from safely engaging in physical activity. People meeting the inclusion criteria can continue in the Webropol survey to read information

about the trial and are then offered the opportunity to provide their contact details to opt-in to the trial.

Power Analysis

The projected sample size was estimated from a statistical power analysis conducted using G*Power (version 3.1; Heinrich-Heine-Universität Düsseldorf). The analysis assumed a small to medium effect size (Cohen *f*=0.235) for the intervention on our primary outcome variable, leisure time physical activity, calculated from an average of effect sizes from meta-analyses of self-determination theory–based interventions (Hedges *g*=0.45 [35]) and interventions targeting self-efficacy (Cohen *d*=0.48 [36]), with α set at .05 and statistical power set at .80 reveal a projected total sample size of 178 participants. We also assumed a projected 30% attrition rate in participants through the study based on similar trials [37], resulting in a sample of 254 participants (ie, 127 dyads) to be recruited at baseline.

Study Procedures

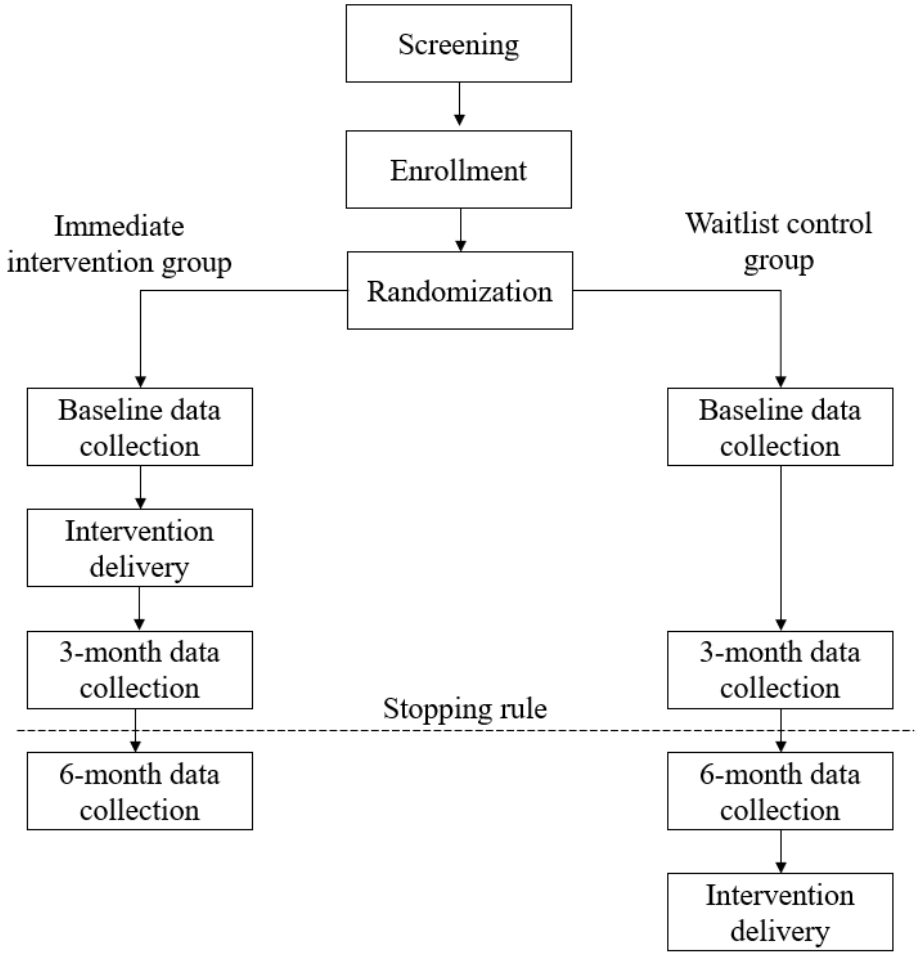
All recruitment materials will be delivered in a web-based format with a URL forwarding participants to a screening and informed consent survey hosted on the Webropol platform. First, parents will be presented with an eligibility questionnaire to assess whether they and their children making reference to themselves and their least active child aged between 8 and 12 years, meet the inclusion criteria. Eligible parents will then be presented with information about the study and an informed consent form. Parents who provide informed consent to participate in the study will be prompted to provide their name, contact details, and the name of their least active child, aged between 8 and 12 years, and will be enrolled in the study.

After enrolling in the trial, dyads will be assigned by computerized random-digit generation to 1 of 2 groups: an immediate intervention group that receives the intervention immediately after baseline data collection, or a waitlist control group that will receive the intervention after all outcome data have been collected.

Participants in both groups will be asked to provide outcome data immediately after randomization, 3 months later, and 6 months later. Outcome data will be collected through web-based surveys hosted on the Webropol platform and through physical activity measurement devices mailed to participants' homes. For web-based surveys, parents will be emailed 2 separate URLs: 1 for themselves and 1 for their child. Parents will be instructed that they may help their child understand the survey items but should avoid influencing their child's answers to the questionnaire.

Participants in the immediate intervention group will receive the intervention between the baseline and 3-month data collection points, while participants in the waitlist control group will receive the intervention after all data collection has been completed. While data are planned to be collected at baseline, 3 months, and 6 months, the trial includes a stopping rule, such that 6-month follow-up data will not be collected if there is no effect of the intervention on the primary outcome (ie, leisure time physical activity) at the 3-month follow-up. The trial design flow diagram is presented in Figure 1.

Figure 1. A flowchart of enrollment and data collection for the ProAct trial.



Intervention

Immediate Intervention Group

The intervention consists of 4 web-based sessions hosted through a videoconferencing platform (Zoom Inc) and facilitated by 1 or 2 members of the research team. The 4 sessions will be delivered in weeks 1, 3, 5, and 8 of the program. Summaries of each session, including the target constructs and behavior change techniques used in each session, are presented in Table 1. The first session will involve only parents and will last 90 minutes. It focuses on instructing parents in the use of autonomy-supporting parenting behaviors. The remaining 3 sessions will involve both parents and children and will last 45 minutes. Session 2 prompts a discussion of the benefits of an active lifestyle, including enjoyment and importance, and gets participants to set individual and joint physical activity-related goals. Session 3 teaches participants how to make action plans and coping plans (ie, problem-solving) when pursuing physical activity goals. Session 4 covers social norms related to physical activity, has participants specify their identity related to physical activity, and prompts social support strategies within each dyad.

Table 1. Content and targets for each intervention session in the ProAct trial. Behavior change techniques preceded by an "M" are drawn from the Motivation and Behavior Change Techniques [38]. Behavior change techniques preceded by a "T" are drawn from the Behavior Change Taxonomy version 1 [39].

Session	Target constructs	Behavior change techniques
Session 1: 90 minutes and parents only	Autonomy supportive parenting	• M3. Use non-controlling, informational language • M5. Provide a meaningful rationale • M6. Provide choice • M7. Encourage the person to experiment and self-initiate the behavior • M10. Show unconditional regard • M12. Use empathic listening • M16. Clarify expectations • T1.1 Goal setting yeah • T1.4 Action planning • T4.1 Instruction on how to perform the behavior • T4.2 Information about antecedents • T5.3 Information about social and environmental consequences • T5.6 Information about emotional consequences • T8.1 Behavioral practice/rehearsal • T16.3 Vicarious consequences
Session 2: 45 minutes, parents, and children	Attitude	• M4. Explore life aspirations and values • M6. Provide choice • M7. Encourage the person to experiment and self-initiate the behavior • M16. Clarify expectations • M17. Assist in setting optimal challenge • M19 Help develop a clear and concrete plan of action • M20 Promote self-monitoring • T1.1 Goal Setting (behavior) • T1.3. Goal Setting (outcome) • T1.5 Review behavior goal(s) • T1.6 Discrepancy between current behavior and goal • T2.3 Prompt self-monitoring of behavior • T4.1 Instruction on how to perform the behavior • T5.6 Information about emotional consequences • T15.3 Focus on past success
Session 3: 45 minutes, parents, and children	Perceived behavioral control and self-regulation	• M15. Address obstacles for change • M19. Help develop a clear and concrete plan of action • M20. Promote self-monitoring • M21. Explore ways of dealing with pressure • T1.2 Problem-solving • T1.5 Review behavioral goals • T1.6. Discrepancy between current behavior and goal • T2.2 Feedback on behavior • T8.7 Graded Tasks • T15.1 Verbal persuasion about capability • T15.3 Focus on past success.
Session 4: 45 minutes, parents, and children	Subjective Norm and perceived autonomy support	• M2 Prompt identification of sources of pressure for behavior change • M8. Acknowledge and respect perspectives and feelings • M9. Encourage asking of questions • M14. Prompt identification and seek available social support • T1.1 Goal Setting (behavior) • T1.3 Goal Setting (outcome) • T1.4 Action planning • T1.5 Review behavioral goals • T1.7 Review Outcome Goals • T3.2 Social Support (Practical) • T3.3 Social Support (Emotional) • T6.2 Social comparison • T6.3 Information on others' approval. • T13.1 Identification of self as role model • T13.5 Identity associated with changed behavior

In addition to the web-based sessions, participants will have access to a website that includes materials that support the content of each session. This includes worksheets, slide decks and recorded versions of the sessions, a menu of physical

activities suitable for parents and children, and further practice materials.

Between sessions, participants will receive SMS text messages that ask them to provide written feedback on their progress; offer advice, suggestions, or reminders; or prompt reflection on their motives for physical activity. Parent participants will also be granted access to a moderated web-based chat forum (WhatsApp group [Meta Facebook, Inc]) in which parents can share their experiences with the sessions and provide and receive social support from other participating parents. Intervention materials are available on the internet [40].

Waitlist Control Group

Participants assigned to the waitlist control group will complete the same data collection procedures as the immediate intervention group but will not be required to undertake any alternative intervention tasks during the data collection period. After the data collection period, participants in the waitlist control group will be invited to receive the intervention and accompanying materials.

Outcomes

Overview

Measures of psychological constructs will be assessed using multi-item scaled survey measures, while leisure-time physical activity is to be assessed using self-reported surveys and observationally through accelerometer measurements. All items were translated into Finnish by native speakers and piloted on a sample of 8- to 12-year-old Finnish children and their parents. Full measures are available on the internet [40].

Primary Outcomes (Physical Activity and Sedentary Time)

Self-reported physical activity and time spent in sedentary activities for both parents and children will be assessed using the Godin-Shepard leisure time exercise questionnaire [41], where participants will be required to report the number of occasions they engaged in light, moderate, and vigorous physical activity for 15 minutes or longer. Sedentary time will be measured using 2 items per participant, targeting weekdays and weekend days separately (eg, “In the past 7 days, how much time did you spend sitting during a typical weekday after school or weekend day?”) [42]. Items are scored on a sliding scale from “no time” upwards in increments of half an hour.

Secondary Outcomes

Device-Measured Physical Activity

Physical activity will also be assessed using a hip-worn triaxial accelerometer (Hookie AM20; Traxmeet Ltd). Each dyad will be mailed 2 accelerometers, detailed instructions on wearing the device, and a diary for recording when they wore the accelerometer, how they commuted to school or work, and any events that may have inhibited accurate data (eg, missed days and exercise done without the device). Raw data from accelerometers will be processed using the *GGIR* package in R software (R Foundation for Statistical Computing) [43], with outcome scores provided as the amount of time spent engaged in sedentary behavior, light physical activity, moderate physical activity, and vigorous physical activity.

Autonomy-Supportive Parenting

Autonomy-supportive parenting practices will be assessed using a 4-item questionnaire based on measures used in a previous study [44], with responses provided on 5-point scales (1=strongly disagree to 5=strongly agree).

Perceived Autonomy Support

Perceived autonomy support will be assessed using the perceived autonomy support scale for exercise settings [45]. For children, the scale refers to autonomy support from parents, while for parents, the scale makes reference to autonomy support received from family. All items are scored on a 5-point Likert scale (1=strongly disagree to 5=strongly agree).

Autonomous and Controlled Motivation

Autonomous and controlled motivation for both parents and children is assessed using 4 items each [46], with responses provided on 5-point scales (1=strongly disagree to 5=strongly agree).

Attitude

Attitude toward engaging in physical activity is assessed using 3 items with a common stem [44,47], with responses provided on a 5-point semantic differential scale (eg, unenjoyable [1] to enjoyable [5]).

Subjective Norms

Subjective norms in parents are assessed using 3 items referring to important others [44,47]. Children answered similar items, but in specific reference to family and friends separately. All items are scored on a 5-point Likert scale (1=strongly disagree to 5=strongly agree).

Perceived Behavioral Control

Perceived behavioral control is assessed in both parents and children using 2 items [44,47], with responses provided on 5-point scales (1=strongly disagree to 5=strongly agree).

Intention

Intention to engage in leisure time physical activity is assessed in both parents and children through 3 items [44,47], with responses provided on 5-point scales (1=strongly disagree to 5=strongly agree).

Self-Monitoring

Self-monitoring toward physical activity is assessed using 2 items [44,48], each scored on a 5-point Likert scale (1=strongly disagree to 5=strongly agree).

Habit

Habits are assessed using the 4-item automaticity subscale of the self-reported habit index [49,50], with responses provided on 5-point scales (1=strongly disagree to 5=strongly agree).

Acceptability

For participants in the immediate intervention group, the postintervention (3 months) web-based questionnaire will include survey items assessing the accessibility and feasibility of intervention procedures. Participants will also be invited to

attend a 45-minute web-based exit interview to explore participant perceptions of the intervention content and possible improvements for future implementation.

Data Analysis

Hypotheses will be tested using R software. All analyses will initially be performed as intention-to-treat, and per-protocol analyses will also be undertaken for comparison. Patterns of missing data will be explored using the Little missing completely at random test. Missing data in the final analysis will be inferred using full-information maximum likelihood analysis. We will test the efficacy of the intervention on our primary outcome, self-reported leisure-time physical activity, using an iterative series of generalized linear models. Independent variables will include time, intervention condition, demographic covariates (eg, start date, gender, and age), delivery group clustering, within-dyad clustering, and person-intervention theory fit $P\Delta$ [51]. Each variable group will be added in a subsequent iteration of the model, and model fit statistics will be examined at each iteration. This process will be repeated for each secondary outcome variable (perceived autonomy support, autonomous motivation, attitude, subjective norm, perceived behavioral control, action planning, coping planning, self-monitoring, and behavioral automaticity).

We also intend to assess the effect of theory-based mediators on change in physical activity using a path model. Specifically, we aim to assess whether the effects of intervention conditions on change scores in physical activity outcomes (both primary and secondary) are mediated by change scores in each of the psychological constructs targeted by the intervention (ie, perceived autonomy support, autonomous motivation, attitude, subjective norm, perceived behavioral control, action planning, coping planning, self-monitoring, and behavioral automaticity).

Ethical Considerations

All study procedures have been approved by the University of Jyväskylä Human Sciences Ethics Committee (statement number 806/13.00.04.00/2023). All parents interested in participating in the study will be presented with detailed information about the intervention, potential risks to participants, the right to withdraw, and data security arrangements. Parents will have the chance to read this information and ask questions of the research team before providing their informed consent to participate. Data will be stored on secure cloud-based servers hosted by the University of Jyväskylä consistent with our data archiving and storage management plan, compliant with university guidelines. At the conclusion of data collection, participants' physical activity and data on psychological measures at each measurement point will be matched using pseudonymized codes and deidentified to the greatest extent possible. Participants will not be offered any financial or other compensation for their participation.

Results

The project team received final notification of research funding approval for the current project from the Finnish Ministry of Education and Culture, Sport Science Funds, in March 2022 (PROJECT 350904), and the trial has been preregistered on ClinicalTrials.gov (ID 806/13.00.04.00/2023). Enrollment into the trial commenced on September 20, 2023. Enrollment is scheduled to continue until March 2024, with the final collection of follow-up data scheduled for December 2024.

We expect that the research will provide valuable formative evidence for the efficacy of a theory-driven family-based physical activity intervention strategy. Further, as the proposed trial includes open materials and tests of the theory-driven mechanistic effects that may encourage behavior change, this research may also serve as a valuable stepping stone to the development of more large-scale, low-cost interventions for family behavior change.

Discussion

Overview

This protocol presents a randomized controlled trial aiming to increase physical activity levels in inactive parent-child dyads within Finland, based on the integrated behavior change model. We hypothesize in this protocol that both parents and children will show increased levels of physical activity, our primary outcome variable, both at the immediate and 3-month postintervention stage, relative to a waitlist control group. Further, we hypothesize we will observe similar changes in the trial's secondary outcomes, the psychological constructs of the integrated behavior change model (ie, autonomy support, autonomous motivation, attitude, subjective norm, perceived behavioral control, self-monitoring, intentions, and habit), in the intervention group relative to the waitlist control group.

Potential Findings and Implications

Children transitioning into adolescence have shown a sharp decline in activity levels [3], while parents are generally less active than similar adults without children [8]. Thus, both populations individually represent valuable targets for intervention. Recognizing this, governments and health departments have recommended behavioral interventions to promote physical activity participation in both groups. However, beyond strategies to influence physical activity in either children or parents separately, research indicates that parents and children likely have a noteworthy influence on each other's physical activity behaviors and beliefs [6,7,9]. Thus, the delivery of interventions in family contexts, such as parent-child dyads, represents a potentially highly valuable strategy to promote physical activity participation in both populations. This is supported to a degree in meta-analysis, as dyadic interventions encouraging an active lifestyle demonstrated slightly larger effects than those targeting individuals [10]. Yet, such interventions remain relatively rare compared to more traditional, individual-targeted programs, particularly those that are based on behavioral theory which may contribute to their efficacy and relevance to health sciences overall [10].

This study tests a theory-based family behavioral intervention aimed at promoting change in physical activity participation in parent-child dyads. The intervention aims to foster autonomous motivation, enhance social support, and reduce perceived barriers to exercise in an atmosphere that is accepting and open. The intervention will make a unique contribution to practice

and theory. Given the low levels of physical activity participation in adult and child populations, demonstrating the efficacy of web-based behavioral intervention in increasing physical activity that is both replicable and potentially scalable will make a valuable contribution to practice in health care contexts. In this research, we aim to enhance the potential usefulness of this intervention in the context of informing refined, scalable interventions based on results with the use of open materials and data, including intervention content and delivery guides. Further, from a scientific perspective, the application of a theory-based intervention developed in line with current practice intervention guidelines presents a potentially valuable test of mechanistic effects presented in the integrated behavior change theory and its component models [12-15], identifying the "active ingredients" of the intervention that are associated with desired outcomes. That is, while the integrated behavior change theory has been supported in several correlational studies [22,23,52], such research only provides an indication of the likely variables most important in determining behavior and can by their correlational nature not be used for any assertions of direction or causality. Thus, a key contribution of this intervention is assessing not only whether the program is successful in changing behavior, but also in assessing which target constructs mediate the effects of the intervention on behavior change and may therefore be most valuable when refining current strategies or developing new programs.

Limitations

Beyond the expected value presented by the research, it is also important to note that the trial faces some expected and inherent challenges and limitations. For example, as the intervention does not include any reward or payment to participants beyond the benefits of the intervention itself, it is likely that parents who consent to enroll themselves and their child in the program will already be at least somewhat motivated to change their physical activity behavior. Such an issue has been noted in the previous parent-for-child interventions [53]. If this is the case, it is likely that the intervention effects will not be as strong as expected, as already motivated participants possess a lesser degree of potential for change than might be expected in families with unmotivated parents. While this nonetheless poses a challenge to the intervention, it is important to note that motivation or knowledge of the need for physical activity is commonplace [9,54], even as actual activity levels remain low. As the strategies used in this intervention include training parents in autonomy support rather than controlling strategies that may inhibit their child's autonomy and thus harm the development of active lifestyles [20,55], as well as strategies to bridge the intention-behavior gap, this trial still has bona fide value in targeting this key population. However, the problem of accessing and enrolling unmotivated families into intervention programs remains a concern for behavior change research.

Conclusions

Given the generally low levels of physical activity in Finnish parents and children, there is a notable need for intervention strategies aiming to encourage an active lifestyle in these populations. This protocol presents an upcoming randomized control trial based upon the integrated behavior change model, which aims to use a series of web-based, theory-based behavior-change strategies delivered to both parents and children as a dyadic program. In doing so, the proposed trial aims to extend upon current literature in several key aspects. First, by targeting parents and children as a dyad, the proposed study aims to add to the available literature on whether physical activity behavior change programs may be more efficacious when targeting the family unit, rather than parents or children individually. Second, as this study uses a theory-based design, testing change in both physical activity and related psychological constructs, the trial also offers an opportunity to test which beliefs and psychological factors are most associated with concomitant change in physical activity. These data, combined with the trial's open materials, may thus serve as a valuable stepping stone to the development of more large-scale, low-cost interventions for family behavior change.

Acknowledgments

This intervention has received funding from the Finnish Ministry of Education, Science, and Culture, Sports Science Funds (grant 350904, principal investigator MH).

Abstract

Background: Disparities in posthospitalization outcomes for people with chronic medical conditions and insured by Medicaid are well documented, yet interventions that mitigate them are lacking. Prevailing transitional care interventions narrowly target people aged 65 years and older, with specific disease processes, or limitedly focus on individual-level behavioral change such as self-care or symptom management, thus failing to adequately provide a holistic approach to ensure an optimal posthospital care continuum. This study evaluates the implementation of THRIVE—an evidence-based, equity-focused clinical pathway that supports Medicaid-insured individuals with multiple chronic conditions transitioning from hospital to home by focusing on the social determinants of health and systemic and structural barriers in health care delivery. THRIVE services include coordinating care, standardizing interdisciplinary communication, and addressing unmet clinical and social needs following hospital discharge.

Objective: The study's objectives are to (1) examine referral patterns, 30-day readmission, and emergency department use for participants who receive THRIVE support services compared to those receiving usual care and (2) evaluate the implementation of the THRIVE clinical pathway, including fidelity, feasibility, appropriateness, and acceptability.

Methods: We will perform a sequential randomized rollout of THRIVE to case managers at the study hospital in 3 steps (4 in the first group, 4 in the second, and 5 in the third), and data collection will occur over 18 months. Inclusion criteria for THRIVE participation include (1) being Medicaid insured, dually enrolled in Medicaid and Medicare, or Medicaid eligible; (2) residing in Philadelphia; (3) having experienced a hospitalization at the study hospital for more than 24 hours with a planned discharge to home; (4) agreeing to home care at partner home care settings; and (5) being aged 18 years or older. Qualitative data will include interviews with clinicians involved in THRIVE, and quantitative data on health service use (ie, 30-day readmission, emergency department use, and primary and specialty care) will be derived from the electronic health record.

Results: This project was funded in January 2023 and approved by the institutional review board on March 10, 2023. Data collection will occur from March 2023 to July 2024. Results are expected to be published in 2025.

Conclusions: The THRIVE clinical pathway aims to reduce disparities and improve postdischarge care transitions for Medicaid-insured patients through a system-level intervention that is acceptable for THRIVE participants, clinicians, and their teams in hospitals and home care settings. By using our equity-focused case management services and leveraging the power of the electronic medical record, THRIVE creates efficiencies by identifying high-need patients, improving communication across

acute and community-based sectors, and driving evidence-based care coordination. This study will add important findings about how the infusion of equity-focused principles in the design and evaluation of evidence-based interventions contributes to both implementation and effectiveness outcomes.

Introduction

Background

Complex care management provides critical support in the days and weeks following hospitalization for individuals with multiple chronic conditions. This postdischarge support can be especially beneficial for nearly 80 million individuals in the United States who are insured by Medicaid [1] and experience higher rates of chronic illness [2], more frequent hospitalizations, and worse clinical outcomes following discharge [3-5]. Readmissions among adults insured by Medicaid ages 45-64 years stand at 24% compared to 20% for older adults insured by Medicare [6]. Similarly, about 34% of individuals insured by Medicaid will experience an emergency department (ED) visit annually, far exceeding the rates of those insured commercially [7]. They experience deficits in primary care assessment and treatment and fewer preventive treatments and guideline-concordant care [8,9]. Thus, Medicaid-insured patients may present to the hospital with poorly managed chronic medical conditions compared with other patients and subsequently require more intensive transitional care coordination in the aftermath of a hospitalization. The need to improve support for Medicaid-insured people following hospitalization prompted our development of the THRIVE clinical pathway. THRIVE is a clinical pathway that supports Medicaid-insured individuals with multiple chronic conditions transitioning from hospital to home by coordinating care, standardizing communication, and addressing unmet needs following hospital discharge, including the social determinants of health.

Most existing postdischarge or transitional care programs were not developed to attend to the specific needs of people insured by Medicaid and instead support older adults or patients with specific chronic illnesses such as heart failure. Other postdischarge support programs require the addition of trained health care providers such as advanced practice nurses or patient navigators to coordinate care [10-12]. At least 1 randomized controlled trial (RCT) evaluating the use of community health workers (CHWs) has demonstrated lower rates of rehospitalization for enrolled low-income individuals with significant social needs [13]. Despite facilitating important links to community-based services, CHWs are unable to manage clinical needs [13-15]. Other postdischarge support programs such as the Camden Coalition Care Model provide transitional care support to people with significant social needs with high rates of health care use, many of whom are insured through Medicaid [16]. An RCT of the Camden Coalition Care Model demonstrated no differences in readmissions at 180 days between treatment and comparison [17]. The care transitions innovation model also provides transitional care support for economically disadvantaged adults, although an RCT found no reductions in 30-day readmissions or ED use [12]. At least 3 additional studies by Liss et al [18], Balaban et al [19], and Jackson et al [20] featured weekly health coaching, self-management education, and medical home follow-up for medically and socially complex patients, although the results of these interventions have been mixed. Inconsistent findings among existing postdischarge support programs suggest the need for alternative innovations that focus on systemic and structural barriers in health care delivery.

Similar to other inequities, posthospitalization disparities among people insured by Medicaid can be traced to a long history of institutional and economic inequities impacting care delivery and outcomes. Racial and ethnically minoritized populations are overrepresented in Medicaid compared to other forms of insurance, with approximately half of Medicaid enrollees younger than 65 years of age being members of racial and ethnically diverse backgrounds [21]. With incomes 138% below the federal poverty level [22], people insured by Medicaid experience the impact of the social determinants of health, including higher levels of financial strain and concerns over out-of-pocket costs, and experience more challenges in accessing specialists and community-based care [23-28]. People insured by Medicaid are also more likely to experience the impact of systemic and institutional racism. Systemic racism refers to the distribution of goods and services in such a way that advantages one group over another or fails to provide adequate resources in the face of need. Systemic factors such as inadequate discharge planning and poor care coordination similarly contribute to unfavorable posthospitalization outcomes [21,27-29]. Interpersonal racism is often expressed through bias and discrimination and is often expressed through microaggressions and stigmatizing language. Distinct from Medicare, Medicaid has its roots in the public welfare system, which has resulted in significant social stigma. Medicaid beneficiaries have described encounters with medical professionals where they were subjected to racial and socioeconomic prejudice [29,30]. These experiences may result in the avoidance of health care settings altogether and more difficulties accessing timely specialty care, all of which paradoxically increase ED use or lead to avoidable

hospitalizations due to delayed management of chronic illnesses [31,32].

Given the long-standing disparities experienced by people insured by Medicaid during and following hospitalization, there is a need for transitional care support focused on systemic and structural barriers to care and social determinants of health. The Centers for Disease Control and Prevention [33] defines health equity as "the state where everyone has a fair and just opportunity to attain their highest level of health." Using an equity lens draws attention to those at greatest risk to how social and economic strata shape access to material resources while also identifying the impact of marginalizing conditions such as racism and health resource constraints that intersect and result in disparate outcomes [34]. Using an equity lens also emphasizes what Peterson et al [35] refer to as the multiple, intersecting spheres of power, defined as the practices, processes, and policies that determine the distribution and access to resources and opportunities needed to be healthy. These spheres of power intersect with individual factors (eg, personal agency) to produce disparate outcomes. From this perspective, addressing postdischarge disparities requires a focus on optimizing service delivery and interdisciplinary collaborations across settings.

Codeveloping the THRIVE Clinical Pathway

Using an equity lens, our interdisciplinary team of clinicians, researchers, and community members formed to engage in meaningful action to support people insured by Medicaid and transform health care practices and processes that impeded sufficient transitional care support [36]. We began with months of participatory activities informed by an equity lens and principles of human-centered design [37], machine learning [38], and mixed methods approaches [39], which culminated in the development of THRIVE [40]. The THRIVE clinical pathway was launched in a large Level 1 Trauma Center in Philadelphia in 2019 and includes five core components: (1) the identification of individuals insured by Medicaid and coordination of home care referral during discharge planning while hospitalized; (2) provision of immediate home care services where nurses perform medication reconciliation, intensive teaching, and chronic disease management; (3) continued clinical oversight by discharging physicians; and (4) standardized communication between community and acute care providers via web-based case management that (5) prioritizes health-related social needs such as housing or food insecurity faced by Medicaid-insured patients (Figure 1). Our work as a team is anchored by our advisory board, which is comprised of community members, some of whom are Medicaid insured. The THRIVE Community Advisory Board meets quarterly to meaningfully engage past THRIVE participants, caregivers, and community members to ensure that the program goals are rooted in the vision and values of the community we serve.

In many health care settings, posthospitalization disparities among economically disadvantaged people are linked to personal deficits or behaviors. They are often referred to by their volume of health resource use, invariably referred to as "high-cost high needs," "superusers," "frequent flyers," "noncompliant," or "bounce backs," and are essentially blamed for poor outcomes. From this perspective, postdischarge disparities are often regarded as immutable social circumstances or moral failures beyond the purview of medicine's reach instead of a result of the impact of the social determinants of health, structural determinants such as failures in service delivery (eg, fragmented care coordination), and interpersonal racism [41]. In developing THRIVE, we sought to counter long-standing stigmatizing views and instead directed our focus on re-engineering service delivery and intensifying resources to those most in need while maintaining active involvement with affected community members in programmatic design and sustainability efforts.

Published results from a nonrandomized pilot of the first year of the THRIVE pathway revealed that participants experienced increased connections to postacute care services, including social support, and a 50% decrease in rates of 30-day readmissions and ED use compared to patients receiving standard care [42]. With these early findings, we are now poised to evaluate a scalable and sustainable postdischarge management process in a new setting and with a more rigorous evaluation and attention to organizational factors influencing success.

This study will deploy a type 1 hybrid effectiveness-implementation stepped wedge cluster RCT across a single hospital in Philadelphia [43]. The advantage of this trial design is that it offers an efficient and practical way to introduce THRIVE to new sites while reducing the ethical concerns of withholding an intervention that has shown benefit for economically disadvantaged populations. This study will also be guided by the Exploration, Preparation, Implementation, Sustainment framework; Proctor's outcomes framework; and the Health Equity Implementation Framework (HEIF) [44-46]. The HEIF adapts the Integrated Promoting Action on Research in Implementation in Health Services framework. The HEIF proposes determinants that are believed to predict the successful and equitable implementation of an intervention. The 3 health equity domains included in the HEIF include cultural factors, clinical encounter factors, and societal context [47]. Our use of the framework will help us to detect any factors that might lead to uneven referrals to THRIVE; disparate benefits to the intervention; and any barriers that might prevent organizations, health care providers, or administrators from engaging in the intervention. In their recently published paper, Brownson et al [48] noted that "Incorporating a strong equity focus in implementation science requires not only a deliberate emphasis on the needs, culture, and history of the populations and communities but also more critical analyses and deeper understanding of systems and policies, including care delivery and provider attitudes from which inequities might arise." They propose action steps for making health equity more prominent in implementation science. To that end, we incorporate and adapt our study design to ensure principles of equity in the approach to data collection, measures, contextual alignment, and dissemination practices (Table 1).

Figure 1. Components of the THRIVE clinical pathway. APP: advanced practice provider; EHR: electronic health record; MD: medical doctor; OT: occupational therapy; PRN: pro re nata (as needed); PT: physical therapy; RN: registered nurse; SW: social worker.

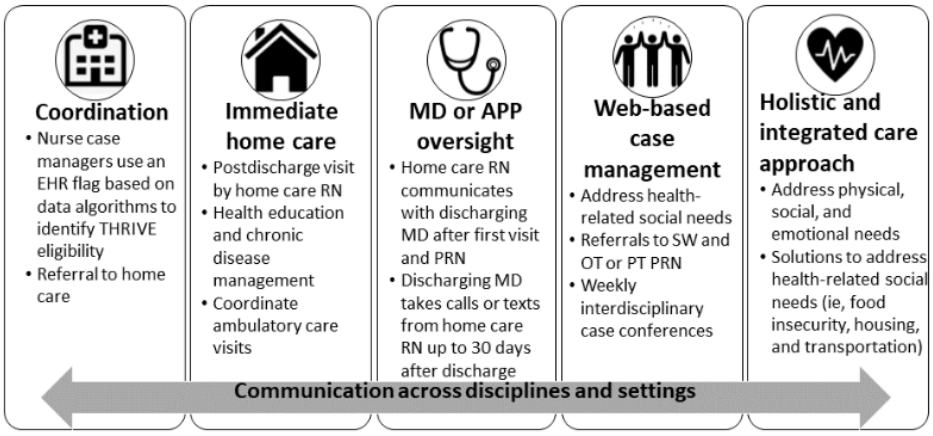

Table 1. Equity-relevant domains included in the implementation and outcome evaluation of THRIVE [48].

Domain	Recommendation	Core elements within this study
Evidence base	Link social determinants with health outcomes	Implement THRIVE for all Medicaid-insured individuals at a new study site to meet the postdischarge clinical and social needs of an economically disadvantaged population.
Methods and measures	Integrate equity into implementation models	Incorporate the 3 domains of the Health Equity Implementation Framework into the implementation evaluation.
Context	Engage organizations in internal and external equity efforts	Engage with clinical partners, administrators, and community advisory board members to implement THRIVE at a new site.
Cross-cutting issues	Focus on equity in dissemination efforts	Plan activities with THRIVE Community Advisory Board to disseminate study results.

Aims and Hypotheses

The specific aims of this research are to:

1. Examine referral patterns, 30-day readmission, and ED use patterns for participants who receive THRIVE support services compared to those receiving usual care.
   - Hypothesis 1: We anticipate that referral patterns will increase and that 30-day readmissions and ED use will decrease for THRIVE participants compared to usual care.
2. Evaluate the implementation of the THRIVE clinical pathway, including fidelity, feasibility, appropriateness, and acceptability.

Methods

Overview

Our study methods are described per the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) statement and the CONSORT (Consolidated Standards of Reporting Trials) extension for stepped wedge cluster RCTs [49,50]. The SPIRIT and CONSORT checklists are included as Multimedia Appendices 1 and 2.

Study Setting

The study setting includes a single site—Pennsylvania Hospital (PAH), the nation's first acute care setting in the country and 1 of 6 hospitals in the University of Pennsylvania Health System. More than 50% of PAH's patient population on the hospitalist service self-identify as racial or ethnic minority individuals, and >25% are Medicaid insured [34]. PAH provides over 40,000 ED visits and >18,000 adult admissions annually.

Design and Randomization

Overview

This is a prospective single-site type 1 hybrid effectiveness-implementation pragmatic stepped wedge cluster RCT. Our stepped wedge design will include a sequential randomized rollout of the intervention to case managers at PAH in 3 steps, and data collection will occur over 18 months. This mixed methods (quantitative and qualitative) study design involves simultaneous collection and analysis of quantitative and qualitative data, giving priority weight to the quantitative data to evaluate program referrals, outcomes, and program fidelity, while qualitative data will evaluate the process through detailed descriptions of perspectives of barriers and facilitators faced by health care providers in implementing the THRIVE intervention [51]. This study includes qualitative interviews and surveys of clinicians and administrators to assess their perspectives on appropriateness, feasibility, and acceptability of THRIVE. Nesting the qualitative interviews within an RCT of the THRIVE intervention will allow us to determine whether the intervention improved primary outcomes (referrals to home care, 30-day readmission, ED use, and connection to primary care providers) and to identify professional and organizational barriers to implementation. Combining these insights with effectiveness outcome data will allow consideration for meaningful contextual factors that are considered critical to the implementation of THRIVE and subsequent outcomes.

Randomization

Groups of case managers (4 in the first group, 4 in the second, and 5 in the third) were randomly assigned by the study methodologist to each sequence using a random number generator. A stepped wedge design—that is, a 1-time crossover design—was used for THRIVE (Table 2).

Specifically, following a baseline data collection period, 4 case managers will be randomized to receive training on the THRIVE clinical pathway. Following training, they begin referring to the THRIVE clinical pathway. At 8-week intervals, the remaining case managers will be trained in the THRIVE intervention and will be able to begin submitting referrals. Since case managers from the sequences work within the same space, the ability to conceal allocation was limited; however, all case managers were made aware of their upcoming ability to refer to the THRIVE clinical pathway.

Table 2. Study design for the type 1 hybrid effectiveness-implementation stepped wedge cluster randomized controlled trial of the THRIVE clinical pathway.

Cluster	Baseline (3 months)	Enrollment period 1 (8 weeks)	Enrollment period 2 (8 weeks)	Enrollment period 3 (8 weeks)	Follow-up (18 months)
Sequence 1 (4 case managers)		✓	✓	✓	✓
Sequence 2 (4 case managers)			✓	✓	✓
Sequence 3 (5 case managers)				✓	✓

THRIVE Eligibility Criteria

Individuals eligible for a THRIVE referral include (1) being Medicaid insured, dually enrolled in Medicaid and Medicare, or Medicaid eligible; (2) residing in Philadelphia; (3) having experienced a hospitalization at the study hospital for more than 24 hours with a planned discharge to home; (4) agreeing to home care at partner home care settings; and (5) being aged 18 years or older. If home care services are declined at any time following discharge, THRIVE services are also discontinued. If palliative or hospice services are ordered following discharge, THRIVE services will not be offered.

Clinician Eligibility and Recruitment

Nurse case managers (CMs), home care nurses, physicians, advanced practice providers, and administrators who are actively involved in supervisory roles or in referring to THRIVE will be invited to provide feedback on the appropriateness, accessibility, feasibility, and workload involved in referring to the THRIVE clinical pathway. During the consenting process, the research coordinator will obtain preferences for the best communication method to schedule the interview (eg, email or telephone call). A total of 22 interviews and surveys are planned. Participants who complete both the surveys and interviews will receive a US $90 gift card by mail.

Ethical Considerations

This study was approved by the University of Pennsylvania's Institutional Review Board (IRB #4 approved this protocol #852910 on March 10, 2023). The study will be conducted according to the Declaration of Helsinki and national regulations. Study participation is voluntary, and written consent will be obtained prior to clinician interviews. Our IRB approval includes a HIPAA (Health Insurance Portability and Accountability Act) waiver of informed consent for THRIVE participants' clinical data. All study data collected will be deidentified, pseudonyms will be used, and data will only be accessible to the research team and stored on password-protected computers. Clinicians will be compensated US $90 by gift card for interview participation. Individual participants will not be identifiable in any published material.

Data Collection and Management

THRIVE Participants and Usual Care Group

Characteristics of THRIVE participants captured in weekly case conferences (eg, home care services, social determinants of health identified and met, and community-based services) will be stored on a Research Electronic Data Capture (REDCap; developed by Vanderbilt University) database. Data will be derived from the patient electronic health record (EHR) and hospital billing system to compare the postdischarge outcomes of participants receiving THRIVE compared to those who do not. These data will be deidentified, and a HIPAA waiver of informed consent was obtained by the University of Pennsylvania's IRB. Data will be stored on a secure password-protected data server, and access will be provided to the study statisticians (MOH), who will be blinded to the assignment of the intervention. All aspects of study design, database integrity, and study conduct will be overseen by our data and evaluation core team, which includes doctorly prepared health service researchers and statisticians.

Clinicians and Administrators

Case managers at PAH will be recruited and enrolled in the study per the stepped wedge design. At 8 weeks and 18 months, we will survey clinicians via Qualtrics (Qualtrics) and convene one-on-one interviews (or focus groups depending on clinician availability). Interviews will be conducted in the setting of the clinician's choice, either in a conference room in the hospital or via Zoom (Zoom Video Communications). During interviews, clinicians and administrators will be asked for permission to audio record the interview. If the participant agrees, all conversations from that point forward will be recorded. If the clinician or administrator consents to the interview but does not agree to recording, to retain the participant, the interviewer will take detailed notes during the conversation instead of recording. Interview documents are labeled with a unique identification number stored separately for identifying information about the participant. The study timeline is outlined in a SPIRIT diagram (Figure 2).

Figure 2. SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) diagram—THRIVE schedule of evaluations. ED: emergency department; PCP: primary care provider.

			Study period

Sample Size

We anticipate a sample size of 534 inclusive of THRIVE referrals and the comparison group (derived from the EHR). Based on a power analysis, a sample size of 472 (236 THRIVE participants and 236 comparisons) for the outcome of readmissions, or a sample of 534 (267 THRIVE participants and 267 comparisons) for the outcome of ED visits, will yield 80% power to detect significance at the .05 level. We will target a sample size of 534 to ensure adequate power for both outcomes. We anticipate consenting 22 clinicians and administrators to complete surveys and interviews to provide data for implementation outcomes.

The THRIVE Intervention

Current Usual Care

To provide evidence of the effectiveness and implementation of THRIVE, we will compare individuals receiving THRIVE services to patients receiving usual care. The current usual care will serve as the control condition that patients will receive during the control phases of the design. Usual care may include discharge care planning that reflects the patient's medical needs, which may or may not include referrals to home care, skilled nursing or rehabilitation facilities, and other outpatient services.

Enrollment in THRIVE

Enrollment in THRIVE begins with identification by CMs during hospitalization using a validated predictive algorithm developed by our team [31]. The algorithm is housed in the EHR and leverages principles of behavioral economics to "nudge" CMs to initiate a THRIVE referral. The THRIVE EHR flag was introduced to alleviate the need for CMs to manually identify THRIVE participants.

Once identified, THRIVE participants will receive a home care referral to Penn Medicine at home care services. The initial home care visit will be scheduled and completed by a nurse within 48 hours of discharge, at which time, medications are reconciled, discharge orders are reviewed, and person-centered goals of care are set. During the initial evaluation, home care nurses will determine the frequency of visits deemed necessary, with weekly visits ranging from 1 to 3 times depending on needs. Participants may receive additional services, such as speech or occupational therapy as required. All THRIVE participants receive a social work referral, their psychosocial needs are further assessed, and connections to community resources are provided. THRIVE participants receive a CHW referral as deemed necessary.

As a part of the THRIVE pathway, physician colleagues will extend continuity of care into the home following discharge to

all THRIVE participants. Home care nurses will provide a brief patient status update to discharging physicians following the first home visit. During calls, nurses can raise questions about medications, clarify discharge orders, and receive guidance on emerging symptoms with the provider most recently involved with care. Extended supervision by discharging physicians will be provided for up to 30 days or until THRIVE participants have seen a primary care provider or specialist.

THRIVE participants will receive further support during discussions in our weekly interdisciplinary case management conferences for 4 weeks following discharge. During case management meetings, we will support connections to postacute primary, specialty care, behavioral health, and substance use services as needed. If a source of primary care is absent, we work to link THRIVE participants to community providers. Our intensive support addresses many of the social determinants of health that are known to influence health inequities such as housing, food insecurity, and limitations in access to behavioral health (Figure 1).

Implementation Strategies

We will use a series of implementation strategies to improve the effectiveness of THRIVE and promote its use [52]. These strategies will include (1) building and sustaining a coalition of diverse stakeholders through regular meetings and providing updates on THRIVE outcomes; (2) developing educational materials and conducting ongoing training of CMs, physicians, and advanced practice providers in the hospital and nurses and managers in home care using a scripted in-person training module to teach them about the elements of THRIVE and their role in implementing it; (3) auditing and providing feedback through the use of a referral dashboard to monitor all eligible THRIVE participants to document the individuals who were eligible for the intervention and not referred and providing feedback to case managers and document reasons for why referrals did not take place; (4) emailing reminders to case managers at weeks 2, 4, and 6; (5) identifying and preparing champions to promote the use of THRIVE; and (6) engaging of our advisory board to seek feedback for improvements.

Evaluation

Aim 1

Aim 1 is to examine referral patterns, 30-day readmission, and 30-day ED use patterns for participants who receive THRIVE support services compared to those receiving usual care.

Outcomes and Measures

The primary outcome includes the referral rate to home care made by CMs compared to baseline and the nonrandomized cluster. The secondary outcomes are 30-day readmissions and ED visits. Additional covariate data at the patient (eg, demographics and comorbidities) and unit levels (eg, type of unit and discharging team or provider) will be collected from analyses. For THRIVE participants, these outcomes will be assessed from the date of hospitalization, which resulted in a referral to THRIVE. For the usual care group, we will identify all readmissions and ED visits occurring after the first index hospitalization identified in the EHR for the calendar year of the study. Outcome measures, guiding framework, data sources, collection, and timing are described in Table 3.

Table 3. Summary of outcomes, measures, data sources, collection method, and timing.

Construct and framework	Design	Method of collection	Timing
Aim 1: Examine referral patterns, 30-day readmission, and ED[a] use patterns for participants who receive THRIVE support services compared to those receiving usual care			
• THRIVE referrals[b] • 30-day readmissions[c] • 30-day ED visits[c] • Primary care visit within 30 days of discharge[c] • Specialty care visit within 30 days of discharge[c]	Stepped wedge cluster randomized controlled trial	Electronic health record	Baseline and at the study end
Aim 2: Evaluate the implementation of the THRIVE clinical pathway, including fidelity, feasibility, appropriateness, and acceptability			
Health Equity Implementation Framework (HEIF)			
• Culturally relevant factors[d] • Clinical encounter[e] • Societal context[f]	Mixed methods approach to determine if HEIF factors are associated with uneven or disparate benefits to the intervention and to assess the implementation of THRIVE at a new site	Interviews with clinicians and administrators involved with THRIVE	8-week postintervention from the start of each sequence and at the study end
Exploration, Preparation, Implementation, Sustainment			
• Adoption[g] • Active implementation[h]	Mixed methods approach to determine the adoption and implementation of THRIVE in a new site	Interviews with clinicians and administrators	8-week postintervention from the start of each sequence and at the study end
Proctor implementation outcomes			
• Acceptability[i] • Appropriateness[j] • Feasibility[k]	Mixed methods approach to determine the Proctor implementation outcomes	Survey and interviews with clinicians and administrators	8-week postintervention from the start of each sequence and at the study end
• Fidelity[l]	Retrospective chart review	Standardized THRIVE checklist	Monthly

[a]ED: emergency department.

[b]Proportion of THRIVE referrals of those who are THRIVE eligible.

[c]Proportion of THRIVE participants experiencing the outcome within 30 days of discharge compared to usual care group.

[d]Organizational commitment to addressing disparities.

[e]Relative advantage of THRIVE to patients, degree of fit with existing practice, competing demands, and bias.

[f]Structures outside of the hospital that affect patient care.

[g]Organizational values, culture embedding, and championing adaption.

[h]Organizational priorities and goals and readiness for change and culture or climate.

[i]How fair or reasonable THRIVE is deemed.

[j]To what extent THRIVE seems suitable.

[k]The practicality and ease of delivering THRIVE.

[l]Fidelity to THRIVE's core components.

Analysis

We will develop monthly reports to monitor the referral patterns to the THRIVE clinical pathway. The target estimate and effect measure is the time-adjusted difference in participant outcomes [53,54]. The analysis of use outcomes (eg, 30-day readmissions and ED use) will use a mixed effects negative binomial regression model with random effects for the medical team and fixed effects for time to account for the stepped wedge cluster randomized design. Sensitivity analyses may be performed using logistic regression for health service use based on the distribution of the data. We will also examine the stability of effect estimates using generalized estimation equations with small sample adjustment, given the study design [55].

Equity Evaluation

Our analyses will consider several equity metrics and include interaction terms to capture racial and ethnic differences and biological sex for THRIVE participants compared to patients receiving usual care. Using all payor data obtained from the EHR, we will also conduct a secondary analysis to examine health service use across all insurance payor types for THRIVE participants and the usual care group, allowing a proxy measurement for differences across socioeconomic strata.

Aim 2

Aim 2 is to evaluate the implementation of the THRIVE clinical pathway, including fidelity, feasibility, appropriateness, and acceptability.

Outcomes and Measures

Fidelity will be assessed using a standardized checklist and monthly report. Surveys and interviews of clinicians and administrators involved with THRIVE will be used to assess the secondary implementation outcomes of interest. These outcomes will be measured twice (at 8 weeks from the start of each sequence and at the end of the study). The surveys will use validated instruments that measure (1) feasibility, practicality, and ease of delivering THRIVE; (2) acceptability, how fair or reasonable THRIVE is deemed; (3) appropriateness, to what extent THRIVE seems suitable; and (4) clinician workload, an objective assessment of the demand of the THRIVE clinical pathway on clinician time. Clinician interviews will assess the determinants of THRIVE implementation using the HEIF [44,45]. Demographics of clinicians and administrators will also be collected.

Analysis

Summary statistics will be produced from the quantitative measures of feasibility, acceptability, appropriateness, and clinician workload. All interview data will be analyzed using constant comparative analysis to examine data across cases. Initially, we will use an iterative process of close readings and discussion of a random sample of interview transcripts and will analyze patterns in the recurrence and distribution of emergent concepts across participants. The principal investigator and research coordinator staff will then create a data dictionary and apply codes for themes that emerge while reading what the respondents say. The HEIF will inform the development of the codebook, including definitions and subsequent integration of the qualitative and quantitative data [47]. The integration of the qualitative data will help to extend and expand the findings of the quantitative findings. We will use NVivo (version 12; Lumivero) to manage our data.

Dissemination

Our team will lead several efforts to promote the dissemination and translation of our findings. First, results will be shared widely through publications, conference presentations, policy briefs, and well-established channels via the Penn School of Nursing Communication Office and the Center for Health Outcomes & Policy Research's national and international networks. Examples of print and public engagements will include up to 5 publications (at minimum 1-2 papers per aim), annual scientific presentations or conferences, infographics, and guest features on podcasts (eg, AmplifyNursing). We have built a customized THRIVE website with plans to share open-access modules on the components of THRIVE and the process for implementation. We will engage with our THRIVE Community Advisory Board to develop equity-focused dissemination efforts that are system and community focused. For example, we have previously participated in health fairs at local churches. We anticipate that the focus of this project will be of equal interest to other faith-based and community organizations and look forward to collaborating throughout the study period, not just at the end.

Results

This project was funded in January 2023. We received IRB approval on March 10, 2023. Data collection will occur from March 2023 to July 2024. Results are expected to be published in 2025.

Discussion

Expected Findings

We anticipate that patients who participate in the THRIVE clinical pathway will experience fewer 30-day readmissions and ED visits as well as more connections to primary and specialty care compared to usual care. We also expect that clinicians will value and appreciate the additional supports provided to patients with an increased burden of health-related social needs.

Comparisons With Prior Work

Most current transitional care programs were not developed to meet the needs of people insured by Medicaid and require additional personnel to implement them [10-12]. Several clinical trials of transitional care programs have resulted in mixed findings, with some noting decreased rehospitalization, while others have found no reductions in 30-day readmissions or ED use [12-17]. Similarly, other transitional care models have incorporated interventions including weekly health coaching and self-management education, though findings are inconsistent [18-20].

Strengths and Limitations

The main strength of this study is the use of a stepped wedge approach. In this design, after all of the case managers have "stepped in" to refer to THRIVE, all eligible patients will be able to receive THRIVE services. A limitation of this study is that it is a single-institution trial. However, we believe this study will yield important findings, given the rigor of the design and the focus on embedding equity-based principles throughout our implementation.

Conclusions

The goal of THRIVE is to reduce disparities and improve postdischarge care transitions for Medicaid-insured patients through a feasible system-level intervention that is satisfying for THRIVE participants, clinicians, and their teams in hospitals and home care settings. By using our equity-focused case management services and leveraging the power of the electronic medical record, THRIVE creates efficiencies by identifying high-need patients, improving communication across acute and community-based sectors, and driving evidence-based care coordination. This study will advance the field of equity-focused evidence-based interventions by testing both the effectiveness of patients' health improvement and the adoption of THRIVE by typical clinical practices. It will add important findings about how the infusion of equity-focused principles in the design and

evaluation contributes to both implementation and effectiveness outcomes.

Acknowledgments

Funding for this project was provided by the Rita and Alex Hillman Foundation (A-3004, to JMBC, principal investigator) and the Center for Health Outcomes & Policy Research (CHOPR) and Office of Nursing Research (ONR), University of Pennsylvania School of Nursing and the National Institutes of Nursing Research T32-NR-007104 (PI McHugh). There are no awards or grant numbers for CHOPR and ONR funding sources.

Data Availability

The data that will support the findings of this study is available from the Penn Data Store and the electronic medical record and is not publicly available.

Authors' Contributions

JMBC, HB, MG-M, JB, DM, DG, KA, and MR contributed to the conceptualization and drafting of the paper. MOH, KS, AM, EF, and RC contributed to the data curation and analytic plan. All authors contributed to the editing of this paper and read and gave the final approval.

Conflicts of Interest

MOH received statistical consulting fees from Unlearn.AI and fees for editorial services from Elsevier and the American Thoracic Society, all for work unrelated to this project. JMBC, HB, MG-M, KS, AM, MR, DM, DG, JB, EF, KA, and RC have no competing interests to declare.

Abstract

Background: Acute severe asthma (ASA) is a leading cause of hospital attendance in children. Standard first-line therapy consists of high-dose inhaled bronchodilators plus oral corticosteroids. Treatment for children who fail to respond to first-line therapy is problematic: the use of intravenous agents is inconsistent, and side effects are frequent. High-flow humidified oxygen (HiFlo) is widely used in respiratory conditions and is increasingly being used in ASA, but with little evidence for its effectiveness. A well-designed, adequately powered randomized controlled trial (RCT) of HiFlo therapy in ASA is urgently needed, and feasibility data are required to plan such an RCT. In this study, we describe the protocol for a feasibility study designed to fill this knowledge gap.

Objective: This study aims to establish whether a full RCT of early HiFlo therapy in children with ASA can be conducted successfully and safely, to establish whether recruitment using deferred consent is practicable, and to define appropriate outcome measures and sample sizes for a definitive RCT. The underlying hypothesis is that early HiFlo therapy in ASA will reduce the need for more invasive treatments, allow faster recovery and discharge from hospital, and in both these ways reduce distress to children and their families.

Methods: We conducted a feasibility RCT with deferred consent to assess the use of early HiFlo therapy in children aged 2 to 11 years with acute severe wheeze not responding to burst therapy (ie, high-dose inhaled salbutamol with or without ipratropium). Children with a Preschool Respiratory Assessment Measure score ≥5 after burst therapy were randomized to commence HiFlo therapy or follow standard care. The candidate primary outcomes assessed were treatment failure requiring escalation and time to meet hospital discharge criteria. Patient and parent experiences were also assessed using questionnaires and telephone interviews.

Results: The trial was opened to recruitment in February 2020 but was paused for 15 months owing to the COVID-19 pandemic. The trial was reopened at the lead site in July 2021 and opened at the other 3 sites from August to December 2022. Recruitment was completed in June 2023.

Conclusions: This feasibility RCT of early HiFlo therapy in children with ASA recruited to the target despite major disturbances owing to the COVID-19 pandemic. The data are currently being analyzed and will be published separately.

Introduction

Background

Asthma is a common chronic disorder of reversible airway obstruction characterized by bronchial smooth muscle contraction, airway inflammation, and increased airway secretion [1]. It is the most common noncommunicable disease in childhood, affecting 1 in 10 children worldwide [2] and causing >1000 deaths per day [3]. Children with asthma are prone to episodes of acute severe airway obstruction, characterized by wheezing and increased work of breathing, and often require hospital treatment. Acute severe asthma (ASA) is a leading cause of hospital attendance in children, accounting for up to 7% of all pediatric emergency visits [4] and 8.5% of pediatric admissions from emergency departments (EDs) [5], the most common single cause. Many preschool children who have not yet been diagnosed with asthma are admitted to the hospital with episodes of acute severe wheezing. They present identically and are treated in the same way as older children diagnosed with asthma, although they can be less responsive to therapy [6]. In this paper, the term ASA is used to describe children presenting with acute wheezing and breathing difficulty, whether they have an established diagnosis of asthma.

Therapy for ASA is directed at (1) relieving bronchoconstriction with bronchodilators, (2) decreasing airway inflammation with corticosteroids, and (3) clearing airway secretions so that they do not become thick and block the airways. Standard first-line emergency treatment [7] for ASA in children starts with burst therapy in the first hour (3 doses of high-dose inhaled salbutamol, sometimes with inhaled ipratropium, via a spacer device or nebulizer) and oral corticosteroids. During the next 1 to 4 hours, many children improve clinically and may be discharged. However, some children fail to respond to standard therapy and require hospital admission for more intensive, second-line treatment; without effective treatment, these children are at risk of fatigue, respiratory failure, and death [8]. Second-line treatment commonly includes intravenous bronchodilators (≥1 of aminophylline, salbutamol, and magnesium sulfate). However, evidence for the efficacy of such treatments is limited and inconsistent, with frequent side effects, including tachycardia, jitteriness, tremor, palpitations, nausea, vomiting, elevated lactate level, and hypokalemia [7], which can cause considerable distress to the child and family. Current guidelines [7,9] provide little guidance (because of the scarcity of evidence) regarding which second-line treatment clinicians should use. Therefore, there is a need to investigate other options for treating ASA to improve the effectiveness of the treatment and reduce adverse effects.

High-flow humidified oxygen (HiFlo) therapy is an innovative health care technology that supports breathing by supplying a warm, humidified mixture of air and oxygen at high-flow rates via fine nasal cannulae that has shown promising results in other acute respiratory conditions in children [10]. Traditional oxygen therapy uses cold, unhumidified oxygen directly from a cylinder or a wall outlet. Although this is helpful in improving oxygenation, it is uncomfortable for patients and causes drying and cooling of the nose and mouth, and potentially of the lower airways, which can cause worsening of airway obstruction and even airway damage. Therefore, unmodified oxygen therapy can only be delivered at very low flow rates. Using HiFlo technology, the air or oxygen percentage mix can be varied; it is warmed to body temperature and delivered at 100% humidity. As a result, much higher flows can be delivered without discomfort or adverse effects on the airways.

There is now considerable experience with the use of this technology in both adults and children [10]. Most of the clinical experience and evidence for the efficacy of HiFlo therapy in children is derived from studies performed in preterm neonates with surfactant deficiency. In this population, HiFlo therapy appears to be as effective as continuous positive airway pressure (CPAP) therapy and has become a standard therapy [11]. The physiological basis of its effectiveness is unclear [10,12]: HiFlo therapy itself may generate CPAP [13,14], but it may also reduce nasopharyngeal dead space, reduce upper airway resistance, and reduce the metabolic demand required to humidify inspired gases [15]. In recent years, there has been increased use of HiFlo

therapy in infants with acute bronchiolitis [16]. Retrospective studies have suggested that introducing HiFlo therapy for acute bronchiolitis is associated with a reduced need for intubation [17,18]. Prospective trials comparing HiFlo with standard bronchiolitis therapy (low-flow 100% oxygen) have shown improved oxygen saturation levels [19], fewer treatment failures [20,21], and a nonsignificant trend toward faster weaning from oxygen [20]. A Cochrane systematic review concluded that HiFlo therapy is feasible and well-tolerated in infants with bronchiolitis but that further evidence for its effectiveness is needed [22].

To date, there have been no substantial randomized controlled trials (RCTs) of HiFlo therapy in children with ASA, although its use in ASA has been rapidly increasing [23]. The pathophysiology of ASA is very different from that of bronchiolitis. Bronchiolitis is characterized by more mechanical distal airway obstruction [22], whereas in ASA, bronchial smooth muscle constriction plays a major role [1,6]. Retrospective observational studies of HiFlo therapy in children with ASA have suggested improvements in physiological parameters and asthma severity scores [24,25] but have also raised concerns that using HiFlo therapy may delay the initiation of other forms of respiratory support [26]. There have been 2 small single-center pilot RCTs on HiFlo therapy in children with acute asthma. Ballestero et al [27] randomized 62 children with ASA with acute respiratory failure to HiFlo therapy versus conventional oxygen therapy. The asthma score of a higher proportion of children on HiFlo therapy reduced (*pulmonary score*—unreferenced) by 2 points in the first 2 hours of treatment; however, there was no difference in the need for admission or length of hospital stay. Gauto Benítez et al [28] randomized 65 children in a single center in Paraguay to HiFlo therapy or conventional oxygen therapy: the inclusion criteria were somewhat unclear, and both groups received continuous intravenous magnesium in addition to inhaled bronchodilators as a standard practice in this institution. They found no difference in the proportion reducing their asthma score (*pulmonary index score*—again unreferenced) by 2 points or in the length of hospital stay. A recent review of HiFlo in children with ASA by Chao et al [23] concluded that "large well-designed randomized controlled trials assessing the clinical efficacy of high-flow nasal cannula oxygen for children with asthma exacerbation are urgently warranted." The evidence from published studies is encouraging but mixed and is lacking in clinical outcomes. It does not provide the feasibility information required to plan an RCT on the clinical effectiveness of early HiFlo therapy in childhood ASA.

In summary, ASA in childhood is a common emergency condition with important impacts on health care costs and quality of life and presents a risk to life. HiFlo is a novel therapy that has the potential to treat patients with ASA more effectively and reduce hospital stays and intensive care admissions. However, its use is becoming widespread in clinical practice despite a lack of good evidence. If HiFlo therapy in patients with ASA is not evaluated objectively, there is a risk that a treatment without proven benefits (but with significant costs) may drift into widespread practice. Therefore, there is an urgent need for a well-designed, adequately powered RCT of HiFlo therapy in patients with ASA. To plan such an RCT, feasibility data are required. A definitive RCT would be large and expensive to run, and it is unclear whether it would be feasible, how large it would need to be, and what are the most appropriate outcome measures. This paper presents the protocol of a feasibility study designed to fill this knowledge gap, which has been successfully executed in 4 children's hospitals in the United Kingdom. The formal results will be published separately.

Study Aim and Feasibility Objectives

This feasibility study aimed to establish whether a full RCT of early HiFlo therapy in children with ASA can be conducted successfully and safely and whether recruitment to such a trial, using deferred consent, is practicable in children aged 2 to 11 years presenting to the hospital with ASA. The underlying hypothesis is that early HiFlo therapy in children with ASA will reduce the need for more invasive treatments, allow faster recovery and discharge from hospital and, in both these ways, reduce distress to children and their families. The trial was designed to generate the data required to plan a definitive RCT that would satisfy the clinical and health economic end points and the requirements of children, parents, clinicians, and health services.

Methods

Primary Feasibility Objectives and Outcome Measures

A total of 6 feasibility objectives and associated outcome measures (Table 1) were established to help determine the feasibility of progressing to a full RCT, which would require the following 4 conditions to be met:

1. At least 50% enrollment rate among eligible children (feasibility outcome 1)
2. At least 70% deferred consent rate [29] (feasibility outcome 2)
3. At least 80% of data collection is complete per participant for candidate primary outcome measures (feasibility outcome 3)
4. Confirmation that the predicted sample size, number of centers, and recruitment rates would allow an appropriately powered RCT to be conducted in the United Kingdom for 3 years (feasibility outcome 5)

Discussions with colleagues indicated that at least 15 large UK pediatric centers would be interested in participating in a definitive RCT on this question. The study has been discussed with two relevant research networks: (1) the UK National Institute for Health and Care Research (NIHR) Children Respiratory and Cystic Fibrosis Clinical Studies Group and (2) Pediatric Emergency Research in the United Kingdom and Ireland [30], a network of research-active pediatric emergency care clinicians who have indicated that they will facilitate the process of identifying appropriate centers for the definitive study.

The 2 candidate primary outcome measures recorded and evaluated are provided in Textbox 1.

Table 1. Primary feasibility objectives and outcome measures.

Feasibility objectives	Feasibility outcome measures	Time point of evaluation
To evaluate enrollment rates	Proportion of enrolled (ie, randomized) children among eligible patients with ASA[a]	Enrollment
To evaluate deferred consent rates	Proportion of children with signed deferred consent among those enrolled into the study	Deferred consent
To assess feasibility of recording candidate primary outcome measures	Proportion of data collection completed per participant for the 2 candidate primary outcome measures	Discharge
To estimate the variability of candidate primary outcome measures	Summary statistics for the 2 candidate primary outcome measures	Discharge
To determine design characteristics for a subsequent definitive study	Proposed design, sample size, and number of centers for a definitive study	End of study
To assess the acceptability of HiFlo[b] therapy and the deferred consent model to children, parents, and staff	Satisfaction ratings on the end-of-study questionnaire	Discharge

[a]ASA: acute severe asthma.

[b]HiFlo: high-flow humidified oxygen.

Textbox 1. Candidate primary outcome measures.

- Treatment failure needing escalation of therapy as defined in the *Treatment Failure and Escalation* section.
- The time (h) between presentation to the emergency department and meeting hospital discharge criteria as defined by the following criteria:
  - The ability of the child to maintain arterial oxygen saturation (SpO_2) measured by pulse oximeter at ≥92% without supplemental oxygen or respiratory support for a 4-hour period
  - The ability of the child to remain clinically stable for a minimum of 4 hours between inhaled bronchodilator doses
  - The ability to maintain these conditions continuously until hospital discharge

Treatment Failure and Escalation

Textbox 2 lists the criteria recorded for treatment failure needing escalation in therapy.

Escalations in therapy for the primary analysis are described in Textbox 3. Pragmatically, senior clinicians on duty managing these patients had the discretion to escalate treatment if deemed clinically appropriate and justified but were asked to clearly state the reason for escalation using the abovementioned criteria. The order in which escalations are listed in Textbox 3 does not imply that they needed to be implemented in that order. The clinicians were free, for example, to implement HiFlo therapy in the standard care group before administering the second or third intravenous agent.

For the primary analysis, administering a first intravenous agent is not categorized as *treatment failure requiring escalation* in the standard care group because starting an intravenous agent would be the standard following step in a child who fails burst therapy. However, it was possible that some children randomized to the standard care group may not have received an intravenous agent directly.

Furthermore, it was useful to examine whether commencing early HiFlo therapy has an effect on the total burden of invasive treatments required. Therefore, a secondary analysis, in which escalations of therapy are defined as in Textbox 4, was carried out.

The candidate secondary outcome measures are provided in Textbox 5.

Textbox 2. Criteria for treatment failure needing escalation in therapy.

- Preschool Respiratory Assessment Measure (PRAM) score [31] rising or not falling
- Respiratory rate rising or not falling
- Heart rate rising or not falling
- Rising oxygen requirement
- Rising partial pressure of carbon dioxide (pCO_2) in capillary, venous, or arterial blood
- Other clinical concerns (specified)

Textbox 3. Escalations in therapy for primary analysis.

High-flow humidified oxygen (HiFlo) group

- Commencing intravenous bronchodilator therapy
- Commencing the second or third intravenous agent
- Re-escalating inhaled bronchodilator therapy to an hourly or more frequent dosage
- Commencing noninvasive ventilation with bilevel positive airway pressure (BiPAP) ventilation
- Intubation for invasive ventilation

Standard care group

- Commencing HiFlo therapy
- Commencing the second or third intravenous agent
- Re-escalating inhaled bronchodilator therapy to an hourly or more frequent dosage
- Commencing noninvasive ventilation with BiPAP ventilation
- Intubation for invasive ventilation

Textbox 4. Escalations in therapy for secondary analysis.

High-flow humidified oxygen (HiFlo) group

- Commencing administration of the first, second, or third intravenous agent
- Re-escalating inhaled bronchodilator therapy to an hourly or more frequent dosage
- Commencing noninvasive ventilation with bilevel positive airway pressure (BiPAP) ventilation
- Intubation for invasive ventilation

Standard care group

- Commencing administration of the first, second, or third intravenous agent
- Commencing HiFlo therapy
- Re-escalating inhaled bronchodilator therapy to an hourly or more frequent dosage
- Commencing noninvasive ventilation with BiPAP ventilation
- Intubation for invasive ventilation

Textbox 5. Candidate secondary outcome measures.

- Time (h) between presentation to the emergency department (ED) and the actual hospital discharge
- Time (h) between presentation to the ED and achieving a Preschool Respiratory Assessment Measure (PRAM) [31] score of ≤3
- Time (h) between presentation to the ED and the ability to maintain oxygen saturation (SpO_2) at ≥92% without supplemental oxygen or respiratory support
- Need for intravenous bronchodilator therapy
- Duration of intravenous bronchodilator therapy
- Requirement for noninvasive ventilation
- Requirement for invasive ventilation (intubation)
- Treatment-related adverse effects:
  - Intravenous or inhaled bronchodilator–related side effects (eg, vomiting, tachycardia, and lactic acidosis)
  - Poor compliance with HiFlo therapy
- Hospital readmission within 48 hours of discharge
- Acceptability and comfort scores for treatment during the episode (recorded using the end-of-study questionnaire and qualitative interview following the episode). These measures were codeveloped with the Lived Experience Advisory Panel before the trial commenced.

Study Design and Setting

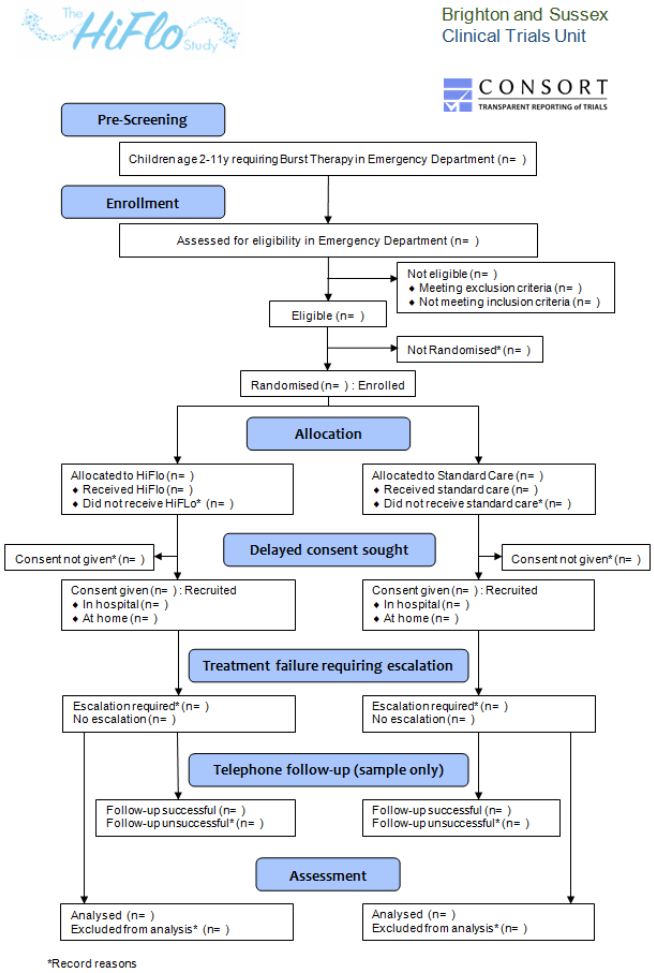
This was a multicenter feasibility RCT of 50 children in the following 4 National Health Service (NHS) Trusts in England:

- The University Hospitals Sussex (UHSx) NHS Foundation Trust, Royal Alexandra Children's Hospital, Brighton
- The King's College Hospital NHS Foundation Trust, London
- The University Hospital Southampton NHS Foundation Trust, Southampton
- The University Hospitals of Leicester NHS Trust, Leicester Royal Infirmary, Leicester

Eligible children were randomized to the intervention (HiFlo therapy) or control (standard care) arms, as shown in the CONSORT (Consolidated Standards of Reporting Trials) diagram (Figure 1). Screening, recruitment, and randomization were performed in the relevant EDs of the participating hospitals. Randomization was stratified by site, age (<5 years and ≥5 years), and severity of acute asthma (the Preschool Respiratory Assessment Measure [PRAM] score at study entry: <8 and ≥8, refer to the *PRAM Scoring* section), with an equal ratio between both arms.

The study was pragmatic, with HiFlo therapy being an add-on to the existing therapy in those randomized to the intervention arm, and was clearly not blinded as this would have been impossible. The children were not denied access to the existing standard second-line interventions (eg, intravenous bronchodilators) because they participated in the study. The treating clinical team was allowed to initiate intravenous bronchodilators as clinically indicated in either treatment arm. In children randomized to the intervention arm, HiFlo therapy was commenced as soon as possible after randomization as the subsequent treatment was initiated rather than intravenous bronchodilators. As the existing treatment guidelines [7,9] make no specific recommendations and because the choice of intravenous bronchodilators is physician dependent across the 4 institutions, the study protocol was physician led and did not specify which intravenous bronchodilator is initiated first. Similarly, if a child randomized to the standard care arm was failing to respond, as defined by the preset criteria, the clinical team could opt to initiate HiFlo as rescue therapy—the child remained in the study on an intention-to-treat basis. The reasons for discontinuing the intervention prematurely or for other protocol violations were recorded.

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) diagram of the study. HiFlo: high-flow humidified oxygen.



Sample Size and Planned Recruitment Rate

The size of the study was determined by the number of children required to provide an accurate estimate of the variability in the candidate primary outcome measures: recommendations for this vary between 50 [32] and 70 [33]. The larger number was chosen to allow 30% attrition to deferred consent [29]. Therefore, the study originally aimed to recruit 70 children aged

<18 months. The recruitment target was subsequently lowered to 48 after an agreement with the NIHR Clinical Research Network that this number was sufficient to meet the objectives of the feasibility RCT. Initially, the recruitment was planned to be from 3 collaborating centers; the fourth site (Leicester) was subsequently added. The subsequent definitive RCT will determine whether HiFlo therapy is an effective intervention for children with ASA.

Participants and Eligibility Criteria

Children aged 2 to 11 years were eligible if they presented to the ED with ASA and failed to respond to standard first-line therapy (high-dose inhaled bronchodilators) based on the eligibility criteria listed in Textbox 6.

The PRAM was chosen because it has been validated across the age range of intended participants [31] and has been shown to be a good predictor of the need for admission and escalation of therapy [35]. A child with a PRAM score of 5 would typically have moderately increased work of breathing, audible wheeze, and oxygen saturation <92% but >90%. The threshold of PRAM score ≥5 was selected based on the advice of the team that designed PRAM (Professor Francine Ducharme, MD, personal communication, April 2019) and because this threshold had been successfully used as an entry criterion in a previous trial of administering nebulized magnesium to patients with acute asthma [36].

Textbox 6. Inclusion and exclusion criteria.

Inclusion criteria

- Participants having an acceptable individual capable of giving consent on their behalf (eg, parent or guardian of a child aged <16 years)
- Participants aged 2 to 11 years
- ASA, defined as respiratory distress combined with wheezing on auscultation (a formal preceding diagnosis of asthma was not necessary)
- Failure to respond to standard initial emergency management [7] with burst therapy (back-to-back 3 consecutive inhaled or nebulized doses of salbutamol with or without the addition of ipratropium bromide for a 1-h period) and systemic corticosteroids, with or without subsequent intravenous bronchodilator therapy as deemed appropriate by the treating physician. Failure to respond will be defined as a Preschool Respiratory Assessment Measure (PRAM) score of ≥5 between 1 hour and 4 hours after starting burst therapy.

Exclusion criteria

- Clinical or radiological evidence of bacterial pneumonia: fever >38.5°C and focal signs on auscultation or chest x-ray
- Signs of impending respiratory failure mandating immediate intubation. These were at the discretion of the treating clinical team but included elevated pCO_2, refractory hypoxemia, and exhaustion
- Contraindications to the use of HiFlo therapy are as follows:
  - Air leak (eg, pneumothorax, pneumomediastinum, or subcutaneous emphysema)
  - Decreased level of consciousness—AVPU (Alert, Voice, Pain, Unresponsive) score [34] P or worse
  - Recent (within 6 wk) bowel surgery
  - Intractable vomiting
- Other major respiratory, cardiovascular, or neurological condition
- Previous participation in the HiFlo ASA study during a prior hospital episode

Study Procedures

This section summarizes the procedures and evaluations conducted to support the feasibility objectives. The timing of the procedures in relation to the established study visits is given in Table 2. A detailed description of each procedure is provided in Section 6 of the study protocol in Multimedia Appendix 1 [1,4-8,10,11,13-15,17-24,27,29,31-33,37-49].

[a]PRAM: Preschool Respiratory Assessment Measure.

[b]HiFlo: high-flow humidified oxygen.

[c]CRF: Case Report Form.

Screening

All children arriving at the participating EDs were routinely triaged by an experienced nurse and reviewed clinically during and after completing burst therapy. Children potentially eligible for the study were identified and actively screened for inclusion by ED clinical staff or research nurses according to their local capacity. Screening information included Trust ID number, age, and reasons for not being eligible for trial participation or if they were eligible but declined participation.

Enrollment and Randomization

The children who met all inclusion criteria and had no exclusion criteria were enrolled in the study and randomized to the intervention (early HiFlo therapy) or control (conventional therapy) arms only after the confirmation of eligibility by a treating clinician delegated to conduct this task. Randomization occurred at enrollment and before consent, as explained in the *Deferred Consent and Recruitment* section; it was implemented using the *Sealed Envelope* (Sealed Envelope Ltd) web-based randomization software [50] and conducted by a member of the research team trained in the study.

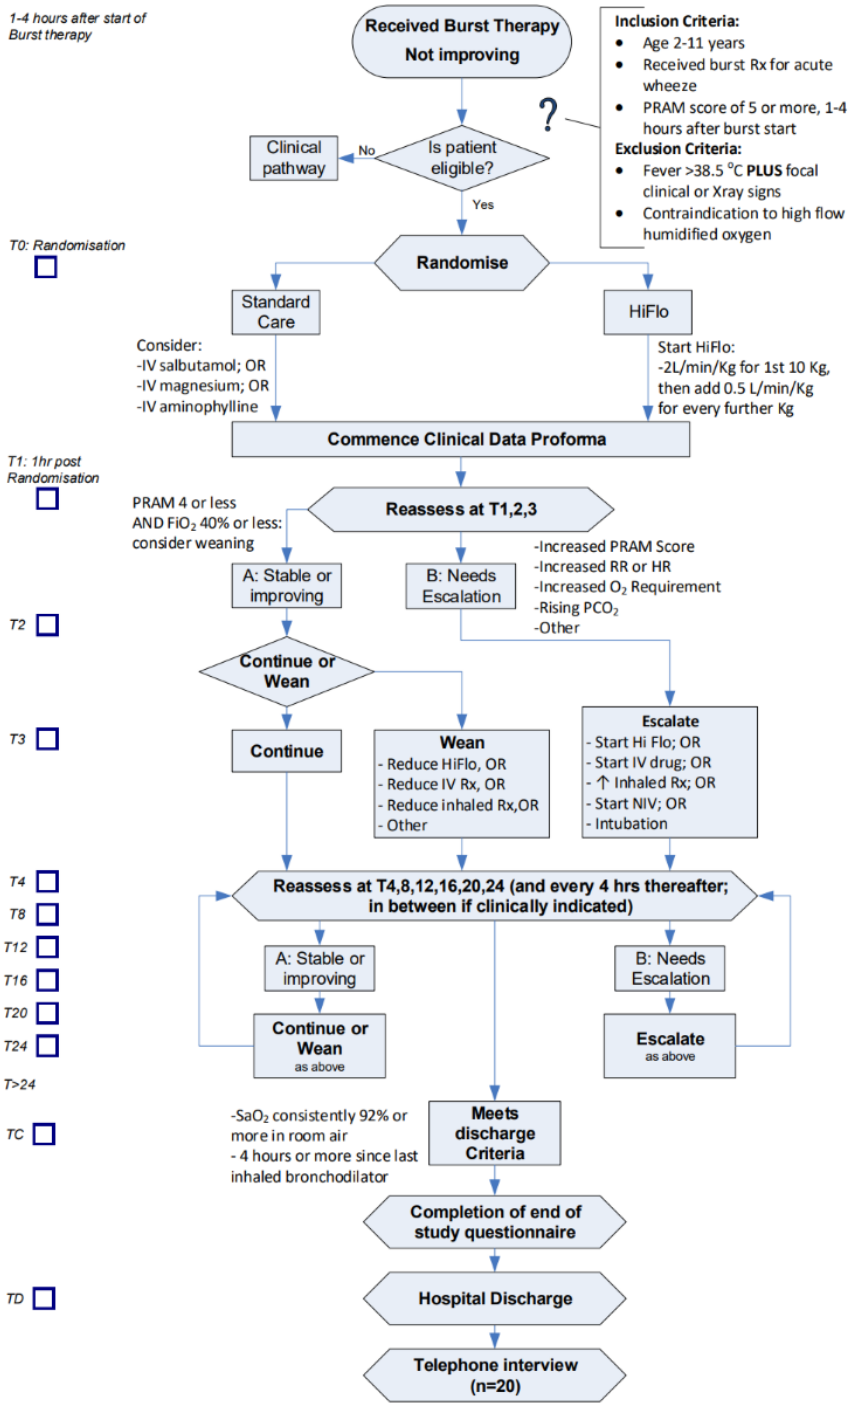
Treatment

The intervention was an add-on to standard care. The key difference between the groups in the 2 arms was the early use of HiFlo therapy, that is, starting HiFlo therapy as the next measure after the failure of burst therapy, and it is this strategy which was examined.

HiFlo Intervention

The use of HiFlo therapy in the study followed established practices and was standardized as far as possible while allowing for clinical judgment (Figure 2). The reasons for escalating and reducing treatment were recorded, and these data will help in defining treatment escalation and weaning pathways for the definitive RCT. The HiFlo therapy was commenced at a flow rate of 2 L/kg/min for the first 10 kg of body weight, with an additional flow rate of 0.5 L/kg/min for every kilogram of body weight >10 kg to a maximum absolute flow rate of 40 L/min, and fraction of inspired oxygen (FiO_2) was adjusted appropriately to maintain oxygen saturation ≥92%. At the discretion of the treating clinician, the flow could be increased to 3 L/kg/min but again with a maximum absolute flow rate of 40 L/min.

Figure 2. Flowchart of the study. FiO_2: fraction of inspired oxygen; HiFlo: high-flow humidified oxygen; HR: heart rate; IV: intravenous; NIV: noninvasive ventilation; O_2: oxygen; pCO_2: partial pressure of carbon dioxide; PRAM: Preschool Respiratory Assessment Measure; RR: respiratory rate; SaO_2: arterial oxygen saturation.



Equipment

Vapotherm, a manufacturer of portable and fixed HiFlo equipment, provided sufficient Precision Flow Plus units and consumables to make the early HiFlo intervention available free of cost in the 4 participating hospitals for the duration of the study.

Aerogen provided in-line Aerogen solo nebulizers and controller units to be used with all Vapotherm systems during the study.

HiFlo Therapy Training

HiFlo therapy was already in use in high-dependency units (HDUs, EDs) in all participating hospitals, and further staff training was undertaken in the setup period before the start of the study. HiFlo hands-on sessions were organized for staff from the EDs, HDUs, and relevant or equivalent clinical wards of participating centers by the UK Vapotherm representative Solus Medical Limited, with the aim of having at least 1 member of staff fully trained per shift. Local nursing and clinical staff members were trained as *super users* to support with

opportunistic training, retraining, and on-site competency checks.

Weaning From HiFlo

Weaning commenced once the child was clinically stable, according to the standard criteria agreed upon across the 4 centers. The weaning strategy was not rigidly protocolized but broadly followed the schema published in the protocol for the FIRST-ABC (FIRST-line support for assistance in breathing in children) study by Richards-Belle et al [51]. Essentially, the reduction in FiO_2 occurred first, and then the flow rate was reduced in a stepwise manner once FiO_2 was consistently ≤40% (Figure 2).

Deferred Consent and Recruitment

A deferred consent model was used to avoid delay in treatment and minimize distress to families who presented to the ED with acutely unwell children. The consent process is summarized in this section (complete details are provided in section 6.4 of the study protocol in Multimedia Appendix 1).

Informed consent was not sought before randomization, but the parents were approached for informed consent within a maximum of 72 hours of randomization once their child's condition was stable. The parents were approached for informed consent by trained staff from the direct care team, who explained the study and provided information sheets to the parents and children (if age appropriate). The parents were given time to read and understand the information and the opportunity to clarify any questions regarding the study and their child's participation. Written informed consent was obtained from all the parents.

If a child was discharged from hospital before parents could be approached for deferred consent, they were contacted by a trained research nurse who explained the study via phone. Written participant information and consent forms were then sent out by post. This model was successfully used, for example, in the Emergency treatment with levetiracetam or phenytoin in status epilepticus in children (EcLIPSE) study by Lyttle et al [52], and feedback from parents was positive [37]. There was a possibility for parents to provide verbal consent via phone in special circumstances. A special process for the sensitive case of having to approach bereaved parents for consent was designed.

If neither written nor verbal consent was received, the child was not recruited into the study, and the data collected were not included in the study analysis.

Hospital Discharge

Hospital Discharge Criteria

It was recognized that the timing of discharge from hospital is affected by multiple factors in addition to the child's medical condition; therefore, criteria of fitness for discharge were defined as a more robust and reproducible candidate primary outcome measure in addition to actual hospital discharge, which was used as a candidate secondary outcome measure. Hospital discharge criteria are defined in Textbox 7.

Textbox 7. Hospital discharge criteria.

- The ability of the child to maintain arterial oxygen saturation (SpO_2) measured by pulse oximeter at ≥92% without supplemental oxygen or respiratory support for a 4-hour period
- The ability of the child to remain clinically stable for a minimum of 4 hours between inhaled bronchodilator doses
- Maintaining these conditions continuously until hospital discharge

End-of-Study Questionnaire

The study included a patient satisfaction questionnaire, tailored to children with acute severe wheezing, for all parents and their children to be collected at the time of hospital discharge.

Although validated measures of satisfaction existed within the ED setting, these were not tailored to the case of children with acute severe wheezing. Therefore, questionnaire items measuring global satisfaction outcomes were adapted with the help of patient and public involvement (PPI) groups (refer to the *PPI group* section).

The items related to treatment effectiveness, treatment satisfaction, service satisfaction, information and consent, physical comfort, pain, and communication [38] were included in the questionnaire to be rated on a Likert or visual analog scale for parents and using pictographic tools, similar to the FACES pain scale [39] and the widely used childhood Asthma-Control Test [40] for children aged ≥4 years.

Follow-Up (Telephone Interviews)

A qualitative substudy was incorporated to explore the acceptability of HiFlo therapy compared with conventional therapy and the acceptability of the deferred consent process among parents and health care professionals. Parents and health care professionals across the 4 sites were invited to participate in a semistructured telephone interview with an experienced qualitative researcher to elicit their views and opinions of the therapy and the study more generally. All telephone interviews lasted for a maximum of 30 minutes and were recorded for later transcribing. Section 6.7 of the study protocol in Multimedia Appendix 1 presents a detailed account of the recruitment and interview process and the qualitative analysis followed during this substudy. A topic guide for the interviews presented in Textbox 8 was devised with the assistance of the Lived Experience Advisory Panel (LEAP) described in the *PPI group* section.

Textbox 8. Topic guide for qualitative interviews with parents and health care professionals (HCPs).

1. How acceptable did parents, children, and health professionals find the treatment approach used in this study?
2. What aspects of the treatment and the study more generally worked well?
3. What aspects of the treatment and the study more generally needed improvement?
4. If applicable, how did the treatment approach differ from those experienced in the past?
5. What would parents, children, and HCPs change about the therapy or study more generally?
6. Were there any outcomes which weren't measured which should have been?
7. What did parents, children, and HCPs think about the deferred consent process?
8. What would encourage other parents, children, and HCPs to participate in this study?

Clinical Data Recording

The standard of care was guided by a well-defined wheezing or asthma care pathway for children agreed upon by the participating centers, which included various observations to aid with treatment decision-making. Key observations and assessments conducted and recorded for this study are summarized in Textbox 9 (a detailed description is available in section 6.7 of the study protocol in Multimedia Appendix 1).

Textbox 9. Trial observations and assessments.

- Physical examination: this includes evaluation of suprasternal retraction, scalene muscle contraction, air entry, wheezing, work of breathing (respiratory distress), chest findings, and cardiovascular system findings.
- Vital signs: vital signs at initial assessment (triage) and during subsequent reassessments include respiratory rate, heart rate, oxygen saturation (SpO_2), capillary refill time, and temperature.
- Preschool Respiratory Assessment Measure scoring: assessments required involve a physical examination and pulse oximetry, which are all routine procedures in the participating centers.
- Oxygen requirement: this includes monitoring of oxygen (O_2) flow and fraction of inspired oxygen (FiO_2).
- Blood gases: a proportion of patients may have blood gas measurements performed routinely. Specifically, partial pressure of carbon dioxide (pCO_2) results (if available) will be used for treatment escalation decisions. In children, these will normally be measured using capillary or venous blood.

PRAM Scoring and Training

Progress was monitored regularly from hospital admission until discharge using PRAM scores (34), assessed hourly in the ED and 4-hourly after admission to an inpatient ward. PRAM scoring was included in the wheeze or asthma care pathway document adapted by the sites for local implementation. In this study, PRAM scoring was considered the standard of care and documented in the pathway document as source data to be used for patient selection (eligibility). If the pathway document could not be implemented at the ED, then the study screening and eligibility process was adapted for the recording and documentation of PRAM scores. After randomization, PRAM scoring was considered study-specific and documented in a clinical data pro forma as source data to be used for treatment monitoring.

In order to ensure consistency across all study sites, intensive training in recording PRAM scores was undertaken. Data quality was reviewed regularly, and training was updated throughout the study. The principal investigator (PI) and local investigators were responsible for promoting the clinical use of the agreed care pathway in advance of the study, for training ED staff on PRAM scoring in the context of the pathway, and for training staff in other departments (eg, HDU and ward) on the use of PRAM. Various training resources were made available to the sites, including locally produced training videos and a web-based PRAM teaching module from Centre Hospitalier Universitaire Sainte-Justine, University of Montréal [53].

Maintaining an adequate level of training for staff regarding the use of PRAM was challenging. Only one of the sites had staff who were familiar with PRAM scoring, and one of the items (palpable scalene muscle contraction) required specific training. Clinical staff had a range of opinions regarding the clinical value of asthma severity scores, and high staff turnover meant that training had to be revisited at frequent intervals.

Safety Reporting

Overview

Section 7 of the study protocol in Multimedia Appendix 1 provides standard definitions of safety reporting technology appropriate for trials other than Clinical Trials of Investigational Medicinal Products, including adverse event (AE), adverse reaction, serious AE (SAE), serious adverse reaction (SAR), and suspected unexpected SAR, and details of the safety reporting procedures (actions and required timelines) used in this study.

Recording of AEs

The operational definitions of the AEs collected from randomization to hospital discharge are given in Textbox 10 and include two types of events:

1. Air leaks: ASA is a well-recognized risk factor for air leak. Higher HiFlo rates (>2 L/kg) can mimic the effects of CPAP, which is a theoretical additional risk factor for air leak. This study used more conservative flow levels, previously used safely in HiFlo therapy in patients with asthma [23]; therefore, the risk of air leaks was regarded as low. Air leaks in any of the following 3 manifestations were regarded as an SAE and prompted immediate reporting: pneumothorax, pneumomediastinum, or subcutaneous emphysema.
2. Standard treatment–related AE: Vomiting, tachycardia, tremor, lactic acidosis, and others are known potential side effects of intravenous or inhaled bronchodilators that could be seen in both the HiFlo and standard care groups. Documentation of their occurrences was needed to evaluate the candidate secondary outcome measures (treatment-related side effects). If serious, they could be reported as SAEs.

Textbox 10. Definitions of adverse events.

1. Pneumothorax: single episode to be reported per patient.
2. Pneumomediastinum: single episode to be reported per patient.
3. Subcutaneous emphysema: single episode to be reported per patient.
4. Vomiting: a period of sequential vomiting is considered a single episode, but if there is a pause of ≥4 hours, then the next occurrence is the start of a new episode.
5. Tachycardia (heart rate ≥160 in children aged 2 to 4 years and ≥140 in those aged 5 to 11 years): an episode lasts for as long as the patient is in tachycardic range, but if there is a pause of ≥4 hours, then the next occurrence is the start of a new episode.
6. Tremor: an episode lasts as long as any tremor is present, but if there is a pause of ≥4 hours, then the next occurrence is the start of a new episode.
7. Lactic acidosis (venous or capillary lactate >2.2 mmol/L or arterial lactate >1.6 mmol/L): an episode starts every time an abnormal laboratory value is detected. The episode lactate value is recorded.
8. Hypokalemia (potassium <3.5 mmol/L): an episode starts every time an abnormal laboratory value is detected.
9. Sedation received to tolerate high-flow humidified oxygen (HiFlo) therapy: single episode to be reported per patient.
10. Patient unable to tolerate HiFlo therapy (HiFlo discontinued): single episode to be reported per patient.
11. Other: any other untoward medical occurrence or serious adverse event in a study participant.

Responsibilities of Safety Reporting

The PI at each site was responsible for reporting any SAE or SAR to the clinical trials unit (CTU). The trial manager (TM) was responsible for ensuring that all SAE and SAR reports were complete and accurate and for following up with the research teams to ensure this. The TM was responsible for maintaining and updating all the SAE and SAR records required for reporting to the sponsor and the Research Ethics Committee (REC). All AEs and SAEs were monitored by the TM at the CTU and reported and reviewed at the trial steering committee (TSC) meetings.

Statistics and Data Analysis

Statistical Analysis Plan

Participant flow through the trial will be represented in a CONSORT flowchart (Figure 1) according to the CONSORT extension for pilot and feasibility trials [41]. The available cases will be analyzed, following the intention-to-treat principles. Normally distributed variables will be summarized by means and SDs, skewed continuous variables by medians and IQRs, and categorical variables by frequencies and percentages. The difference in means between the trial arms for the primary and secondary outcomes will be estimated, together with bootstrapped 95% CIs. All analyses will be conducted using Stata (version 18; StataCorp LLC).

Qualitative Data Analysis

The interview transcripts will be anonymized and transcribed verbatim. Thematic content analysis will be performed on the interview transcripts based on a 14-stage structured approach [42]. The initial codes will be semantically clustered into subthemes, and finally, these subthemes will be clustered into main themes. The final thematic structure will be described and supported with illustrative interview quotes.

Subgroup Analyses and Participant Population

Subgroup analysis will be limited to 3 variables on which randomization was stratified: site, age, and severity of acute episode. The analysis will be conducted on an intention-to-treat basis; all the recruited participants with consent received will be included in the analysis. In addition, we will examine the screening logs at the sites to identify factors involved in the failure to recruit, which may be relevant to the design of the full RCT. Furthermore, per-protocol analysis will be performed, in which deviation from the trial protocol will result in exclusion from data analysis from that point of protocol deviation onward. Examples of protocol deviations include the following:

- A child is randomized to the HiFlo therapy arm, but for logistical reasons (eg, no equipment is available), this therapy never commenced.
- A child in the HiFlo arm is commenced on therapy, which is later discontinued or changed to another modality because of transfer to a ward area that is unable to provide this care.

The per-protocol analysis will be interpreted cautiously because of the small sample size.

Data Management

A research team pack was used to ensure accurate data collection and included clinical observation sheets and case report forms to record the outcome data. Pseudonymized data were electronically entered by trained research nurses at each site onto a web-based, password-protected data management system (REDCap; Research Electronic Data Capture; Vanderbilt University) designed by a data manager from the Brighton and Sussex CTU (BSCTU). The data manager oversaw data quality and ensured that the database was ready for analysis. Once the data had been cleaned and the database locked, they were transferred securely to the trial statistician for descriptive analysis by the trial arm.

It was agreed that all investigators and trial site staff must comply with the requirements of the General Data Protection Regulation 2018 guidance for researchers—Health Research Authority (HRA) [54]. A specific data management plan and a monitoring plan were developed for this study (available from BSCTU). Archiving will be authorized by the sponsor following the submission of the end-of-trial report. All essential documents will be archived for a minimum of 5 years after trial completion. Destruction of essential documents will require authorization from the sponsor.

Trial Management and Monitoring

The BSCTU oversaw the management of the study. A TM worked closely with the chief investigator (CI) and research team to ensure that the timelines were met, recruitment was tracked, and remote monitoring was undertaken for quality assurance. The TM supported the setup of the sites, ensuring that all documentation and processes were in line with the research governance and HRA processes. Monthly trial management group (TMG) meetings with the CI, DM, statistician, PIs, and research nurses from the sites were conducted to oversee the study's progress.

The TSC consisted of the TMG and 3 independent members (a lay member—parent of a child with asthma, a pediatrician with relevant expertise, and a statistician). The TSC reviewed the reports from the TMG and met to oversee the overall progress. With its independent membership, the TSC also reviewed the data and safety issues, fulfilling the role of this feasibility trial of a data and safety monitoring board. Financial management for the study was overseen by the TM with institutional supervision by the head of research at the UHSx NHS Foundation Trust.

Ethical Considerations

The study protocol and all applicable documents and amendments were approved by the West Midlands–Solihull Research Ethics Committee (REC) and the Health Research Authority (HRA) according to applicable regulations (REC reference: 19/WM/0219, IRAS: 261627). This study was registered with International Standard Randomised Controlled Trial Number registry (ISRCTN78297040) [55]. The HiFlo ASA project proposal was successful in competition 35 of the NIHR Research for Patient Benefit Program after 2 stages of independent peer review by the program's designated expert advisory panel. The study protocol for this feasibility study was further developed and discussed by researchers from the participating centers, with the involvement of the BSCTU.

Dissemination

In this feasibility trial, the important aspects of dissemination concern the use of trial data in designing a full RCT and preparing an application to fund it. Therefore, dissemination will be principally among the study team, the PPI groups involved, and the stakeholders (both professional and patient or parent groups) to be involved in the full multicenter RCT. We intend to publish a protocol for this feasibility trial.

Trial Sponsorship

The sponsor was responsible for ensuring that the trial was being conducted under appropriate governance. The sponsor is the UHSx NHS Foundation Trust.

Committees

The composition, roles, and responsibilities of the TMG, TSC, and LEAP are described in the *General Information* section (part 6) at the beginning of the study protocol in Multimedia Appendix 1.

PPI Group

PPI was sought at different stages in the development of the study, with a plan for continuing input during the research and its dissemination.

The detailed involvement of the following PPI groups is described in section 11.3 of the study protocol in Multimedia Appendix 1:

- Two local patient groups from Kent, Surrey, and Sussex (KSS), funded by the NIHR, participated in the trial design and will be informed of the findings of the study: KSS young people's advisory group and KSS parent and carer advisory group (KSS, Generation R).
- A separate NIHR research support grant enabled the creation of a LEAP—a group of 6 to 8 parents whose young children have been admitted with ASA, together with 4 children with experience of ASA—to provide disease-specific PPI into the study.

Results

The trial was opened to recruitment at the lead site in February 2020, but a month later, the COVID-19 pandemic reached the United Kingdom, and the study was put on hold in March 2020. There was a 15-month pause because of a combination of factors, including general concerns about face-to-face research, specific concerns about HiFlo therapy as an *aerosol-generating procedure*, and redeployment of research staff to clinical duties during the pandemic. The trial was reopened at the lead site in July 2021 and opened at the other 3 sites between August and December 2022. The follow-up was completed in July 2023. The results are currently being analyzed and will be reported separately.

Discussion

This paper describes the protocol for a multicenter feasibility RCT of 50 children that has been successfully executed at 4 sites in the United Kingdom. The trial aimed to establish whether a full RCT of early HiFlo therapy in ASA can be conducted successfully and safely and whether recruitment for such a trial, using deferred consent, is practicable in children aged 2 to 11 years presenting to hospital with ASA. If it is determined that a definitive RCT is feasible, the data from the study will inform the outcome measures and sample size needed for adequate power.

A total of 2 previous pilot RCTs of HiFlo therapy in acute asthma have been published [27,28], but neither provided the feasibility data required to design a definitive RCT to assess the clinical effectiveness. Both studies used an asthma severity score as the main outcome measure, but neither the *Pulmonary Score* used by Ballestero et al [27] nor the *Pulmonary Index Score* used by Gauto Benítez et al [28] were referenced, and it is unclear what any differences in these outcomes would mean for clinical management. In this protocol, we chose 2 candidate primary outcome measures that had been determined by clinicians and by parents and children to be meaningful and likely to impact practice. Both the need for escalation of therapy owing to treatment failure and the time to reach readiness for discharge are important in determining resource use and care costs.

We used an asthma scoring system and selected PRAM because it was the only asthma scoring system validated across the entire age range of 2 to 11 years. At least 17 different asthma severity scores have been published, but few EDs in the United Kingdom regularly use any of them as part of routine clinical practice [56], and only one of our sites had any prior familiarity with PRAM. The study protocol used the PRAM score in 2 ways: as one of the entry criteria (PRAM score ≥5 after first-line treatment) and as a candidate (secondary) outcome measure (time to achieve a PRAM score of ≤3). As noted above, implementing PRAM at the study sites and maintaining PRAM competency, despite high staff turnover, required considerable input of training resources. The advantage of using a validated asthma score as an entry criterion was that it standardized the severity of acute asthma in children entering the study, allowed comparison with other acute asthma trials [36], and allowed us to stratify randomization by asthma severity at entry. A potential disadvantage was that it risked reducing out-of-hours recruitment owing to PRAM-trained staff not being available.

As with many clinical trials since 2019, the conduct of this study was severely affected by the COVID-19 pandemic. It was necessary to pause recruitment for a prolonged period because of general logistic issues affecting all clinical research and specific concerns relating to the theoretical risks of aerosol generation and COVID-19 transmission from HiFlo therapy. The experience gained by the research team (both in adapting trial procedures and disseminating new research findings on aerosol generation) to allow the successful completion of the trial will be valuable in planning a definitive RCT.

Acknowledgments

This project was funded by the UK National Institute for Health and Care Research under its Research for Patient Benefit Program (grant PB-PG-1217-20024). The views expressed are those of the authors and not necessarily those of the National Institute for Health and Care Research or the Department of Health and Social Care.

The sponsor of this study is the University Hospital Sussex NHS Foundation Trust. The sponsor's representative is Mr Scott Harfield.

We would like to acknowledge the support of Vapotherm Inc who loaned the HiFlo equipment, and Aerogen Ltd who loaned the nebuliser equipment for the study.

Conflicts of Interest

In March 2023, PS chaired an advisory board for Aerogen Ltd, who loaned nebulizer equipment for the study, and received an honorarium. ML attended the same advisory board, and received an honorarium. All other authors declare no other conflicts of interest.

Abstract

Background: The quality of the therapeutic relationship is pivotal in determining psychotherapy outcomes. However, facilitating patients' self-awareness, reflection on, and sharing of their affective responses toward their therapist remains underexplored as a potential tool for enhancing this relationship and subsequent treatment outcomes.

Objective: The primary objective of this study is to examine whether and how the patients' regular self-monitoring and self-reflection (fostered by the systematic compilation of a brief postsession battery) on their affective reactions toward the psychotherapist impact the quality of the therapeutic relationship and treatment outcomes in individual psychotherapy. Secondary objectives are to (1) explore whether and how the characteristics of the patient, the therapist, and the process moderate the effect of regular self-monitoring on the therapeutic relationship and outcomes; (2) examine the relationships between the affective response of the patient, the alliance, and the result of the therapy session outcome; and (3) explore how the affective responses of the patient unfold or change throughout the course of the therapy.

Methods: We conducted a 1:1 randomized controlled trial of adults in individual psychotherapy versus individual psychotherapy plus self-monitoring. Participants will be enrolled through the web-based recruitment platforms "ResearchMatch" and "Research for Me," and data will be collected through web-based surveys. Participants in the control group will receive only their regular individual psychotherapy (treatment as usual) and will not complete postsession questionnaires. Participants in the intervention group will continue their regular individual psychotherapy sessions and complete the "in-Session Patient Affective Reactions Questionnaire" and the "Rift In-Session Questionnaire" following each therapy session in the 10 weeks of the trial. Additionally, after completion of the postsession battery, they will receive general written feedback encouraging them to discuss their feelings and reflections with their therapist. Participants in both groups will complete a comprehensive psychological assessment at baseline, midtrial (week 5), and end-of-trial (week 10). The primary outcome measure of the trial is the "Clinical Outcomes in Routine Evaluation-Outcome Measure," while the secondary outcomes are the "Real Relationship Inventory-Client-Short Form,"

the "Working Alliance Inventory-Short Revised," and the number of scheduled therapy sessions that the patient has missed or canceled.

Results: The trial was approved by the institutional review board of the University of North Carolina at Chapel Hill. Recruitment started in September 2023. A total of 475 individuals completed the baseline assessment. Data collection was completed in February 2024. The results are expected to be published in the autumn of 2024.

Conclusions: This study could reveal key information on how regular self-monitoring and introspection can influence both the therapeutic relationship and treatment outcomes. Findings have the potential to shape interventions, enhance the efficacy of psychotherapeutic sessions, and possibly offer a cost-effective strategy for improving patients' well-being.

Introduction

Background

Emotions lie at the core of human existence, emerging as products of evolutionary mechanisms designed to equip individuals to handle critical interpersonal interactions and life challenges [1,2]. Since the dawn of psychotherapy, the role of emotions, whether emanating from the patient or the therapist, has been recognized as crucial to the therapeutic journey [3-5].

Studies on emotional expression within the therapeutic realm emphasize their substantial influence on the outcomes of both single sessions and the entire treatment journey [2,6,7]. Emotions intertwine with both specific and generic therapeutic methodologies that underpin clinical success [8,9]. Facilitating patients to gain emotional awareness and use these emotions constructively stands central to therapeutic transformation [10,11]. For this transformative effect, therapists must engage collaboratively with the patient's in-session emotions, guiding them through recognition, acceptance, regulation, and management [12-14].

The therapeutic setting can illuminate suppressed emotions, allowing patients to confront neglected self-awareness and experience new emotional dimensions. Such insights present valuable data on patients' inherent needs and reactions, offering a platform to confront past fears and integrate new experiences [11,15]. Emotions directed toward the therapist during sessions hold significant implications for the therapeutic journey's success [16,17]. An environment characterized by empathy and affirmation determines if the emotional engagement will steer the therapy positively or detrimentally [18]. Furthermore, such an environment is both the catalyst for change and the foundation for effective psychotherapy [19].

The dawn of the new millennium saw the advent of routine outcome monitoring and feedback [20]. These systems, which track and report the patient's therapeutic progress, have seen widespread adoption and study in varied mental health contexts over recent years. These feedback mechanisms, unified by their use of standardized measures, monitor outcomes like well-being, symptomatology, and functional aspects, sometimes focusing on specific therapeutic processes like the working alliance [21]. Meta-analyses show that systematic feedback enhances therapy outcomes by reducing symptom intensity and attrition rates [22,23]. They also highlight reductions in treatment time frames and associated costs [24-26].

Given these insights, the American Psychological Association has been advocating for feedback and outcome monitoring since the early 2000s [27,28]. Feedback systems are now integral to mental health frameworks globally, especially in countries such as Australia, the Netherlands, and the United Kingdom, where monitoring outcomes is a statutory mandate for health service providers. With the capacity to tweak treatments based on progress or disruptions in the therapist-patient relationship, many experts regard progress monitoring as a pivotal strategy to enhance real-world therapy outcomes [29,30].

Study Objectives

In light of the above, the primary objective of this study is to examine the influence of a brief postsession battery, which is apt to foster patient self-monitoring and reflection on their emotional reactions toward their psychotherapist and on the quality of the therapeutic relationship and treatment outcomes.

Secondary objectives are to (1) explore whether and how the characteristics of the patient, the therapist, and the process moderate the effect of regular self-monitoring on the therapeutic relationship and outcomes; (2) examine the relationships between the affective response of the patient, the alliance, and the result of the therapy session outcome; and (3) explore how the affective responses of the patient unfold or change throughout the course of therapy.

Methods

Ethical Considerations

The institutional review board of the University of North Carolina (UNC) at Chapel Hill approved this study (23-1067) on July 31, 2023. This research was designed and executed in accordance with ethical standards for studies involving human participants.

Before starting the baseline survey, participants will receive a detailed web-based consent form regarding the study. This form will include the purpose, rationale, and methodology of the study, as well as the contact information for both the principal investigator and the institutional review board. It will be explained to potential participants that to protect their identities, only relevant and minimally necessary information will be collected. Furthermore, it will be assured that any published results will report on groups, not individual participants. Participants will be prompted with a consent statement and given options: "I consent to participate in this study" or "I do not consent to participate in this study." Those who choose not to consent will be immediately directed to a closing page. All participants are informed that they can opt out of the study at any time without providing a reason.

Only the central research team will have access to the data until the research results are published. Once the study concludes and the primary findings are released, external applications for access to deidentified data will be entertained. These applications must adhere to data privacy rules, and the intended research must be scientifically and ethically robust. Following the publication of the research findings, the data will be publicly shared through the Open Science Framework [31].

No financial incentives were offered for participation in this trial. However, upon completing the trial, participants from both the intervention and control groups were given the opportunity to request a free copy of the scales and general feedback used in the intervention group by emailing the principal investigator.

Study Design

This study is a randomized controlled trial (NCT06038747) of 1:1 for individual psychotherapy versus individual psychotherapy plus self-monitoring. A predetermined computer-generated randomization list will be generated to assign patients to 1 of the 2 arms. Patients will not be blind to treatment allocation. Patients will be enrolled through the web-based recruitment platforms "ResearchMatch" and "Research for Me," and data will be collected through web-based surveys facilitated by the Qualtrics software hosted by the UNC at Chapel Hill.

Intervention

Participants in the intervention group will continue their regular individual psychotherapy sessions. Additionally, after each session, they will complete a brief postsession battery consisting of 2 scales on the affective reactions of the patients toward their therapist during the session and read general feedback encouraging them to discuss their feelings and reflections with their therapist. This questionnaire aims to prompt reflection on one's own experience of the therapeutic relationship.

Treatment as Usual

Patients in the control group will receive only their regular individual psychotherapy (treatment as usual) and will not complete postsession questionnaires. Additionally, they will not receive any communication encouraging them to discuss their emotional responses with their therapist during the session.

Measures

This study uses a comprehensive set of self-report instruments to collect extensive data on the therapeutic process and various patient-related factors. The data will cover 5 main domains. The sociodemographic and clinical domains capture the patient's demographic, clinical, and treatment specifics. The mental health state domain focuses on the present symptoms of anxiety and depression that impact the daily lives of respondents. The therapeutic relationship domain evaluates the specific facets of the relationship between the patient and the therapist. The last domain evaluates session and therapy outcomes.

The primary outcome measure of the trial is the "Clinical Outcomes in Routine Evaluation-Outcome Measure" (CORE-OM) [32], while the secondary outcomes are the "Real Relationship Inventory-Client-Short Form" (RRI-C-SF) [33], the "Working Alliance Inventory-Short Revised" (WAI-SR) [34], and the number of scheduled therapy sessions that have been missed or canceled by the patient.

Sociodemographic Domain

The "sociodemographic data form" collects self-reported details such as the patient's age, gender, education level, and ethnicity.

Clinical Domain

The "clinical data form A" gathers patient-provided data on the duration and frequency of the ongoing psychotherapy, session attendance method (in-person, video call, telephone, and mixed), presence or absence of a diagnosed mental disorder, any prescribed psychotropic medications, and the therapist's gender.

The "clinical data form B" records information on sessions attended, missed, and canceled over the last 5 weeks and any change in psychiatric medications during this time frame.

Mental Health State Domain

The Patient Health Questionnaire-9 (PHQ-9) [35] is a 9-item self-report depression screening tool that captures the severity of depressive symptoms during the past week. It allows the evaluation of symptoms according to the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5) criteria for major depression. The PHQ-9 administered in the primary care sample showed a Cronbach α of 0.89.

The Generalized Anxiety Disorder-7 (GAD-7) [36] is a 7-item self-report anxiety screening tool with a focus on symptoms of generalized anxiety disorder. It assesses the severity and frequency of anxiety symptoms during the past week. GAD-7 showed a Cronbach α of 0.92.

Therapeutic Relationship Domain

The RRI-C-SF [33] is an 8-item self-report tool measuring the "real relationship" between a therapist and patient from the patient's viewpoint. It includes 2 subscales: "genuineness" and "realism," both of which represent closely related dimensions of authenticity and perceptual accuracy within the therapeutic relationship. The RRI-C-SF has a McDonald's ω total of 0.93.

The WAI-SR [34] is a 12-item self-report measure of the quality of the working alliance between patient and therapist from the patient's perspective. WAI-SR includes three 4-item subscales

that focus on agreement on therapy tasks, goals, and the development of an emotional bond. Items are rated on a 6-point Likert scale, with higher scores indicating a more robust alliance. The Cronbach α for the total scale was 0.91, while the α coefficients for the subscales spanned a range from 0.85 to 0.90.

The "in-Session Patient Affective Reactions Questionnaire" (SPARQ) [37,38] is a patient-reported tool that comprises 8 items that explore the patterns of thought, feeling, and behavior activated and experienced by the patients toward their therapist during a session. It consists of 2 scales: "positive affect" and "negative affect." The positive affect scale exhibited a Cronbach α coefficient of 0.84 and an average interitem correlation of 0.51. On the other hand, the negative affect scale demonstrated an α of 0.76 and an average interitem correlation of 0.39.

The "Rift In-Session Questionnaire" (RISQ) [37] is a 4-item self-report questionnaire designed to measure the patient's risk of experiencing ruptures in the therapeutic relationship. The RISQ measures feelings of belittlement, rejection, disparagement, and attack, as well as any tendencies toward disobedience or "naughtiness" toward the therapist. The RISQ demonstrated good internal consistency with a Cronbach α coefficient of 0.73 and an average interitem correlation of 0.35.

Session and Therapy Outcomes Domain

The Session Evaluation Scale (SES) [39] assesses the quality of the therapy session from the perspective of the patient. The SES comprises 5 items rated on a 5-point Likert scale and showed Cronbach α coefficients ranging from 0.88 to 0.89.

The CORE-OM [32] is a 34-item self-report measure of change in psychotherapy that comprises 4 domains: subjective well-being, symptoms, function, and risk. The CORE-OM demonstrated good internal and test-retest reliability between 0.75 and 0.95, and convergent validity against a battery of validated measures.

Efforts to Minimize Potential Sources of Bias

In our research, extensive steps will be taken to minimize potential biases. First, participants will be sourced from ResearchMatch, a national web-based registry that boasts a broad and varied volunteer pool from all over the United States, reducing selection bias and enhancing the external validity of our study. Second, our methodology is closely tuned to gender perspectives, giving weight to nonbinary gender as a key factor in both data evaluation and result interpretation, fortifying the scientific rigor and clinical significance of the study. Third, our comprehensive set of measures covers a spectrum of therapeutic and individual aspects, from sociodemographic details to personality characteristics, providing a comprehensive snapshot of the therapeutic landscape and limiting measurement bias. Data will be gathered through Qualtrics, a trusted web-based tool that protects respondent privacy and minimizes potential biases in responses. Furthermore, great care was taken in calculating the required sample size, accounting for potential dropouts, to ensure that we had ample statistical power, thereby sidestepping the pitfalls of weak analyses or insufficient representation.

Sample Size Calculation

Assuming a power of 0.80, a 2-tailed α level of .05, an effect size (*d*) of 0.50, and an allocation ratio of 1:1, we calculated a minimum sample size of 128 patients, or 64 participants per group, using the *R package pwr* (version 1.3-0; The Comprehensive R Archive Network). However, to enhance statistical power and precision, we aim for a target total sample size of 520 participants, with 260 participants per group. This adjustment also accounts for the possibility that only 50% of participants in the intervention group will complete all postsession scales.

Inclusion and Exclusion Criteria

Participants are eligible for the study if they are aged 18 years or older, fluent in English, and currently undergoing individual psychotherapy with a minimum frequency of 2 sessions per month. Individuals with a legal guardian will be excluded from the study.

Recruitment

Patients will be enrolled through ResearchMatch and Research for Me. ResearchMatch [40] is a disease-neutral, institution-neutral, US national web-based registry designed to enroll volunteers for clinical studies. Established by various educational entities and supported in part by the National Institutes of Health's National Center for Advancing Translational Sciences, this platform provides access to more than 155,000 volunteers across the United States and has proven effective. Research for Me is a community of volunteers acting as the primary gateway for patients and local residents who wish to participate in research at the UNC at Chapel Hill. This initiative was established by the North Carolina Translational and Clinical Sciences Institute, which is the central component of the National Institutes of Health's Clinical and Translational Science Awards program at UNC at Chapel Hill. Data suggest that individuals enrolled through online research platforms reliably report their demographic and psychological details, especially when there is no monetary incentive involved [41].

Randomization

Participants will be assigned to either the intervention or control group using a pre-established computer-generated randomization list. This assignment will occur after the baseline assessment is completed.

Data Collection Process

Participants in both the intervention and control groups will undergo assessments at baseline, midtrial (week 5), and end-of-trial (week 10). Additionally, those in the intervention group will have postsession evaluations. These assessments will be delivered through Qualtrics, a secure web-based survey platform hosted by the UNC at Chapel Hill.

Baseline assessment: All participants will complete the demographic and clinical data forms in addition to the measures for mental health state, therapeutic relationship, and session and therapy outcome domains (Table 1).

Table 1. Instruments and time line for assessment in the trial.

Domains and measures	Baseline	Midtrial[a]	End-of-trial[b]

Session Evaluation Scale [39]	✓	✓	✓
Clinical Outcomes in Routine Evaluation-Outcome Measures [32]	✓	✓	✓

[a]5 weeks after the baseline assessment.

[b]10 weeks after the baseline assessment.

Postsession assessment (only for the intervention group): participants in the intervention group will be required to complete SPARQ and RISQ [37] after each session throughout the 10-week duration of the trial. Immediately after completion of the postsession battery, participants will be presented with a general feedback statement emphasizing the importance of discussing session-related feelings with their therapist.

Mid-trial assessment: 5 weeks postbaseline evaluation, all participants will retake the scales used in the baseline assessment (Table 1).

End-of-trial assessment: 10 weeks after the baseline, all participants will again be asked to complete the initial assessment battery (Table 1).

Dealing With Missing Values

We will examine data for degree and patterns of missingness at the patient and scale level, use propensity scoring to model the pattern of missingness, and include the propensity score as a covariate in analyses if indicated [42]. Missing items will be prorated so long as at least 75% of the items are available, and otherwise the scale score will be treated as missing [43].

Planned Analysis

A comprehensive statistical strategy will be formulated and documented before starting the data analysis. R (R Foundation for Statistical Computing) will be used for data cleaning, labeling, scale scoring, and subsequent analyses. The basic characteristics of the study participants will be clearly described for each arm while also being aggregated to a sufficient level to reduce the risk of deductive identification. Baseline categorical variables will undergo a comparative evaluation between the intervention and control groups using chi-square evaluations. Continuous variables will be compared using 2-tailed *t* tests and Mann-Whitney *U* tests. Outcome metrics will be presented for each research group at various intervals. These outcomes will be detailed based on cumulative scores and the percentage of participants that demonstrate improvement from the start point.

Statistical Analysis

Analysis of covariance will be used to evaluate the influence of treatment conditions on primary and secondary outcomes since it is the most appropriate statistical method for the analysis of continuous outcomes in RCTs [44,45]. Analysis of covariance is a linear regression in which treatment assignment and baseline scores are included as covariates. Patient clinical and demographic characteristics, as well as therapist demographic and professional characteristics, will be included as exploratory variables. A total of 2 analyses will be carried out: the intention-to-treat analysis to examine the general effect and the per protocol analysis as a sensitivity analysis. The time will be measured in weeks, and the baseline is coded with the value 0. Analyses will be performed using R statistical computing software (version 4.3.1 or higher; R Foundation for Statistical Computing).

Trial Status

At the time of submission of this protocol's manuscript, recruitment is complete.

Dissemination Policy

The results of this research project will first appear as preprints and subsequently be shared through scholarly journals and

presentations at conferences. The Open Science Framework will host a repository containing study tools and data, scoring guidelines, presentations, and preprint versions. Wikiversity pages, tailored to offer technical assets for both practitioners and researchers, will feature links directing to this repository. Furthermore, this study's conclusions could be communicated to pertinent mental health associations, contributing to future studies and potential improvements in psychotherapeutic relationships. Our goal is to adopt a comprehensive and broad-based communication approach that engages scholars, health care professionals, and the general public.

Results

Participant recruitment started in September 2023. Baseline data collection was completed in December 2023, with a total of 520 recruited participants, 475 of whom completed the baseline assessment (243 participants were assigned to the intervention group and 232 were assigned to the control group). Data was completed February 2024. Data analysis has not begun as of the time of submission. The results are expected to be published in the autumn of 2024.

Discussion

This clinical study is designed to assess the impact of introducing a concise postsession questionnaire able to trigger the self-awareness and introspection of patients about their experience of the psychotherapeutic relationship. The primary goal is to understand its influence on the effectiveness of treatment, with the CORE-OM serving as the primary outcome measure.

Should our battery prove to increase symptom reduction rates or improve overall well-being, its ease of delivery directly to patients—requiring no additional therapist involvement—suggests potential for seamless adoption across therapeutic contexts without incurring extra expenses for patients or placing added demands on therapists. This could make the system highly cost-efficient. Furthermore, the insights from this study could shed light on the nuanced interaction between specific elements of the therapeutic bond and the results of sessions or general treatment. This knowledge would empower clinicians and policy makers to recognize and prioritize those aspects of the therapeutic relationship that strengthen or hinder the efficacy of psychotherapy.

One of the main strengths of this study is its ability to gauge the benefits of regular patient self-monitoring and subsequent reflection on their emotional reactions toward their therapists in a real-world setting. The study sample accurately represents the diverse patient population within the United States, further enhancing its relevance. Other key advantages include robust statistical power, the use of an external outcome measure not related to the intervention, and a comprehensive consideration of the patient, the therapist, and treatment variables. However, there are limitations, such as the lack of information from the clinician or observer and the extended duration of data collection. Furthermore, an important potential limitation inherent in our approach concerns the adherence of the participants to the research protocol, specifically the regular completion of the battery after each therapy session, and their compliance with the recommendation to share their emotional responses toward their therapist directly and openly with the therapist.

To this day, efforts to implement and test regular self-monitoring of patient affective experiences during sessions, with systematic feedback provided directly to patients without the therapist's intervention, seem inadequate. The introduction of a newly developed systematic client feedback system for psychotherapy may offer improvements in treatment outcomes while also serving as a cost-effective tool in real-world clinical practice.

Data Availability

Data sharing is not applicable to this article, as no data sets were generated or analyzed during this study protocol. The data sets generated during the actual research study will be made available in the Open Science Framework repository [31].

Conflicts of Interest

Abstract

Background: Chronic pain affects approximately 8 million Canadians (~20%), impacting their physical and mental health while burdening the health care system with costs of upwards of US $60 billion a year. Indeed, patients are often trialed on numerous medications over several years without reductions to their symptoms. Therefore, there is an urgent need to identify new therapies for chronic pain to improve patients' quality of life, increase the availability of treatment options, and reduce the burden on the health care system.

Objective: The primary objective of this study is to examine the feasibility of a parallel 3-arm pilot randomized controlled trial whereby patients are randomized to either intravenous ketamine alone, cognitive behavioral therapy (CBT) and mindfulness meditation (MM) training (CBT/MM), or the combination of intravenous ketamine and CBT/MM. The secondary outcome is to assess the durability and efficacy of combination intravenous ketamine and CBT/MM for treatment of chronic pain as compared to CBT/MM or intravenous ketamine alone (assessed at week 20 of the study).

Methods: This is a single-center, 16-week, 3-arm pilot study that will take place at the Chronic Pain Clinic at St. Michael's Hospital, Toronto, Ontario, which receives 1000 referrals per year. Patients will be enrolled in the study for a total of 20 weeks. Participants who are allocated CBT/MM therapy will receive remote weekly psychotherapy from week 1 to week 16, inclusive of health coaching administered through the NexJ Health Inc (NexJ Health) platform. Patients who are allocated ketamine-infusion therapy will receive monthly ketamine infusion treatments on weeks 2, 7, and 12. Patients who are allocated ketamine+CBT/MM will receive weekly psychotherapy from weeks 1 to 16, inclusive, as well as ketamine infusion treatments on weeks 2, 7, and 12. We will be assessing recruitment rates, consent rates, withdrawal rates, adherence, missing data, and adverse events as pilot outcome measures. Secondary clinical outcomes include changes relative to baseline in pain intensity and pain interference.

Results: As of November 1, 2023, the recruitment process has not been initiated. Given the recruitment, consent, and intervention target of 30 participants for this feasibility study, with each patient undergoing monitoring and treatments for a course of 20 weeks, we expect to complete the study by December 2025.

Conclusions: This study assesses the feasibility of conducting a 3-arm randomized controlled trial to examine the effects of ketamine administration with the concurrent use of CBT/MM in a population with chronic neuropathic pain. The results of this pilot randomized controlled trial will inform the development of a larger-scale randomized controlled trial. Future studies will be aimed at including a sufficiently powered sample that will inform decisions about optimal treatment calibration and treatment effect duration.

KEYWORDS

3-arm parallel group; cognitive behavior therapy; ketamine hydrochloride; pain intensity; pain interference; psychotherapy; randomized controlled trial

Introduction

Chronic pain affects approximately 8 million Canadians (~20%) and profoundly impacts their physical and mental health. The broad ranging consequences of this disease are evidenced by estimated health care system costs upwards of US $60 billion a year [1]. In the United States, chronic pain also affects 1 in 5 people, and the annual cost is estimated as greater than US $0.5 trillion [2]. Indeed, chronic pain is associated with poor quality of life, psychiatric symptoms, and mobility restrictions. It has significant physical, functional, social, and economic impacts at the individual and system levels. Current pain therapies aim to decrease pain to manageable levels. In most cases however, chronic pain cannot be completely eliminated. Patients are often trialed on numerous medications without adequate relief, and therapies are often limited by their lack of durability and adverse effects. There is an urgent need to identify new therapies for chronic pain to improve patients' quality of life and the availability of treatment options, while reducing health care system burdens.

Ketamine is an N-methyl-D-aspartate receptor antagonist which results in pain reduction. It is also associated with reductions in opioid-induced hyperalgesia and opioid consumption [3]. At high doses, it is an agonist at the mu receptor, the D2-R, and L-Type voltage-gated calcium channel. Current evidence supports intermittent ketamine therapy for neuropathic pain. Double-blind randomized controlled trials (RCTs) investigating the use of ketamine for neuropathic pain have demonstrated clinically significant reductions (25% to 43%) in chronic pain versus control conditions [3]. However, ketamine appears to have limited durability as studies have shown short term reductions in neuropathic pain secondary to spinal cord injury and fibromyalgia but no long-term benefits [4,5]. Although timelines and follow-ups vary significantly, the lack of durability is consistent across all ketamine infusion regimens studied [6]. Indeed, a systematic review by Cohen et al [3] indicated a lack of evidence for durable benefits, affirming the need for adjunctive therapies that improve durability and improve outcomes.

Internet-delivered cognitive behavioral therapy (CBT) for chronic pain, depression, and anxiety is associated with significant reductions in pain disability, symptoms of depression, and pain catastrophizing at 1 year follow-up [7]. Nonetheless, an integrative review [8] concluded CBT research must further address longer-term efficacy (>12 months). This same review highlighted the significant variations in the duration and total dose hours of CBT interventions and delivery methods (remote, group, or individual). Despite variations, existing studies and emergent guidelines support the synergistic effects of pharmacological therapies strategically combined with CBT-based strategies [7].

The primary objective of this trial is to study the effects of concurrent ketamine and CBT for chronic neuropathic pain relief. Biological and neurocognitive factors suggest that concurrent pharmacotherapy and psychotherapy can result in more durable and effective analgesic responses than either intervention alone. Ketamine administration induces physiological changes during and after delivery that result in powerful experiential responses with important psychological and emotional impacts [9]. The physiological changes associated with ketamine therapy are likely to influence important habitual thinking and behavior patterns. Studies suggest that ketamine alters functional brain connectivity, even to the point of disrupting spatiotemporal patterns of neural activity and increasing functional communications between brain regions typically isolated [9].

Despite the biologic plausibility of ketamine-assisted psychotherapy being an effective cotreatment for chronic neuropathic pain, there is a lack of rigorous evidence supporting its use. Our group conducted a systematic review to examine existing evidence on concurrent ketamine dosing and psychotherapy [10]. This knowledge synthesis showed substantial methodologic variations across 17 studies. The most common indications studied included posttraumatic stress disorder (6 studies), major depressive disorder (6 studies), substance use disorder (6 studies), and obsessive compulsive disorder (2 studies). Only 2 publications (a case report and a case series) examined continuous multiday ketamine infusions with concurrent psychotherapy in individuals with chronic pain.

Ocker et al [11] described a 5-day continuous ketamine infusion regimen combined with CBT to successfully taper opioids in a patient with complex regional pain syndrome who was taking 330 mg of daily morphine equivalents. They attribute the sustained results to an observed synergism between ketamine and the outpatient CBT protocol. Keizer et al [12] described a case series of 11 patients who received ketamine-enhanced psychotherapy for comorbid neuropathic pain and posttraumatic stress disorder. A 96-hour ketamine infusion was delivered with daily bedside psychotherapy. Although it resulted in a moderate but clinically meaningful reduction in pain symptoms, the brief follow up of 5 days precluded in-depth examination of the potential synergism.

This systematic review also revealed no evidence that a single protocol or therapy strategy was decidedly more beneficial than any other. To date, no RCT has combined ketamine and psychotherapeutic intervention for patients with chronic pain. The results of this review highlight the poor methodological quality of existing studies and need for higher quality evidence on the potential impact of combined interventions. By means of this pilot study, our intention is to determine whether a customized CBT along with mindfulness and meditation (MM; ie, CBT/MM) psychotherapy regimen can be effectively and safely integrated with a ketamine-induced state in a chronic neuropathic pain sample.

The Psychotherapy for Ketamine's Enhanced Durability in Chronic Neuropathic Pain study has received partial funding from the Canadian Pain Society in partnership with the Pfizer Early Career Investigator Award as well as the St. Michael's Hospital Association Innovation Fund.

Methods

Aim

The primary objective of this study is to enroll 30 participants with chronic neuropathic pain and assess the feasibility of conducting a 3-arm parallel group pilot RCT. The secondary aim of the study is to examine whether the combined effects of ketamine and CBT/MM (as delivered through the NexJ Health Inc platform by trained navigator-coaches) can reduce pain intensity and pain interference by week 20 of the study (ie, limited efficacy at week 20).

Recruitment and Randomization

Recruitment will occur at the Chronic Pain Clinic at St. Michael's Hospital, Toronto, Ontario. The clinic receives approximately 1000 referrals per year. An estimated 3% of these referrals would be eligible for inclusion in this trial.

A staff member who does not belong to the study team will be provided with the instructions to use a remote random number generator, the "Sealed Envelope" website to generate an allocation sequence at random. The allocation list will be sent to the Research Pharmacy staff at St. Michael's Hospital directly, without the knowledge of the study team, to maintain the blindness. After participant enrollment, the pharmacy staff will randomize the patient and inform a delegated research team member as to the allocated intervention arm. The delegated unblinded research team member will then notify the patient which arm they have been randomized to and will coordinate with the anesthesiologists and psychologists, who will be unblinded, to schedule in-person study visits on weeks 2, 7, and 12 according to the randomized treatment arm. For patients randomized to Arm 1 or 3, the Research Pharmacy staff will prepare ketamine-hydrochloride for weeks 2, 7, and 12. The outcome assessors are the only research staff to remain blinded to patient treatment (currently, we only have 1 delegated outcome assessor).

Participants will be randomized to receive either (1) ketamine-hydrochloride infusions alone, (2) CBT/MM alone, or (3) a combination ketamine-hydrochloride infusion and CBT/MM.

Participants will be eligible for this study as per the inclusion and exclusion criteria listed (Textbox 1).

Textbox 1. Inclusion and exclusion criteria regarding participant eligibility for PYSKED-NP.

Inclusion criteria

- Aged 18 years or older.
- Diagnosis of chronic neuropathic pain as determined by a pain specialist with moderate to severe neuropathic pain as per ID pain questionnaire, with mean pain scores >3 on an 11-point (0-10) Numeric Rating Scale, in the 7 days preceding inclusion.
- For participants of childbearing potential, use of highly effective or double-barrier methods of contraception. Abstinence is acceptable if it is the preferred and usual lifestyle of the participant.
- Capacity to provide informed consent

Exclusion criteria

- Patients aged younger than 18 years.
- Current or lifetime history of schizophrenia, psychotic disorder, bipolar disorder, or borderline personality disorder.
- Known history of hypersensitivity or allergy to ketamine-hydrochloride.
- Current history of dissociative disorders.
- Current concomitant use of theophylline or aminophylline.
- Current elevated intracranial pressure.
- Pregnancy or ongoing breastfeeding in female participants.
- Concomitant active substance use in the 6 months preceding enrollment (amphetamines, alcohol, and ketamine).
- Contraindication to receiving ketamine-hydrochloride (eg, current or lifetime history of cerebrovascular accident, current significant hypertension [systolic blood pressure higher than 160 mm Hg in combination with or with an isolated diastolic blood pressure higher than 100 mm Hg], and current severe cardiac decompensation [eg, presence of dyspnea, peripheral edema, elevated jugular venous pressure, hepatomegaly, pulmonary rales, and pleural effusions]).

Withdrawal Criteria

A participant will be withdrawn if the participant presents with a severe adverse event or unknown allergic reaction during the first administration of ketamine-hydrochloride or if the participant wants to withdraw from the study for any reason. The participant will receive the necessary treatment to alleviate any untoward events and will be monitored by the study physician until judged appropriate for discharge. Participants will be followed up on the following day to ascertain more details on their condition. Data from a participant who has been withdrawn will be collected up to the day following their withdrawal to ensure that the participant has no more complications. If a participant withdraws from the study at any time, the reasons for withdrawal will be collected and documented as a feasibility study outcome.

Since this is a feasibility study without a specific sample size required to analyze any outcome, participants will not be replaced or added.

Intervention

Intervention Description

Participants will be randomly assigned to one of 3 arms. Arm 1: Ketamine-hydrochloride infusions alone, Arm 2: CBT in combination with MM (CBT/MM), or Arm 3: Ketamine-hydrochloride infusions in combination with CBT/MM.

Ketamine-hydrochloride will be delivered intravenously for patients in Arm 1 and Arm 3. For this study, 1 mg/kg of ketamine intravenous will be dosed by total body weight and administered over 2 hours up to a maximum dose of 100 mg as per our local institutional protocol.

Arm 1: Ketamine-Hydrochloride Infusion Alone

Patients in Arm 1 receiving a ketamine-hydrochloride infusion alone will receive ketamine infusions on weeks 2, 7, and 12 of the study. After the study intervention, participants will have their vital signs and adverse events monitored for one hour. The anesthesia provider will be responsible for assessing the participant before discharge. Participants will not be allowed to drive after the intervention; therefore, measures will be taken to ensure the participant has an adequate plan of transportation (ie, a companion or suitable transportation).

For safety reasons, the anesthesia provider administering the medication will not be blinded. However, the study personnel designated to collect the outcome data will be unaware of the treatment assignment. Patients will not be blinded to their therapy for the purposes of this feasibility study.

Arm 2: CBT/MM Alone

Participants in Arm 2 receiving CBT/MM alone will receive weekly CBT/MM treatment in collaboration with NexJ Health Inc and supplemented by the designated psychotherapist trained for and experienced in previous studies [13]. About 16 hours of CBT/MM therapy will be delivered over 16 weeks. Participants will be assigned to a 3-hour CBT/MM workshop remotely, to be administered by the delegated psychotherapist. The CBT-MM programming will combine exposure to smartphone- and computer-accessible workbooks with phone-based mental health counseling (16 hours in 16 weeks)

that coordinates with ongoing software interactions (eg, secure text messaging) [14,15].

The software for delivering the CBT/MM therapy is a standalone platform, called "Connected Wellness Platform," developed by NexJ Health Inc. Connected Wellness Platform is a customized, secure (2-level log-in with 128-bit encryption) interface accessible through both a smartphone and a computer.

Arm 3: Ketamine-Hydrochloride Infusion in Combination With CBT/MM

Finally, participants in Arm 3 receiving ketamine infusion+CBT/MM will receive both the standard CBT/MM and ketamine-hydrochloride infusion protocols as described above. Participants in this arm will have psychotherapy delivered concurrently with their ketamine infusions on weeks 2, 7, and 12 in person by the delegated psychotherapist. Participants in Arm 3 will also receive 16 weeks of CBT/MM remotely.

Hypothesis

In line with the primary aim of this study, this pilot study will prove to be feasible for a large-scale clinical trial. We expect that we will be able to successfully meet our recruitment target (30 participants) within the 1-year time frame of the study and expect this study withdrawal rate to be less than 10% (3/30 patients). Feasibility of this study will be determined by the following set variables and cutoff percentages; recruitment success with the specific aim to recruit all necessary patients within the first year of the trial period, adequate consent rate (30/100, >30% of eligible patients consent to participate in the study), intervention adherence as define by the percentage of patients who complete all medication and psychotherapy visits (27/30, >90%), percentage of patients who withdraw from the study (ie, due to side effects; 6/30, <20%), percentage of patients with incomplete pain intensity and pain interference data at 1 month, (eg, withdrawal due to side effects, loss to follow up, or missing data; 3/30, <10%), and rate of adverse outcomes. We do not foresee any issues arising with the protocol of the study or the delivery of each arm.

While not powered to examine these effects, we hypothesize that patients allocated to the combination ketamine and CBT/MM arm of this study will have the greatest reduction in pain intensity and pain interference.

Blinding Mechanism

The intervention delivery providers (anesthesiologists and psychologists) and other members of the research team will be aware of each participant's assigned intervention. Within the research team, blinded members will be responsible for inputting all of the data into the REDCap (Research Electronic Data Capture; Vanderbilt University) database, with the exception of any ketamine-specific data, that is, semistructured interviews after the ketamine intervention and any adverse events. Following data collection, we will request blinded staff to record their "best guess" of each patient's intervention to assess blinding efficacy. The research team currently has 1 blinded member who will serve as the outcome assessor and be responsible for data input.

Emergency Unblinding

To optimize study quality, emergency unblinding will only occur when knowledge of the intervention is essential for participant care, as determined by the principal investigator. In the case of emergency unblinding, the timing, reason for doing so, and personnel involved will be recorded in the case report form, while blinding is maintained by as many other study personnel as possible.

Outcome Measures

Primary Outcome

The primary outcome of this pilot trial is to determine the feasibility of a large-scale multicenter trial. Feasibility outcomes will include the following variables, with all thresholds listed in parentheses:

1. Recruitment success (with the specific aim of recruiting all necessary patients within the first year of the trial period).
2. Adequate consent rate (>30% of eligible patients consent to participate in the study).
3. Percentage of patients who complete all medication and psychotherapy visits (ie, intervention adherence; >90%).
4. Percentage of patients who withdraw from the study (eg, due to side effects or other reasons; <20%).
5. Percentage of patients with incomplete pain intensity and pain interference data at 1 month and stated or ascribed reason (eg, withdrawal due to side effects, loss of follow-up, or missing data; <10%).
6. Rate of adverse outcomes (ie, 0 serious adverse events).

Based on the result for each primary feasibility outcome, we will determine whether the definitive study is feasible as proposed (ie, all feasibility targets are met), feasible with protocol modifications (modifications specified), or not feasible because feasibility targets could not be met even with protocol modifications. These cutoffs, identified in the parentheses above, will help determine whether protocol changes are required before proceeding with a definitive trial.

Secondary Outcome

The secondary outcomes chosen for the definitive trial follow consensus recommendations of core domains that should be addressed in studies examining chronic pain. Information will be collected in these domains as part of the pilot trial using survey-based outcome assessments, either in person during study visits or over the telephone by trained research personnel. The following pain score questionnaires will be used:

1. Pain intensity on an 11-point (0-10) Numeric Rating Scale.
2. Pain interference on the Patient-Reported Outcomes Measurement Information System (PROMIS-PI) scale.
3. Catastrophic thinking about pain, as measured by the Pain Catastrophizing Scale (PCS).
4. Features of depression, as measured by the Patient Health Questionnaire-9 (PHQ-9).
5. Features of anxiety, as measured by the Generalized Anxiety Disorder-7 (GAD-7).
6. Patient Global Impression of Change Scale (PGIC).

Secondary clinical outcomes will include changes relative to baseline assessment in pain intensity and pain interference at week 20 (4 weeks post-completion of treatment; Figure 1). Scores for all outcomes at weeks 2, 7, 12, 16, and 20 will be compared to baseline scores to assess any progressive additive effects between the treatments. For any patients who withdraw before week 20, their last documented responses will be used as a comparison against baseline data. Patients will be allowed to adjust the dosages of other analgesic medications in conjunction with their primary physician. Analgesic medication use and doses will be tracked at the above time points to assess changes over time. Semistructured interviews will be conducted at 2 points within the study period: at weeks 1 and 20 and after the ketamine infusions (Table 1). The interviews will be audio-recorded to ensure the responses are accurately captured. In-person interviews will be recorded with an encrypted device, and phone interviews will be recorded through the Unity Health Zoom (Zoom Video Communications Inc) recording option. The audio recording files will be saved on St. Michael's Hospital secure and restricted servers, and the files will be labeled by the study number. The recordings will be transcribed by the research team, and after verifying that the transcriptions are accurate, the audio recordings will be destroyed. Questionnaires will be delivered to patients at prespecified time points, as outlined in the study timeline below.

[a]MINI: Mini International Neuropsychiatric Interview.

[b]CBT/MM: cognitive behavior therapy/mindfulness and meditation.

[c]Participants randomized to receive CBT/MM alone (arm 2), will receive a semistructured interview on weeks 1 and 20.

[d]Participants randomized to receive ketamine-hydrochloride infusion + CBT/MM (arm 3) will receive a semistructured interview on weeks 1 and 20 as well as a semistructured interview during the ketamine infusion on weeks 2, 7, and 12.

[e]Only female participants randomized to receive ketamine-hydrochloride alone (arm 1) or the ketamine-hydrochloride infusion + CBT/MM (arm 3) will require a pregnancy test on the day of infusion.

[f]PROMIS-PI: Patient-Reported Outcomes Measurement Information System.

[g]PGIC: Patient Global Impression of Change Scale.

[h]GAD-7: Generalized Anxiety Disorder-7.

[i]PHQ-9: Patient Health Questionnaire-9.

[j]PCS: Pain Catastrophizing Scale.

Ethical Considerations

This study will be conducted in accordance with the ethical principles laid down in the Declaration of Helsinki, the protocol, Good Clinical Practice guidelines, and applicable regulatory requirements. This study received a “No Objection Letter” from Health Canada on October 13, 2022, indicating the study protocol was deemed acceptable.

Full written informed consent will be obtained from participants before conducting any study activities. The study was reviewed and approved by the Research Ethics Board at St. Michael’s Hospital on May 5, 2023 (22-217). This trial was designed and will be reported according to the CONSORT (Consolidated Standards of Reporting Trials) clinical trials statement checklist and the CONSORT-Outcomes 2022 extension [16].

Results

Prestudy Screening

Eligible participants will be screened at the Chronic Pain Clinic at St. Michael’s Hospital. Participants diagnosed with chronic neuropathic pain that meet the criteria from the ID pain questionnaire will be approached and asked to consider study participation.

After participants have provided informed consent, they will be asked about their medical comorbidities, psychiatric history as based on the Mini International Neuropsychiatric Interview, history of ketamine hypersensitivity, and concomitant medications to confirm eligibility. If a participant is eligible to participate in the study, the participant will be enrolled in the study, and the study coordinator will book an appointment for the participant’s study intervention.

At this current point, November 1, 2023, the study has not started enrolling and consenting patients.

Baseline Data

After initial screening and informed consent are obtained, the following data will be collected at baseline (week 1):

1. Demographic information: age, sex, gender, height, and weight.
2. Detailed data regarding current medications and medical comorbidities, as well as medication history, is collected by our standard intake form.
3. Chronic neuropathic pain severity and other relevant covariates will be assessed at baseline using:
    - PROMIS-PI
    - PCS
    - PHQ-9
    - GAD-7
    - PGIC

Follow-Up Data

In all arms, at each follow-up visit, participants will complete the PROMIS-PI scale, PCS, PHQ-9, GAD-7, and the PGIC to assess outcome measurements. Follow-ups will be conducted every 4 weeks over the phone to maintain the blindness of the research team.

For females, a urine pregnancy test will be required for those randomized to the ketamine-hydrochloride infusion alone or the ketamine-hydrochloride infusion+CBT/MM arms in order to confirm that the patient is not pregnant before each ketamine infusion treatment.

Outcome Analysis

Based on the primary end points, we will determine whether or not this pilot study is as follows:

1. Feasible: all feasibility outcomes are met; no protocol modifications are needed,
2. Feasible with modification: all feasibility outcomes are met or can be met with protocol modifications, and
3. Not feasible: Even with protocol modifications, some feasibility outcomes cannot be met.

In terms of statistical analyses for this feasibility study, preliminary analyses will consist of univariate tests to compare clinical and demographic variables of interest. Linear regression analysis will be used to quantify the strength and magnitude of the relationship between the intervention and the coprimary outcomes. Secondary outcomes will be analyzed as continuous measures using generalized linear regression models.

For any missing data where patients do not attend the allocated sessions or do not complete all components of the relevant questionnaires, this will be noted and documented to assess the overall feasibility of this study. Data will not be extrapolated or interpreted for these missing data sets.

Study Status As of Date

As of the current date, November 1, 2023, the study has not started to recruit patients.

Discussion

It is hypothesized that concurrent pharmacotherapy and psychotherapy have combined effects on the analgesic response. In addition to ketamine's anesthetic-analgesic properties, it also uniquely alters the individual's level of consciousness at variable doses. Some researchers posit that the therapeutic experience of psychotherapy may be augmented by ketamine's alteration of conscious awareness [10]. As demonstrated by this systematic review, few studies have examined ketamine-assisted psychotherapy (KAP) for chronic neuropathic pain. RCTs have not been published on this topic. In addition, there appears to be wide variability in the indication, dosage, and patient treatment setting, such that the current literature is inconclusive.

The 3-arm design allows us to compare the feasibility of KAP with ketamine alone and CBT/MM. We will track feasibility outcomes, including recruitment rate and adverse event rate, to estimate the acceptability of this intervention compared to controls. There are also limitations to this study. Due to the participatory nature of CBT/MM, we are unable to blind patients and the research team to patients' assigned interventions. To mitigate this, the outcome assessors will be blinded to minimize bias, and we will request and report their "best guess" estimate of each patient's assigned intervention at the end of the study. We also recognize that there may be different patient outcomes based on the mode of CBT/MM delivery. Patients in arm 1 receiving ketamine alone will have no CBT/MM as part of the trial design. Patients assigned to CBT/MM alone (Arm 2) will be receiving their intervention sessions remotely rather than in-person for 16 weeks. Patients in Arm 3 will be receiving ketamine on weeks 2, 7, and 12 and in-person CBT/MM at this time. They will also be involved with remote CBT/MM sessions from weeks 1 to 16 (except for weeks 2,7, and 12). This hybrid intervention will allow us to collect data on the feasibility of in-person versus remote psychotherapy for this patient population.

This study will inform the development of a larger-scale multicenter RCT. Our results will help inform the sample size calculation to ensure an adequately powered, definitive RCT. We anticipate that the psychotherapy and ketamine protocols developed in this study will be easily replicable and scalable should they show clinical and statistical benefits in the chronic neuropathic pain population. Furthermore, future studies developed by our research team will aim to study longer-term outcomes associated with KAP and the need for ongoing therapy in this patient subset.

Acknowledgments

This study was partially funded by the Canadian Pain Society in partnership with the Pfizer Early Career Investigator Award, and the St. Michael's Hospital Association Innovation Fund. KL and H Clarke are recipients of Merit Awards administered by

the Department of Anesthesiology and Pain Medicine at the University of Toronto. Abstract

Background: Relative motion between the residual limb and socket in individuals with transtibial limb loss can lead to substantial consequences that limit mobility. Although assessments of the relative motion between the residual limb and socket have been performed, there remains a substantial gap in understanding the complex mechanics of the residual limb-socket interface during dynamic activities that limits the ability to improve socket design. However, dynamic stereo x-ray (DSX) is an advanced imaging technology that can quantify 3D bone movement and skin deformation inside a socket during dynamic activities.

Objective: This study aims to develop analytical tools using DSX to quantify the dynamic, in vivo kinematics between the residual limb and socket and the mechanism of residual tissue deformation.

Methods: A lower limb cadaver study will first be performed to optimize the placement of an array of radiopaque beads and markers on the socket, liner, and skin to simultaneously assess dynamic tibial movement and residual tissue and liner deformation. Five cadaver limbs will be used in an iterative process to develop an optimal marker setup. Stance phase gait will be simulated during each session to induce bone movement and skin and liner deformation. The number, shape, size, and placement of each marker will be evaluated after each session to refine the marker set. Once an optimal marker setup is identified, 21 participants with transtibial limb loss will be fitted with a socket capable of being suspended via both elevated vacuum and traditional suction. Participants will undergo a 4-week acclimation period and then be tested in the DSX system to track tibial, skin, and liner motion under both suspension techniques during 3 activities: treadmill walking at a self-selected speed, at a walking speed 10% faster, and during a step-down movement. The performance of the 2 suspension techniques will be evaluated by quantifying the 3D bone movement of the residual tibia with respect to the socket and quantifying liner and skin deformation at the socket-residuum interface.

Results: This study was funded in October 2021. Cadaver testing began in January 2023. Enrollment began in February 2024. Data collection is expected to conclude in December 2025. The initial dissemination of results is expected in November 2026.

Conclusions: The successful completion of this study will help develop analytical methods for the accurate assessment of residual limb-socket motion. The results will significantly advance the understanding of the complex biomechanical interactions between the residual limb and the socket, which can aid in evidence-based clinical practice and socket prescription guidelines.

This critical foundational information can aid in the development of future socket technology that has the potential to reduce secondary comorbidities that result from complications of poor prosthesis load transmission.

Introduction

Background

For individuals with lower limb loss who use a prosthesis, relative motion between the prosthetic socket and the residual limb, including vertical translation and axial rotation, is a common problem that can lead to skin integrity concerns [1]. Excessive motion between the residual limb and socket can lead to discomfort, pain, and gait deviations that can limit mobility [2], which has been correlated with worse quality of life [3]. Up to 40% of individuals with transtibial limb loss experience issues involving the residual skin and soft tissue, which can be directly attributed to the movement of the residuum relative to the prosthetic socket and liner during dynamic activities [4]. Restricting residual bone motion within the socket may therefore help improve the quality of life and comfort for individuals with lower limb loss. Although some efforts have been made to advance socket technology [5-7] and improve suspension techniques [8], clinical practice has been slow to adopt these new technologies and continues to primarily rely upon unscientific methods for socket fabrication [9,10]. The challenge of developing enhanced socket technology and suspension techniques can be partially attributed to the multifactorial nature of socket fit, which is complicated by the complex mechanical interaction between the residual limb (bone and tissue), the liner, and the socket during dynamic activities. Furthermore, there has traditionally been a lack of accurate analytical techniques to quantify the complex, dynamic biomechanics of the socket-residual limb interface.

Although biomechanical assessments of the relative motion between the residual limb and the prosthetic socket have been performed, the existing data are suboptimal or lack an appropriate resolution. Radiological methods have been widely used to measure the relative motion of the bone and socket in 2 dimensions, but these methods have only provided static analyses of the residual limb-socket relationships [11,12]. Ultrasound has been used to monitor residual limb motion in individuals with above-knee limb loss [13], but the mounting technique has been found to be too cumbersome to implement on a clinical basis. Advanced imaging methods including computed tomography (CT) and spiral x-ray CT offer higher spatial resolution, but imaging must be performed in the supine position, resulting in non–weight-bearing, static assessments [14-16]. Roentgen stereophotogrammetric analyses have been used to characterize the motion between the residual limb and socket in 6 degrees of freedom (DOF) by using biplanar imaging [17]; however, these techniques use static loading protocols. Dynamic assessments of 3D in-socket residual limb-socket kinematics are currently only possible using dynamic stereo x-ray (DSX), which can provide submillimeter bone pose [18-21] and in vivo strain analysis. Currently, only 1 study performed a dynamic investigation of residual tibia motion in participants with transtibial limb loss [10], but the methods relied on subjective input and were time intensive, which can affect accuracy [22] and sample size. In individuals with transfemoral limb loss, Maikos et al [23] used DSX to compare 3D residual femur kinematics between 2 different prosthetic socket types. Gale et al [3] also used DSX for 3D markerless tracking of the residual femur for individuals with transfemoral limb loss during late swing and early stance to calculate the 6 DOF kinematics of the residual femur relative to the socket but did not include terminal stance. DSX may help fill the substantial gap in our understanding of the complex mechanics of the residual limb-socket interaction during dynamic activities that limit the ability to improve prosthetic design.

During the cyclical loading and unloading of the residual limb during the gait cycle, the skin of the residual limb is exposed to nonphysiological stresses and strains, including excessive shear forces [24]. Although the skin is well adapted to compressive force, excessive shear force can be damaging, leading to abrasions, wounds, and ulcers [25,26]. Understanding in-socket skin strain biomechanics is critical for enhancing prosthetic socket fit, limb health, and overall comfort. However, whole-limb skin strain analysis is complicated by the heterogeneous composition of the skin and its anisotropic mechanical properties. Some investigations have used 3D digital image correlation (DIC) to create full-field deformation and strain maps of an unsupported residual limb [27]. Lin et al [28] examined skin strain in a flexed biological residual limb from an individual with transtibial limb loss and showed that the anterior patella region of the limbs exhibited predominantly tensile strains, whereas the posterior patella region exhibited predominately compressive strains. Although 3D DIC evaluations have provided critical data to help improve the mechanical interface of sockets and liners to limit relative motion and shear forces on the skin surface, these investigations only considered strain on an unloaded residual limb. Whole-limb strain fields can drastically change during dynamic, weight-bearing activities while using a prosthetic interface. Furthermore, 3D DIC and other imaging techniques are further complicated by the need for transparent biomechanical interfaces to accurately compute the strain analysis. Other techniques, such as magnetic resonance imaging and CT, can be used to evaluate in vivo strains, but they are also limited by static protocols, low resolution, motion artifacts, and shape distortion [29]. Gale et al [30] used DSX to measure residual limb skin strain and strain rate for individuals with transfemoral limb loss during gait and found that shear strain increased from proximal

to distal regions of the residual limb. The proposed investigation will use time-efficient and highly accurate analytical techniques to measure in-socket residual limb skin strain for individuals with transtibial limb loss during dynamic activities.

Study Objectives and Aims

There remains an unmet need to fill the gap of accurate, biomechanical evaluations of residual limb-socket kinematics, which can then be effectively translated into evidence-based clinical practice. Furthermore, quantifying dynamic shear and tissue deformation is yet to be efficiently evaluated to determine the exact mechanism of tissue strain. Therefore, the objective of this investigation is to develop quantitative, dynamic analytical tools to quantify both 3D bone movement as well as soft tissue and liner deformation at the socket-residual limb interface for individuals with transtibial limb loss. To meet the study objective, the following aims will be addressed: (1) to optimize the DSX procedural setup for the accurate tracking of the prosthetic socket, skeletal kinematics, and tissue and liner deformation; (2) to quantify the relative motion between the residual tibia and the prosthetic socket during dynamic activities; and (3) to measure the deformation of the skin and liner in the prosthetic socket during dynamic activities. The proposed investigation will use a state-of-the-art DSX system to accurately quantify 3D in vivo residual limb-socket kinematics during dynamic activities. To verify the sensitivity of this technique and its relevance to individuals with transtibial limb loss, residual limb-socket kinematics will be evaluated in 2 different socket suspension systems: elevated vacuum (EV) and traditional suction. It is hypothesized that an efficient and highly accurate method to quantify the dynamic interaction between the residual limb and the prosthetic socket will be sensitive enough to distinguish between different types of prosthetic socket suspension systems, which will further enhance the biomechanical understanding of residual limb-socket kinematics.

Methods

Study Overview

To address the study aims, first an iterative cadaver study will be conducted to optimize the placement of an array of radiopaque beads and markers on the socket, liner, and skin to simultaneously assess both dynamic skeletal movement and residual skin and liner deformation. Using a gait simulator, stance phase gait will be simulated using cadaver limbs during each DSX session to induce bone movement as well as skin and liner deformation. The number and placement of markers will be evaluated after each session to refine the marker placement to best track skin and liner deformation and skeletal movement. Once an optimal marker setup is identified, 21 participants with transtibial limb loss will be fitted with a socket capable of being suspended via both EV and traditional suction. Participants will undergo a 4-week acclimation period using the new socket and will then be evaluated at the DSX facility at Rutgers New Jersey Medical School. DSX will be used to track skeletal, skin, and liner motion under both suspension techniques during 3 dynamic activities: treadmill walking at a self-selected speed, treadmill walking at fast walking (10% faster), and a step-down movement. The performance of the 2 suspension techniques (active EV and traditional suction) will be tested by quantifying the 3D bone movement of the residual tibia with respect to the prosthetic socket and quantifying liner and skin deformation at the socket-residuum interface. This study has been registered on ClinicalTrials.gov (NCT05287646).

Cadaver Study to Optimize DSX Setup

The aim of the cadaver study is to optimize the placement of an array of radiopaque beads and markers on the socket, liner, and skin, which will then be used in the human trial to accurately measure the dynamic skeletal movement and residual tissue and liner deformation simultaneously during functional tasks. Five cadaver limbs will be used in an iterative process to develop an optimal marker setup to distinguish markers placed on the socket, liner, and skin as well as to visualize the tibia. The number, size, shape, and placement of markers will be evaluated after each cadaver test to determine the optimal marker set for the measurement of skin and liner deformation and bone movement. The goal is to develop a skin and liner marker set that is free of occlusion during tracking while also not interfering with bone tracking. Although it is understood that the cadaveric tissue may not produce accurate tissue displacement and deformation profiles compared to living tissue, the main intent of cadaver testing is to accurately position the skin and liner markers during an iterative process to reduce or eliminate occlusion during tracking.

Cadaver Preparation and Socket Casting

Five fresh-frozen, whole, lower extremity cadaveric specimens without a history of significant trauma or major surgery at or below the knee will be used. Lower extremity cadaver specimens will be from individuals aged <80 years and with a BMI of <38 kg/m^2 to account for the predicted upper limits of the human trials. Cadavers will be thawed at room temperature for 24 hours and will be transected at the midthigh to keep the knee intact. The cadaver specimens for the initial assessments will be amputated below the knee to a length between 12.5 cm and 17.5 cm below the medial joint line, which is considered an ideal length for transtibial amputation [31]. Myodesis will be performed to stabilize the muscles, and the remaining skin flap will be sutured in place. After initial cadavers of ideal length have been used to determine an optimized marker set, subsequent cadaver limbs will be amputated at shorter lengths to ensure that the marker set does not need to be modified to account for different residual limb lengths. A liner will be placed over the amputated cadaver limbs and then cast with fiberglass to create a negative mold. The negative mold will be filled with plaster to create a positive cast, which will be used to fabricate a ThermoLyn socket. Cadavers will be fitted with the socket and prosthetic componentry, including a pylon and prosthetic foot. A rocker bottom shoe will be placed on the prosthetic foot to aid in simulating dynamic gait.

Cadaver CT Scans

A single CT scan will be acquired for each cadaver experiment. The residual limb will be marked with radiopaque paint. A silicone liner will be applied to the residual limb, and a thermoformed plastic socket marked with solid, 2-mm diameter embedded brass spheres will be placed on the limb before

scanning. The socket will maintain the unloaded 3D shape of the residual limb and the relative positioning of the radiopaque makers. The CT scan will be used to create gray-scale volumes and high-resolution 3D bone surface models required for computing all outcome variables in DSX. CT volume images will be acquired at a resolution of 512×512×0.625 mm^3 (120 kVp; SMART mA).

Experimental Design

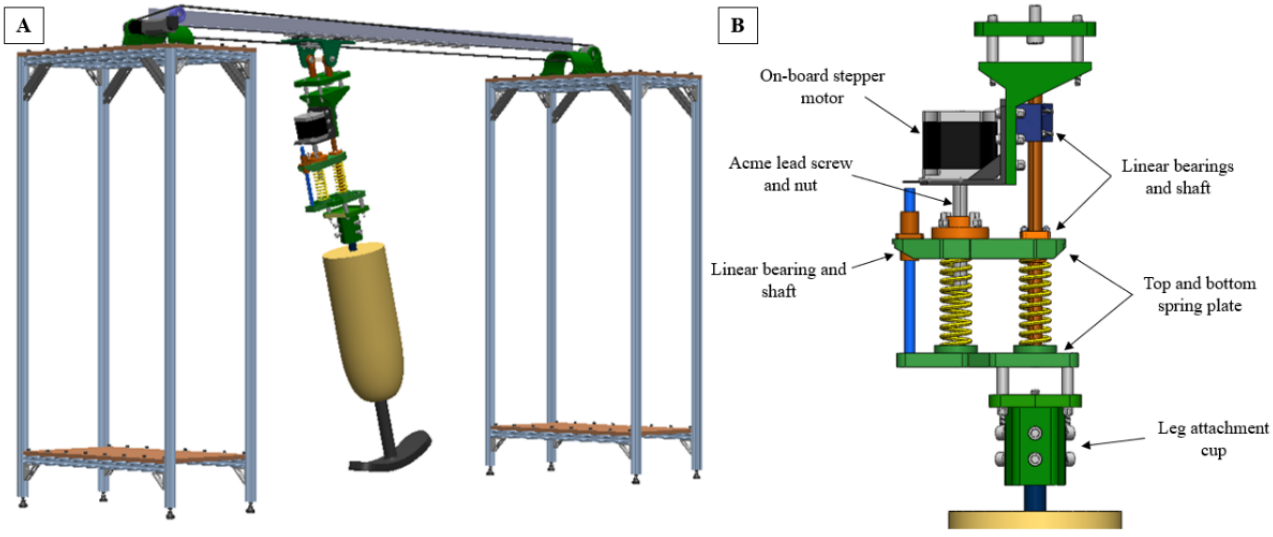
To determine the areas of highest strain on both the skin and inner liner surface (to serve as a starting point for appropriate marker placement), the first cadaver experiment will use a grid of circular radiopaque markers distributed across the circumference of the residual limb and the inner surface of the liner (in separate experiments). Although this grid pattern will cover the entire surface to help quantify areas of highest strain on the liner and skin, the high density of radiopaque markers will make it unlikely to track the movement of the residual tibia, liner, skin, and socket accurately and simultaneously. Therefore, this initial cadaver experiment will serve only to help determine areas of importance for subsequent cadaver studies. However, previously reported skin strain findings from the scientific literature will be considered to ensure that areas of interest are included [10,27]. For clarity, the procedures will be first carried out with markers on the skin and no markers on the liner. The experiment will then be repeated using a liner with no markers on the skin.

A custom grid stencil will be fabricated by cutting specific patterns of circles on a thin vinyl sheet using an electronic die-cutting machine (Cricut, Inc). The circles on the grid will be cut to diameters of either 2 mm or 4 mm and spaced 2 cm apart within each row and column. Each row and column of circles will alternate between the larger and smaller circles, which will help uniquely identify them during marker tracking. The stencil will then be applied to the cadaver limb or liner (in separate experiments), and radiopaque paint will be applied to the pattern to transfer the grid onto the residual limb or liner. The liner will then be placed over the limb, the socket will be donned, and the limb will be placed in the DSX capture volume. Averaging the DSX data collected from 10 to 20 frames from the unloaded-donned socket in the static pose will produce the relative resting grid positions, which will account for any skewness after donning the liner and socket. The circles will then be digitized in dynamic trials to relate their dynamic positions to the resting grid.

Stance Simulation

An electromechanical stance simulator will be designed to apply a compressive load on a cadaver limb through simulated stance phase (Figure 1). The framework will be designed to interface with the DSX system while allowing for remote control of the load and trajectory of a cadaver limb during DSX data capture. Using this setup in conjunction with DSX data capture, simulated stance phase will be performed to determine areas of highest strain on both the skin of a cadaver leg and the inner liner surface, while simultaneously tracking tibial movement during dynamic activities during the clinical trial. To ensure accurate results, the system will be able to apply 100% body weight in compression to induce tissue deformation. The applied load will be monitored using a force plate (AMTI Inc).

Figure 1. Overview of the stance simulator design for simulation of the stance phase for cadaver testing. (A) Isometric view of the stance simulator assembly. (B) Detailed view of the force applicator mechanism.



To avoid interference with the DSX system, the main support structure of the simulator will consist of 2 stands with an angle bar spanning the length between them (Figure 1A). Weights placed on the outer stands will ensure that the system remains fixed despite varied applied loads. A linear track attached to the beam will provide a low friction path for the leg to travel along the plane of forward progression, and the beam will ensure minimal deflection of the track. The leg will pivot around this attachment point, allowing it to attain a full range of motion to mimic heel-strike to toe-off. The drive motor will be placed off-board and will move the leg with a timing belt and pulley. A second, on-board motor will control the deflection of 2 springs to actuate the load applied to the leg. The force applicator mechanism (Figure 1B) will include a stepper motor with a built-in Acme lead screw and nut to add spring compression, allowing for consistent control of applied forces at high loads.

In addition, 3 linear bearings in the assembly allow the assembly to compress without direct control from the on-board motor because of the natural compression of the springs as the leg rolls over in stance under the fixed-height track. The cadaver leg will be placed in extension to limit bending of the knee or the knee will be fixed in place with a titanium rod, increasing the lever arm and ensuring that the springs apply a compressive force. A 3D-printed cup fixture will be secured to the exposed femur of the leg by tightening 6 separate bolts. This attachment method will allow for alignment flexibility, varying the load path through the leg. The entire system will be controlled electronically by 2 separate motor drivers, 1 each for the off-board motor and on-board stepper motor.

Marker Tracking

For each cadaver trial, the images will be analyzed using Locate3D (C-Motion, Inc), which is an application in the DSX suite of software. Locate3D tracks radiopaque markers in x-ray trials by locating the weighted center of circular regions on the images. The circles will be digitized in both the unloaded (resting) and loaded dynamic conditions to relate dynamic positions to the resting grid. Each circle will be tracked throughout the simulated stance phase to calculate the 3D position of each circle in the socket reference frame during dynamic movement. Point clouds will then be calculated in a common frame. Vector fields (ie, movement of the circles) will be computed between the loaded and the resting trial. The distance between each circle and its 8 closest neighbors will be calculated and measured from the resting to the loaded conditions during dynamic trials. From these measurements, the circle clusters that have the largest changes in distance will be determined. The displacement field on the limb surface will be calculated by correlating the time series of images during the dynamic movements. From the correlated skin displacement field, the Green-Lagrange strain and Euler-Almansi strain will be calculated. The areas of the highest strain from these trials will provide a strong estimate of the most appropriate placement of markers on the skin and liner for the human trials.

Subsequent Cadaver Experiments

The results from the initial cadaver experiment will help inform the placement of markers on the liner and skin for subsequent cadaver experiments. Figure 2 illustrates example marker shapes (Figure 2A) and the setup on a cadaver limb (Figure 2B). To track the pose of the socket, brass beads (2 mm diameter) will be secured to the socket. The initial marker shapes on the skin will be lines (10×3 mm) of radiopaque paint that will be placed in a circular pattern (6 cm in diameter—black lines in Figure 2A). Lines organized in the shape of a circle were chosen because the end points of each line in each marker cluster will be able to be independently tracked. However, there is a possibility that there may be a substantial overlap between markers on the surface of the skin, particularly on opposite sides, which would limit their ability to be tracked throughout the movement trials. Therefore, additional shapes (eg, triangles and stars) will also be tested during initial cadaver experiments to determine which marker types are easiest to track throughout the movement trials. Overall, these sizes and shapes were chosen to provide a large surface area on the skin while also permitting visualization of the tibial bone edges. For the inner surface of the liner, radiopaque paint consisting of double lines (10×3 mm) in the shape of a square will be used (Figure 2A). The number of markers, marker shape, placement, and size will be evaluated after each testing session to determine the optimal placement to avoid any overlapping or occlusion of the bone edges. If the markers overlap or interfere with DSX, the sizes will be reduced, the placement of the markers will be changed, or different shapes will be used. An initial, sample cadaver marker set was tested in the DSX system under static conditions to determine if the DSX software had the ability to distinguish markers placed on the socket, skin, and liner (Figure 3). Brass beads were embedded in the socket and radiopaque markers were placed on the skin and liner (similar to that presented in Figure 2). The anteroposterior and oblique x-ray views were fused with the CT imaging into a 3D entity with coregistration of the socket markers, liner markers, skin markers, and bone geometry. It was confirmed that the DSX software could distinguish markers on all surfaces. Subsequent cadaver testing will be performed under dynamic conditions while the skin, liner, and socket markers are tracked in conjunction with bone tracking throughout the simulated stance phase.

Figure 2. Example skin marker shape and setup for the cadaver trials. (A) Circles (lines: 10 mm in length, 3 mm wide) and squares (lines: 10 mm in length, 3 mm wide) will be placed on the skin and liner, respectively. (B) Example marker placement on the skin on a scanned, translucent residual limb in the anterior-lateral view.

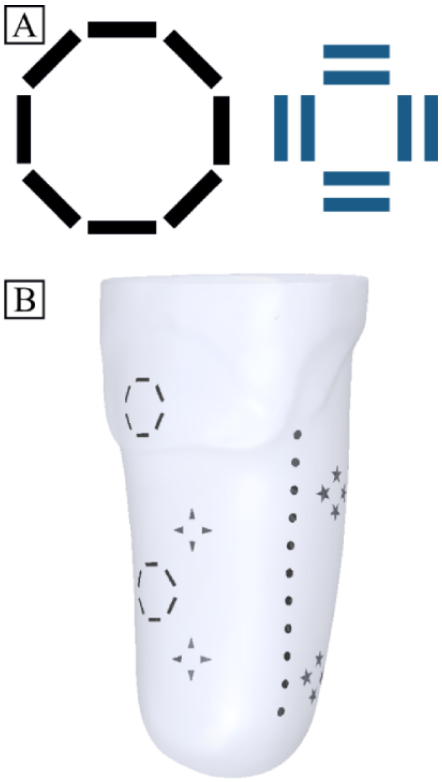


Figure 3. Static testing of a sample cadaver marker set in the dynamic stereo x-ray system. (A) and (B) X-ray images of the residual tibia, socket, and skin markers from the inline and offset x-ray views. Note the cluster of skin (lines in the shape of a circle), liner (triangles), and socket (beads) markers and the bone edges. (C) The x-ray and computed tomography images are fused to create a 3D model with coregistration of the socket and skin markers and bone geometry.

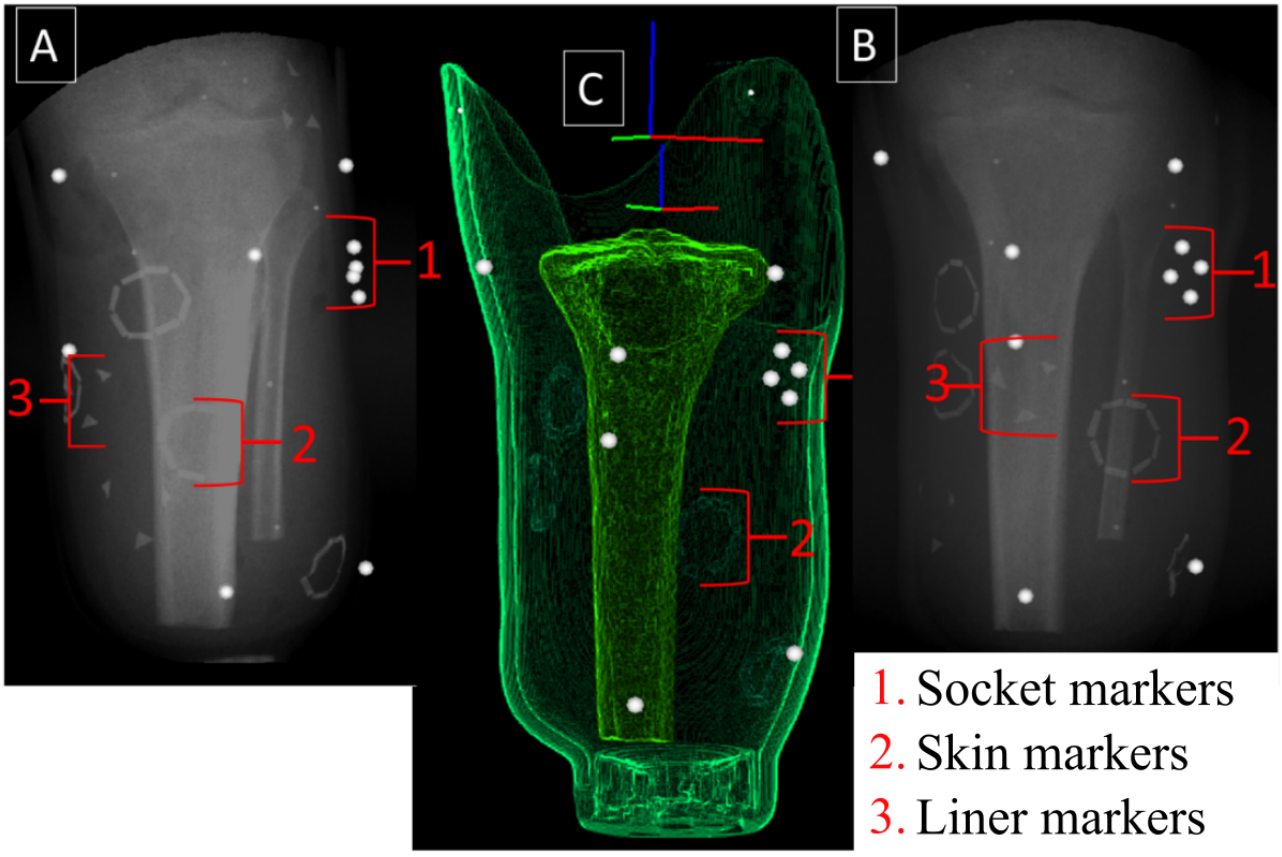

Optimization of the Marker Set

An iterative, heuristic approach will be used with the goal of accurately tracking all end points of each line for the skin and liner marker sets without (or minimal) occlusion while simultaneously tracking the underlying tibial movement. Notably, if there is too much overlap of the lines and tracking is not possible with the lines, additional shapes will be evaluated, and the centroid of each shape will be tracked. Cadaver trials will be sequential, and the marker set will be evaluated through tracking of each marker and performing preliminary deformation analysis after each cadaver trial. Once an acceptable marker protocol has been achieved heuristically, it will be tested on subsequent cadavers to ensure that it is robust for differing anatomies and residual limb lengths. Shorter residual limbs could potentially limit the number of markers that could be applied to the skin. As such, a minimum length may be required for skin and liner marker tracking, which would be then reflected in the inclusion and exclusion criteria.

Deformation Analysis

The markers on the cadaver skin and the inner surface of the liner will be tracked during the simulated stance phase, and their trajectories in both the socket and tibia coordinate systems will define the motion of the skin relative to the socket and tibia, respectively. Their positions in the socket and tibia coordinate systems during the static trial will serve as their baseline positions. Visual3D (C-Motion, Inc) contains the tools to define the socket and tibia coordinate systems and track the motion of the skin and liner markers within these reference frames. Two metrics will be used to quantify skin and liner deformation. The first, shear, is defined as the change in angle between the lines painted on the skin and liner from the baseline position. The end points of the lines forming the circles and squares will be digitized, and the 3D trajectories will be used to reconstruct the 3D shape of the line at each time frame. The angles between the lines will be measured in the static pose to quantify the baseline skin shear. The change in angles will be measured during the simulated stance phase. Shear will be measured as the change in angle relative to the angle in the static position. The second, compression, will be quantified by calculating the change in distance between the lines and a neutral position. As with shear, baseline distances will be calculated from the static trial. From these values, 3D strain maps of the highest areas of deformation will be developed for both the liner and the skin.

Validation of DSX Strain Measurements

In conjunction with the cadaver experiments, to validate the accuracy of proposed methods to measure skin deformation, a customized, mechanical testing setup (Acumen 3AT axial-torsion system, MTS Systems Corp), which can directly interface with the DSX system, will be used. This system permits mechanical testing of soft tissue to be simultaneously performed during DSX data captures (Figure 4). This setup will be used to apply displacements to cadaveric lower limb tissue (mimicking tissue deformation in the socket) to validate the measurements from the proposed DSX analysis. To perform this validation test, 5 segments of cadaveric skin and subdermal tissue will be dissected to be mechanically tested in conjunction with DSX imaging. Each tissue sample will be affixed in tension between the opposing rings of a radiolucent plastic fixture with the skin held taut between the rings using radiolucent hardware. To validate the deformation analysis, radiopaque markers used in the cadaver experiments will be painted on the tissue. A CT scan, as previously described, of each tissue sample with applied markers will be obtained before testing to model the tissue specimen and locate the markers in a 3D space. The DSX apparatus will be angled at a maximum of 30° to distinguish the markers on the horizontal surface to avoid occlusion by the metal structures of the mechanical testing system. The mechanical testing compression rings will allow translation while the center of the fixture below the sample will be open to allow the tissue to freely deform with the applied force. Both the plastic circular fixture attachment and compressive bending fixture will be fabricated from polylactic acid thermoplastic, which is radiolucent. The Acumen 3AT axial-torsion system will be used for mechanical testing with a maximum axial testing capacity of 3 kN. To remove the effects of tissue freezing, the samples will be preconditioned at 0.1 mm/s with an axial displacement loading between 0.1 and 0.5 cm, for 50 cycles, based on the results of a previous study [32]. This displacement (0.5 cm) corresponds to the minimum bone-socket displacement associated with patellar straps, sleeves, or suspension liners [11]. Following this, the displacements associated with vacuum (1.3 cm) and traditional suction (1.8 cm) for the bone-socket interface [11] will be tested for 10 cycles each in compression at a displacement rate of 1 mm/s [32]. The axial displacement, axial force, and time will be recorded with high-speed data acquisition while the tissue is simultaneously imaged by the DSX system. A digital input-output connection will be used to synchronize the 2 systems. The compressive force on the skin tissue is proportional to the distance from the origin of the bending load, and the skin strain and shear stress can thus be calculated for a given symmetric, circular geometry. The skin strain will be compared directly to the strain calculations derived from the position of the markers collected by the DSX system. To account for the asymmetry present in the skin, the geometries, boundary conditions, material properties, and the loading regimen will be simulated using finite element analysis (Ansys, Inc). This analysis will be compared to the mechanical testing results along the skin to determine the degree to which the asymmetry of the skin affects the strain measurements.

Clinical Experiment

Upon completion of the cadaver trials, a robust marker set will have been developed to evaluate skin strain and residual tibial movement for human participants as part of the clinical experiments. The residual tibial motion will be compared relative to the prosthetic socket for individuals with transtibial limb loss while separately using 2 suspension methods: EV suspension and traditional suction (EV system not activated). Participants will be assessed while walking at a self-selected speed on a treadmill, at a speed 10% faster, and during a step-down task. These activities were chosen for three distinct reasons: (1) their relevance to normal activities [33], (2) the fact that the forces exerted on the lower limb during stepping and walking can displace the prosthetic socket relative to the residual limb, and (3) these movements are suitable for recording by the DSX system. These 2 common suspension conditions (EV and traditional suction) were chosen because of their clinical relevance and expected measurable differences between these conditions.

Recruitment and Enrollment

The study sample will consist of 21 individuals with unilateral transtibial limb loss recruited from Veterans Affairs New York Harbor Healthcare System. The inclusion and exclusion criteria are presented in Textbox 1.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Veteran, service member, or civilian with unilateral transtibial limb loss of any etiology
- Aged ≥18 years
- ≥6 months after limb loss
- Current prosthesis users for ≥6 hours per day

Exclusion criteria

- Inability to tolerate socket suspension
- Length of the residual limb prohibits socket fitting, marker placement, or dynamic stereo x-ray data capture
- Mental impairment that impedes study compliance
- Cognitive deficits or mental health problems that would limit the ability to participate fully in the study protocol
- Skin conditions and those with severe contractures that prevent prior prosthetic wear
- Neuropathy, uncontrolled diabetes, receiving dialysis, insensate feet, severe phantom pain, a history of severe skin ulcers, or any other significant comorbidity that would interfere with the study
- Severe circulatory problems including peripheral vascular disease and pitting edema
- Women who are pregnant or who plan to become pregnant during participation in the study

Ethical Considerations

This study was approved by the Veterans Affairs New York Harbor Healthcare System institutional review board (protocol ID 1655582) and the Rutgers University institutional review board (protocol ID Pro2022001576). All participants will provide informed consent before participating in any study activity. No research data will be acquired until the informed consent form has been signed. The principal investigator or study staff will explain the protocol, and participants will be given adequate time to review and comprehend all information before agreeing to participate in the study. After the informed consent form is signed, the study prosthetist will then screen each participant to confirm all inclusion and exclusion criteria and will inspect the residual limb to ensure that there are no issues that could prevent socket fitting. The appropriate residual limb measurements will be taken, and the residual limb will be cast to prepare for socket fabrication. Each participant's involvement will last approximately 8 weeks, including 4 weeks for socket fabrication and fitting, a 4-week acclimation period, and a data collection visit for CT scans and DSX testing on both socket suspension conditions. Study participants will be compensated US $50 for each of the socket fitting visits (up to 4 maximum) and US $100 for the 1-day data collection and testing at Rutgers. Compensation will be given in the form of a direct deposit voucher, processed through the Veterans Affairs New York Harbor Healthcare System fiscal department.

To protect the privacy and confidentiality of the human participants, each participant will be given a unique identification number that will be used in all study-related paperwork. The specific code system will not contain any personally identifiable information. All information collected throughout the study will be methodically recorded, handled, and stored to allow for accurate reporting, interpretation, and verification. Veterans Affairs (VA) complies with the requirements of the Health Insurance Portability and Accountability Act of 1996 and its privacy regulations and all applicable laws that protect the privacy of research participants. The principal investigator and study staff will ensure that research records are stored in a manner that protects the confidentiality of human participant information. All electronic data collected will be deidentified and will not contain any Health Insurance Portability and Accountability Act identifiers, and the physical study forms (ie, signed consent forms and data collection forms) will be stored in secured and locked filing cabinets at the on-site office of the principal investigator. Computer files will be secured through password protection. Throughout the study, deidentified data (video data and electronic data) will be shared using VA information security office–approved secured VA computer systems with password protection and firewall. The study materials will be stored in accordance with the VA record control schedule.

Prosthetic Suspensions

Individuals with transtibial limb loss will be provided with a prosthesis capable of being suspended via both EV and traditional suction, with the prosthetic ankle-foot devices they currently use. Participants will be tested under 2 conditions: with the EV suspension active and with the EV inactive (traditional suction suspension). The order of the conditions will be counterbalanced.

Socket Fitting and Prosthetic Alignment

Before fitting the prosthetic socket, the study prosthetist will capture measurements of the residual limb (eg, length, circumference, and percentage of the sound limb). The study prosthetist will also document any areas of potential concern on the residual limb (eg, excessive redness, scar tissue, redundant tissue, heterotopic ossification, sensitivities, or evidence of previous wounds). A total of 2 to 3 preliminary "check" sockets will then be fabricated to ensure proper fit before the fabrication of the definitive socket. Each socket will

be fitted with a Harmony vacuum pump (Ottobock Inc). Continued fittings will occur, as needed, to get to a comfortable, consistent daily volumetric fit throughout several consecutive days. Each participant will use their own ankle-foot device. Once a consistent, comfortable fit is achieved, fabrication of a definitive, laminated study socket will occur. Participants will use the study socket for a minimum period of 4 weeks before DSX testing occurs. Participants will be asked to use each suspension method equally during the 4-week acclimation period.

Subjective Surveys

Following the 4-week acclimation period, participants will complete 3 surveys for each suspension method. Participants will complete the Prosthesis Evaluation Questionnaire (PEQ), which is a self-reported visual analog-style survey for individuals with lower limb loss [34]. The PEQ has 9 independent domains as well as separate, non–domain-specific questions that can be evaluated individually. For this investigation, the domains for utility, appearance, sounds, residual limb health, and ambulation will be used. The PEQ questions on satisfaction and pain will also be assessed. In addition, participants will complete the PEQ Addendum, which asks 2 open-ended questions regarding any falls and stumbles that the participant may have experienced over the previous 4 weeks [35]. To specifically assess socket comfort, participants will complete the socket comfort score scale, which is a numerical scale of socket comfort that has shown good repeatability and sensitivity to change [36].

DSX Experimental Design

Following the 4-week acclimation period, the participants will be evaluated at the Rutgers New Jersey Medical School DSX facility. To evaluate the 6 DOF kinematics of the residual limb within the socket, participants will separately walk on a treadmill at a self-selected speed, at a speed 10% faster, and during a step-down task from an 18 cm–high platform. The DSX system will be oriented such that all tasks can be recorded with the same configuration. These movement tasks will be completed under 2 conditions: with the EV suspension active and with the EV system inactive (traditional suction). For testing with the traditional suction suspension (EV inactive), the vacuum connector will be replaced with a PushValve (Ottobock, Inc) [11]. A randomized block, crossover design will be used to evaluate the residual limb-socket fit. A group of 11 participants (group 1) and a group of 10 participants (group 2) will be formed. Participants in group 1 will first be tested in the DSX system with the EV on, and then, they will repeat all procedures with the EV inactive. Participants in group 2 will first be tested in the DSX system with the EV inactive, and then, they will repeat the tasks with the EV active. After each suspension method is applied, participants will be instructed to perform normal daily activities for 2 hours to allow for acclimation and for transient changes (eg, volume loss) to manifest. A period of 2 hours was chosen so that both conditions can be tested on the same day while still capturing 90% of the volume loss during socket use [1]. Up to 4 trials of DSX will be conducted for each task for each socket condition, giving a maximum of 24 trials per participant. For each task, DSX data will be collected and analyzed to determine the underlying bone movement and skin strain with respect to the socket. Separate CT scans of the residual limb and socket will also be captured for each participant to generate participant-specific socket and bone models of the residual limb for tracking kinematics.

DSX technology has a limited field of view (about the size of a basketball). Careful placement of the x-ray sources will permit a view of the knee, tibia, and socket. Because participants will be walking on a treadmill, the DSX setup will likely be able to capture the entire gait cycle; but at a minimum, stance phase will be collected. The 3D kinematics of the thorax, pelvis, lower limbs, and prosthesis will be recorded synchronously using a 6-camera motion capture system (Qualisys Inc). Marker-based motion capture will be used to record the overall position and orientation of the body segments that are out of the viewing volume of the DSX during the movement to establish the participants' overall movement patterns.

Clinical Study CT Scans

After the radiopaque markers have been applied to the residual limb and liner, the socket with embedded brass beads will be donned by the participant and a single CT scan of the residual knee joint and tibia will be acquired while participants lie in the supine position with their socket and liner on and with the knee extended. CT scans provide gray-scale volumes for use with DSX and high-resolution 3D surface models required for computing all outcome variables. CT volume images will be acquired at a resolution of 512×512×0.625 mm^3 (120 kVp; SMART mA). Surface3D (C-Motion Inc) will be used to segment 3D models of the socket, liner, and tibia from the CT volumes.

Quantification of the Relative Motion Between the Residual Bone and the Prosthetic Socket

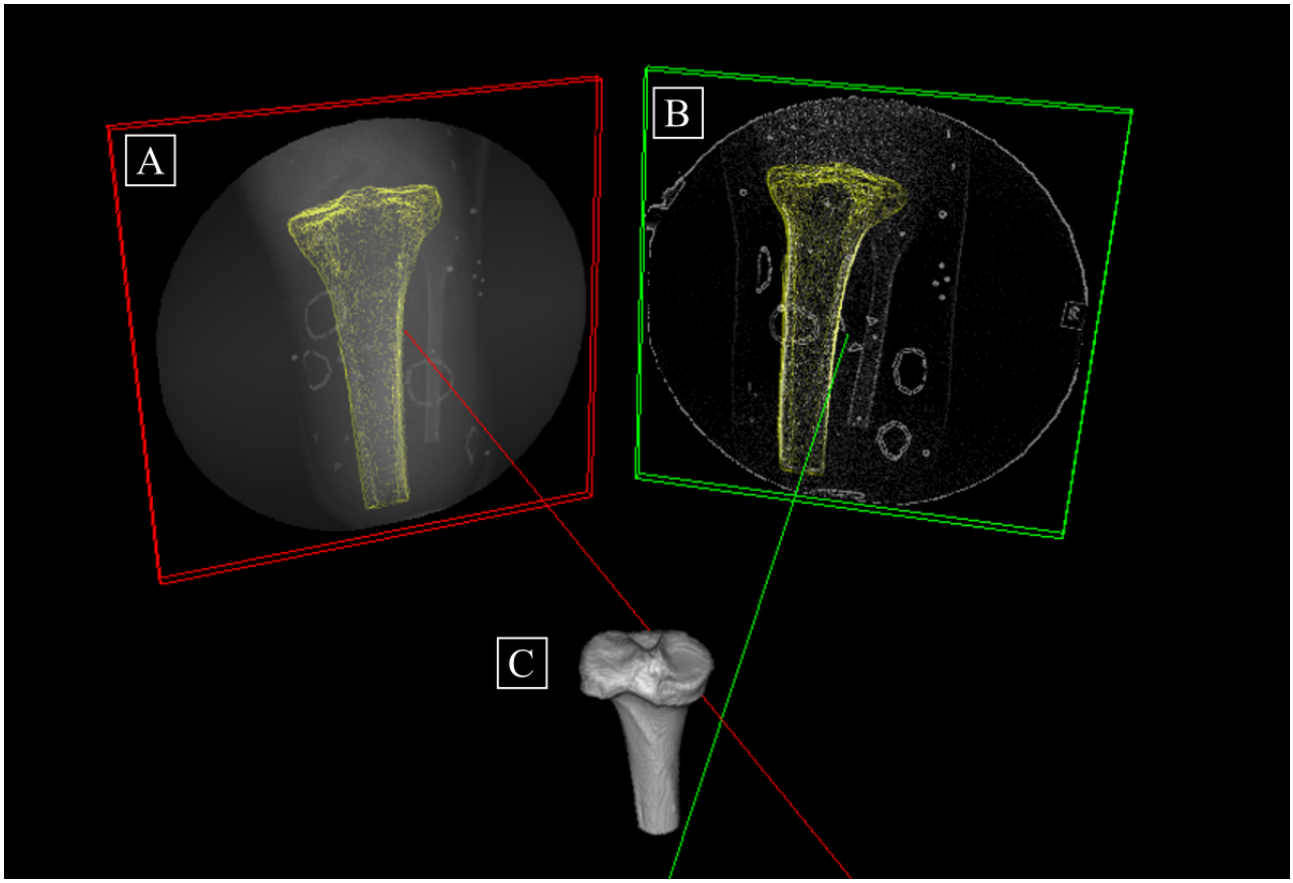
Quantification of the 3D position and orientation of the residual limb has been previously described in detail [23]. In brief, the residual tibia will be tracked throughout the gait cycle, with the coordinate system defined in the CT space using a morphology-based coordinate systems adapted from previous studies [37,38]. These coordinate systems will be registered between Visual3D (C-Motion, Inc) and CT space using the coregistration transformation matrix. The position and orientation (pose) of the socket will also be tracked with 2-mm brass beads secured to the exterior of the prosthetic socket. To provide a context for the relative motion of the residual tibia and socket, 3D infrared motion capture will synchronously be recorded with the DSX data for each participant. Anatomical frames of the thorax, pelvis, and thigh will be constructed by placing retroreflective markers on anatomical locations. Visual3D will be used to establish the anatomical reference frames, estimate the position and orientation of all segments, and compute the kinematics. The reference frames for the socket will be established based on the sagittal plane of the prosthesis. The sagittal plane will be defined by the long axis of the foot. The axial direction will be defined by the pylon. The lateral direction will be perpendicular to the sagittal plane. The anterior direction will be the cross-product of the axial and lateral directions.

To use the same reference frames for both imaging techniques, the global coordinate systems of the optical motion capture and DSX systems will be coregistered by simultaneously capturing the static position of a rigid lattice consisting of 11 radiopaque, spherical markers outfitted with retroreflective tape. The transformation matrix for the coregistration of each global coordinate space will be computed and applied to the respective kinematic data sets. The pose of the socket will be estimated using a standard 6-DOF pose estimation with a set of beads as tracking markers implanted into the socket. The socket reference frame will be established by structural landmarks on the prosthesis in the CT image.

Data Processing

Validation of DSX systems for 3D volumetric model-based tracking has been previously reported [39-41]. For each participant, the residual tibia will be segmented from the CT volume to construct a polygonal mesh of the tibia surface. Digitally reconstructed radiographs (DRRs) created from participant-specific CT scans will be matched to the DSX images in the inline and offset views to calculate the 3D pose of the tibia (Figure 5) [18,41]. DRRs will be generated by positioning the segmented CT volume within a virtual x-ray system and projecting rays through it to create a simulated x-ray image [23]. The optimal position and orientation of the bone will be defined as the pose that maximizes the similarity between the pair of DRR images and their corresponding x-ray images. To track each trial, the tibia will first be manually positioned in every fourth frame of data. Subsequently, a cubic spline will be fitted to the set of manual positions and orientations of the bone, which can be interpolated by the model-based tracking algorithm to determine a pose of the bone in every frame.

Figure 5. A 3D representation of the synchronized x-rays. The inline x-ray image is the red frame (A), whereas the offset x-ray image is the green frame (B). The 3D residual tibia (C) is reconstructed from computed tomography (CT) data. The red and green lines are the perpendiculars from the x-ray image planes to the x-ray sources. The outlines of the tibia (shown in yellow) superimposed over each x-ray image are created by casting rays from each x-ray source through the CT tibia to the x-ray planes.



The algorithm output will be a set of 4×4 transformation matrices representing the pose of the residual tibia. The position and orientation of the socket will be calculated using beads placed on the rigid socket for each time frame. Excursions for relative tibial rotations and translations will be defined as the difference between the maximum and minimum values for each variable within the gait cycle. The differences between the residual bone movement with the EV and traditional suction will be determined in 6 DOF for each participant. Group differences for tibial rotations and translations will be compared at initial contact, toe-off, and swing phase as well as for the total excursions of the residual tibia during the gait cycle.

Quantification of Skin and Liner Deformation

Motion between the bone and the skin (skin deformation) and motion between the skin and the inner surface of the liner will be examined simultaneously with bone movement in the prosthetic socket. Motion between these interfaces can be directly associated with discomfort while wearing a prosthesis [3,30]. In addition, motion between the socket and both the skin

and inner surface of the liner will be examined for a complete understanding of the motion between the limb and the prosthesis.

The results from the cadaver experiments will inform the final placement of markers on the liner and skin. The final number, sizes, shapes, and placement of markers will be based on the results of the cadaver experiments and any potential overlap or bone occlusion. However, the proposed shapes will make identification of the markers in the x-ray images easier and will foster the ability to examine both shear and compression. The ends of each line will be digitized manually from the 2 sets of x-ray images. Reconstruction of the 3D trajectories of the markers will be performed using the DSX software (C-Motion Inc). Visual3D will be used to estimate the deformation of the skin and liner from the relative movement of the markers in the socket reference frame.

Motion of the Skin and Interior of the Liner Relative to the Socket and Residual Tibia

The ends of the lines on the skin and liner will be tracked during the dynamic trials, and their trajectories in the socket coordinate system will define the motion of the skin and liner relative to the socket. Their positions in the socket coordinate system during the static trial will serve as the baseline positions. Visual3D contains the tools to define the socket coordinate system and track the motion of the skin markers within this reference frame. The motion of the lines will also be calculated in the coordinate system of the residual tibia. Their positions in the tibia coordinate system during the stationary trial will serve as their baseline positions. The tibia coordinate system will be defined to track the motion of the skin and liner markers within this reference frame.

Deformation of the Skin

Deformation of the skin will be evaluated in the same way as in the cadaver experiments. In brief, 2 primary metrics will be used to quantify skin deformation: shear and compression. For shear, the end points from the lines will be digitized and the 3D trajectories will be used to reconstruct the 3D shape of the line at each time frame. The angles between the lines will be measured in the static pose to quantify the baseline skin shear. The change in angle will be measured during each dynamic task. Shear will be measured as the change in angle relative to the angle in the static position. Compression will be calculated by the change in distance between lines as well as a neutral position. As with shear, baseline distances will be calculated from the static trial.

Data and Statistical Analysis

Overview

Descriptive statistics will be used to summarize demographic and continuous baseline variables. Median and IQR will be used to classify nonnormal or ordinal data. For the clinical experiment, a between-participant factor at 2 levels (EV on and EV off) will be used. The interaction of the suspension condition (EV on or off) will determine the efficacy of the EV system on the outcome measures.

Bone Movements

The differences between the residual bone movement with the EV and the traditional suction suspension will be determined in 6 DOF for each participant. Briefly, group differences for tibial rotations and translations as well as total excursions of the bone for each suspension condition will be compared during the gait cycle. Paired *t* tests will be performed and a between-participant factor at 2 levels (EV on and EV off) will be used. A hierarchical linear model will be used to evaluate the tibial range of motion (ie, maximum translation and rotation) as a function of tibial position and potential confounding factors (eg, gender, age, etiology, and time since limb loss). The hierarchical linear model will also be used to evaluate the tibial motion path and the effect of rate during the 3 different activities.

Skin and Liner Deformation

The characterization of 3D skin deformation will be performed by comparing the 3D position of the skin markers at rest, or unloaded position, to the 3D positions of the markers when deformed during each task to produce relative strain assessments for marked regions of the residual limb. The characterization of 3D deformation will be measured between the suspension methods. Paired *t* tests will be performed as previously described for bone movements. Linear regression models will be used to evaluate the potential confounding factors.

Power Analysis

Table 1 outlines the sample size estimate required to achieve 90% power for the key variables of interest. A previous pilot investigation for individuals with transfemoral limb loss [23] indicated an effect size of 0.77 for residual femur axial translation. Assuming an α of .05, using paired *t* tests, 21 participants are required to achieve 90% power to detect a 0.5 cm difference in axial translation. Owing to the paucity of highly accurate data on movement between the residual tibia and socket, data from Board et al [1] were used to calculate an effect size for tibia translation (1.75) for suction and EV suspension. Given an effect size of 1.75 and an α of .05 for a paired *t* test, a sample size of 21 will be powered at >99% to detect differences between EV on and off. For skin strain, Gale et al [30] found a maximum shear strain of approximately 0.08. Assuming a shear strain of 0.08 with a moderate effect size of 0.75 (α=.05), a sample size of 21 will be required to achieve 90% power to detect differences between EV on and off.

Table 1. Power analysis.

Measure	Values, mean (SD)	Sample size for achieving 90% power, n
Femur distal translation (cm)	2.0 (0.6)	21
Tibial translation (cm)	4.0 (0.4)	6
Skin shear strain	0.08 (0.02)	21

Results

This study was funded in October 2021. Cadaver testing began in January 2023. Enrollment began in February 2024. Clinical data collection is expected to be completed in December 2025, and the study is expected to be completed in April 2026. Data analysis of the full data set will begin after final data collection. Initial dissemination of results is expected in November 2026, with subsequent publication of secondary analyses in 2027.

Discussion

Expected Outcomes and Anticipated Principal Findings

It is expected that the outcomes of this investigation will significantly contribute to the understanding of the complex mechanics of the residual limb-tissue-socket interfaces during dynamic activities for individuals with lower limb loss. It is also expected that by using DSX in combination with novel mathematical algorithms, relative movement between the residual limb and socket and skin deformation can be accurately measured during dynamic motions for individuals with lower limb loss. Ultimately, this foundational information can be critical for developing a database of biomechanical socket parameters deemed important for socket fit, limb health, and comfort. By using the techniques developed in this investigation to perform future comparative effectiveness research of current prosthetic socket technology, better information about the benefits, risks, and costs of different socket options can be generated to provide health care decision makers (eg, patients, clinicians, and policy makers) with highly accurate, evidence-based information. Furthermore, the methodology detailed in this study should speed up the processing time, which, to date, has been burdensome for researchers. This will allow for faster dissemination of information and greater throughput of data to inform clinical guidelines for prosthetic suspension systems. Finally, this investigation can provide vital foundational information that can be used by leading manufacturers in prosthetic design to create enhanced socket technology that has the potential to reduce long-term secondary physical comorbidities and degenerative changes [42].

As the number of individuals with limb loss continues to grow [43], substantial resources will be required for rehabilitation and prosthetic services for this population. Effective outcomes-based clinical practice will be necessary to reduce long-term disabilities associated with prosthetic use. As such, it is the objective of this investigation to examine the dynamic in vivo kinematics between the residual limb and prosthetic socket in 6 DOF of motion, as well as to quantify residual tissue and liner deformation for individuals with transtibial limb loss.

Dissemination Plan

For large-scale dissemination in the Department of Veterans Affairs and Department of Defense, results will be presented through webinars offered by the Extremity Trauma and Amputation Center of Excellence, which are available across the entire Department of Veterans Affairs and Department of Defense health care networks. These webinars are offered to researchers and health care professionals who provide care for individuals with limb loss. For stakeholders in the civilian health care systems, the outcomes and important techniques developed in this study will be published in highly rated peer-reviewed scientific journals (eg, *Gait & Posture, Clinical Biomechanics, Journal of Biomechanics, Frontiers,* and *Orthotics and Prosthetics International*). The results will also be presented at professional conferences that are specific to clinical limb loss care teams (eg, the American Academy of Orthotists and Prosthetists, American Society of Biomechanics, and Military Health System Research Symposium). The findings and methods of this study will also be directly distributed to industry partners. Because most prosthetic technologies used by veterans and service members with limb loss are developed by industrial entities, sharing new evidence-based information with industry leaders will support the development of future products to better meet the needs of individuals with lower limb loss.

Limitations

The heterogeneity of the population, including varied ages, etiology of limb loss, prosthesis experience, and time since limb loss, may limit the generalizability of the outcomes to a more diverse population. However, the statistical analysis models will adjust for these specific confounding factors. Although participants will use the same type of prosthetic socket, the ankle-foot devices will not be prescribed, which could introduce additional variability. The tibia and skin markers will likely be manually positioned at every fourth to tenth time frame, which may cause intratracker errors that could be improved with automated algorithms. Finally, the limited field of view for DSX may restrict collecting data for the entire gait cycle and will be unable to record the overall position and orientation of the lower limbs and pelvis that are out of view.

Acknowledgments

At the Department of Veterans Affairs New York Harbor Healthcare System, the authors would like to acknowledge Eric Baksh for assisting with socket fabrication and socket alignment during stance simulator testing as well as Kenneth Breuer for his assistance during protocol design. The Rutgers Orthopeadic Department would like to thank the radiology department at the Rutgers School of Dental Medicine for assisting with the preclinical computed tomography (CT) scans. The authors would also like to thank Dr Sheldon Lin, Dr Joe Ippolito, and Dr Joseph Galloway for conducting cadaveric amputation procedures. The authors would like to thank the radiology department at University Hospital for assisting with pre- and postclinical CT scans. Finally, the authors would like to acknowledge the Narrows Institute for Biomedical Research and Education for their assistance in grant management. This work was supported by a Veterans Affairs Merit Review Award (I01 RX003700) from the United States Department of Veterans Affairs, Rehabilitation Research and Development Service. This funding source had no role in

the design of this study and will not have any role during its execution, analyses, and interpretation of the data or in the decision to submit results.

Data Availability

All data generated or analyzed during this study are included in this published paper. The final results will be available via a publicly available data repository.

Disclaimer

The views expressed in this paper are those of the authors and do not necessarily reflect the position or policy of the Department of Veterans Affairs or the US government. The identification of specific products or scientific instrumentation is considered an integral part of the scientific endeavor and does not constitute endorsement or implied endorsement on the part of the authors, the Department of Veterans Affairs, or any component agency.

Authors' Contributions

JTM, JPL, and SED participated in the conceptualization of the study. JTM, JMC, DVH, DNP, CW, JPL, and SED participated in methodology development. JTM, JMC, DVH, DNP, and CW participated in data collection. JTM, JMC, DVH, DNP, CW, JPO, MJH, JPL, and SED participated in writing, review, and editing of the manuscript. JTM, JPO, and MJH participated in project administration. JTM and JPO participated in supervision of the project and staff. JTM, DNP, JPL, and SED participated in funding acquisition. All authors have read and approved the final manuscript.

Abstract

Background: Children in Lao People's Democratic Republic (Lao PDR) receive suboptimal nutrition because of low breastfeeding rates, undermining their developmental potential. While major public health campaigns have attempted to increase breastfeeding rates, they have been largely unsuccessful. One explanation for these unsuccessful interventions is the economic and financial constraints faced by mothers. A potential solution for alleviating these pressures is providing social transfers to support breastfeeding; defined as a cash or in-kind transfer. Capitalizing on key strategies used in previous social transfer programs, we will assess the effectiveness of social transfer intervention for increasing exclusive breastfeeding rates in Vientiane, Lao PDR.

Objective: This study aims to conduct a randomized controlled trial (RCT) designed to assess whether social transfers can increase exclusive breastfeeding rates in Vientiane Capital, Lao PDR.

Methods: A prospective, parallel cluster-RCT was conducted among 300 mothers who recently gave birth and initiated breastfeeding. Enrolling 100 participants for each intervention arm provided us with 80% power to detect an increase in exclusive breastfeeding from the anticipated 21% in the control arm to 40% in either of the 2 intervention arms. Mother-infant dyads were enrolled at approximately 1 month post partum. Follow-up visits will occur at 6 months, 1 year, 2 years, and 3 years post partum; with the ambition to extend the follow-up period. Mother-infant dyads were enrolled between August 2022 and April 2023 with follow-up until 3 years post partum (2026). A local study team comprised of 2 nurses and 2 laboratory technicians is responsible for enrollment and follow-up of participants. Participants were randomly assigned to one of three groups during the baseline, 1-month visit: (1) control group, no social transfer; (2) intervention group 1, an unconditional social transfer at 6 months post partum; and (3) intervention group 2, a social transfer at 6 months post partum conditional upon mothers exclusively breastfeeding. All groups received educational materials supporting mothers to exclusively breastfeed. The primary end point will be exclusive breastfeeding at 6 months post partum. Secondary end points will include exclusive and complementary breastfeeding duration, childhood wasting and stunting, child growth, maternal and infant stress, predictors of early breastfeeding cessation, intestinal inflammation, anemia, maternal weight loss, maternal blood pressure, maternal anxiety, and GRIT personality score. Questionnaires and physical examinations were used to collect information.

Results: As of November 2023, the study has enrolled 300 participants. Study participation is ongoing until December 2026 at minimum. Over the study lifetime, 93% have completed all visits.

Conclusions: We see potential for a long-term program that may be implemented in other low- or lower-middle-income countries with only minor modifications. The RCT will be used as a basis for observational studies and to investigate the impact of human milk on child fecal microbiota and growth.

Introduction

Breastfeeding provides important benefits for infants and societies [1,2]. Despite its well-known and widespread benefits, breastfeeding rates remain low in many parts of the world. In Vientiane, the capital of Lao People's Democratic Republic (Lao PDR), only 21% of children aged 0-5 months were exclusively breastfed, and less than half (42.3%) were predominantly breastfed in 2017 [3]. Complying with the World Health Organization's breastfeeding recommendations can help countries meet the United Nation's sustainable development goals with respect to good health and well-being, economic growth, and reduced inequalities [4].

Even though most mothers recognize the benefits of breastfeeding, they also face a complex web of factors that make breastfeeding difficult, including formal labor commitments without sufficient parental leave or breastfeeding support, and television ads promoting infant formula [5,6]. Over the last 30 years, the Ministry of Health in Lao PDR has attempted to increase breastfeeding rates through standard public health behavior change campaigns, including a safe motherhood program and a large United Nations children's fund supported exclusive breastfeeding promotion campaign; however, these programs were largely unsuccessful [5].

One probable explanation for these unsuccessful interventions is the economic and financial constraints faced by mothers. A potential solution for alleviating these pressures is providing social transfers to support breastfeeding; defined as a cash or in-kind transfer. Evidence suggests that social transfers have helped increase breastfeeding rates in other settings. In a previous experiment, Puerto Rican mothers were provided US $25 per month after successful observation of breastfeeding (ie, conditional cash transfer), which resulted in significantly higher breastfeeding rates at 6 months postpartum compared with mothers who did not receive the cash transfer [7]. A similar model providing a social transfer with a letter encouraging mothers to spend time with their infant (ie, labeled social transfer) in a US neonatal intensive care unit increased the daily provision of breastmilk [8]. However, all evidence on social transfer programs for breastfeeding comes from high-income countries. In fact, no study has implemented a social transfer program for breastfeeding promotion in low- or middle-income countries despite a large number of successful social transfer programs targeting other health behaviors in these settings [9].

Capitalizing on key strategies used in previous social transfer programs, we will assess the effectiveness of social transfer programs for increasing breastfeeding rates in Vientiane, Lao PDR. A previous qualitative, community-engaged project in Vientiane focused on identifying breastfeeding norms and social transfers that would support breastfeeding mothers (unpublished data). Using the results from this study, we designed a culturally grounded social transfer program that is responsive to the identified needs of new mothers.

The overall objectives of this project are to assess (1) the effect of social transfers on exclusive and complementary breastfeeding duration and (2) the long-term impacts of breastfeeding on child development.

Methods

Overview

The Social Transfers for Exclusive Breastfeeding (STEB) is a prospective, parallel cluster-randomized trial in the Vientiane Capital, of Lao PDR. Mother-infant dyads will be enrolled at approximately 1 month post partum and followed for 3 years; with the ambition to extend the follow-up period. The study period runs from August 2022 to December 2026.

Participants and Recruitment

Our study is nested within an ongoing birth cohort (the Vientiane Multigenerational Birth Cohort [VITERBI]). Women were recruited for VITERBI if they (1) lived in one of the following districts of Vientiane: Chanthabuly, Sikhottabong, Sangthong, or Mayparkngum; (2) had an expected due date/or gave birth between July 1, 2022, and June 30, 2023; (3) did not plan to permanently move outside the study area; (4) did not have a medical, intellectual, or psychological disability; and (5) agreed to participate and sign an informed consent; if younger than 18 years, a legal representative had to agree to sign the informed consent.

The target sample size for the STEB randomized control trial was 300 mothers and their children. All pregnant women enrolled in VITERBI were eligible to participate in our study if they gave birth within the last 4 weeks, were exclusively breastfeeding at the time of recruitment, had no illnesses that contraindicate breastfeeding, and had a healthy singleton infant of 37 weeks or more gestation with a birth weight of at least 2500 g.

A local study team comprised of 2 nurses and 2 laboratory technicians was responsible for enrollment and follow-up of participants. Using pregnancy records from VITERBI, a list of potential participants was created. In order to identify women

who recently gave birth (≤1 month), the following data were used: (1) approximate due date or (2) weeks gestation when an approximate due date was not provided. When both variables were missing, the average week of gestation was set at 40 weeks and added to the interview date to provide the latest possible birth date. All potential participants were screened on a telephone call to ensure they met the eligibility criteria. If the participant met the inclusion criteria and agreed to participate in the study, a baseline visit was scheduled.

Sample Size Calculation and Power

Enrolling 100 participants for each intervention arm provided us with 80% power to detect an increase in exclusive breastfeeding from the anticipated 21% in the control arm to 40% in either of the 2 intervention arms.

Study Logistics

During the baseline visit, if informed consent was given, a random number was generated within the Open Data Kit (ODK) platform that assigned the mother to a control or intervention group. If they were randomly assigned to an intervention group, mothers were allowed to choose from the following social transfers: (1) money (US $75); (2) developmental toys, clothes, and diapers for the child; or (3), a combination of money and developmental toys, clothes, and diapers for the child (Figure 1). We created a shopping catalog with different toys and clothes for them to choose from. At the end of the visit, the study team encouraged intervention group 1 to meet their breastfeeding goals and told them that the social transfer would be provided at 6 months post partum to show our support for their breastfeeding efforts. Mothers randomly selected for the third intervention arm were told that they would only receive their social transfer if they exclusively breastfed and nurses could observe breastmilk expression at the 6-month visit. All intervention and control groups received educational material about the benefits and recommendations of exclusive breastfeeding.

During a follow-up visit when the child is 6 months of age, nurses will collect an end-line survey from mothers, collect infant fecal samples, and observe breastmilk expression.

Figure 1. Screenshot from shopping catalog for Social Transfers for Exclusive Breastfeeding (STEB) participants.

Data Collection Instruments

Overview

STEB has a total of five questionnaires: (1) a screening questionnaire to assess eligibility; (2) baseline enrollment conducted at approximately 1 month post partum; (3) an endline questionnaire at 6 months post partum; (4) a follow-up visit at 1 year post partum; and (5) a follow-up visit at 2 years post partum. All source documents were created in English and translated into Lao. We briefly describe each questionnaire below.

Screening Questionnaire

A screening questionnaire was conducted on the telephone in order to assess the inclusion and exclusion criteria. A maximum of 10 questions were asked. If an answer to one of the questions rendered them ineligible for the study, no further questions were asked. Questions included date of birth and expected birth date in order to determine prematurity of the infant, birth parity, birthweight, current breastfeeding status, breastfeeding exclusivity, long-term medical problems of the infant, and if the mother experiences galactosemia, human immunodeficiency virus, human T-cell lymphotropic virus type 1 or 2, illicit drug use (ie, cocaine), Ebola, artificial breast implants, or infectious tuberculosis.

Baseline—1 Month Postpartum

The baseline questionnaire is conducted at approximately 1 month post partum and includes employment questions, the short Grit scale [10], family and gender roles, child health and vitamin, mineral or other medicine intakes, breastfeeding and infant feeding, Breastfeeding Self-Efficacy Scale–short form [11], and maternal diet. The Demographic and Health Surveys household characteristics questionnaire. Hemoglobin levels of the mother and infant were taken using the HemoCue Hb 301. Biospecimen samples included infant feces, human milk, and a saliva sample from the mother and infant. Anthropometric measurements of the child included skinfold thickness of the triceps, subscapular, quadriceps, and flank, weight, length, mid-upper arm circumference (MUAC), and head circumference. Anthropometric measurements of the mother included skinfold thickness of the triceps, subscapular, quadriceps, and flank, blood pressure, height, weight, and heart rate.

Endline—6 Months Postpartum

The endline questionnaire is conducted at approximately 6 months post partum and includes employment questions; child health; vitamin, mineral, or other medicine intake; breastfeeding and infant feeding; maternal diet; participation in cultural postpartum activities (eg, hotbeds and mother roasting); perceived stress scale [12]; Postpartum Specific Anxiety Scale [13]; and caregiver-reported early development instruments [14]. A variety of additional health measurements were assessed. Hemoglobin levels of the mother and infant were taken using the HemoCue Hb 301. Biospecimen samples include infant feces, human milk, and a saliva sample from the mother and infant. Anthropometric measurements of the child included skinfold thickness of the triceps, subscapular, quadriceps, and flank, weight, length, MUAC, and head circumference. Anthropometric measurements of the mother included skinfold thickness of the triceps, subscapular, quadriceps, and flank, blood pressure, height, weight, and heart rate.

1- and 2-Year Follow-Up

Visits will occur at 1, 2, and 3 years post partum (SD 1 month). The questionnaire includes child health and vitamin, mineral or other medicine intake; breastfeeding and infant feeding; maternal diet; alcohol consumption; Postpartum Specific Anxiety Scale [13]; Edinburgh Postnatal Depression Scale [15]; and the brief infant sleep questionnaire–short form [16]. At 1 year post partum, child development will be assessed using caregiver-reported early development instruments [14]. At 2 and 3 years post partum, child development will be assessed using the Global Scale for Early Development [17]. Hemoglobin levels of the mother and infant will be taken using the HemoCue Hb 301. Biospecimen samples include infant feces and human milk. Anthropometric measurements of the child included foot length, skinfold thickness of the triceps, subscapular, quadriceps, and flank, weight, length, MUAC, and head circumference. Anthropometric measurements of the mother included skinfold thickness of the triceps, subscapular, quadriceps, and flank, blood pressure, height, weight, and heart rate.

Retention of Participants

In order to reduce participant dropout, we collect a variety of contact information. Participants provide their first and family name, address, phone number, email address, village leader name, temple or religious organization, and the contact information of a family member or close friend. In addition, we provide a small incentive. Immediately after the physical examination, all participants receive the test results for both the mother and child and can track their progress over time at each visit. Test results include blood pressure, hemoglobin levels, and all anthropometric values. Results are explained in person and written on an information pamphlet. All participants who complete the baseline questionnaire receive a small gift that equates to approximately US $1.

Outcomes

The primary end point will be exclusive breastfeeding at 6 months postpartum. Secondary end points will include exclusive and complementary breastfeeding duration, childhood wasting and stunting, child growth (height and weight), maternal and infant stress, predictors of early breastfeeding cessation, intestinal inflammation, anemia, maternal weight loss, maternal blood pressure, maternal anxiety, and GRIT personality score.

Data Management

The ODK is used for all questionnaires and data management. All study staff have access to an Android tablet with the ODK Collect app. Data collection is completed offline on password-protected devices. Data connectivity is only used to send the final questionnaire data.

Project data will only be accessible to authorized personnel who require the data to fulfill their duties within the scope of the research project. On the case report forms and other project-specific documents, participants are only identified by a unique participant number. The unique participant number will be taken directly from VITERBI, and is a combination of

the household number, district, village, and individual within the household. Health-related data will be stored for 15 years, following institutional storage and safety policies. Only samples will be kept for an unidentified amount of time if the separate consent for reuse of health data has been signed. Data storage is on a locally secured server using the ODK Aggregate server and secured via a secure sockets layer.

Biological material in this project is not identified by participant name but by a unique participant number. Biological material is appropriately stored in a restricted area only accessible to authorized personnel. The biological specimens will be stored with their code at Lao TPHI and Swiss TPH.

Ethical Considerations

Ethical approval for the study was obtained from the Ethics Commission of Northwestern and Central Switzerland (EKNZ, 2020-00037) and from the National Ethic Committee for Health Research (044/NECHR; June 30, 2021). This research project will be conducted in accordance with the protocol, the Declaration of Helsinki [3], the Swiss Human Research Act, and the Swiss Human Research Ordinance [1], as well as other locally relevant regulations. Patients or the public were not involved in the design, conduct, reporting, or dissemination plans of our research. Eligible participants will be visited initially by study staff. The purpose of the study and its procedures will be explained to participants and written informed consent will be obtained. Pregnant women will be giving consent for themselves and their newborns. For minors (aged <18 years), both the pregnant woman and her parents will provide consent. For participants who are illiterate, there will be an additional witness who is not part of the study team. Participation is voluntary and patients have the right to withdraw from the study at any given point in time with no further obligations. If the participant withdraws at any time, all data will be deleted and biospecimen samples destroyed. Confidentiality of information will be assured to the participants. All participants younger than 18 years are considered vulnerable populations according to the Lao PDR legislation. If the respondent is underage and agrees to participate, he or she needs the authorization of a parent or legal guardian, who cosigns the study informed consent.

Results

As of November 2023, the study has enrolled 300 participants. Study participation is ongoing until December 2027 at minimum. Over the study lifetime, 93% have completed all visits. Primary results from the 6-month visit are expected in early 2024.

Discussion

Conditional cash transfer programs have been used in a wide range of settings to reduce poverty, with proven benefits for short- and long-term health [18]. STEB is to our knowledge the first longitudinal and randomized social transfer program evaluation for breastfeeding in a low- or middle-income country. We will follow participants for a minimum of 3 years post partum—providing an excellent platform to investigate the short- and long-term benefits of a breastfeeding social transfer program.

During the first year of the program, we encountered a variety of barriers. To start, enrolling new mothers at approximately 1 month post partum was difficult due to the high rates of infant formula use. We strategically enrolled at 1 month post partum to reduce coercion among mothers who did not want to breastfeed. However, a large majority of mothers provided infant formula before 1 month post partum. Enrolling mothers earlier in the postpartum period who want to exclusively breastfeed may reduce the early introduction of infant formula. Second, distances between the 4 study districts in Vientiane, Lao PDR are large. Transportation of staff to the rural districts is a major challenge because of the time spent traveling and the high burden of transportation costs. For example, during the rainy season, many streets become impassable—reducing the capabilities of the study staff to reach participants. Collection of infant fecal samples at 1-month was also difficult because of the irregularity of bowel movements at this age.

Despite the substantial size of the social transfers made, we believe that interventions that include financial support for breastfeeding can be highly cost-effective in this setting. In 7 Southeast Asian countries alone, the short- and long-term benefits of breastfeeding are estimated at US $1.9 billion a year [1]. We believe that social transfer programs focused on breastfeeding have the potential to be more effective in low- or middle-income countries, where monetary compensation may reduce additional barriers not present in high-income countries.

STEB has some limitations worth noting. The small sample size will prohibit more nuanced data analysis. Enrollment does not occur immediately after birth; instead, all participants are enrolled at 1-month post partum. Many mothers face significant barriers to exclusive breastfeeding during the first month postpartum; therefore, the study population of STEB may be slightly different. Recall of the exact timing of complementary foods provided is likely biased; yet, previous research has shown that recall bias for breastfeeding is minimal.

STEB was designed to provide a unique platform to investigate the short- and long-term impacts of exclusive and complementary breastfeeding on child health and development. Further, the longitudinal sampling of human milk and infant feces provides a unique opportunity to study human milk as a biological system and how this impacts the gut microbiome. If proven effective, we see potential for a long-term program that may be implemented in other low- or lower-middle-income countries with only minor modifications.

Abstract

Background: This study will pilot-test an innovative just-in-time adaptive intervention to reduce severe respiratory illness among children with severe cerebral palsy (CP). Our intervention program, Respiratory Exacerbation–Plans for Action and Care Transitions (RE-PACT), delivers timely customized action planning and rapid clinical response when hospitalization risk is elevated.

Objective: This study aims to establish RE-PACT's feasibility, acceptability, and fidelity in up to 90 children with severe CP. An additional aim is to preliminarily estimate RE-PACT's effect size.

Methods: The study will recruit up to 90 caregivers of children with severe CP aged 0 to 17 years who are cared for by a respiratory specialist or are receiving daily respiratory treatments. Participants will be recruited from pediatric complex care programs at the University of Wisconsin–Madison (UW) and the University of California, Los Angeles (UCLA). Study participants will be randomly assigned to receive usual care through the complex care clinical program at UW or UCLA or the study intervention, RE-PACT. The intervention involves action planning, rapid clinical response to prevent and manage respiratory illness, and weekly SMS text messaging surveillance of caregiver confidence for their child to avoid hospitalization. RE-PACT will be run through 3 successively larger 6-month trial waves, allowing ongoing protocol refinement according to prespecified definitions of success for measures of feasibility, acceptability, and fidelity. The feasibility measures include recruitment and intervention time. The acceptability measures include recruitment and completion rates as well as intervention satisfaction. The fidelity measures include observed versus expected rates of intervention and data collection activities. The primary clinical outcome is a severe respiratory illness, defined as a respiratory diagnosis requiring hospitalization. The secondary clinical outcomes include hospital days and emergency department visits, systemic steroid courses, systemic antibiotic courses, and death from severe respiratory illness.

Results: The recruitment of the first wave began on April 27, 2022. To date, we have enrolled 30 (33%) out of 90 participants, as projected. The final wave of recruitment will end by October 31, 2023, and the final participant will complete the study by April 30, 2024. We will start analyzing the complete responses by April 30, 2024, and the publication of results is expected at the end of 2024.

Conclusions: This pilot intervention, using adaptive just-in-time strategies, represents a novel approach to reducing the incidence of significant respiratory illness for children with severe CP. This protocol may be helpful to other researchers and health care providers caring for patients at high risk for acute severe illness exacerbations.

Introduction

Background

Children with severe cerebral palsy (CP) have spastic quadriplegia and are classified in level IV or V on the Gross Motor Function Classification System (GMFCS), often resulting in little or no independent mobility and serious respiratory consequences [1]. The mechanisms of respiratory illness in severe CP vary, paralleling those of other neuromuscular diseases [2], and include respiratory muscle weakness, recurrent infections and aspiration with inflammatory fibrosis, impaired airway clearance from altered tone, upper airway abnormalities, and poor chest wall compliance [3,4].

Respiratory illness is consistently the leading cause of death and hospitalization in severe CP [5,6]. Respiratory illness accounts for 59% of the deaths [5,7] and 25% of the hospitalizations [8-10] in severe CP. Moreover, respiratory illness strongly predicts future risk: respiratory hospitalization risk is 10-fold higher with a respiratory illness in the past year. Nevertheless, respiratory illness risk factors in severe CP are considered modifiable [11]. The prevention of these events is a significant need and a key to improving the quality of life and decreasing mortality [1,12].

Preventing hospitalization requires the opportunity for families and clinical teams to connect early enough to change trajectory [13-15]. Parents of children with CP have expressed the need for interventions focused on crisis management and self-efficacy [9,13,16]. However, respiratory illness in severe CP has broad comorbid triggers (eg, emesis, dysphagia, aspiration, and seizures). Because of this complexity, simple action plans or coaching alone may not address the breadth of respiratory illness triggers or potential responses; for example, if a parent of a child with severe CP follows an action plan directed toward bronchospasm, it would not effectively address an acute infectious lower respiratory infection. Parents of children with severe CP need comprehensive action planning and coaching; they also need an efficient direct extension to their clinical team for a just-in-time (JIT) adaptive clinical response directed specifically to acute real-time problems.

Currently, difficulty identifying when JIT care is needed is a barrier to effective illness response. Concerns may not reach clinical teams until an emergency department (ED) visit or hospitalization is inevitable. A national expert panel to identify interventions to prevent the hospitalization of children with complex diseases concluded that enhanced access, proactive crisis planning, and support for caregiver technical skills were crucial strategies to lower hospital use [17]. Prior postdischarge research has confirmed that admissions and ED visits could be better predicted by identifying when parents were not confident that their child with chronic conditions could avoid hospitalization or an ED visit than by other clinical or demographic indicators [18,19]. Preliminary work with a cohort that included children with severe CP demonstrated that parent confidence, monitored prospectively and repeatedly by SMS text message, is feasible, is acceptable, and predicts hospitalization within 2 weeks. This program of research will drive care forward by providing JIT care triggered by parents' self-reported period of low confidence, thus matching the intervention to the immediate clinical need and preventing respiratory crisis.

Prior Work

This team developed the earlier Plans for Action and Care Transitions (PACT) intervention to prevent hospitalizations for children with complex chronic diseases, including severe CP. After integrating a systematic literature review [20], parent interviews [21], and a national expert panel [17], each focused on preventing hospitalization, the team designed PACT to leverage evidence-based strategies from different populations: asthma action planning [22-24], health coaching [25-27], and feedback from parent advisory group meetings. The PACT intervention delivered action planning and coaching activities to children with diverse complex diseases, including severe CP, and observed 40% lower hospitalization rates for intervention versus control patients [28]. Simultaneously, our prior multisite research observed that confidence to avoid hospitalization, measured through repeated SMS text messaging, predicted hospitalization over the subsequent 2 weeks. Our clinical team and family partners hypothesized that periods of low confidence might be a useful tailoring variable to prompt intervention delivery [29].

The pact intervention has now been adapted to prevent severe respiratory illness in children with severe CP and to integrate SMS text messaging as a tailoring variable within a JIT adaptive intervention framework [29,30].

Objectives

This pilot study (ClinicalTrials.gov: NCT05292365) is designed to establish the feasibility, acceptability, and fidelity of our intervention program, Respiratory Exacerbation–Plans for Action and Care Transitions (RE-PACT) in up to 90 children with severe CP and to establish a preliminary effect size of RE-PACT to inform a future efficacy study to reduce severe

respiratory illness. This intervention consists of three related parts: (1) universal action planning, (2) an ongoing assessment of hospitalization risk, and (3) an algorithm to determine when to increase clinician contacts and tailor action plans. The study period will be divided into 3 waves; after each wave, feasibility, acceptability, and fidelity data will be reviewed against predefined measures of success to adjust the protocol and overcome implementation barriers. We describe the design and protocol of this trial in the following sections.

Methods

Participants and Setting

This intervention will recruit primary caregivers of children with severe CP. Up to 90 caregivers of children with severe (GMFCS level IV or V) CP aged 0 to 17 years and cared for by a respiratory specialist or receiving daily respiratory treatments will be enrolled. Participants will be recruited from pediatric complex care programs at the University of Wisconsin–Madison (UW) and the University of California, Los Angeles (UCLA). These programs were established to deliver care to children with medical complexity. The key components of each program include pediatric clinicians, care coordinators, and extended visit lengths, which aid in delivering comprehensive care to children with CP. Both clinical programs have been described in more detail elsewhere [28,31].

Inclusion Criteria

Participants are caregivers of children with severe CP. Individuals must meet all inclusion criteria to be eligible to participate in the study. Caregiver criteria include (1) being aged at least 18 years, (2) being the primary caregiver to an eligible child, (3) ability to speak English or Spanish well enough to be interviewed, and (4) having a mobile phone capable of sending and receiving SMS text messages. Child criteria include (1) age 0 to 17 years, (2) GMFCS level IV or V CP [32], and (3) being cared for by a respiratory specialist or receiving daily respiratory treatments (oxygen, ventilation, airway clearance device, and medications).

Exclusion Criteria

During this study, participants are asked to reply to SMS text messages when received at random times during daytime hours and connect with an intervention clinical responder either at home, in person at a mutually agreeable location, by mobile phone, or over the internet. Any individual lacking the ability or willingness to engage in SMS text messaging or clinical responder interactions during the study will be excluded from participation in the study.

Recruitment and Screening

We will recruit caregivers of children with severe CP aged between 0 and 17 years. We will recruit up to 90 participants (n=45, 50% at each site) divided across 3 waves. In each wave, there is a 1- to 2-month enrollment period. We anticipate that approximately 80% of those screened will enroll, requiring approximately 110 individuals to be screened.

Using diagnostic codes for CP (International Classification of Diseases, Tenth Revision [ICD-10]: G80-83), we will identify potential participants by reviewing clinic registries and electronic health record data, which contain detailed information about children and their diagnoses. We will send an *opt-out* letter that alerts families that a research study is being conducted and their child may be eligible, with a contact number to call if they wish to opt out of the research or if they wish to receive additional information or have any questions. Potentially eligible caregivers will be contacted by telephone to screen for eligibility and interest.

If the research team is not notified that a family wishes to opt out of the research, the study research personnel will attempt to call the families (or meet them at an upcoming visit) to complete screening, informed consent, baseline questionnaires, and random group assignment. CP status and additional eligibility criteria will be determined with a reliable and valid parent questionnaire and screener conducted at the beginning of the initial telephone contact [32].

Individuals who do not meet the criteria for participation in this trial (screen failure) because they meet ≥1 exclusion criteria that are likely to change over time may be rescreened. Theoretical examples might include a child developing a need for respiratory treatment or families acquiring a mobile phone capable of sending and receiving SMS text messages.

All study participants will undergo informed consent, including authorization to view the child's medical record and participate in action planning, rapid clinical response, and weekly SMS text message surveillance.

Study Design

This is a 2-site pilot randomized controlled clinical trial to establish the RE-PACT protocol's feasibility, acceptability, and fidelity as well as an estimate of effect size. We anticipate being underpowered to assess the efficacy of the intervention in this pilot study; however, to inform future randomized controlled trial power estimates, we will test differences between the intervention and control groups in primary and secondary clinical outcomes.

Study participants will be randomly assigned to receive usual care through the complex care clinical program at UW or UCLA or the study intervention, RE-PACT. Random allocation will be concealed from the research staff conducting recruitment and will use a 1:1 allocation with random block sizes of 2 and 4. Block randomization will be achieved with a computer-generated random number list prepared by the study biostatistician without clinical involvement in the trial. Randomization will be stratified by site to account for site-specific study characteristics.

RE-PACT will be run through 3 successively larger 6-month trials (*waves*), allowing ongoing protocol refinement between waves, guided by prespecified definitions of success for feasibility, acceptability, and fidelity measures. Each wave has a specific protocol refinement focus (wave 1: onboarding, training, recruitment, and data collection; wave 2: randomization and intervention activities; and wave 3: rapid enrollment and the conduct of all protocol activities with high fidelity). Participants in both groups will undergo assessments of demographic, clinical, and caregiving measures using

questionnaires and medical record review case report forms at baseline and at 6 months after enrollment. Intervention feasibility, acceptability, and fidelity data will be collected from parent reports, medical records, and research team logs using case report forms.

Description of the Intervention

RE-PACT uses a dynamic JIT adaptive intervention design [33] to deliver proactive intervention based on risk modeling and partnership between the care team, patients, and families. Although the causes of respiratory illness in severe CP are modifiable, they are also broad and require distinct responses, even for the same child, over time. RE-PACT assumes that (1) every patient with severe CP has a risk of hospitalization, (2) some risks are knowable via the ecosystem of data generated around patient care, and (3) an intervention delivered when risk is increasing can reduce hospitalizations. RE-PACT's design addresses the changing needs of a child and family. RE-PACT involves action planning, rapid clinical response to prevent and manage respiratory illness, and weekly SMS text messaging surveillance of caregiver confidence for their child to avoid hospitalization.

Action Planning

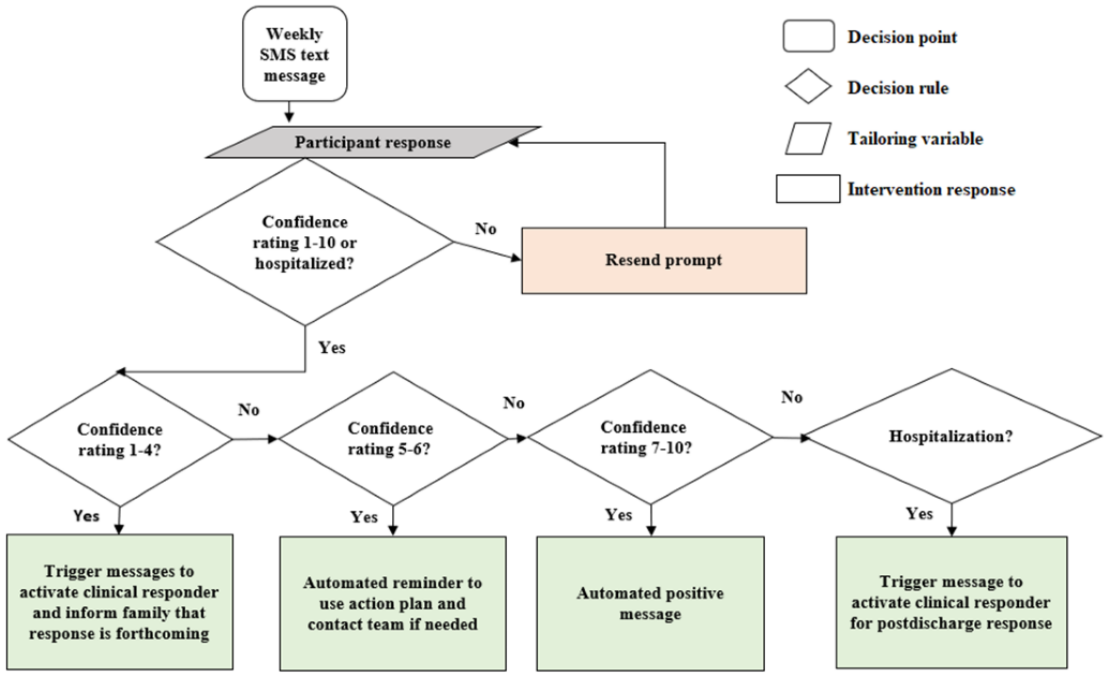
Overview

All intervention families will receive respiratory illness action plans within 1 month of study entry. The action plan format and process are adapted from the original PACT study, and the contents include (at minimum) recognizing, describing, and managing the child's known contributors to respiratory illness. The three main components of the action plans are (1) *focus area* for the action plan (eg, asthma, aspiration, and seizures); (2) *severity levels* corresponding to objective and subjective indicators of baseline (*green*), concerning (*yellow*), and severe (*red*) statuses (eg, >2 L/min of oxygen); and (3) *specific actions* that caregivers should take to manage each status (eg, increase vest therapy, albuterol, suction every 4 hours, and use oxygen up to 4 L/min). As needed, JIT plans are also created at times of low confidence by parent request or by clinician determination during the study period. Any plan created will be developed with families, target an issue that plausibly will recur and lead to respiratory illness–related ED or hospital visit, and, when relevant, be harmonized with prior plans and reflect pulmonologist agreement.

Mobile Health Platform

The mobile health (mHealth) platform is built from an earlier study, *Assessing Confidence at Times of Increased Vulnerability* (ACTIV) [29], which was designed to elicit a SMS text rating of confidence to avoid hospitalization in the next month (ratings range from 1 to 10, where 1 is lowest confidence, and 10 is highest confidence; Figure 1). The platform supports English and Spanish languages. Beginning on the Sunday after enrollment, families will start receiving weekly SMS text messages asking them to rate their confidence for their child to avoid hospitalization in the next month. SMS text messages are programmed to be sent at random days and times to caregivers, averaging once weekly (Sunday to Thursday) between 8 AM and 9 PM (local time). The Sunday-to-Thursday time frame was chosen to support a feasible response during business days and hours. After 2 hours of nonresponse, a reminder is sent, and this is repeated up to 2 times at 2-hour intervals. Clinical responders will receive an email notification in real time if a participant reports low confidence. In addition, clinical responders will receive an SMS text message notification between 9 AM and 6 PM with the report of low confidence. If a response comes outside of these hours, it will be delayed until the next day.

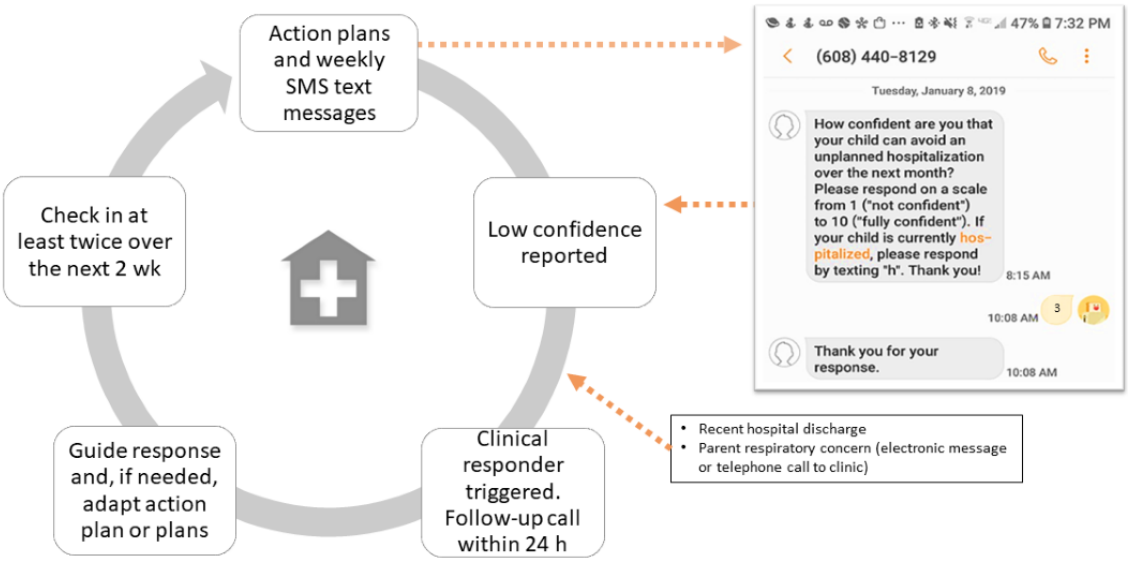
Figure 1. Schematic of the mobile health (mHealth) SMS text message process in which all study participants receive weekly SMS text messages asking them to rate their confidence for their child to avoid hospitalization in the next month.



Rapid Clinical Response

This response is adapted from our prior intervention (PACT) [28]. In RE-PACT, a clinical responder guides the JIT response, adapting to the current child and family situation. Triggers for the clinical responder include (1) low family-reported confidence (a confidence rating of <5) during mHealth messaging, (2) hospital discharge, and (3) family call or electronic message to the clinic owing to acute respiratory concerns (Figure 2). Clinical responders are clinicians, including medical doctors, nurse practitioners, registered nurses, and care coordinators (or equivalent). The same responder intends to work with the family throughout study enrollment.

Figure 2. Summary of the Respiratory Exacerbation–Plans for Action and Care Transitions (RE-PACT) intervention. The figure illustrates low-confidence SMS text messages as the trigger of rapid clinical response. Other triggers include hospital discharge or family-expressed respiratory concerns through telephone call or electronic message to the clinic.



Rapid clinical responses include 3 interactions between family participants and clinical responders. First, a triage contact occurs within 24 hours of a trigger (during business hours). The triage contact goals are to determine the nature of the trigger, whether an action plan exists for the situation, and whether the issue is within the clinical responder's clinical practice scope. If not within the scope, the issue is referred to the relevant support (eg, a specialty physician or clinic social worker). Second, a response planning visit occurs either as a component of the triage contact or at a mutually agreed upon time within 72 hours of the trigger. Third, at least 2 follow-up contacts occur within 2 weeks of the trigger, with additional follow-ups as indicated by ongoing need until the issue is resolved. All contacts can occur through any of the following, at the preference of the family: telephone call, clinical encounter (telehealth, clinic, and hospitalization), or a home visit. The follow-up contacts can occur through electronic communication if the clinical responder and family determine this to be appropriate. At each contact point, there are two goals: (1) ensuring that the family understands red flags, relevant medications, and whom to call and when and keeps notes about the issue; and (2) coaching and skill transfer for the family to generate solutions and lead actions, with the responder intervening if the family is stuck or if clinical needs dictate intervention. Each contact point has scripting to guide the clinical responder as well as electronic health record documentation templates. At the end of a clinical responder event, the responder determines whether the issue affects respiratory health, is likely to recur, and poses a risk for future ED or hospital visits. If all of these are true, the responder either updates existing action plans or creates a new one to address the issue. A participant is considered to have completed the study if they have completed the baseline and 6-month follow-up assessments (Table 1; Figure 3).

Figure 3. Schematic of the study design of Respiratory Exacerbation–Plans for Action and Care Transitions (RE-PACT) intervention enrollment period, enrollment visit, postenrollment evaluation, and protocol refinement. The protocol is refined between each of the 3 waves of the RE-PACT study. Outcomes

Primary Study End Points: Feasibility, Acceptability, and Fidelity

The specific measures and prespecified definitions of success for primary study end points, including feasibility, acceptability, and fidelity, are listed in Table 2. These measures will be summarized between each of the 3 waves, with protocol adjustments made for any measures that do not meet the definition of success.

Table 2. Primary study end points to evaluate the feasibility, acceptability, and fidelity of Respiratory Exacerbation–Plans for Action and Care Transitions (RE-PACT; n=90).

Measure and measure detail		Success definition
Feasibility		
Recruitment	Days to enroll target, mean (SD)	<14 (1)
Intervention onset	Days between randomization and "T_0[a]" intervention activities, mean (SD)	<7 (1)
Time to action plan	Days to action plan creation	<30
Intervention time	Time logged (min) for action planning and for coaching activities, mean (SD)	N/A[b]
Intervention costs	Mileage and travel costs; personnel salary; training costs; and other incurred costs, total	N/A
Intervention triggers	Number per patient (annualized), both respiratory and nonrespiratory focused	N/A
Acceptability		
Enrollment	Enrollment rate (number of patients enrolled/number approached)	>80%
Consent refusal	Categorized reasons for refusal	N/A
Loss and dropouts	Dropout rate (active or passive) before 6 mo (number of dropouts/number enrolled)	<10%
Action plan, SMS text messaging and clinical responder satisfaction	Do caregivers use the action plan, coaching, and texting? How could it be improved? Would caregivers recommend this to another family?	N/A
Fidelity		
Enrollment duration	Time (mo) of participant enrollment in the study, mean (SD)	6 (1)
Action plan creation	Number of respiratory and overall action plans per patient and action plan focus areas	≥1
Rapid clinical response: home or web-based visit	Success rate (number of visits completed and number expected); stratify by trigger and by "respiratory" and "nonrespiratory"	>80%
mHealth[c] texting	Response rates (number of SMS texts responded and number expected); "respiratory" and "nonrespiratory"	>90%
Crossover	Number of patients inappropriately receiving any intervention component	0
Data collection	Complete entry and exit questionnaire, monthly questionnaire, and chart review data (number of data collection events completed and number of total data collection events)	>95%

Clinical End Points

The study's secondary objective is to estimate the effect size of RE-PACT. The clinical end points are listed in Textbox 1. The primary clinical end point is severe respiratory illness, defined as a respiratory diagnosis requiring hospitalization. *Respiratory diagnosis* is defined as a discharge diagnosis of any of the following: asthma, pneumonia (community or hospital acquired), bronchiolitis, influenza, upper or lower respiratory tract infection, tracheitis, aspiration pneumonia and pneumonitis, chronic lung disease, and respiratory failure [34]. *Hospitalization* is defined as a nonelective, unscheduled hospital encounter (inpatient or *observation* status), accompanied by both an admission history and physical examination as well as a discharge summary note signed by a physician or advanced practice provider. Field-testing the assessment of this end point with trained research personnel at study sites demonstrated high interrater reliability (κ>0.9).

Textbox 1. Clinical end points of Respiratory Exacerbation–Plans for Action and Care Transitions (RE-PACT).

Primary clinical end point

- Severe respiratory illness, defined as a respiratory diagnosis requiring hospitalization

Secondary clinical end points

- Hospital days during severe respiratory illness
- Systemic steroid courses (systemic steroids [exclude inhaled or topical steroids for the purposes of defining an illness]: hydrocortisone, prednisone, prednisolone, dexamethasone, methylprednisolone, and triamcinolone acetonide; common inhaled steroids: fluticasone, budesonide, mometasone, beclomethasone, and triamcinolone [14-16,35])
- Systemic antibiotic courses (antibiotics: amoxicillin or amoxicillin/ and clavulanate, ampicillin, ampicillin and sulbactam, azithromycin, cefdinir, cefepime, cefixime, cefpodoxime, ceftazidime, ceftriaxone or cefotaxime, ceftibuten, cefuroxime, cephalexin [Keflex], clarithromycin, clindamycin, ciprofloxacin, doxycycline, erythromycin, ertapenem, imipenem, levofloxacin, linezolid, meropenem, metronidazole, moxifloxacin, oseltamivir, penicillin, piperacillin and tazobactam, rifampin, and vancomycin [14-16,35])
- Respiratory emergency department visits
- Death

The secondary clinical outcomes (Textbox 1) include total hospital days during severe respiratory illness; the number of systemic steroid courses, systemic antibiotic courses, and respiratory ED visits; and death. Hospital days are calculated through resolution if admission occurs in the study time frame, even if discharge occurs after the study exit date. *Systemic corticosteroid course* is defined by oral or parenteral corticosteroids prescribed for respiratory diagnosis, including hydrocortisone, prednisone, prednisolone, methylprednisolone at least 1 mg/kg/d (or 30 mg/d) × minimum 3 days, or dexamethasone at least 0.15 mg/kg/d (or 10 mg/d) × ≥1 days. Physiologic or stress replacement doses in adrenal insufficiency are excluded. *Systemic antibiotic course* is defined by oral or parenteral antibiotics prescribed for respiratory diagnosis for a minimum of 3 days. The specific antibiotics are derived from the Infectious Diseases Society of America pediatric pneumonia guidelines [36] and published literature [35]. Respiratory ED visits are any ED visits not resulting in admission and having a discharge respiratory diagnosis.

Exploratory Study End Points

The objectives of the tertiary study are to explore the mediating relationships between RE-PACT and capability, opportunity, motivation, and behavior (COM-B) measures [37]. By blending our foundational research on preventing hospitalizations [17,21] with behavioral intervention theory [38], our conceptual model suggests that decisions to seek care (behaviors) are influenced by capability (family capacity), opportunity (health system and susceptibility), and motivation (confidence). A theorized mechanism of RE-PACT's effect is that combining action planning, mHealth surveillance, and coaching will increase caregiver COM-B measures to manage respiratory illness in severe CP. The tertiary end points are listed in Textbox 2.

Textbox 2. Exploratory study end points of Respiratory Exacerbation–Plans for Action and Care Transitions (RE-PACT).

Capability

- Family Caregiver Activation in Transition (FCAT) tool [39]: mean composite score
- Caregiver General Self-Efficacy Scale (GSES) [40]: mean composite score

Opportunity

- Family Experiences with Care Coordination (FECC) [41]: percentage top-box score for selected items

Motivation

- Confidence responses mobile health SMS text messaging: mean weekly score

Assessment Procedures

Data about research participants (children and their families) will be collected by study research assistants on case report forms using electronic family self-administered questionnaires, structured interviews with research personnel by telephone or in person with enrolled caregivers, and abstraction of child medical record data. Family and child measures will be recorded at baseline, and end points will be recorded at study exit (6 months after the enrollment visit [T_0]). Caregiving measures, which may change as a result of the intervention, will be collected at baseline and study exit. Clinical responders will enter data for intervention group families into a clinical response event case report form.

Feasibility, acceptability, and fidelity end point data will be collected during each of the 3 waves by research personnel reviewing study logs, conducting monthly chart reviews, and administering surveys (by telephone, in person, or sending electronic self-administered links) with caregivers randomized to the intervention. For control group participants, the feasibility

of assessments will be evaluated by completion rates at study exit. In addition, intervention and control participants will be debriefed at study exit on their experiences in the study and asked for feedback on the strengths and weaknesses, as well as any concerns about the protocol. Between each wave and after the third wave, clinical teams at each site will be debriefed on the strengths and weaknesses, as well as concerns about the protocol.

The CP GMFCS measures and all caregiving measures have been well documented as reliable in the literature [39-45]. We have separately established the reliability of identifying respiratory illnesses in our preliminary research (κ>0.9). We will ensure reliability in data collection through direct observation, data auditing, establishing clear data dictionaries and definitions, using uniform variable definitions, and use of a central data repository coordinated and maintained by UW.

Data Collection, Storage, and Protection

Clinical data (including adverse effects) and clinical laboratory data will be entered into Research Electronic Data Capture (REDCap; UW) managed by the University of Wisconsin, a 21 Code of Federal Regulation Part 11–compliant data capture system provided by the UW Institute for Clinical and Translational Research. The data system includes password protection and internal quality checks, such as automatic range checks, to identify inconsistent, incomplete, or inaccurate data. Clinical data will be entered directly from the source documents or entered directly from secure self-administered questionnaires (surveys) sent via REDCap to participants.

Sample Size Considerations

We will enroll up to 90 participants. On the basis of this team's preliminary work, we estimate that half (45/90, 50%) of the participants will experience at least 1 respiratory illness during the enrollment period. We expect to be able to maintain contact and collect data from ≥90% (≥81/90) of the participants at the final follow-up, evenly divided between the intervention and control groups. We assume that this sample will not be powered to establish the efficacy of the intervention; however, it will provide a sufficient sample to determine feasibility and estimate effect sizes, which will be used for power calculations in the future large randomized clinical trial. Attainable power levels were calculated for detecting differences in severe respiratory illness rates (primary clinical outcome) between the study arms at the 2-tailed <.05 significance level based on a negative binomial (NB) regression model with an overdispersion parameter of ϕ=1.0 (Table 3). Hence, large effect sizes with relative risks ranging between 3.0 and 5.0 for comparing the severe respiratory illness rates between the study arms will be detected with 19% to 88% power at the 2-tailed <.05 significance level.

Table 3. Attainable power levels for detecting differences in severe respiratory illness rates between the study arms, assuming a sample size of 45 participants per arm with a missing value rate of ≤10%.

Relative risk (control vs intervention)	Number of severe respiratory illnesses in the intervention arm over the 6-mo follow-up period				
	5 (λ=0.02)[a], %	10 (λ=0.40)[a], %	15 (λ=0.06)[a], %	20 (λ=0.08)[a], %	25 (λ=0.10)[a], %
3.0	19	29	38	45	52
4.0	31	41	59	68	75
5.0	42	62	74	83	88

[a]Severe respiratory illness rate per patient-month.

Statistical Analysis Plan

The primary outcome data will assess the RE-PACT intervention's feasibility, acceptability, and fidelity using descriptive statistics. Categorical variables will be displayed as percentages and continuous variables as means with SDs (if normally distributed) or medians with IQRs (if skewed). We will compare observed values with the prespecified definitions of success for each of our feasibility, acceptability, and fidelity measures. We will also determine overall positive, neutral, and negative reports of feasibility and acceptability using content analysis of qualitative (open-ended comments) data. We will explore any patterns if challenges emerge (eg, enrollment refusal or dropout or low reported use of the intervention activities).

We anticipate being underpowered to assess efficacy using the clinical end points of the intervention in this pilot study. Analyses will also estimate the effect size estimates of clinical end points to allow precise sample size calculations for a future large-scale efficacy trial. We will compare differences between the intervention and active control group outcomes at 6 months. The primary clinical outcome is the severe respiratory illness rate, defined as the total number of severe respiratory illnesses divided by the person-months over the 6-month follow-up period. The severe respiratory illness rate will be analyzed using an NB regression model to account for overdispersion in the count data. For the primary analysis, univariate NB regression analysis will be conducted with a study arm as a predictor variable. The study site will be included as a stratification factor in the primary analysis to account for stratified randomization. The observed effect size of the analysis will be quantified in terms of relative risk and reported along with the corresponding 95% CI. As a secondary analysis, multivariate NB regression analysis will be performed to compare the severe respiratory illness rates between the study arms. This analysis will include clinical and demographic characteristics as covariates in an initial nonparsimonious model. The least absolute shrinkage and selection operator and elastic net penalty methods for NB regression models will be used to identify a parsimonious model with independent covariates.

Longitudinal changes in the severe respiratory illnesses within and between study arms will be evaluated with a generalized linear mixed effects model with a logit link function and

participant-specific random effects. An autoregressive correlation structure will be used to account for within-participant correlations. In this analysis, the presence or absence of severe respiratory illness at the monthly assessments will be the dependent variable, the study arm will be included as a predictor variable, and the study site will be included as a stratification variable to account for the stratified randomization.

The secondary clinical outcomes include total hospital days during severe respiratory illness; the number of systemic steroid courses, systemic antibiotic courses, and respiratory ED visits; and death. The number of systemic steroid courses, systemic antibiotic courses, and respiratory ED visits over the 6-month follow-up period will be analyzed using NB regression analysis as described previously for the primary outcome. Observed effect sizes and the corresponding 95% CIs will be reported. The presence or absence of systemic steroid courses, systemic antibiotic courses, and respiratory ED visits will be documented at the monthly assessments, and longitudinal changes within and between study arms will be analyzed using generalized linear mixed effects modeling with a logit link function and patient-specific random effects. The total number of hospital days over the 6-month follow-up period will be analyzed using ANOVA with the study site as a stratification factor. In a secondary analysis, an analysis of covariance (ANCOVA) will be performed where clinical and demographic baseline characteristics will be included as covariates, and the least absolute shrinkage and selection operator method will be used to identify a parsimonious model. Longitudinal changes in the number of hospital days per hospitalization will be analyzed using a normal mixture linear mixed effects model with patient-specific random effects. The normal mixture component will be included in the model to capture the probabilities of hospitalization at the monthly follow-up. Parameter estimation will be performed using the expectation-maximization algorithm, the standard method for the parameter estimation of mixture models.

Two-tailed *P* values of <.05 will be considered statistically significant. Missing values (eg, owing to loss of follow-up and missing monthly visits) will be evaluated by conducting a sensitivity analysis comparing the results obtained from the complete case analysis with those obtained from imputation-based analyses. Specifically, multiple imputations will be used to impute the missing values of the primary and secondary clinical outcomes. For monotonic missing value data structures, we will use regression-based multiple imputation techniques. By contrast, we will use Markov Chain Monte Carlo–based imputation techniques for nonmonotonic missing value data structure.

Although we anticipate that the intervention and control groups will be similar owing to random assignment, we will adjust for any variables in our analysis that are not equal between the groups, given the small sample size. In addition, we will analyze for any effect of primary home language on the study outcomes because this may affect families' ability to navigate the systems of care in the United States.

Finally, as a planned exploratory analysis, we will test the mediating effect of caregiver COM-B measures on the relationship between intervention and respiratory illness outcomes. The mediating effects will be evaluated by conducting a multistep analysis approach. In the initial step, NB regression analyses will be conducted to examine whether there are differences in respiratory illness outcomes (the number of severe respiratory illnesses, systemic steroid courses, systemic antibiotic courses, and respiratory ED visits) between the intervention and control arms. In the next step, we will conduct a sequence of univariate analyses by regressing each potential mediator variable (caregiver capability COM-B measures) on the binary study arm variable. If significant associations between the potential mediator variables and the study arm are detected, we will regress the respiratory illness outcomes on both the mediator variables and study arm indicator variables using ANCOVA. The mediation effect for each potential mediator variable will then be tested using the Sobel *z* test based on the slope parameter estimates from the corresponding regression models.

Ethical Considerations

This study received initial approval from the UW health system's institutional review board on January 19, 2022 (20211532). All participants will provide informed consent before taking part in the study. Informed consent materials will be provided in private spaces in both written and verbal formats and will review in detail the study design, including random assignment to the intervention and control groups, potential risks of participation, protections against risk, and the rights of human research subjects. The informed consent process will also include review and signing of the Health Insurance Portability and Accountability Act waiver, allowing researchers to review the child's medical records. Parents will be able to decline parts of the study and still participate in other parts and can revoke their consent at any point. Any identifying information kept for the purpose of contacting participants will be kept secure, in REDCap, a locked filing cabinet or in a password-protected electronic file and will be destroyed when the study is complete. The study is monitored by the Data Monitoring Committee at the UW-Madison Institute for Clinical and Translational Research. All participants receive an incentive of US $200, divided in 2 parts: US $100 at enrollment and US $100 after the exit survey, in the form of a gift card, check, or cash.

Results

The recruitment of the first wave began on April 27, 2022. To date, we have enrolled 30 (33%) out of 90 participants, as projected. The final wave of recruitment will end by October 31, 2023, and the final participant will complete the study by April 30, 2024. We will start analyzing the complete responses by April 30, 2024, and the publication of results is expected at the end of 2024.

Discussion

Summary

We describe the protocol for a pilot clinical trial of RE-PACT, a JIT adaptive intervention to reduce respiratory illness in severe

CP. A recent expert consensus statement on preventing and managing respiratory disease in young people with CP highlighted the need for 4 activities: early identification of risk factors; regular assessment of risk; effective partnerships among multidisciplinary teams, families, and individuals with CP; and proactive treatment of respiratory disease [46]. The RE-PACT intervention protocol aligns with each of these 4 critical areas.

For children with severe CP, RE-PACT was designed by families and clinicians from promising earlier interventions to manage health crises with proactive action planning, simple surveillance of family confidence to avoid hospitalization through frequent SMS text messaging, and JIT adaptive rapid clinical responses. This intervention breaks down barriers to equitably connect families and clinical teams precisely when it matters most. This approach is innovative because we tailor the intensity of the response (eg, telephone call and clinic visit) and its content to family- and illness-specific needs. The adaptive nature of the intervention ensures that it meets caregiver needs for that specific instance, flexibly changing for individuals over time in response to each intervention trigger. RE-PACT is also designed to acknowledge that respiratory illness in severe CP is driven by both respiratory and nonrespiratory comorbid and social conditions [11,46] (eg, neuromuscular weakness, seizures, dysphagia, feeding intolerance, health system navigation barriers, and coordination problems).

By conducting successively larger waves of the RE-PACT protocol, we expect to produce a final high-quality protocol that has been developed sufficiently to support the implementation of a large-scale multisite clinical efficacy trial.

Limitations

This study has several limitations. Although we anticipate achieving a feasible, acceptable, and high-fidelity protocol by the end of the third wave, it is possible that some challenges may remain. We anticipate being underpowered to assess intervention efficacy. Despite the randomized design, allocation concealment is not possible. As randomization occurs at the level of the family, inadvertent intervention contamination to nonintervention patients in the same clinical program may occur. This risk will be minimized by having research staff (not clinical staff) manage action planning and SMS text messaging procedures. In future studies, we will consider alternative designs (such as a stepped wedge trial), randomizing at the clinic level to avoid this threat. Threats to external validity will reflect the relatively narrow population of families recruited from 2 complex care programs. Although it is a strength that the intervention will be conducted in English and Spanish, future expansion to populations of children with CP outside of complex care programs and from more geographically and culturally diverse settings will be helpful. As research continues, it will be important to examine whether this intervention design, which relies in part on the use of digital technology, addresses disparities in access to care and inequities in outcomes.

Conclusions

Despite the limitations, our pilot RE-PACT intervention represents an innovative and promising strategy to reduce severe respiratory illness among children with severe CP. RE-PACT operationalizes universal action planning, mobile SMS text messaging, and a JIT adaptive rapid clinical response to deliver timely customized care to families of children with severe CP. This protocol describes detailed methods to assess intervention feasibility, acceptability, and fidelity. This line of research may be relevant to other researchers and health care providers who wish to adopt a similar early intervention strategy for patients with chronic and complex conditions at high risk of future hospitalization.

Acknowledgments

The research reported in this publication was supported by the National Heart, Lung, and Blood Institute of the National Institutes of Health (R34HL153570). Abstract

Background: Interventions focused on remote monitoring and social needs care have shown promise in improving clinical outcomes for patients with heart failure (HF). However, patient willingness to use technology as well as concerns about access in underresourced settings have limited digital platform implementation and adoption. There is little research in HF populations examining the effect of a combined digital and social needs care intervention that could enhance patient engagement in digital platform use while closing gaps in care related to social determinants of health. Here, we describe the protocol for a clinical trial of a digitally enabled community health worker intervention designed for patients with HF.

Objective: This study aims to describe the protocol for a randomized controlled trial assessing the acceptability, feasibility, and preliminary effectiveness of an intervention that combines remote monitoring with a digital platform and community health worker (CHW) social needs care for patients with HF who are transitioning from hospital to home. Given the elevated morbidity and mortality, identifying comprehensive and patient-centered interventions at the time of hospital care transitions that can improve clinical outcomes, impact cost, and augment the quality of care for this cohort is a priority.

Methods: This trial randomized adult inpatient participants (n=50) with a diagnosis of HF receiving care at a single academic health care institution to the 30-day intervention (digital platform+CHW pairing+usual care) or the 30-day control (CHW pairing+usual care) arms. All study participants completed baseline questionnaires and 30-day exit interviews and questionnaires. The primary outcomes will be acceptability, feasibility, and preliminary effectiveness.

Results: This clinical trial opened for enrollment in September 2022 and was completed in June 2023. Initial results are expected to be published in the spring of 2024, and analysis is currently underway. Feasibility outcome measures will include the use rates of the biometric sensor (average hours per day), the digital blood pressure monitor (average times per day), the weight scale (average times per day), and the completion of the symptoms questionnaire (average times per day). The acceptability outcome will be measured by the patients' response to the truthfulness of the statement that they would be willing to use the digital platform in the future (response options: very true, somewhat true, or not true). Preliminary effectiveness will be measured by tracking 30-day clinical outcomes (hospital readmissions, emergency room visits, and missed primary care and cardiology appointments).

Conclusions: The results of this investigation are expected to contribute to our understanding of the use of digital interventions and the implementation of supportive home-based social needs care to enhance engagement and the potential effectiveness of

clinically focused digital platforms. These results may inform the construction of a future multi-institutional trial designed to test the true effectiveness of this intervention in HF.

Introduction

Background

Heart failure (HF) is one of the most common causes of 30-day readmissions and is a morbid and burdensome disease for patients [1]. Factors related to clinical complexity [2,3] and unmet social needs [4] have been identified as key culprits contributing to rising costs of HF care associated with HF exacerbations and recurrent hospitalizations [5]. While individual interventions focused on digital solutions to augment either clinical care [6-8] or home-based care [9-11] to address unmet social needs have the potential to improve HF clinical outcomes, these interventions are challenged by specific barriers that limit their effectiveness.

Digital platforms with remote monitoring capabilities can track fundamental biometrics, such as heart rate, blood pressure, and body weight, which are critical for the home management of HF [12-15]. These biometrics can be used to evaluate clinical status at home with automated reporting back to patient teams [16-19]. Some platforms also offer daily symptom questionnaires and even embed artificial intelligence algorithms with the ability to tailor alerts to individual patient norms, which can improve platform accuracy and precision [13]. These digital platform capabilities have improved the detection of markers signaling clinical decline (eg, changes in weight, activity tolerance, heart rates, blood pressure, and symptomatology), and a number of studies have demonstrated an early benefit of digital platform use for clinically complex patients, including those managing HF at home [6,8,20,21].

However, the integration of digital platforms among patients with HF has been incremental, at best, for reasons ranging from infrastructure limitations of health care institutions to patient-related barriers [22,23]. Specifically, several patient care barriers have been identified including knowledge gaps, lack of willingness to gain familiarity with technology, reduced health care access, and marginal internet connectivity [22,23]. Concordantly, valid concerns about the exclusion of digital platform use in low-resourced, aging, or less technology-facile populations exist [19]. A number of these challenges could be resolved by integrating a home-based human resource, with basic knowledge of the digital platform who could also deliver social needs care.

Home-based care that focuses on social needs is often delivered by community health workers (CHWs) [24,25]. CHWs, with basic knowledge of chronic conditions, can address unmet social needs and reinforce clinical care plans in ways that improve outcomes by bolstering connections to clinical care teams [26]. Specifically, CHW outreach includes telephone calls; home visits; health care coaching; accompaniment to clinic visits; and identification of low or no-cost resources to close gaps in care related to food insecurity, transportation, rental assistance, or other unmet social needs. CHWs can also provide elbow-to-elbow support with the completion of insurance forms or agency applications. Through motivational interviewing, goal setting, and psychosocial support, CHWs can work closely with patients to identify and address logistical barriers to care [27]. While the evidence base for CHW-focused interventions to improve outcomes and reduce readmissions for patients with chronic diseases including HF is robust [10,11,28-31], CHWs generally rely on one-to-one in-person or phone or text-based patient interactions without symptom or biometric monitoring [32]. In this way, CHW care remains largely siloed without the tools needed to care for larger, clinically complex populations. As such, CHWs inadvertently spend more time with patients who are healthier and engaged in care and less time with patients who are harder to reach and would benefit from early intervention [33,34]. While manageable in smaller cohorts and studies, this can stifle the impact of CHWs on clinical outcomes when scaled.

A combined intervention with a digital platform and CHW care (ie, digitally enabled CHW care) could address important barriers associated with platform use. Specifically, CHW care, through home visits, phone calls, and connections to care teams, can address digital platform knowledge gaps and connectivity issues [27]. CHWs can also act as navigators for digital platforms by encouraging use and engagement that can improve platform usability and adoption. In this way, CHWs are uniquely positioned to enhance the use and reach of digital platforms. In addition, pairing patients at high risk for readmission, especially those with HF, with a CHW and a digital platform could address key barriers to CHW care delivery related to the historical reliance on one-to-one outreach [35]. Digital platforms can better inform the timing and prioritization of CHW outreach with real-time access to streamlined basic biometric data (weights, steps taken per day, or a daily clinical score) and patient response data (collected in a daily questionnaire). This access can augment the ability of CHWs to connect patients to clinical care teams earlier for interventions that can potentially prevent hospital readmissions or emergency department (ED) visits.

This trial, based on a single-arm observational study performed prior [27], will study the effect of a digitally enabled CHW intervention created for patients with HF. In this way, the study addresses a gap in current knowledge of home-based care for patients with HF as one of the first randomized controlled trials

(RCTs) examining the effect of a digital platform combined with social needs care delivery from a CHW in patients with HF. This work is important because it seeks to reduce hospital readmissions for HF, which is imperative for Centers for Medicare and Medicaid stakeholders [36]. This study intervention also occurs at the time of hospital discharge, a particularly vulnerable time point as patients are transitioning out of the hospital. The results of this clinical trial may also contribute to a novel and innovative model for home-based care in a high-risk HF population. Specifically, this study will add value to ongoing conversations about the applications and implementation of digital solutions and unmet social needs, particularly in chronic disease populations with serious illness.

The goal of this trial is to determine if a remote monitoring and social needs care intervention deployed at the time of hospital discharge is feasible, acceptable, and can demonstrate preliminary effectiveness relevant to clinical outcomes (hospital readmissions, ED visits, and missed appointments). We expect to see a higher degree of engagement and adherence to clinical care among those assigned to digitally enabled CHW care compared to those assigned to CHW care alone. The methodology described here will add insight into the implementation of similar digital interventions for patients transitioning from hospital to home with HF.

Primary Objective

The objective of this trial is to assess the acceptability, feasibility, and preliminary effectiveness of a digitally enabled CHW intervention.

Hypothesis

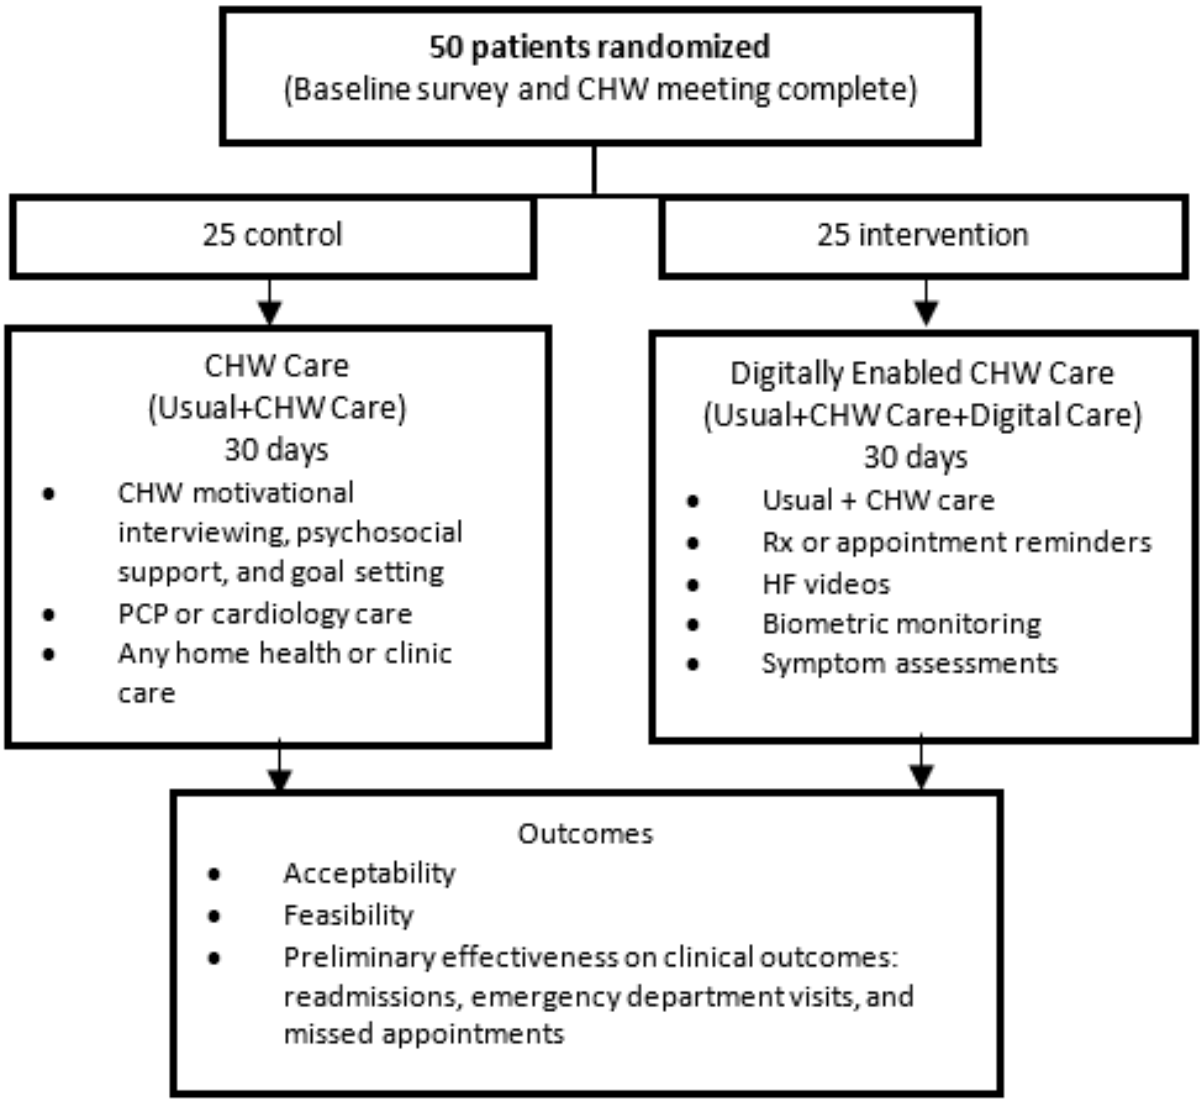
The central hypothesis is that pairing patients with a digitally enabled CHW intervention that addresses clinical, social, and behavioral barriers to HF care will (1) be feasible for patients with HF at home, (2) be acceptable for patients with HF at home, and (3) demonstrate preliminary effectiveness in improving clinical outcomes.

Methods

Study Overview and Design

An RCT design was applied to evaluate the intervention (digital platform+CHW+usual care) group compared to the control (CHW+usual care) group during the 30 days after discharge from the hospital to home. Figure 1 describes the study's procedural flow. Eligible patients were screened via the electronic medical record (EMR) on 8 inpatient study floors (6 internal medicine floors and 2 cardiology floors) in a single health care institution. Research staff approached patients after obtaining permission from bedside nursing. After verifying eligibility and introducing the study design, interested patients completed consent processes and all enrollment questionnaires. Participants were randomized to the intervention or the control arm for the 30-day intervention and study period. Both intervention and control participants were contacted by their assigned CHW within 24 weekday hours of enrollment and received teaching via an American Heart Association–sponsored HF patient education tool (educational control). Intervention participants received study equipment and were oriented to the use of all platform components by research staff prior to hospital discharge. All enrolled participants completed an exit questionnaire and interview via phone at the end of the 30-day intervention.

Figure 1. Trial design, study arm assignment, and outcomes of a pilot randomized controlled trial. CHW: community health worker. PCP: primary care provider. Rx: medical prescription. HF: heart failure.



Clinical Setting of Patient Population

Massachusetts General Hospital (MGH) is a 999-bed academic medical center in Massachusetts with 75,000 to 100,000 hospital admissions each year. The MGH Corrigan Minehan Heart Center serves over 27,000 patients with cardiac disease each year, many of whom have HF. As an accountable care organization and medical home in partnership with the Mass General Brigham system, MGH inpatient teams are comprised of full and part-time staff clinicians, including board-certified internists or cardiologists, residents, fellows, nurses, advanced clinicians (nurse practitioners and physician assistants), and students. The majority of inpatients are supported by Medicare or Medicaid-based insurance products.

Subject Eligibility and Recruitment Strategy

Eligibility criteria were established based on prior clinical trials and qualitative studies focused on care transitions from hospital to home [27,37-39]. Eligibility criteria for participants who were approached and introduced to the study while hospitalized included the following: being 18 years and older, living within a 50-mile radius of MGH, having a diagnosis of HF listed in the EMR problem list, a history of ≥1 hospitalization within the previous 12 months, a clinician managing their HF, cognitive ability to participate in the intervention, and English fluency. Patients were ineligible if they had an active alcohol or substance use disorder, were living in a long-term care facility, were unable to provide consent, had invoked health care proxy, or had prisoner status. Research staff attempted to enroll patients up to 3 times if they were unsure or unable to be engaged in the initial approach.

CHW Training and Supervision

Extensive experience training CHWs gained during our prior CHW clinical trial was applied for CHW training purposes [9]. CHW staff participating in the trial were trained in the core competencies of CHW care delivery for HF and other common diagnoses associated with hospital readmissions (eg, pneumonia, atrial fibrillation, and pulmonary disease). These CHW core competencies included motivational interviewing, behavioral change, and psychosocial support. Additional skill sets and

activity building occurred for medication reconciliation, common management and postdischarge follow-up plans, general American Heart Association guideline–concordant care, patient educational tools, and commonly used community resources. CHW supervision was led by a CHW manager experienced in supervising CHWs caring for clinically, socially, and behaviorally complex patients. Supervision occurred through daily huddles (with the CHW staff supervisors) and weekly meetings with the CHW staff supervisors and the principal investigator (JC). All clinical aspects of CHW care were also supervised by the principal investigator.

For the intervention arm, CHW staff were also trained on the use of the digital platform. The training was fulfilled using participatory methods, case scenarios, and video clips for optimal teaching and application for the patient-facing mobile app as well as the team dashboard. Specific training on the digital platform features (Figure 2) was designed to enhance communication and monitoring in concert with the application of core competencies and skill sets associated with traditional CHW care. This occurred during multicomponent didactics involving feedback, consultation, and supervision. Extensive role play and case studies with simulation experiences for troubleshooting and technology-based challenges were performed over a 14-day period. After training, simulation and behavioral interviewing–based proficiency testing were used to evaluate both CHW best practices and digital platform proficiency. CHW staff were also trained on how to interpret digital platform symptom assessments and biometric monitoring. In the platform, these symptoms and biometrics were translated into a color-coded schematic (Figure 3: green=no new symptoms or biometric variance or clinical symptom score of ≤0.7; yellow=1 new symptom or clinical score of 0.8-0.9; red= more than 1 new symptom or a clinical score of ≥1.0). For any participants with a yellow categorization on any given day, CHWs (1) contacted the participant to verify symptoms and ask probing questions, (2) contacted the participant's designated care clinic, and (3) coordinated a patient visit with CHW staff or a visiting home nurse for expedited clinical evaluation. For participants with a red categorization, all yellow categorization steps were followed and CHWs partnered with the clinical care team to arrange for expedited transfer to MGH or in-home evaluation if clinically indicated per the clinical care team providers.

Figure 2. Procedural workflow overview for study participants. CHW: community health worker.

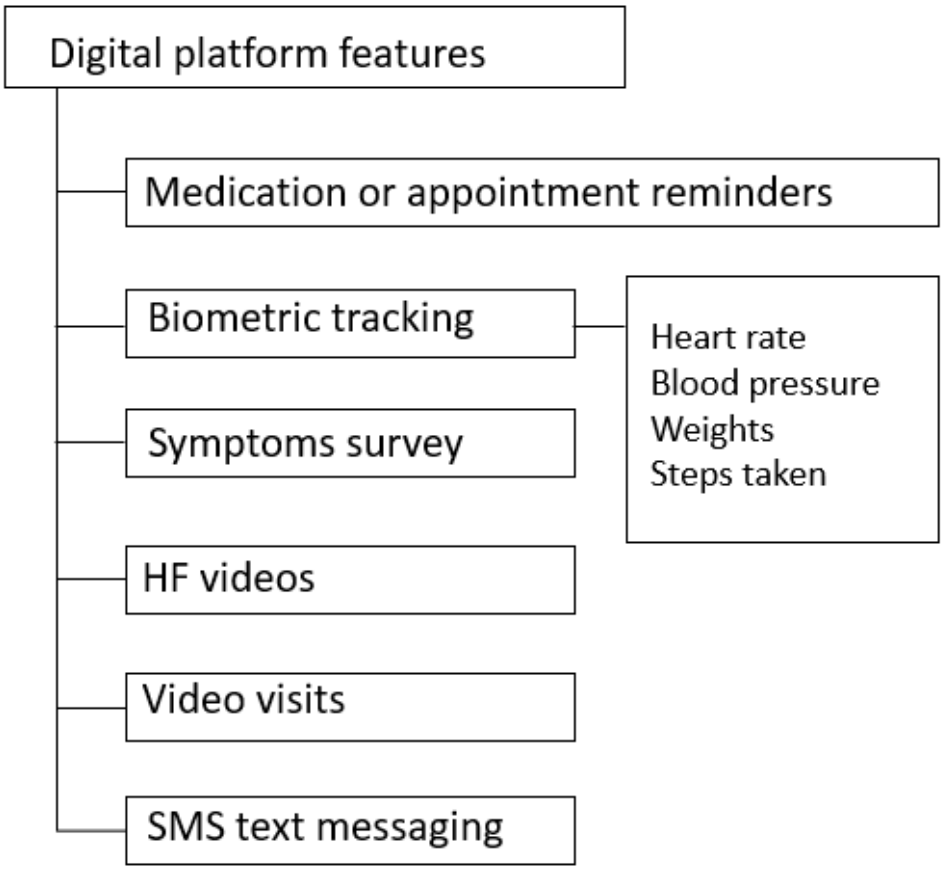


Figure 3. Digital platform components (intervention arm only). HF: heart failure.

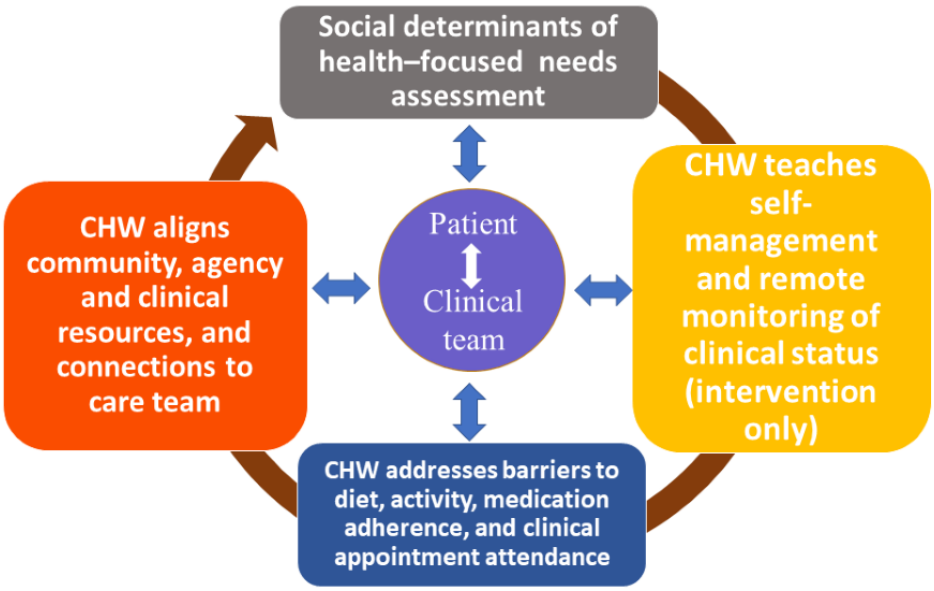
Digital platform biometric algorithm			
Digital platform biometric data score and color key			CHW action taken
≤0.7	Green	• No new symptoms or biometric variation	• Continued CHW care
0.8-0.9	Yellow	• 1 new symptom or • 1 biometric variant change by ≤7% baseline	• Contact patient; call clinic care team, arrange for clinical eval with CHW staff
≥1	≥1 Red	• >1 new symptom • ≥1 biometric variant change by >7% baseline	• See "Yellow" action taken + arrange for timely MGH transfer if deemed indicated by providers

Control

Participants were contacted routinely by CHW staff to review medication adherence, nutrition, physical activity, symptoms, and clinic appointments and discuss any unmet social needs. CHW staff (n=1) paired with enrolled participants reviewed individual participant's discharge care plans and integrated the patient's clinical, social, and behavioral goals with clinical care plans. As such, CHWs also identified resources to reduce gaps in care caused by unmet social needs and connected patients to clinical care teams for clinical questions. One CHW with expertise in CHW core competencies [25] (motivational interviewing, goal setting, behavior change, and psychosocial support) delivered the control arm treatment. Daily huddles occurred to discuss patient interactions and plans for goal achievement. CHW staff documented all participant encounters in the EMR. In addition, all CHW interactions were logged in a web-based research team REDCap (Research Electronic Data Capture; Vanderbilt University) database. All social, behavioral, and clinical activities (clinical care team and community agency interactions, as well as time spent engaged in phone, in-person, and email modalities) were tracked. Pre-existing clinical team members were copied on all EMR notes and contacted directly, when necessary, by the CHW or supervisory staff during the intervention. Figure 4 shows an overview of the study participant workflow.

Figure 4. Color schematic depicting the relationship between the biometric clinical status score generated by the digital platform algorithm and the action taken by CHW staff. CHW: community health worker; MGH: Massachusetts General Hospital.



Intervention

Enrolled intervention participants were introduced to the digital platform features prior to hospital discharge: an HF mobile phone app within a smartphone (Android) that included a daily checklist for patients, educational HF videos, a portal CHW video visits, and a daily symptom questionnaire. In addition, participants were given a digital blood pressure monitor, a digital weight scale, and a sensor attached to a lightweight armband to be worn on the nondominant arm tracking basic biometric data (heart rates, oxygenation, and steps taken). As described, CHWs were trained to assist patients with technology setup and troubleshooting. Any unreconciled technical difficulties were addressed by research study staff and the platform vendor as needed. An artificial intelligence algorithm within the mobile app generated a daily score along with alerts sent to the CHW team dashboard, indicating if participants were at or moving away from their clinical baseline in terms of symptoms,

biometrics, and functionality. This team dashboard was used in conjunction with a color schematic described (Figure 3). Any scores or alerts indicating that participants were moving away from their baseline were discussed with a CHW project manager. When indicated, CHWs notified clinical team staff during weekday office hours within 2 hours of a biometric or other clinically related concern (ie, significant change in heart rate, blood pressure, body weight, or patient-reported symptoms). Participants were instructed to engage with clinical care teams or urgent or emergent care as they would normally if they experienced symptomatic changes or other concerns outside weekday hours of operation.

Participants were contacted routinely by CHW staff to review medication adherence, nutrition, physical activity, symptoms, and clinic appointments and discuss any unmet social needs as described in the control treatment arm. All elements of other CHW outreach activities were performed as described in the control arm.

Data Collection and Measures

All study participants completed an enrollment questionnaire focused on health habits and patient experience with home self-care. This questionnaire was developed based on prior patient qualitative interviews and CHW focus groups with those caring for patients with HF [37,38]. These questions were adapted by study investigators for interviewer-assisted administration with inpatients prior to hospital discharge. We used a qualitative process to identify core domains through key informant interviews with patients, community-based primary care physicians, cardiologists, and internal medicine hospitalists. This was coupled with a review of the literature on patient experience in hospitalized settings along with consultations with survey and health services research experts. Draft surveys were pretested with 3 patients with the opportunity for revision prior to study administration. The enrollment questionnaire included 59 items from 7 distinct categories: health-related habits, understanding of the care plan, smartphone knowledge, quality of life (Kansas City Cardiomyopathy Questionnaire) [40], perceptions of physical and mental health, unmet social needs, loneliness (Three-Item Loneliness Scale) [40], and depression (Patient Health Questionnaire-2) [40]. Additional domains included confidence in the ability to perform self-care after discharge and patient-predicted likelihood of readmission within 30 days. Open-ended questions were asked to patients regarding anything that would help them manage their health outside the hospital.

An exit questionnaire administered at the study end (after 30-day enrollment) was also developed. This questionnaire mirrored domains in the enrollment questionnaire to assess any changes (eg, health-related habits and care plan understanding) associated with intervention or control arm assignments. Intervention participants also completed an acceptability questionnaire focused on the digital platform (adapted from components of the Technology Assessment Model Measurement Scales [41] as described by Ben-Zeev et al [42]). Similarly, the exit questionnaire was initially pretested with 3 patients, and no additional changes were made (all pretested questionnaire data will be included in the final analysis).

Separately, participants also completed an exit interview after completion of the 30-day enrollment period. The exit interview was conducted via phone and prompted participants to describe their experience with the digital platform and CHW staff interactions. Specific questions included: *What was it like to work with a CHW for the last month? What was it like using this technology in your home for the last month?* and *Are there things that could have made your time in the study better for you?* Semistructured interviews occurred via phone at times designated by participants and lasted 5-12 minutes. All semistructured interviews were audio-recorded and transcribed verbatim.

Process Measures, Source, and Timeframe Associated With Primary Outcomes of Feasibility, Acceptability, and Primary Effectiveness

The primary outcomes of feasibility, acceptability, and preliminary effectiveness will be tracked (Table 1). We will report feasibility outcome measures including daily use rates of the biometric sensor (mean hours per day), the digital blood pressure monitor (mean times per day), the weight scale (mean times per day), and completion of the symptom questionnaire (mean times per day). The acceptability outcome measure will be patient responses to the truthfulness of a statement indicating willingness to use the intervention in the future (response options: very true, somewhat true, or not true). Preliminary effectiveness will be measured by tracking 30-day clinical outcomes (hospital readmissions, emergency room visits, and missed primary care and cardiology appointments). Demographic data and survey item responses were captured in REDCap. These items will be summarized, and univariate analysis will be completed for any domains connected to the outcomes. Structured medical record review data extracted from the EMR will also be captured in the REDCap database.

Table 1. Outcome measures or covariates for the digitally enabled CHW[a] intervention.

Outcomes and process measures	Source	Timing
Feasibility		
Use of the digital platform (wearing the biosensor[b], use of the blood pressure monitor[c], use of the digital weight scale[c])	Platform database	At 30 days
CHW engagement (number of CHW interactions, types of CHW interactions)	CHW interaction log	At 30 days
Acceptability		
Willingness to use the intervention again	Patient exit questionnaire	At 30 days
Preliminary effectiveness		
30-day readmissions	Electronic health record	At 30 days
Emergency department visits	Electronic health record	At 30 days
Missed appointments	Electronic health record	At 30 days

[a]CHW: community health worker.

[b]Hours worn per day.

[c]Number of times recorded per day.

Statistical Analysis

All standards for trial design, analysis, and reporting will be adhered to per the CONSORT (Consolidated Standards on Reporting Trials) checklist [43]. Univariate analysis will include demographic covariates of participants as well as intervention use frequencies, means, and SDs related to feasibility and acceptability outcomes. For the 30-day clinical outcomes of readmission, ED visits, and missed primary care and specialty appointments, we will use the proportion with any readmissions, emergency visits, or missed clinic visits will be compared between the 2 arms using Pearson ^{2} tests. We will also use a logistic regression model to include other potential predictors of the outcome to improve the precision of the estimate. The number of readmissions, ED visits, or missed appointments will be compared using Poisson models.

For exit interviews, we will use a framework analysis to identify main themes along with verbatim transcription for coding and analysis. Interview transcripts will be uploaded into Dedoose (version 8.3.47b.exe; SocioCultural Research Consultants, LLC). An analytic framework will be developed based on the major domains of the patient interview guide. To help facilitate reliability, 2 members of the research team (JC and NS) will serve as coders and familiarize themselves with the raw transcription data. They will then independently identify key themes raised by respondents. An iterative reapplication of this thematic framework will be used to identify all transcript components mapping to these specific themes. Coders will identify associations between themes, user characteristics, and outcomes for all interviews prior to achieving intercoder reliability. Any discrepancies unable to be resolved through discussion by the 2 coders (JC and NS) will be reviewed by a third researcher with expertise in qualitative data. These methods will be completed in concordance with the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist standards [44]. All trial procedures will also be in concordance with ClinicalTrials.gov regulations (NCT05130008).

Ethical Considerations

Institutional review board approval (2018P002014) was obtained from the Mass General Brigham Human Research Committee on September 22, 2020. All patients interested in enrollment participated in an informed consent process with the opportunity to ask questions and review all study procedures, data collection, and data analysis processes (primary and secondary) prior to signing an informed consent form. Privacy and protection standards were upheld with secure and password-protected database storage for all study data (which will be presented in deidentified form on publication). All participants were offered US $250 for remuneration for study participation.

Results

Between September 2022 and June 2023, enrollment was completed (n=50) with participants from inpatient general internal medicine and cardiology study floors at the MGH. The analysis is expected to be completed by January 2023, with results published in the spring of 2024. The study was approved by the IRB on June 4, 2019.

Discussion

Anticipated Findings

Here, we describe the protocol of an RCT designed to assess the feasibility, acceptability, and preliminary effectiveness of a novel digitally enabled CHW intervention for patients managing HF at home. The results of this trial are expected to deepen our understanding of experiential barriers patients with HF patients face while living at home and underline the potential value of a home-based CHW-supported digital platform solution. Assessment of the intervention's ability to augment patient engagement, adherence to care plans, and impact clinical outcomes will be addressed. Given the rising cost of care for patients with HF and heightened morbidity and mortality, the findings of this study may also carry important economic lessons in terms of designing value-based care that can assist in avoiding

preventable readmissions for patients with HF who are at high risk for hospitalization.

This study may also add context to our understanding of how digital interventions for patients with HF and other serious illnesses are best implemented. Numerous barriers to adoption have been well documented, and the results generated from this study may aid in the development of a framework, leading to best practices for addressing individual clinical and social barriers that may arise for patients engaging with digital platforms at home. The use of qualitative exit interviews adds to the patient centeredness of the study by highlighting the patient perspective and experience that may generate important solutions for the home management of HF and for unmet social needs. These results may also demonstrate how home-based CHW care can potentially advance patient use and engagement with digital platforms, adherence to clinical care plans, and connections to clinical homes. These study results may be used to strengthen and inform the feasibility and adoption of future digital interventions. Finally, this study also will provide opportunities to clarify our understanding of which types of interactions and resources provided to certain patients with HF by CHWs are most beneficial with regard to clinical outcomes.

Comparison to Prior Work

Remote monitoring studies have shown some improvements in outcomes for patients with HF. In a large trial with 1571 patients randomized to remote monitoring versus usual care, intervention patients had fewer days lost to unplanned cardiovascular admissions (4.88% vs 6.64%; 95% CI 0.65-1.0; *P*=.046) and decreased all-cause death rate (7.86 vs 11.34; hazard ratio 0.70, 95% CI 0.5-0.96; *P*=.028). However, most studies of remote monitoring have demonstrated mixed results [6]. A large study randomized 1437 participants to a combined health coaching and telemonitoring intervention for 180 days but showed no significant difference in readmission (50% vs 49%; *P*=.74) [45]. Similar outcomes were seen in other large-scale studies [46-48]. Nevertheless, systematic reviews have been suggestive of improved outcomes. In a systematic review analysis of 25 studies inclusive of structured telephonic support and telemonitoring (n=9332), telemonitoring reduced all-cause mortality (n=3740; RR 0.80, 95% CI 0.68-0.94) and HF-related hospitalization (n=2148; RR 0.71, 95% CI 0.6-0.83) [20]. However, all-cause 30-day readmission rates were unchanged. Concordantly, in a meta-analysis of 21 analyzed RCTs assigning patients to different remote patient monitoring interventions (n=6317) with medical personnel support or telephone support, results showed that those interventions that included staff delivering some home-based support (either clinically or administratively) reduced mortality (HR 0.77, 95% CI 0.55-1.08) [49].

While the majority of CHW studies are focused on cancer, there is a growing evidence base demonstrating the impact of CHWs on chronic disease and HF populations. In an RCT (n=426) pairing CHWs with patients who have chronic disease insured by Medicaid at the time of hospital discharge, adherence to posthospital care was improved (60% vs 47%; *P*=.02) [10], but no difference in 30-day readmissions was seen. Another RCT that focused on patients with 2 or more chronic diseases (n=322) demonstrated a reduction in systolic blood pressure associated with a 6-month CHW postdischarge intervention (–11.2 mm Hg vs 1.8 mm Hg; overall *P*=.08) [11]; a 28% reduction in 1-year hospitalizations was also seen, although it did not achieve statistical significance. A large RCT (n=525) testing a nurse practitioner and CHW intervention among patients with cardiovascular disease showed reductions in reduced total cholesterol (difference 19.7 mg/dL), low-density lipoprotein cholesterol (difference 15.9 mg/dL), triglycerides (difference 16.3 mg/dL), systolic blood pressure (difference 0.2 mm Hg), and glycated hemoglobin (difference 0.5%), as compared to enhanced usual care [50]. Some smaller studies have also supported these outcomes. In a study with 28 patients with HF paired with CHWs at the time of hospital discharge, participants paired with a CHW for 12 months saw a decrease in HF-related ED visits (0.71 vs 0.18; *P*<.001), and an 89% decrease in HF readmission (0.64 vs 0.07; *P*<.005) [51]. No significant difference in 30-day readmissions or ED visits was seen compared to matched controls. Systematic review data have also been positive. In a meta-analysis of 16 CHW-focused RCTs, 5 RCTs demonstrated a significant reduction in ED visits (23%-51% reduction; *P*=.05), hospitalizations (21%-50% reduction; *P*<.05), and urgent care visits [52]. We expect that this study will build on this knowledge by filling knowledge gaps related to adoption and adherence to a digitally enabled CHW intervention that has yet to be studied in a clinical trial powered to test its effect.

Strengths and Limitations

This methodology describes a small pilot trial performed at a single, urban, academic health care center. Since there are limited survey instruments designed to assess user experience with this particular digital platform, we adapted a prior questionnaire with established generalizability to assess this digital platform [37]. While formal patient-reported outcome measure scales were unable to be incorporated for all patient questionnaire covariates due to burdensome instrument length, Patient Health Questionnaire-2, Kansas City Cardiomyopathy Questionnaire, and the Three-Item Loneliness Scale were included as well as a number of items related to health behaviors and satisfaction used in our previous studies [27]. The study strengths include the RCT design focused on a unique intervention for an at-risk cohort of patients facing a burdensome and morbid condition. We also believe that the inclusion of feasibility as an outcome adds strength to the structure and actionability of the trial methodology in 2 ways: by further informing implementation science and strategic deployment of the intervention and by identifying potential barriers and facilitators of this intervention delivery and engagement for future larger trial performance. Additionally, the use of patient response data gathered from questionnaires and exit interviews adds a quasi-mixed methods design element that not only contributes to our understanding of the patient experience with living with HF at home but can also add depth and context to the study outcomes. While this trial will not be adequately powered to assess the true effectiveness of the intervention and our sample size will be limited to a single academic institution that may not be generalizable to other settings, the methodological quality and integrity of the study performance

may generate preliminary results that may later be tested in a large multisite clinical trial powered to assess the intervention's effect on clinical outcomes in larger populations.

Conclusions and Future Directions

The findings of this trial are expected to contribute to the implementation of digital platforms, as well as the role of CHWs in supporting digital care for a patient with HF. In this way, these findings may improve the performance of a large-scale and multisite RCT and help determine the true effectiveness of this intervention with regard to clinical outcomes. In addition, this trial may answer important questions about what types of CHW interactions can offer the greatest value for patients relevant to demographic, clinical, and social domains. As total medical expenditures for those affected by HF are expected to grow exponentially in the next decade, creating value-based and patient-centered solutions is a fundamental priority for health care institutions and stakeholders alike.

Abstract

Background: Pressure injuries are one of the most challenging secondary conditions for individuals with spinal cord injuries and related disorders (SCI/D) owing to inherent, lifelong risk factors that include a lack of sensory and motor function below the level of injury and reliance on a wheelchair for daily mobility, resulting in prolonged periods of sitting. Although many factors contribute to the development of pressure injuries, the pressure between the skin and a surface is always a factor and the development of injury is dependent on the magnitude and duration of the pressure. Clinically, broad recommendations for relieving pressure are used because we know very little about the unique day-to-day life patterns of the individual wheelchair user. Typically, it is after the occurrence of a pressure injury that the therapist will check equipment fit and the effectiveness of pressure offloading and ask about other surfaces they sit on in their home and community. This time-lapsed, largely self-reported data are fraught with recall bias and inaccuracies that the therapist incorporates into a plan of care.

Objective: This study's objective is to pilot-test the implementation and clinical effectiveness of a telehealth model of care combined with our mobile health (mHealth) Assisted Weight-Shift device for remote monitoring of factors related to maintaining skin health and wheelchair setup. Our overall hypothesis is that this study will result in an effective implementation plan, and the enhanced connected model of care using remote monitoring of pressure management will result in pilot-level, improved clinical outcomes for adults with spinal cord injury at high risk for pressure injury recurrence.

Methods: For all aims, we will use a mixed methods design using an exploratory, sequential approach to include the strengths of both qualitative and quantitative data. For aims 1 and 2, we will iteratively collect qualitative data from therapists, patients with SCI/D, and other stakeholders. For aim 3, we will perform a hybrid effectiveness-implementation randomized controlled trial to pilot-test the intervention. The projected results include an iteratively developed and tested implementation plan that meets moderate to high levels of acceptability, feasibility, and appropriateness. Additionally, the pilot trial results are expected to show positive trends in relevant clinical outcomes related to reduced pressure injury incidence, recurrence, and improved healing when compared with the standard of care.

Results: Currently, 6 participants have been recruited for our aim-1 qualitative study.

Conclusions: This study will expand upon our previous study to move the Assisted Weight-Shift system into routine clinical care, which was a strong desire of adults with SCI/D for improved individualized care plans to prevent pressure injuries. The results of this study will guide the next steps in a full, hybrid effectiveness-implementation trial with the goal of improving care to prevent pressure injuries.

Introduction

Background

Pressure injuries are one of the most challenging secondary conditions for individuals with spinal cord injuries and related disorders (SCI/D) owing to inherent lifelong risk factors that include a lack of sensory and motor function below the level of injury and reliance on a wheelchair for daily mobility, resulting in prolonged periods of sitting. A 2022 report stated that the incidence of pressure injuries in adults with SCI/D was 25% to 38%, with incidence increasing with time after SCI/D onset [1,2]. Recurrence rates as high as 80% [3-5] have been reported. Pressure injuries are also the second most common reason for rehospitalization at a rate of 11% to 20%, and these numbers are also increasing with time since SCI/D onset [1]. Pressure injuries are the only secondary condition consistently correlated with mortality risk [1,6], and they cause a significant negative impact on the individual, health care system, and society owing to the costs to manage them once they are present.

Interface Pressure Is a Major Risk Factor for Pressure Injuries

Although many factors contribute to the development of pressure injuries [7,8], the pressure between the skin and a surface is always a factor and the development of injury is dependent on the magnitude and duration of pressure [9,10]. An individual's pressure versus time curve is based on their ability to physiologically tolerate mechanical loads over time [11]. The longer the pressure is applied without mitigation, the higher the risk for tissue damage. Some individuals can tolerate more load over longer periods of time than others; therefore, individualization is important for prevention.

Individualized Solutions Are Necessary for Effective Prevention

Unique risk factors are present for individuals with SCI/D, including motor and sensory impairment; changes to muscle and bone tissues; and for up to 80% of those with SCI/D, the reliance on a wheelchair for mobility [1]. Individuals with more complete injuries have more impaired sensory function [12] and tend to fare worse in their ability to prevent pressure injury over time [13-15]. Movement is a key mechanism in offloading pressure, and there is high variability in daily movement patterns across the SCI/D population [16], which makes it difficult to standardize the recommendations for performing weight shifts. In addition, some individuals are physiologically better able to tolerate more or longer duration of pressure than others [17]. Each person has unique levels of risk awareness, daily routines, habits, and contexts within which they function, and these influence their ability to adhere to preventative behaviors [18]. Thus, for preventative behaviors to be added successfully to daily life, they need to be customizable and individualized to fit within each person's unique scenarios.

Standard of Care for Pressure Injury Prevention Is Individualized but Includes Limited Data About Daily Life

For the occupational or physical therapy seating specialists, care is provided in a client-centered manner such that education, treatments, and recommendations are individualized to the person as much as possible. This client-centered approach includes education about minimizing prolonged pressures under bony areas [3,11,19,20], with movement strategies to redistribute pressures [21-26] that are specific to the individual's injury level, functional level, body habitus, and so on. However, although the wheelchair, seating surface, and mechanism of pressure offloading (leaning or tilt) are specialized to the person, the clinical recommendations for the frequency and duration of skin-protective movement patterns are broadly applied to all people and range from performing weight shifts every 15 minutes to every hour and holding them for up to a 2-minute duration [3,7,19]. Broad recommendations are used because we know very little about the unique day-to-day life patterns of the individual wheelchair user. If a patient returns to their therapist after the occurrence of a pressure injury, the therapist can check equipment fit and the effectiveness of pressure offloading, and they can ask about other surfaces they sit on in their home and community. This time-lapsed, largely self-reported data are fraught with recall bias and inaccuracies that the therapist does their best to incorporate into an effective care plan.

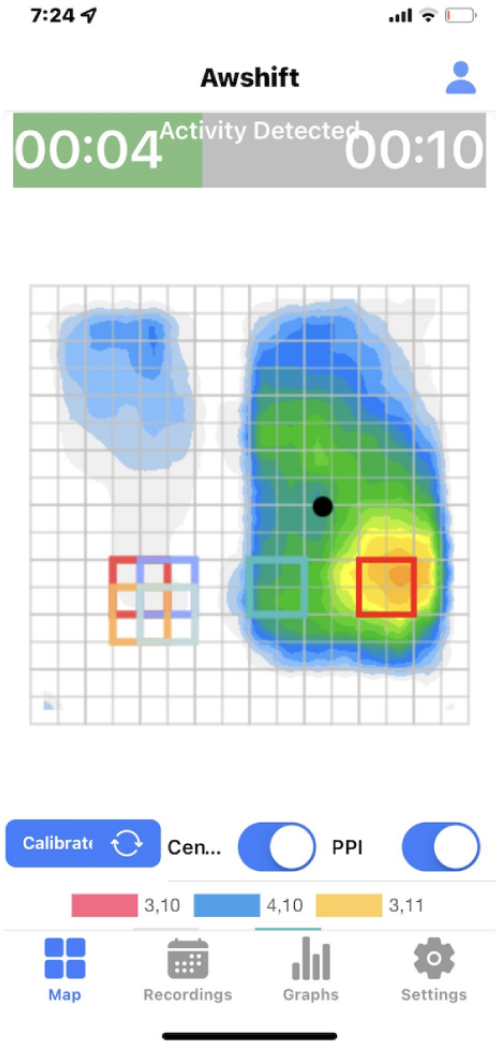
However, based on the rates of pressure injury incidence and recurrence, there is a gap in the care we can provide to individuals with SCI/D. We hypothesize that this gap is largely owing to the limited availability of data about the patient's daily life. On the basis of our own preliminary data, we know that therapists want to know the following objective and contextual data about their patients: (1) frequency and duration of daily pressure offloading behaviors, (2) effectiveness of pressure offloading during their daily weight shifts, and (3) pressure distribution on the other sitting surfaces the patient interacts with (chair, car seat, commode, etc). Without the necessary client-centered data gathered in context, the therapist is significantly limited in developing an individualized care plan.

The Assisted Weight-Shift System Monitors Factors of Individualized Pressure Management

In our Department of Defense (DoD) Spinal Cord Injury Research Program–funded project (W81XWH-15-1-0484), our group, in collaboration with veterans with SCI/D, developed the Assisted Weight-Shift (AW-Shift) system (formerly called the comprehensive mobile assessment of pressure system) to capture objective data regarding pressure management during daily life to be used by the patient or consumer and clinical partners to better prevent pressure injuries [27]. In a current National Institute of Health (NIH)–funded project (R01 AG056255), we have improved the hardware and software design of the AW-Shift system and are performing a clinical trial of the system in a consumer-use model. The AW-Shift system provides real-time pressure mapping visualization

(Figure 1), tracks weight shift behaviors, and provides weight shift reminders and high-pressure alerts. The data provided by the AW-Shift system offer unique, client-centered information to drive individualized goals and intervention plans. With this level of information about daily life, each person's unique daily occupations, routines, and rituals that influence their pressure management profile can be directly integrated into individualized care. Through DoD and NIH funding, we have demonstrated the efficacy of the system in terms of improving pressure injury prevention awareness, self-efficacy, and pressure management behavior in a consumer-use model. The proposed project advances our past studies through implementation of the AW-Shift system and evaluation of its impact on the clinical care of adults with SCI/D.

Figure 1. Assisted Weight-Shift (AW-Shift) real-time pressure map and countdown to next weight shift. PPI: Peak Pressure Index.



Structured Implementation Studies Are Necessary for Clinical Practice Improvement

Implementation research is the study of methods to optimize the systematic uptake of evidence that has been shown to be efficacious (has the intended effect) and effective (has the intended effect in the intended setting). As noted, emerging technologies such as AW-Shift may provide safe, efficient, and effective pressure injury prevention, but additional studies are needed to determine what approaches are optimal for integrating this technology and individualized data into clinical practice. The implementation of the AW-Shift system into routine clinical practice is far more complex than simply providing proof that the system works in a research setting.

Implementation into practice requires the commitment and active involvement of practitioners and patients, collaboration with relevant stakeholders who influence care delivery, and modifications to the intervention that meet the needs of providers and patients in dynamic practice settings. We have designed this project to assess the current clinical practices, iteratively modify the intervention to meet the clinical practice needs, and identify what factors may influence its uptake.

Overall Objective and Specific Aims

Overview

Our long-term objective is to facilitate the effective prevention of seating-related pressure injuries throughout the lifetime of individuals with SCI/D with the use of our evidence-based, real-time pressure management solution, the AW-Shift system (Figure 1). Our short-term objective for this study is to pilot-test the implementation and effectiveness of a telehealth model of care combined with our mobile health (mHealth) AW-Shift

device for remote monitoring of factors related to maintaining skin health and wheelchair setup. Our overall hypothesis is that our development plan will result in an effective implementation plan, and the enhanced connected model of care using remote monitoring of pressure management will result in pilot-level improved clinical outcomes (wound recurrence, early identification of wounds, and wound healing) for adults with spinal cord injury (SCI) at high risk for pressure injury recurrence. We will pursue our objective through the following specific aims.

Aim 1: Clinical System Development (Develop mHealth Report and Integrate Within the Medical Electronic Environment)

The current remote monitoring interface was built for research use. Through a user-centered, mixed methods design, we will engage with patients and clinicians through focus groups, interviews, and surveys to determine the optimized design for the capture and reporting of data to the patient and the clinician through a connected care model. After the capture and reporting method is developed, the data flow will be integrated within electronic medical record infrastructure.

Aim 2: Rapid Cycle Quality Improvement (Integrate System Into Connected Care and Telemedicine Infrastructure)

Using best practices for rapid cycle quality improvement, we will integrate our connected care solution into a current telehealth infrastructure. We will test the ability of our connected care solution to perform patient visits and short-term remote monitoring of pressure management focused on the system integration aspects to cycle through improvements in a 3-month time frame to prepare for aim 3.

Aim 3: Pragmatic, Hybrid Implementation Trial (Implement the Connected Care Solution via a Pilot, Pragmatic Trial Comparing Clinical Outcomes Between the Connected Care Model and Standard Practice)

Patients identified as having high risk for pressure injury recurrence will be randomized to either the connected care model (Figure 2) or the standard model of care for a 1-year follow-up time frame. Our implementation outcomes include important stakeholders' assessment of feasibility, acceptability, appropriateness, costs, and improved monitoring. Our pilot effectiveness outcomes are rate of wound healing for prevalent cases, incidence and recurrence of pressure injuries, early identification of wounds, and hospital admissions or readmissions.

Figure 2. Through a connected care model and the Assisted Weight-Shift mobile health system, the provider guides the patient to change high-risk pressures (phone image on the left) into safe pressures (phone image on the right).

Methods

Study Design

For all aims, we will use a mixed methods design using an exploratory, sequential approach to include the strengths of both qualitative and quantitative data. For aims 1 and 2 of the study, in an iterative manner, we will collect qualitative data from therapists, patients, and other stakeholders. For aim 3, using both qualitative and quantitative data, we will perform a hybrid effectiveness-implementation randomized controlled trial to pilot-test the intervention. For implementation outcomes, we will assess the feasibility, acceptability, and appropriateness for the in-home use by the patients and the feasibility, acceptability, and appropriateness of the previsit information from clinical stakeholders. For pilot effectiveness, we will assess the clinical outcome measures of wound recurrence, early identification of wounds, and wound healing.

Ethical Considerations

All research activities for aims 1 to 3 will be performed under institutional review board (IRB) oversight and with IRB approval. At the time of the writing of this manuscript, aim 1 was approved by the University of Texas Medical Branch IRB (22-0280) as an exempt study that waives the requirement for informed consent. The study is no more than minimal risk and fits the second exemption category (interviews), including recording data in such a manner that the identity of the human participants cannot be readily ascertained through identifiers linked to the participants. IRB approval for aims 2 and 3 will be sought under the minimal risk category. We expect that owing to the iterative nature of aims 2 and 3, modifications will be

required throughout the study to accommodate updates to the protocol and procedures, motivated by study staff and participant experiences and feedback. Participants for aim 1 are compensated for their participation with a gift card worth US $50. Participants for aims 1 and 2 will be compensated for their time with payment commiserate with the time required to complete the study.

Rationale for Hybrid Effectiveness-Implementation Study Design

Hybrid designs were developed to improve efficiency in moving promising interventions along the efficacy-effectiveness-implementation continuum, as implementation research focuses on the adoption of evidence-based interventions by systems of care. Integrating implementation planning into the study design helps to promote the full adoption of an intervention into the practice in which it was tested. We propose to use a hybrid-1 design [28], wherein the study is designed to test a pilot clinical intervention while gathering information about its delivery during the effectiveness trial and about its potential implementation in "the real world" of clinical practice. We will simultaneously plan for implementing AW-Shift into practice while testing its effectiveness in changing clinical outcomes. Our design includes formative evaluations of clinical staff during the study period, which will provide a rigorous assessment of what potential internal and external influences are critical for a successful implementation and add qualitative data to enrich the data analysis and evaluation.

Rationale for Using Consolidated Framework for Implementation Research Implementation Model to Guide Implementation

We propose to use Consolidated Framework for Implementation Research (CFIR) to inform which implementation targets will be critical for successful implementation. CFIR is a meta-theoretical framework that is based on a synthesis of 19 implementation frameworks and models with a goal to "foster knowledge-building into why implementations succeed or fail." It includes 5 domains: outer setting, inner setting, intervention characteristics, individual characteristics, and process. Each domain includes common constructs, 39 in total, associated with successful implementation. The framework does not specify hypotheses or causal pathways, allowing flexibility in evaluating constructs that are unique to a study. It has been described as a "menu of constructs" that enables systematic and comprehensive exploration and identification of potential factors that can influence implementation [29]. In general, the framework helps researchers and interventionists to assess the structural capacity for an intervention, culture for change, perceptions from stakeholders about the need for change, quality of the proposed solution, and way in which the intervention should be planned and executed. Regarding the qualitative work for aim 1, we will explore the potential constructs in each domain (eg, design quality and packaging, patient needs and resources, compatibility, relative priority, leadership engagement, and self-efficacy) from the CFIR model that will inform the efforts for the rapid cycle assessment in aim 2 and pilot trial in aim 3.

Specific Aim-1 Methods: Clinical System Development

The goal of aim 1 is to define the scope of the implementation of the AW-Shift system into a connected care model and operationalize that scope into a testable plan for aim 2. Each step of the plan will be guided by the end users and other key stakeholders through qualitative and survey feedback.

Patient and Clinician Needs Assessment

Overall, 2 focus groups, 1 for adults with SCI/D and 1 for clinicians from the Seating Clinic and Wound Care, will be conducted to determine the needs and priorities of each group for improving the assessment of seating and mobility needs. A focus group guide, drawn from CFIR's Interview Guide Tool [30], will be used for each group to better understand how expanded seating pressure information captured during the daily life of patients could better inform seating and mobility therapy visits. The discussion will include brainstorming of types of information that would be of value and identifying barriers to and facilitators of attaining the information. There will be an emphasis on understanding the concerns about the complexities of a new process as it relates to the outer setting, inner setting, and individual characteristic constructs of the CFIR model [31]. The focus groups will be conducted through a Health Insurance Portability and Accountability Act–compliant web-based meeting format (Zoom; Zoom Video Communications). The discussion will be recorded for analysis.

Qualitative Outcome Measures and Data Analysis

The qualitative data from the focus groups will be transcribed by a transcriptionist. Investigators will import transcripts and field notes into computer-assisted coding software such as NVivo (Lumivero) to structure the transcripts and enable them to be "openly coded" by the researchers. The CFIR constructs will guide the development of the code book, as these constructs are key to effective implementation. Qualitative analysis of the interview transcripts will combine deductive and inductive approaches using an initial coding template structured around the interview guide topics and then refined through full data set coding [32]. The coding template refinement process will include an element of reflexivity owing to clinical expertise of coders, thus offering an efficient process to generate high-value design requirements layered with contextual rationale. Through memo-taking and iterative meetings to discuss data, the team will reach consensus about the code book and the assignment of text segments to particular codes. Investigators will independently review the transcripts and codes to provide a measure of internal validation. A coalescence of major themes from the coders will be used for the interpretation of findings and the subsequent theory development. The survey data will be used to define the areas of strengths and weaknesses of the intervention and implementation plan.

Sample Size

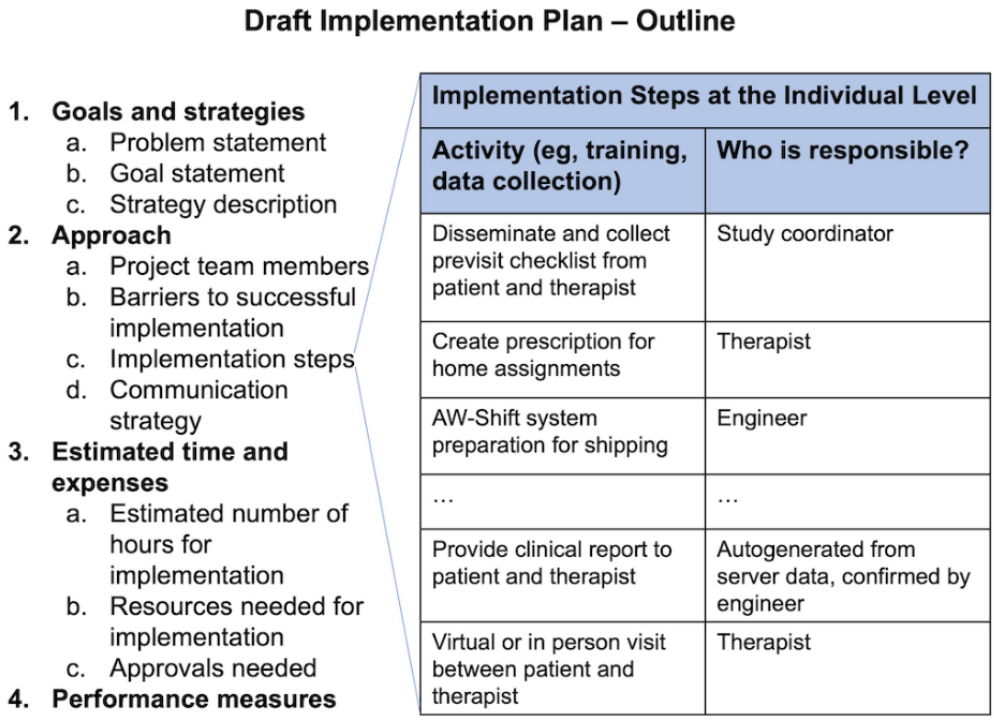
For focus groups, we will follow the recommended practice by having no more than 10 participants per group [33]. For the patient focus group (n=10), we aim to purposively sample patients with various levels of SCI/D, wheelchair type (power and manual), history of pressure injuries, and age to seek a wide breadth of user experiences. For the therapist focus group

(n=10), we aim to purposely sample therapists with a range of years of experience, to seek a breadth of perspectives about providing seating and mobility care to patients with SCI/D.

Draft Plan and Follow-up Focus Group

Needs assessment will be used to refine the draft implementation plan (Figure 3). Following the refinement of the draft plan, a follow-up focus group with clinicians and patients will be conducted, wherein the draft plan will be presented along with a description of the AW-Shift system. Through this focus group, we seek to understand the specific types of data and activities to measure during daily life that can inform the clinical assessment. In addition, the participants may be queried about specific aspects of the plan using survey responses that will likely use a Likert scale for assessing the level of satisfaction or acceptability with aspects of the plan. We will learn from these focus groups and survey responses regarding what needs to be adapted in the draft plan and what data will be used in the mHealth report. We will operationalize the implementation plan based on the participant feedback and use the CFIR constructs to increase the usability and acceptance of the AW-Shift system by participants or patients with SCI/D.

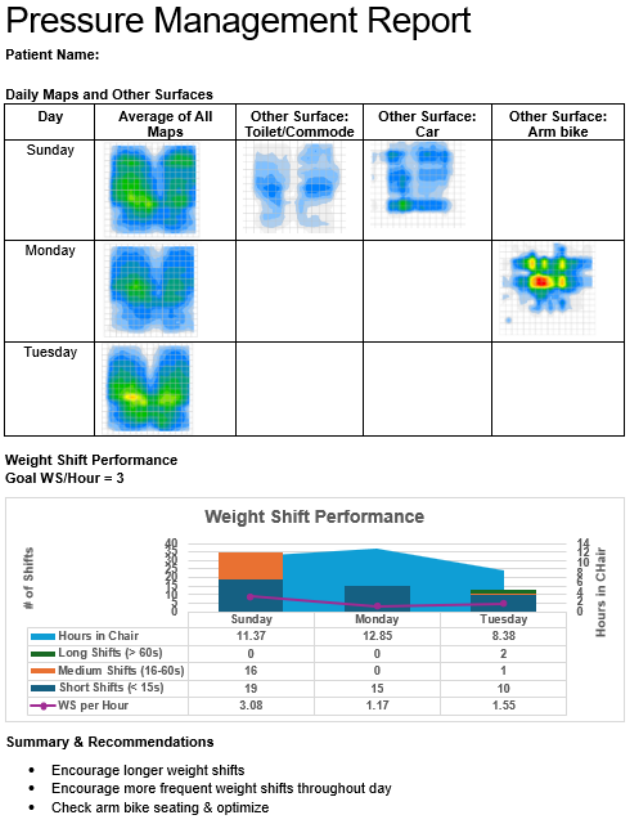
Figure 3. Implementation outline with example implementation steps. AW-Shift: Assisted Weight-Shift.



mHealth Report

The mHealth report will provide summary data and visualizations that provide an informative snapshot of the home testing period (a partial example is shown in Figure 4).

Figure 4. Example of a partial mobile health report. AW-Shift: Assisted Weight-Shift.



Integration of the mHealth Report Into the Clinical Electronic Environment

On the basis of the focus group findings, the team will perform the following tasks in collaboration with necessary stakeholders. We will adapt the current, remote data capture process and infrastructure to meet the patient and therapist priorities and requirements for use during the clinical visit. A likely solution for communication of the data will involve the mHealth report being autogenerated on the server and provided back to the patient through the mobile app before the telehealth visit. The patient, being the ultimate owner of their data, will then send their report to their therapist through a secure patient website or mobile app that allows direct communication to the care team and patient access to their web-based medical record. With this data flow plan, the report would be available to the therapist for easy viewing during their visit. In addition, the patient will have full awareness of the data that the clinician is viewing.

Iterative Process for User-Designed Implementation of the AW-Shift System Into Clinical Care

Through a series of iterative focus groups and further refinement steps, the team, along with the users of the system (patients and therapists), will co-design the full implementation plan that will be ready for testing in aim 2. We estimate this step will take 2 to 3 iterations of focus groups and refinement steps.

Specific Aim-2 Methods: Rapid Cycle Quality Improvement

Overview

Rapid quality improvement assessment of the implementation plan will be completed in aim 2 by testing the plan with an estimated 10 patients with SCI/D. For the first 3 to 5 patient participants, each participant will be run 1 at a time through the implementation plan. Rapid adjustments will be made as each participant goes through the steps of the plan. For the final 6 to 8 participants, participants will be scheduled in pairs such that at least 2 participants will be run in parallel to test the ability of the implementation plan to adjust to concurrent use of the system in the participants' home and community. After each participant set, we will make rapid adjustments to optimize the implementation plan. Owing to participant heterogeneity, we will be mindful about how plans will need to be optimized differently depending on patient characteristics such as injury level and whether a caregiver or personal aid is required by the patient to use the system.

Protocol for Connected Care Model

Although the specific details of this protocol may change, we propose an outline of the procedures that will occur after participant consent and enrollment.

Individualized AW-Shift Prescription

A seating clinic therapist will review the clinical notes of the participant for their seating and mobility history. We presume from our preliminary data from therapists and the knowledge of the clinical team members in this project that a simple initial checklist will be effective in determining the possible "home

assignments" that therapists could give to patients to gather the pertinent information specific to the patient, including recording pressure across different surfaces, using weight shift reminders, and recording weight shifts performed during specific tasks. In addition, the patient will be asked to complete a checklist to identify their seating and mobility concerns including, for example, new areas of concern about their skin, seat cushion, weight shifting habits, pressure on other surfaces, sitting posture, or weight relief quantity or quality. On the basis of the checklist information, an individualized prescription will be developed for the participant to fulfill (with extensive team support) during the 2-week daily life testing period.

System Setup and Prescription Delivery

The participant will be shipped an AW-Shift system and scheduled for a virtual visit to set up the system by the study coordinator. The system will include the hardware components, a user manual, and a study-provided smartphone or tablet if the participant does not have their own device. If the participant is using their own phone, they will be instructed to download the AW-Shift mobile app from the Apple App Store or Google Play Store. During the system setup visit, the participant will be provided with training regarding how to use the AW-Shift system with the study coordinator and engineering and therapy experts on the study team. The team will review the individualized prescription with the participant, and knowledge about system use will be tested to determine sufficient mastery of using the system.

Home and Community Use of the AW-Shift System

Participants will use the system for an estimated 2 weeks before their clinical visit. Participants will have easy access via phone; secure, web-based format; email; and SMS text message for technical and therapy support. A potential prescription could include (but not be limited to) mapping the variety of surfaces the participant sits on in the home and community (the system can be used on any surface), completion of daily weight shift protocols to assess participant positioning on their cushion, measurement of how the participant performs weight shifts with and without reminders provided by AW-Shift, and measurement of the effectiveness of the weight shifts to offload pressure.

Summary Report

Before the telehealth clinic visit, the prepared mHealth report will be delivered via the AW-Shift mobile app to the participant. The participant will be instructed about how to upload the report 1 day before their telehealth clinical visit. The therapist will view the mHealth report via the participant's medical records during the clinical visit.

Telehealth Clinical Visit

During the visit, the therapist will use the standard clinical notes and the data provided on the mHealth report to guide the patient participant through the typical steps of a therapy visit focused on the seating and mobility needs related to pressure injury prevention. The telehealth visit will be completed using the standard Zoom interface. The therapist will use all the information they have available to determine the next steps in the patient's care plan. The clinic visits will be recorded, so that the study team can provide additional observations for use in process improvement. The therapist will ask for confirmation of a skin check performed on the day of the visit with assistance from a caregiver, if necessary.

Assessment

Following the telehealth visit, both the patient participants and the therapists will complete a series of surveys to assess usability (System Usability Survey [34]), acceptability (Unified Theory of Acceptance of Use of Technology [35,36]), feasibility (Feasibility of Intervention Measure [37]), and appropriateness [37] of the procedures, and each of them will participate in a short interview to gather qualitative feedback to improve the implementation plan.

Rapid Assessment Procedure

Rapid assessment procedures are a pragmatic option for producing timely, contextually rich evaluative information about complex interventions implemented into dynamic clinical settings [38]. We will use rapid assessment procedures after each participant in the first 3 to 5 participants or after each pair of the final 6 to 8 participants to improve the plan for the next set of participants.

Stakeholder Input About Case Summaries

The findings from aim 2 will be written as a case summary that will be presented to the patient and therapist focus groups from aim 1 to gather additional stakeholder input about the optimization process. Any points regarding necessary improvement or inconsistencies will be discussed by the research team until consensus is achieved for the final plan for aim 3.

Outcome Measures and Data Analysis

The qualitative data from focus groups and interviews will be managed and analyzed as described for aim 1. The quantitative data from the survey scores will be used to define the areas of strengths and weaknesses of the intervention and implementation plan for further refinement.

Sample Size

For the rapid assessment testing for aim 2, we provide a robust approach by cycling the process through single and paired visits. Similar to the focus groups, we will sample to attain a breadth of user experiences. A total of 10 participants for each round is an effective sample size to be able to narrow down and optimize the process [33].

Data Management

All study data will have unique identifiers removed before the final analysis. Study data will be imported from the various clinical data sets into a central REDCap (Research Electronic Data Capture; Vanderbilt University) database that can be accessed by the study team. The study coordinator managing the database will keep the electronic key secure in accordance with Health Insurance Portability and Accountability Act and patient privacy regulations.

Potential Limitations and Alternative Strategies

Failure of the System in the Field

We will monitor system use and will be available for troubleshooting. We currently have 25 full systems and will be able to accommodate equipment swapping by mail.

Recruitment

We have experienced very little difficulty in reaching our goals for participation in past studies with similar methodology. We will continue to collaborate closely with clinical staff and consumer groups to ensure successful recruitment.

Skin Safety

We will continue to track skin safety during the study and will discontinue use if we notice any signs of skin issues.

Sensing Technology

The current resistive sensors used in the selected pressure map have inherent limitations including a tendency to creep under prolonged loaded states, but we mitigate this through specific calibration protocols. The mat was selected because it stretches and is durable for whole day use.

Specific Aim-3 Methods: Pilot

Pragmatic Hybrid Implementation Trial

The proposed pilot randomized controlled trial will test whether our novel AW-Shift system intervention adds value to the clinical care of adults with SCI/D to inform our next steps in translation.

Study Design

This single-site randomized controlled trial will use a modified intention-to-treat analysis. Randomization will be a stratified, block randomization with stratification based on wheelchair type (manual vs power) and current wound severity (no wound or stage 1 vs stage 2 or stage 3). The intervention group (26/52, 50%) will receive the connected care model that used AW-Shift in combination with telehealth. The control group (26/52, 50%) will receive the standard of care that uses telehealth when appropriate. The statistician will be masked to the group allocation information for the outcome measure analysis.

Randomization

We will stratify based on wheelchair type (2 groups: power and manual), and current wound severity (2 groups: no wound or stage 1 and stage 2 or stage 3). We will block randomize in groups of 4. This randomization scheme will ensure distribution of important confounders between arms of the study. Furthermore, the blocking will ensure equal distribution of group assignment during the study.

Study Population

Adults with SCI/D with high risk of recurring pressure injury who answer "yes" to one of the following questions are eligible: (1) I get pressure ulcers about every couple of years; (2) I get at least 1 pressure ulcer a year; and (3) I always seem to have sores, often requiring surgery or hospitalization [39]. Our rationale for choosing individuals at high risk for recurring injury is that once a person has one pressure injury, their chances are significantly high to have another; hence, it has been recommended that interventions focus on this group of individuals [39].

Initiating and Conducting the Pilot Clinical Trial

The principal investigators (PIs), coinvestigators, and study staff will manage the process of study initiation with a modified standard checklist that covers essential items. Pilot clinical trial initiation meeting will occur early in mid–year 1, wherein all the steps will be reviewed, and the specific timeline will be determined. Standard operating procedures and field guidebooks will be developed to follow throughout the trial period. Weekly phone calls or web-based meetings among all study members will be used for study management. Any urgent communication regarding the pilot clinical trial will be managed with a phone call to the PI made within 18 hours of the event and reported to the IRB.

Study Procedures

For initiation and administration of the intervention, the following procedures will be followed:

1. Project initiation: The project will be initiated following a study initiation checklist by the PI and local site investigators.
2. Staff training for the intervention: Staff will be instructed about how to use the AW-Shift system, view and use the mHealth report, and administer data collection elements as is appropriate for each study role. Data collection procedures will be standardized and tested for consistency across study team members.
3. Participant recruitment: Recruitment and enrollment during year 2 will occur primarily through clinical staff in collaboration with the study coordinator.
4. Intervention study period: The intervention will begin with 2 weeks of AW-Shift use at home by the patient with SCI/D, followed by a web-based clinical visit with a seating clinic therapist. Before mailing AW-Shift to participants, individualized tasks will be assigned by the seating specialist. The tasks are meant to inform the seating assessment process during the clinical visit. Participants and seating specialists will complete surveys after the seating clinic visit and participate in a guided interview.

Intervention Protocol

The planned intervention protocol is similar to that described for aim 2, for the rapid quality assessment as described in the *Protocol for Connected Care Model* section. We expect that the protocol will be improved through the iterative process we are using to optimize the implementation of our intervention. Full demographic variables relevant to SCI/D will be collected during the consent visit. The same surveys and structured interview will be completed after each visit by the intervention group participants and the therapists including assessment of usability (System Usability Survey [34]), acceptability (Unified Theory of Acceptance of Use of Technology [35,36]), feasibility (Feasibility of Intervention Measure [37]), and appropriateness [37] of the procedures.

Control Protocol

If participants are randomized into the control group, the standard of care protocol will be followed as used in the seating clinic. Demographic and additional variables will be collected from participants similar to those in the intervention group, and their clinical visit will be recorded for assessment of the visit.

General Statistical Methods

All tests are 2 sided, with a 0.05 type-1 error rate. Analysis will be conducted using SAS (SAS Institute) and R software (GNU Project). Mean and SD or median and IQR will be reported for all demographic, predictor, and outcome variables, as appropriate. For all outcome measures, the effect of relevant biological variables including sex, age, level of sensation, and pressure injury history will be assessed as covariates in the analysis. In addition, wheelchair type will be included as a covariate. Variables will be transformed as necessary to meet the appropriate distributional assumptions for modeling (eg, normality). For missing data, mixed models can be used to handle missing data naturally, so that all available data points may be analyzed, irrespective of whether the participant had some outcome data missing. However, analyses of data with multiple imputation for missing data may be attempted if the data are likely to be missing at random.

Primary Pilot Clinical Trial Effectiveness Outcomes

The primary effectiveness of the intervention will be captured via the collection of the following clinical outcomes: wound recurrence, early identification of wounds, wound healing, and hospital admission or readmission. The data for these metrics will be abstracted during the full year (365 days) after the study-related clinical visit for both the control and intervention group participants. Then, 2 independent therapist team members will abstract the medical records of each participant to search for the occurrence of an incident wound, stage at which wounds are identified, time frame of wound healing, and occurrence of a hospital admission or readmission directly related to a seating area pressure wound. Comparisons between groups for the primary outcome measures will be made using a 2-tailed *t* test. Additional comparisons will be made with regression and mixed effect models to explore the role of covariates on the study findings.

Secondary Pilot Clinical Trial Effectiveness Outcomes

As a proxy outcome measure for clinical effectiveness, each clinical visit for the control and intervention groups will be assessed using the review of visit checklist shown in Figure 5 by the therapists leading the clinical visit. Then, 2 independent raters, who are seating specialists, will assess the checklist for each participant and will be blinded to the identities of the patients and therapist. The reviewers will rate the visit information on a 5-point Likert scale (eg, “Rate the effect of AW-Shift data on clinical recommendations: (1) significantly diminished, (2) diminished, (3) neither improved nor diminished, (4) improved, or (5) significantly improved”). The reviewer ratings will be analyzed with a 2-sample Mann-Whitney *U* test to determine if the ratings are different between groups to test our hypothesis that the AW-Shift data will significantly improve clinical recommendations. Effectiveness will also be assessed qualitatively in the interviews.

Figure 5. Clinical visit review checklist.

Clinical Visit Checklist

Used for retrospective chart review and for study visit video observation.

Participant ID:

Visit Date:

Does the documentation indicate that:	Yes	No
○ Participant has a concern regarding pressure?		
○ Pressure mapping completed during the visit?		
○ There were concerns about pressure management?		
○ Mention of surfaces other than the seat cushion/wheelchair used during the visit?		
○ There is a need for further evaluation of pressure on other surfaces?		
○ New equipment or modification of current equipment needed?		
○ A change in daily routine or daily activities is needed?		
○ There is a need for change in weight shift practice		
○ Frequency		
○ Duration		
○ Consistency		
○ Method for improved pressure distribution		

Comments (indicate the recommendations and strategies that were documented):

Implementation Outcome Measures

Implementation success will be assessed using feasibility, acceptability, and appropriateness surveys regarding the in-home system use of participants and therapists. This information will guide the broad implementation of the intervention.

Additional Study Variables, Controls, and End Points

Demographic variables relevant to SCI/D will be collected and used in the analysis as appropriate. Additional metrics include self-efficacy in managing pressure, assessed using the Skin Care Belief Scales [40]; consistency of weight shift performance, as measured by the AW-Shift system during home use; and the SCI–Quality of Life scale.

Feasibility Study Variables

For future clinical trial planning, the study variables of screening rate, recruitment rate, enrollment rate, and retention rate will be measured. In addition, the treatment adherence rate and treatment fidelity rates will be measured, and the assessment process will be evaluated. The assessment process includes documenting the planned assessments and data collection instruments that are completed in addition to the duration of the visits.

Sample Size

The sample size for this pilot study (N=52; n=26, 50% per group) is based on guidance that for a trial with 90% power and 2-sided 5% significance, pilot trial sample size of 25 participants per treatment arm is sufficient for an expected small, standardized effect size (0.2) [39]. We do not have the needed data for our primary outcomes to directly determine the power of our planned study design; however, this pilot study will be used to power the full clinical trial. Furthermore, we have used approaches to optimize our statistical power including blocking within the design itself that adjusts for covariates during randomization to reduce imbalance and triangulating the findings of quantitative analyses with qualitative data in mixed methods designs [41].

Potential Limitations and Alternative Strategies

In addition to the potential limitation described for aim 2, aim 3 has the added potential of loss to follow-up. As the long-term follow-up data are passively extracted from the medical record, we acknowledged that patients may seek care outside the original health system they were recruited from. In addition, for participants who have data that we cannot access, we will seek the approval of the participant to access their medical records from other medical systems.

Human Participants

Study Population

Focus groups and structured interviews will be conducted for all aims. Qualitative methods will include adult patients with SCI/D and seating and mobility therapy specialists. Adults with a SCI/D will be the participants for aims 2 and 3. As needed, we will capture additional input from other stakeholders involved in the proposed implementation process to ensure that we are gathering views from a broad range of affected individuals as per the CFIR framework. These individuals may include therapy managers, IT staff, data security staff, scheduling staff, and industry representatives.

Recruitment

Following IRB guidelines, manual and power wheelchair users with traumatic or atraumatic SCI/Ds will be enrolled for the study. The inclusion and exclusion criteria were chosen to include wheelchair users with SCI/D who are at risk for pressure injury development. Recruitment will be purposeful in achieving the desired equal distribution of power and manual wheelchair users and individuals with paraplegia and tetraplegia. For study randomization in aim 3, we will use a stratified, blocked randomization method to ensure even distribution of important predictor and confounding variables in the intervention and control groups. Announcements for participation in this study will be made by personnel directly to patients through mailed letters, phone calls, and word of mouth. Upon determining a person's eligibility, an appointment (via phone or in person) will be made with the study coordinator to explain the research project, confirm eligibility, and collect the necessary demographic data.

Inclusion and Exclusion Criteria

We will enroll adult men and women, aged between 18 and 80 years, with SCI/D at C4 or below, who have a lack or absence of sensation, are primary wheelchair users, and are at high risk for pressure injury. For aims 2 and 3, participants must have had a seating clinic visit or be scheduled for a seating clinic visit. Participants must demonstrate the ability to independently access the AW-Shift system app on a mobile phone or tablet and be able to participate in web-based visits or meetings with the research team. Participants will be excluded if they are unable to consent, have an active stage-4 wound at the seating surface site, do not have adequate resources or support for use of the AW-Shift technology in their home environment, or are currently receiving palliative care. We will enroll current occupational or physical therapy staff for aim-1 qualitative and survey feedback.

Potential Risks

There is the potential for skin irritation from sitting on a pressure mat for long periods. Participants may sit on the pressure mat throughout the day or may simply use it for short periods while performing their prescribed activities. Participants will be instructed to do a skin check every day and log their findings.

Participants are instructed to call the study coordinator if a new area of skin breakdown or wound occurs while they are using the pressure mat or if a current wound worsens. The participant will be asked to remove the mat until the skin breakdown or wound resolves. If the area does not resolve and worsens further, the participant will again contact the study coordinator and will then be referred to their typical clinical care provider in the case of a potential, new-onset incidence of pressure ulcers of stage 3 or 4. Initializing and deploying the AW-Shift system will require performing transfers and weight shifts. Transfers always have some risk of injury or fall, and the participant will be advised to transfer in their usual manner. Weight shifts will include typical functional movements, such as leaning forward and sideways, but participants will be instructed to only perform weight shifts with which they are comfortable. Risks from transferring on their own while the sensors are on the wheelchair are no different than transferring without the sensors present.

Focus Group Guide

Questions were created for the clinicians' structured interviews and focus groups. A sample of the question list is shown in Textbox 1.

Textbox 1. Sample of question list.

- What are some of the challenges you come up against when teaching a patient with spinal cord injuries and related disorders (SCI/D) about pressure relief?
- On the basis of feedback from our patients of how very useful real-time information is to their pressure relieving behavior. What do you think about the having the real-time image available all the time to the patient?
  - Do you think having that image available will assist you in monitoring and teaching seating behavior?
- What other information, or data, would you want to be readily available to you to monitor the patients' learning of pressure injury prevention behaviors?
  - For example, would it help you to know how many pressure reliefs the patient conducted during the previous hour?
- Would you like the data available for you to be in a particular format?
  - For example, an average number of pressure reliefs conducted over the past four hours, or the percentage of offload over a certain period?
  - How far back would you want data available for monitoring or educating pressure relieving behaviors?
  - Do you want the information pushed to you?
- Can you think of any data that would not be helpful for you to be able to access?
  - For example, when reviewing the patients pressure relieving behavior would you find it useful to know the actual peak psi's that occurred over the previous period of monitoring, or would that be too much information?

Implementation Strategies

We developed the draft of our study-specific implementation strategies (Table 1). From this chart, a refined, operational implementation guide would be created.

Table 1. Implementation strategies chart.

Study phase	Implementation strategies
Prestudy	• Conduct local needs assessment • Conduct local consensus discussions • Fund and contract for the clinical innovation • Use an implementation advisor • Develop an implementation glossary • Identify and prepare champions • Identify early adopters • Inform local opinion leaders • Build a coalition • Assess for readiness and identify barriers and facilitators • Promote network weaving • Develop and organize quality monitoring systems • Develop and implement tools for quality monitoring
Aim 1: Clinical system development: define scope of implementation of AW-Shift[a] into a Connected Care model	• Develop a formal implementation blueprint • Build a coalition • Conduct educational meetings • Distribute educational materials • Promote adaptability • Prepare patients or consumers to be active participants • Involve patients or consumers and family members • Obtain and use patients or consumers and family feedback • Shadow other experts • Use data warehousing techniques
Aim 2: Rapid cycle quality improvement: rapid quality improvement assessment of the implementation plan	• Facilitation • Conduct educational meetings • Conduct cyclical small tests of change • Provide ongoing consultation • Provide local technical assistance • Provide clinical supervision • Organize clinician implementation team meetings • Prepare patients or consumers to be active participants • Involve patients or consumers and family members • Purposely reexamine the implementation • Obtain and use patients or consumers and family feedback • Tailor strategies • Remind clinicians • Intervene with patients or consumers to enhance uptake and adherence • Shadow other experts • Facilitate relay of clinical data to providers • Use data warehousing techniques
Aim 3: Hybrid pilot clinical and implementation trial: randomized controlled trial to test whether AW-Shift system adds value to clinical care of people with SCI/D[b]	• Stage implementation scale up • Provide ongoing consultation • Provide local technical assistance • Provide clinical supervision • Remind clinicians • Recruit, designate, and train for leadership • Use data warehousing techniques • Obtain formal commitments

[a]AW-Shift: Assisted Weight-Shift.

[b]SCI/D: spinal cord injuries and related disorders.

Results

This study was funded in January 2023, and the IRB approval for Aim 1 of the study was December 5, 2022. We have recruited 6 participants into the clinician arm of our Aim 1 qualitative study as of manuscript submission. Expected results for Aim 1 to be published in winter 2024.

Discussion

Expected Outcome

Pressure mapping performed in rehabilitation clinics can effectively determine appropriate equipment and positioning in a wheelchair [42-44], but the translation of the same information from daily life into clinical care has not been previously tested. The day-to-day uncertainty of ulceration leads to patient

appointments simply to “be mapped” as a preventative action often involving long distances and, sometimes, with an active pressure injury. A system such as AW-Shift can be integrated into a connected care model to allow for the integration of real-world data into the clinical practice of wheelchair users with SCI/D. The system has the potential to enhance the prevention of pressure injuries. Our mapping system has the ability to address and correct the contributors to pressure ulceration that have been observed in seating and mobility clinics: undetected cushion failures; caregivers who are unexpectedly late or absent, leaving the patient in the chair longer than necessary; frequent caregiver turnover; inexperienced caregivers; and caregivers who struggle with positioning the patient. AW-Shift can provide meaningful information about the daily life of people with SCI/D to the patient, caregivers, and clinicians to significantly improve the management of patient needs.

This project will demonstrate the ability to use an mHealth solution for improvement in pressure injury clinical outcomes. The success of this project will have sustained, powerful influence in the field of SCI/D through enhanced evidence of pressure injury risks that are present in a wheelchair user’s daily routine and environment that are not identifiable through routine, in-person evaluations in the clinic. It will further demonstrate the opportunity for the clinician and individual with SCI/D to work together to plan effective strategies for more expeditious interventions.

We hypothesize that an enhanced connected model of care using remote monitoring of pressure management will result in improved clinical outcomes (wound recurrence, early identification of wounds, and wound healing) for adults with SCI at high risk for pressure injury recurrence. We have performed extensive studies assessing the acceptability, usability, and efficacy of the AW-Shift system with adults with SCI/D. We now need to partner with patients and clinicians (therapists) to capture seating pressure information during daily life to inform clinical visits for individualized seating and skin health recommendations. On the basis of our projects funded by DoD, NIH, and Veterans Administration, we know that adults with SCI/D and therapists who treat them have the strong desire for a visual system and expanded access to data from daily life. Changing current clinical practices will require engagement and collaboration with providers and patients about what information is critical and how it should be used with clinical guidelines. This project will expand upon our previous study to move the AW-Shift system into routine clinical care, which was a high desire of adults with SCI/D for improved individualized care plans to prevent pressure injuries.

Acknowledgments

Funding support for this project is provided through the generous support of the Craig H Neilsen Foundation.

Conflicts of Interest

TLV-D, MMM, and Mayo Clinic have a financial interest related to this study. MMM and TLV-D are inventors of the Assisted Weight-Shift system. The previous study reported in this paper has been reviewed by the University of Minnesota and Mayo Clinic Conflict of Interest Review Board and has been conducted in compliance with both policies.

Abstract

Background: Multiple sclerosis (MS) is an autoimmune inflammatory disease of the central nervous system that causes myelin sheath damage and axonal degeneration. The glycolipid (2S, 3*S*, 4*R*)-1-O-(α-d-galactosyl)-2-tetracosanoylamino-1,3,4-nonaetriol (OCH-NCNP1 or OCH) exerts an immunoregulatory action that suppresses T helper (Th)1 cell–mediated immune responses through natural killer T cell activation, selective interleukin-4 production, and Th2 bias induction in human CD4-positive natural killer T cells.

Objective: This trial aims to investigate the efficacy and safety of the immunomodulator OCH in patients with relapsing MS through 24-week repeated administration.

Methods: This protocol describes a double-blind, multicenter, placebo-controlled, randomized phase II clinical trial that was initiated in September 2019. The participants were randomly assigned to either a placebo control group or an OCH-NCNP1 group and the investigational drug (3.0 mg) was orally administered once weekly for the 24-week duration. Major inclusion criteria are as follows: patients had been diagnosed with relapsing MS (relapsing-remitting and/or secondary progressive MS) based on the revised McDonald criteria or were diagnosed with MS by an attending physician as noted in their medical records; patients with at least two medically confirmed clinical exacerbations within 24 months prior to consent or one exacerbation within 12 months prior to consent; patients with at least one lesion suspected to be MS on screening magnetic resonance imaging (MRI); and patients with 7 points or less in the Expanded Disability Status Scale during screening. Major exclusion criteria are as follows: diagnosis of neuromyelitis optica and one of optic neuritis, acute myelitis, and satisfying at least two of the following three items: (1) spinal cord MRI lesion extending across at least three vertebral bodies, (2) no brain MRI lesions during onset (at least four cerebral white matter lesions or three lesions, one of which is around the lateral ventricle), and (3) neuromyelitis optica–immunoglobulin G or antiaquaporin-4 antibody-positive. Outcome measures include the primary outcome of MRI changes (the percentage of subjects with new or newly expanded lesions at 24 weeks on T2-weighted MRI) and the secondary outcomes annual relapse rate

(number of recurrences per year), relapse-free period (time to recurrence), sustained reduction in disability (SRD) occurrence rate, period until SRD (time to SRD occurrence), no evidence of disease activity, and exploratory biomarkers from phase I trials (such as gene expression, cell frequency, and intestinal and oral microbiome).

Results: We plan to enroll 30 patients in the full analysis set. Enrollment was closed in June 2021 and the study analysis was completed in March 2023.

Conclusions: This randomized controlled trial will determine whether OCH-NCNP1 is effective and safe in patients with MS as well as provide evidence for the potential of OCH-NCNP1 as a therapeutic agent for MS.

Introduction

Multiple sclerosis (MS) is considered to be an autoimmune disease triggered by environmental factors that act on a genetically susceptible host. Both major histocompatibility complex (MHC) and non-MHC genes are risk factors for the development of MS. In addition, environmental factors such as low vitamin D, low ultraviolet radiation exposure, cigarette smoking, obesity, and Epstein-Barr virus exposure can increase the risk for both the development of MS and a more severe disease course. Accumulating evidence suggests that dysregulation of the intestinal microbiome (dysbiosis) constitutes an important factor contributing to MS pathogenesis. The microbiome regulates T cell function, with both regulatory and pathogenic effects, thereby playing an important role in autoimmune responses [1].

MS is a cell-mediated autoimmune disease directed against central nervous system (CNS) myelin antigens involving both CD4+ and CD8+ T cells, especially the so-called pathogenic T helper (Th)17- and Th1-type and CD8 myelin autoreactive T cells. The development of MS is likely triggered or promoted by breakdown of the delicate balance between autoreactive T cells and regulatory lymphocytes [1].

Although MS has historically been considered a demyelinating disease of the CNS and white matter, in recent years, neurodegeneration of the cortical and deep gray matter has been recognized to play a role in the pathogenesis of MS. Cortical atrophy is associated with disease progression, which has emerged as one of the best predictors of neurological disability in MS [1].

According to a recent worldwide epidemiological study, the number of patients with MS is estimated to be 2.8 million, which has been increasing in every world region since 2013 [2]. The estimated total economic burden of MS in the United States is US $85.4 billion, with a direct medical cost of US $63.3 billion and indirect and nonmedical costs of US $22.1 billion [3].

Relapsing-remitting MS (RRMS) initially involves clinical relapses with near or complete recovery; however, recovery over time may be incomplete and disability often worsens [4]. Approximately 20% of patients with RRMS develop a progressive form of MS accompanied by chronic neuroinflammation. Such cases are referred to as secondary progressive MS (SPMS). The term “relapsing MS” (RMS) is used to describe the condition of patients with repeated relapses of either RRMS or SPMS.

As understanding of the pathomechanism of MS progresses, various disease-modifying drugs have been used in clinical practice, including sphingosine-1-phosphate receptor modulators (fingolimod, siponimod), a monoclonal antibody that selectively binds the α4 integrin subunit (natalizumab), and CD20 monoclonal antibodies (ofatumumab, ocrelizumab), resulting in an overall improvement of patient prognosis. However, there are patients for whom current treatments are ineffective and there are cases where current treatments are intolerable due to side effects. Furthermore, progressive MS remains refractory to current drugs and constitutes an unmet medical need [4]. These observations highlight the need for new, safer therapeutic oral agents.

In 1997, Kawano et al [5] reported the discovery of sponge-derived α-galactosylceramide (α-GC) as a glycolipid ligand that stimulates natural killer T (NKT) cells. However, because this glycolipid stimulates NKT cells and induces the production of both interleukin (IL)-4 and interferon (IFN)-γ, a search for glycolipids that selectively induce IL-4 production was initiated to treat Th1 cytokine–dependent autoimmune diseases such as MS. These efforts led to the discovery of (2*S*, 3 *S* , 4*R*)-1-O-(α-d-galactosyl)-2-tetracosanoylamino-1,3,4-nonaetriol (OCH-NCNP1; hereafter referred to as OCH), which was detected during screening for glycolipids that selectively induce the production of Th2 cytokines [6].

OCH is a derivative (synthetic glycolipid) of α-GC with a shortened fatty-acid chain (sphingosine chain). The compound is a white to slightly yellow powder that is extremely insoluble in methanol or ethanol and is practically insoluble in water. OCH exhibits an immunoregulatory action that suppresses Th1 cell–mediated immune responses through NKT cell activation,

selective IL-4 production, and Th2 bias induction in human CD4+ NKT cells [7].

Although the mechanism by which OCH induces Th2 bias in NKT cells is not fully understood, it has been suggested to involve both cell intrinsic and extrinsic factors [8,9]. As a cell intrinsic mechanism, IFN-γ production by NKT cells was reported to be more susceptible to the sphingosine length of the glycolipid ligand compared to IL-4 production, and the length of the sphingosine chain determined the half-life of NKT cell stimulation by CD1d-associated glycolipids. As an extrinsic regulatory mechanism, OCH suppresses the production of IFN-γ, not only by NKT cells but also by NK cells, compared with that of α-GC. OCH induced lower IL-12 production due to ineffective primary IFN-γ and CD40 ligand expression by NKT cells, which resulted in lower secondary IFN-γ induction.

Animal studies verified that OCH can be administered orally to control Th1 cell–mediated autoimmune pathology in mice, with efficacy against autoimmune disease models such as experimental autoimmune encephalomyelitis, collagen-induced myelitis [10], nonobese diabetes [11], and inflammatory enteritis [12].

We here describe a protocol for a feasibility study that will be conducted in patients with RMS to investigate the efficacy and safety of OCH immunomodulators. Through 24 weeks of weekly administration, this trial was performed to confirm changes in exploratory T cell and NK cell biomarkers that fluctuated in the phase I trial [13], as well as measures of efficacy, including recurrence, dysfunction, and magnetic resonance imaging (MRI) changes, and their association with combined endpoints. In alignment with past clinical trials [14,15] and European Medical Agency guidelines, the primary outcome will be the percentage of subjects with new or newly expanded lesions at 24 weeks on T2-weighted MRIs.

Methods

Study Design

This is a double-blind, multicenter, placebo-controlled, randomized phase II clinical trial with a 24-week duration. This trial investigates the efficacy and safety of the immunomodulator OCH in patients with RMS through 24-week repeated administration. The protocol was also designed to confirm exploratory biomarkers of T cells and NK cells that fluctuated in the phase I trial [13], as well as efficacy-related clinical endpoints, including relapses, disability, and MRI changes, and their association with combined endpoints. Recruitment opened in September 2019 and concluded in June 2021, with participants randomly assigned to either a placebo control group or an OCH group using a clinical-based management system (Translational Research Center for Medical Innovation, Kobe, Japan). The researchers were blinded to the participant group assignments, and the packaging appearance of the control and investigational drugs was confirmed to be indistinguishable.

An independent data monitoring committee will regularly audit all available data, including safety, and recommend trial continuation to the principal investigator.

Selection Criteria

Inclusion and exclusion criteria for this study are provided in Textbox 1.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Patients who provided written consent for trial participation
- Patients had been diagnosed with relapsed multiple sclerosis (MS), including relapse-remitting MS and/or secondary progressive MS, based on the revised McDonald criteria or were diagnosed with MS by an attending physician as noted in their medical records
- Patients with at least two medically confirmed clinical exacerbations within 24 months prior to consent or one exacerbation within 12 months prior to consent
- Patients with at least one lesion suspected to be MS on screening magnetic resonance imaging (MRI)
- Patients with 7 points or less in the Expanded Disability Status Scale during screening
- Patients who were 20-65 years old at the time of consent
- Patients who can practice contraception until 90 days after final administration of the investigational drug
- Patients with no clinical or test findings suggesting acute recurrence based on evaluation by a neurologist

Exclusion criteria

- Diagnosis of neuromyelitis optica and one of the three following three criteria: optic neuritis, acute myelitis, and satisfied at least two of the following three items: (1) spinal cord MRI lesion extending across at least three vertebral bodies, (2) no brain MRI lesions during onset (at least four cerebral white matter lesions or three lesions, one of which is around the lateral ventricle), and (3) neuromyelitis optica–immunoglobulin G (IgG) or antiaquaporin-4 antibody-positive
- Currently pregnant or nursing
- Contraindication for MRI (eg, those with metal implants or a pacemaker) or cases in which MRI is difficult to perform (eg, claustrophobia)
- History of allergic or hypersensitive reaction to gadolinium contrast
- History of liver disease, including liver transplantation, viral hepatitis, autoimmune hepatitis, cirrhosis, and hepatic malignancies
- Liver dysfunction determined by the screening test or baseline test (alanine aminotransferase, aspartate aminotransferase, γ-guanosine triphosphate, or alkaline phosphatase) exceeding twice the upper limit of normal and total bilirubin exceeding 1.5-fold the upper limit of normal
- History of malignant tumors in the past 5 years (however, patients deemed to have no recurrence for at least 5 years prior to consent can be enrolled)
- Varicella-zoster virus IgG antibody–negative
- Positive for syphilis serum reaction (treponema pallidum latex agglutination, rapid plasma reagin)
- positive for β-D glucan (exceeding the standard value) or T-spot
- positive for antiaquaporin-4 antibody
- history of human immunodeficiency virus infection or who have been confirmed positive by a screening test
- History of hepatitis B infection (hepatitis B surface antigen–positive or hepatitis B core antibody–positive), or patients who have been confirmed positive by a screening test
- History of stem cell transplantation, organ transplantation, and treatment for rejection
- Physical, mental, or social condition affecting the ability to provide consent to or complete the trial
- Participation in other clinical trials that received the investigational drug within 4 months prior to enrollment
- Blood donation (200 mL within 2 months, 400 mL within 3 months) prior to enrollment
- Peripheral blood lymphocyte count <600/mm^3 by screening or baseline examination
- With or suspected of having an infectious disease
- Immunocompromised patients
- Inflammatory bowel disease
- Use of the following prohibited concomitant therapies:

interferon-β preparation (prohibited 1 month before trial enrollment); fingolimod hydrochloride (prohibited 6 months before trial enrollment); natalizumab (prohibited 3 months before trial enrollment); glatiramer acetate (prohibited 1 month before trial enrollment); dimethyl fumarate (prohibited 3 months before trial enrollment); drugs other than azathioprine that have immunosuppressive, immunostimulatory, or myelosuppressive effects (prohibited 3 months before trial enrollment); pulse therapy using corticosteroids (prohibited 1 month before clinical trial registration, except when MS recurs); plasmapheresis, immunoadsorption therapy, lymphocyte depletion therapy (prohibited from the time of consent acquisition); immunoglobulin preparation (prohibited 2 months before trial enrollment); vaccines (prohibited 1 month before trial enrollment, except when permitted by the investigator); other investigational drugs (prohibited 4 months before trial enrollment); nonsteroidal anti-inflammatory drug (liver damage at the time of screening should be checked, and for patients who take it regularly, this drug can be used in combination by fixing the dosage and administration. Additionally, when used for adverse events, it should be possible to use this drug within the minimum necessary range)

Additional exclusion criteria:

- Patients with evident prolongation of the QT/QTc interval prior to the trial (eg, patients with repeating QTc interval>450 ms)
- Patients with a history of other risk factors for torsades de pointes (eg, family history of heart failure, hypokalemia, and long QT syndrome)
- History of severe drug or food allergy
- Patients with drug or alcohol dependence in the past or present
- Asthma (excluding patients with no history of treatment or attack for at least 10 years)
- Diagnosis of epilepsy or patients with a history of seizures (excluding febrile seizures)
- Other pathological symptoms, illnesses, or history that may affect this trial
- Other factors resulting in unsuitability for this trial as deemed by the principal investigator; if such exclusion occurs, the specific rationale will be described in the trial results

Sample Size Estimate

The target number of participants was 30 (15 per group) based on feasibility. The detection power was calculated when the primary outcome (proportion of subjects with new or enlarged existing lesions detected on T2-weighted images) was compared using the Fisher exact test. With 60% of patients placed in the placebo group based on the results of the domestic phase II study (D1201 study) at the time of fingolimod development [16] and assuming a 5% proportion in the OCH group, the detection power was 86.5%. Furthermore, when the OCH group was set to 10%, the detection power was 74.6% (the significance level was set to 5% using a two-tailed test).

Patient Clinicodemographic Characteristics

The following clinicodemographic information was recorded for each participant: (1) subject background (eg, birth date, sex, body height, body weight); (2) urine pregnancy test; (3) infectious disease or antibody test; (4) vital signs (blood pressure, pulse rate, body temperature, and breathing rate); (5) neurological symptoms rating scale (Expanded Disability Status Scale [EDSS] or functional disability scale); (6) clinical tests (hematological test, hematobiochemical test, or urine test); (7) 12-lead electrocardiogram; (8) echocardiography; (9) chest or abdominal X-ray; (10) abdominal computed tomography; (11) MRI; (12) peripheral blood gene expression level (reverse transcription–polymerase chain reaction); (13) frequencies of NK, NKT, T cells, or other lymphocyte subsets; (14) frequencies of Th1, Th2, or Th17 cells; (15) intestinal and oral microbiome; (16) adverse events; (17) combination drugs and important nondrug therapies; and (18) Columbia Suicide Severity Rating Scale.

Outcome Measurements and Study Timeline

The outcomes that will be measured repeatedly throughout the trial and the corresponding time points are shown in Multimedia Appendix 1. The main outcome is MRI changes (the percentage of subjects with new or newly expanded lesions on T2-weighted MRI). In addition, the annual relapse rate, cumulative number of new or newly expanded lesions on T2-weighted MRI, percentage of subjects who did not have lesions at 12 and 24 weeks on T2-weighted images of head MRI compared to those at the preobservation period at 24 weeks, brain atrophy in T1-3D images, percentage of subjects with no contrast-enhanced lesions on gadolinium-enhanced T1-weighted images, number of contrast-enhanced lesions on gadolinium-enhanced T1-weighted images, changes in volume of demyelinating lesions on fluid-attenuated inversion recovery 3D images, diffusion tensor imaging changes in myelin sheath lesions, and changes in myelin sheath lesions by a myelin map will be assessed. Additional outcomes include the relapse-free period (from randomization to earliest relapse), sustained reduction in disability occurrence rate, period until sustained reduction in disability (from randomization), no evidence of disease activity, and exploratory biomarkers from phase I trials (peripheral blood gene expression, frequencies of lymphocyte subsets, and intestinal and oral microbiome) [13].

Adverse Events

Adverse events, defined as any undesired or unintended sign (including abnormal fluctuations in each test value), symptoms, or illness that occurs between the start of investigational drug administration and end or discontinuation of the investigational drug (regardless of its association with the study drug), will be recorded. The recordings will include the degree of symptoms on a 1-5 scale (1=asymptomatic or mild adverse events, 5=death due to the adverse event), outcomes from 1 to 6 (1=event disappeared or normalized, 6=death), and association with the

investigational drug from 1 to 4 (1=associated, 4=not associated).

Discontinuation Criteria

Discontinuation of involvement in the clinical trial may occur for any patient because of voluntary withdrawal or for any of the following reasons: (1) serious adverse events; (2) pregnancy; (3) alanine aminotransferase and aspartate aminotransferase >5-fold higher than the standard value upper limit; (4) total bilirubin exceeding 2.0 mg/dL; (5) number of peripheral blood lymphocytes <500/mm^3 and administration of the investigational drug is stopped three times in a row without recovery, even after three tests; (6) occurrence of a grade-3 event based on Common Terminology Criteria for Adverse Events v4.0-JCOG; (7) new neurological symptoms with unpredictable MRI findings observed from the course of MS; (8) more than one recurrence of MS; (9) at least three courses of pulse steroid therapy performed; (10) an important management problem is discovered (subject noncompliance); (11) significant deviation from the protocol; (12) administration of the investigational drug is stopped at least three times, regardless of the reason; and (13) at the discretion of the principal investigator. If discontinuation occurs because of this final criterion, justification will be provided in the results report.

Administration of Trial Compound

The investigational drug OCH (3.0 mg) in the form of granules (total of 0.3 g) or placebo granules alone (0.3 g) was orally administered with approximately 150 mL of water 30 min before breakfast once weekly for the 24-week trial duration. The white granules were composed of crystalline cellulose, mannitol, sodium croscarmellose, low-substituted hydroxypropyl cellulose, and polysorbate 80.

Statistical Methods

Patient clinicopathological data will be summarized using descriptive statistics for each group. The proportion of subjects with new or enlarged existing lesions on T2-weighted MRIs in each group will be calculated and compared using the Fisher exact test with 95% CIs. The proportion of data between groups related to the primary endpoint will also be compared using the Fisher exact test with 95% CIs. For time-to-event data such as relapse-free periods, Kaplan-Meier estimates will be calculated for each group and groups will be compared using the log-rank test. The expression rates of safety-related outcomes and adverse events will be calculated for each group. For various test values, a list of measured values will be created for each group. The summary statistics for each group and measurement time point will also be calculated.

Patient and Public Involvement

Patients were first involved in this study during the recruitment and screening processes. Based on previous experiences with patients with MS, the importance of the outcomes measured in this study was evaluated and determined based on their medical importance and impact on the patients' quality of life. The patients recruited for the study agreed to the methods of disseminating the aggregate results when providing informed consent.

Ethical Considerations

This study was conducted in compliance with the Declaration of Helsinki and all applicable local and national regulatory laws with approval from the National Center of Neurology and Psychiatry institutional review board (approval number II-013). The legal representatives of each patient provided written informed consent prior to participation in the study. Copayment reduction fees were paid to the trial participants in accordance with the regulations of the implementing medical institution.

Dissemination

The results will be disseminated in peer-reviewed journals and presented at relevant conferences.

Results

The first patient completed registration in December 2019 and the last patient completed registration in June 2021. The full analysis set comprised 30 cases and the study analysis was completed in March 2023. Preliminary analysis suggests that OCH may be effective for RMS (particularly SPMS).

Discussion

Principal Results

This will be the first randomized double-blind placebo-controlled trial to study the efficacy and safety of OCH. This randomized controlled trial will determine whether OCH is effective and safe in patients with MS. The results of this trial are expected to provide evidence for the potential of using OCH as a therapeutic agent for MS.

A single-dose trial (STEP 1) trial was conducted in healthy adults from November 2012 to July 2013 and a repeated-dose trial (STEP 2) was conducted in patients with RRMS from March 2014 to August 2017 [13]. In a phase I trial consisting of STEP 1 and STEP 2, OCH was administered to 28 patients (STEP 1: 3 patients×5 groups in all cohorts, STEP 2: 7 patients×1 group in a cohort, 3 patients×2 groups in a cohort).

Grade-1 adverse events and side effects were noted in STEP 1 and there were no serious adverse events or discontinuations. In STEP 2, serious side effects (acidosis and altered state of consciousness, depression, muscle weakness, and malaise) were reported in three patients in the 0.3 and 3 mg groups. Two patients discontinued treatment; however, all patients recovered. No other serious events were observed, confirming that the patients tolerated doses of 0.3, 1, and 3 mg. After OCH administration, there was no significant change in the neurological symptom evaluation scale score (EDSS or functional disability scale) even in STEP 2 because of the short observation period. MRI revealed clinically significant abnormalities in one patient in the 0.3 mg group; this patient discontinued the study.

A phase I physician-led clinical trial, conducted as an early exploratory clinical trial, determined that the dose was likely to have pharmacological action (fluctuations in some biomarkers) in humans. The dose at which pharmacological action was observed in experimental autoimmune

encephalomyelitis model mice was 0.4-0.5 mg/kg. Considering that the area under the curve $(AUC)_{0-\infty}$ following oral administration of 5 mg/kg to mice was 2922 ng·h/mL, the $AUC_{0-\infty}$ following oral administration of 0.5 mg/kg (dose at which pharmacological action was observed) was estimated as 292.2 ng h/mL. Assuming a correlation between systemic exposure ($AUC_{0-\infty}$) and pharmacological effects and systemic exposure in monkeys ($AUC_{0-\infty}$ after oral administration of 10 mg/kg was 2376, SD 1164 ng), pharmacological action may be expected in humans if at least approximately 1.2 mg/kg is orally administered.

In STEP 1 of the phase I trial, administration of OCH at doses of 0.3, 1, 3, 10, 30, 100, and 300 mg to healthy adults was planned. However, STEP 1 was completed at 30 mg; in the subsequent STEP 2, OCH at 0.3, 1, and 3 mg was administered to patients with MS. Importantly, no tolerability problems were noted.

The following changes in exploratory biomarkers were observed. In analysis of the immune cell subsets using flow cytometry, (1) inhibitory T cells (Foxp3+T cells) and effector regulatory T cells (CD45RA-$FoxP3^{high}$ T cells) tended to increase and (2) granulocyte-macrophage colony-stimulating factor–producing Th cells transiently decreased in both healthy subjects and patients with MS. Recently, granulocyte-macrophage colony-stimulating factor–producing Th cells were identified as pathogenic cells in MS [17]. These changes suggest that oral OCH administration can correct the proinflammatory changes linked with disease activity in MS. Moreover, by conducting DNA microarray analysis of whole blood cells, we identified upregulation of several immunoregulatory genes and downregulation of several inflammatory genes in both healthy subjects and patients with MS, further supporting the immunoregulatory effect of OCH.

Based on the above safety profile and biomarker analysis results, a dose of 3 mg was selected as the investigational dose for this trial.

Limitations

The primary limitation of our trial design is the small sample size. The sample size in this study was determined to be 30 participants based on the results of the previous phase I study. This study was limited to a small cohort of patients over a 24-week timeline and involved weekly administration of one dose of OCH. Although necessary in this early stage of the investigation, the small sample size could limit the ability to identify potential adverse events that may be rare or related to specific clinicodemographic traits of patients not captured in this study. However, the robust and clinically relevant nature of our primary outcome measure and sample size determined in prior studies are expected to provide indications of drug efficacy.

Conclusions

This article describes an NKT cell–stimulatory glycolipid (OCH) protocol. This randomized controlled trial will determine whether OCH is effective and safe in patients with MS. The results of the trial are expected to provide evidence for the potential of OCH as a therapeutic agent for MS.

Acknowledgments

Editorial support—in the form of medical writing and assembling tables based on authors' detailed directions, collating author comments, copyediting, fact checking, and referencing—was provided by Editage (Cactus Communications). This study was supported by the Japan Agency for Medical Research and Development (grant number 20ek0109342h0003). EA Pharma Co, Ltd (Tokyo, Japan) provided monitoring and audit costs. The study was designed, conducted, analyzed, and interpreted by the investigators independently from EA Pharma Co, Ltd. Generative artificial intelligence was not used in the ideation or writing process.

Data Availability

Data are not included in this protocol, but will be presented in an upcoming paper summarizing the results of this clinical trial. The data sets are available from the corresponding author upon reasonable request taking into account our patent strategy.

Authors' Contributions

TO, TI, RS, YA, HN, WS, and T Yamamura conceived and designed the study and were involved in protocol development. TI, RS, YA, and HN were involved in administrative and regulatory aspects of the study. TI and HN wrote the first draft of the manuscript. YS and YN were involved in patient recruitment. TO, YN, T Yokota, YL, and WS were responsible for data acquisition.

Conflicts of Interest

TO, WS, and T Yamamura disclose that royalties were received from EA Pharma Co, Ltd based on a license agreement. The other authors have no conflicts of interest to declare.

Abstract

Background: Cortical hyperarousal and ruminative thinking are common aspects of insomnia that have been linked with greater connectivity in the default mode network (DMN). Therefore, disrupting network activity within the DMN may reduce cortical and cognitive hyperarousal and facilitate better sleep.

Objective: This trial aims to establish a novel, noninvasive method for treating insomnia through disruption of the DMN with repetitive transcranial magnetic stimulation, specifically with continuous theta burst stimulation (cTBS). This double-blind, pilot randomized controlled trial will assess the efficacy of repetitive transcranial magnetic stimulation as a novel, nonpharmacological approach to improve sleep through disruption of the DMN prior to sleep onset for individuals with insomnia. Primary outcome measures will include assessing changes in DMN functional connectivity before and after stimulation.

Methods: A total of 20 participants between the ages of 18 to 50 years with reported sleep disturbances will be recruited as a part of the study. Participants will then conduct an in-person screening and follow-on enrollment visit. Eligible participants then conduct at-home actigraphic collection until their first in-residence overnight study visit. In a double-blind, counterbalanced, crossover study design, participants will receive a 40-second stimulation to the left inferior parietal lobule of the DMN during 2 separate overnight in-residence visits. Participants are randomized to the order in which they receive the active stimulation and sham stimulation. Study participants will undergo a prestimulation functional magnetic resonance imaging scan and a poststimulation functional magnetic resonance imaging scan prior to sleep for each overnight study visit. Sleep outcomes will be measured using clinical polysomnography. After their first in-residence study visit, participants conduct another at-home actigraphic collection before returning for their second in-residence overnight study visit.

Results: Our study was funded in September 2020 by the Department of Defense (W81XWH2010173). We completed the enrollment of our target study population in the October 2022 and are currently working on neuroimaging processing and analysis. We aim to publish the results of our study by 2024. Primary neuroimaging outcome measures will be tested using independent components analysis, seed-to-voxel analyses, and region of interest to region of interest analyses. A repeated measures analysis of covariance (ANCOVA) will be used to assess the effects of active and sham stimulation on sleep variables. Additionally, we will correlate changes in functional connectivity to polysomnography-graded sleep.

Conclusions: The presently proposed cTBS protocol is aimed at establishing the initial research outcomes of the effects of a single burst of cTBS on disrupting the network connectivity of the DMN to improve sleep. If effective, future work could determine the most effective stimulation sites and administration schedules to optimize this potential intervention for sleep problems.

Introduction

Overview

The sleep disturbances of insomnia include difficulty falling asleep, staying asleep, or inability to fall back to sleep after premature awakenings, or any combination of these, along with daytime sleepiness and dysfunction. Difficulty falling and remaining asleep affected nearly 30% of the US population, with approximately 20% of the general population experiencing occasional difficulties and an additional 10% meeting the clinical criteria for an insomnia disorder [1]. However, this protocol was conducted during the COVID pandemic, when the prevalence of insomnia symptoms increased to 53% and insomnia disorder prevalence jumped from 10% to 17% [2]. Insomnia symptoms have been linked with poorer health across multiple domains and exacts a high societal cost in the workplace, on the health care system, and on an individual's and family's quality of life [3-5]. Moreover, side effects from medications used to manage insomnia increase these factors in some cases. Novel approaches that facilitate sleep are critically needed, and some potential neural mechanisms of insomnia create a viable treatment target [6].

The most widely accepted theory of primary insomnia is the hyperarousal hypothesis, which suggests that problems with sleep initiation and maintenance are due largely to the disruptive effects of somatic or cognitive hyperarousal [7,8]. In particular, cortical hyperarousal can emerge from excessive focus on repetitive negative thoughts, including intensive problem-solving, self-reflective rumination, and worry [9-11]. Subjectively, people who struggle with insomnia often make comments such as "I wish I could just turn my mind off" or "I just keep replaying conversations over in my head." In fact, one of the major features of insomnia is the tendency toward self-reflective rumination and worry [9,12-15]. This internal dialogue contributes to a cycle of self-referential thought and hyperarousal that appears to hinder sleep onset and maintenance [9,16-18]. In fact, worry and sleep disruptions are associated in the general population [3]. In individuals with insomnia, cortical hyperarousal contributes to difficulty initiating and maintaining sleep [19].

Neuroimaging research has shown that internally focused self-reflective processes of this type tend to activate an interconnected system within the brain known as the default mode network (DMN) [20,21]. Moreover, negative ruminative thinking is associated with changes in DMN connectivity and other brain regions associated with cognitive arousal or negative emotion [22]. Patients with insomnia often show abnormalities in the functioning of the DMN that are consistent with the hyperarousal hypothesis [23-25]. The core nodes of the DMN typically include the medial prefrontal cortex, posterior cingulate cortex, precuneus, and bilateral inferior parietal cortex regions but can also include several ancillary smaller regions, including the hippocampus, medial temporal lobes, and other subcortical structures [26]. Individuals with insomnia disorder tend to have increased resting-state functional connectivity (FC) between spatially segregated nodes of the DMN [27,28]. Increased connectivity and activation of the DMN could contribute to the ongoing self-referential processing and internal dialogue that maintains a hyperaroused state and perpetuates difficulties falling and remaining asleep [27,29]. Individuals with insomnia disorder show greater activation of the DMN compared with healthy controls while viewing word lists associated with past, present, and future worries, particularly when the words are self-referential [29].

Mainstream approaches to treating primary insomnia include cognitive behavioral therapy for insomnia and pharmacologic sleep aids, such as hypnotic sedatives [30-33]. While cognitive behavioral therapy for insomnia often helps to reduce ruminative cognitions and is effective at improving sleep for many individuals, there are many who fail to achieve meaningful benefits [34,35]. Similarly, pharmacologic sleep aids also tend to have modest effect sizes [36] and are often associated with unwanted side effects (eg, daytime drowsiness and memory problems) and health-related morbidities [37]. Various noninvasive neuromodulatory approaches have been shown to improve insomnia symptoms, including repetitive transcranial magnetic stimulation (rTMS) [38]. However, low-frequency rTMS has a cortical inhibition effect that has been shown to improve insomnia symptoms, which may be due to hyperarousal across multiple psychological and physiological domains [39].

The proposed protocol aims to bridge the gap between cognitive and neuromodulatory interventions to facilitate sleep onset and longer maintenance by temporarily inhibiting the brain FC that is associated with cortical hyperarousal and presleep ruminative cognitions. Our proposed approach will involve using rTMS prior to bedtime to briefly disrupt the strength of FC among cortical regions of the DMN. As we propose to inhibit connectivity within the DMN, we will use continuous theta burst stimulation (cTBS), which induces long-term depression of cortical neural firing following a sustained stimulation period of 40 seconds [40]. Thus, we hypothesize that the application

of cTBS to an easily accessible node of the DMN will suppress the local neural activity of that node and propagate inhibition throughout the DMN, thereby reducing ruminative thinking and worry prior to sleep onset. Decreased DMN connectivity is expected to improve sleep quality and quantity. An increase in slow-wave and rapid eye movement sleep stages has been proposed as mechanisms of rTMS in increasing restorative sleep in individuals with insomnia, so polysomnography (PSG) parameters are the primary outcome measures in the outlined protocol [41]. This phase 1 clinical trial will be the first study to investigate the effects of cTBS targeted to the left inferior parietal node of the DMN on objectively measured sleep outcomes.

Research Aims and Hypotheses

This study aims to explore the effects of cTBS on (1) the activation and connectivity of the DMN and (2) sleep outcomes. We hypothesize that modulating the DMN by stimulating a targeted region of the left inferior parietal lobule with a single cTBS administration will decrease FC within the DMN and thereby improve sleep parameters (ie, PSG) relative to an identical sham administration.

Study Design and Randomization

This phase 1 clinical trial (ClinicalTrials.gov NCT04953559) will be conducted with a randomized, double-blind, sham-controlled, counterbalanced, crossover design. Participants serve as their own controls as they undergo 2 identical study sessions separated by at least 5 days (ie, washout period). Participants and study personnel who interact with the participants will be blind to the specific condition (active cTBS vs sham) the participant receives during each study visit. Using a prespecified, equally balanced, block randomization procedure, participants will be assigned to the order in which they receive active cTBS and sham stimulation conditions. The randomization list will be generated by a computer random number generator, with the constraint that half of the participants of each biological sex will receive sham first and half will receive the active cTBS first. This design will allow us to examine the intraindividual effects of the active cTBS and establish the superiority of active cTBS compared with sham stimulation in improving PSG sleep outcomes.

Methods

Study Procedures Overview

The study procedures were completed over 3 separate visits. Screening to determine eligibility and baseline assessments was conducted during visit 1. Eligible participants were asked to wear a wrist actigraph for at least 5 days prior to their first in-laboratory overnight visit (visit 2). Based on a preestablished counterbalanced crossover randomization schedule, participants were then assigned to receive either the active cTBS or sham stimulation for their first overnight visit (visit 2) followed by the alternative intervention during their second overnight visit (visit 3) at least 5 days later. As shown in Figure 1, each in-laboratory session lasted 18 hours, including a 2-hour cognitive testing block, 1 hour of preintervention magnetic resonance imaging (MRI), followed by either active cTBS or sham stimulation, and a postintervention hour of neuroimaging. Participants were then fitted with PSG electrodes and were permitted 8 hours of sleep while undergoing PSG sleep monitoring in the lab. The next morning, participants completed another 2-hour cognitive testing block before being released.

The full study execution takes approximately 38-40 hours with 2-3 hours allocated for baseline screening and enrollment (visit 1) and 18 hours allocated for each overnight visit (visits 2 and 3). Table 1 presents the specific assessment measures administered at each visit.

Figure 1. Overview of the pilot randomized controlled trial study design. Participants first complete a web-based eligibility survey screening for sleep disturbances. Potentially eligible volunteers complete an in-lab enrollment process and baseline assessment (visit 1) at a large Southwestern University medical research center. Participants are then randomized to a stimulation order condition. After at least 5 days with actigraphically measured sleep, participants return for an 18-hour overnight session involving 2 MRI scans and overnight sleep (visit 2) at the medical research center. Depending on their condition assignment order, they either receive active cTBS or sham intervention. Participants then undergo a washout period of at least 5 days that includes actigraphically measured sleep. They then return for an identical overnight visit that involves the alternate intervention condition. cTBS: continuous theta burst stimulation; MRI: magnetic resonance imaging.

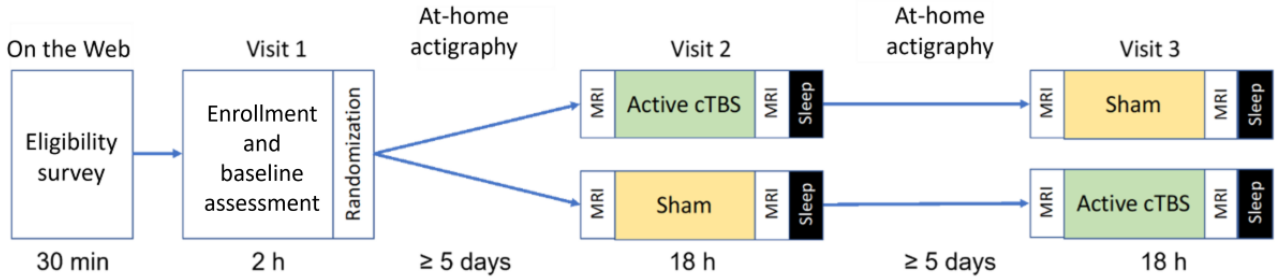

Table 1. List of study activities and assessments performed during study visits during a pilot randomized controlled trial evaluating the preliminary effectiveness of continuous theta burst stimulation in improving sleep in individuals with reported sleep disturbances.

Ethical Considerations

All study activities and study personnel were approved by the University of Arizona's Institutional Review Board (IRB) and by the Department of Defense Office of Human Research Oversight (OHRO) in March 2021 (approval 2007900971). Any protocol amendments and reportable new information were disseminated to both IRB and OHRO. All participant information was deidentified for confidentiality. Participants were compensated 500 dollars via check for their participation in the study if they were fully compliant with the study procedures. The study team maintains dissemination control of the final deidentified data set. Final results will only report cumulative population data to respective regulatory and scientific reporting agencies and along with peer-reviewed publications. Access to the deidentified data set will be available upon request to the principal investigator and in conjunction with proper regulatory requirement.

Participants and Recruitment

A total of 20 otherwise healthy adults with self-reported sleep disturbances were recruited from the greater Tucson and Phoenix metropolitan areas. Recruitment strategies include flyers posted on community boards, advertisements in local newspapers, sponsored social media posts, and email lists at local universities. Individuals who were recruited from the community were directed to complete a web-based survey in a HIPAA (Health Insurance Portability and Accountability Act)–compliant server. If participants met the initial inclusion criteria, a study member then completed a preliminary phone screening with the participant. Study personnel then scheduled an in-person screening visit for eligible individuals.

Power Analyses

During the study design, we conducted a power analysis to determine the sample size necessary to compare mean changes in DMN connectivity before and after cTBS using a within-subjects ANOVA approach. From prior cited work on transcranial magnetic stimulation (TMS) and FC, a total sample of 20 was found to have sufficient power to answer the research questions to include analysis of 2 groups (within-subject active and sham), 2 repeated measurements (before and after TMS), and a correlation between the change in DMN activation and sleep outcome metrics [42,43].

Inclusion and Exclusion Criteria

Individuals between the ages of 18-50 years with reported sleep disturbances were included in the study. Individuals were excluded if they reported or exhibited any health conditions beyond insomnia-related symptoms. Exclusionary criteria were based on one or more of the following considerations: the criterion in question is (1) known to alter sleep, (2) known to substantially increase interparticipant variability, (3) known to put the volunteer outside the range of what is considered healthy, or (4) required by regulation. Detailed inclusion and exclusion criteria are referenced in Textbox 1.

Textbox 1. A detailed description of inclusion and exclusion criteria of a pilot randomized controlled trial evaluating the preliminary effectiveness of continuous theta burst stimulation in improving sleep in individuals with reported sleep disturbances.

Inclusion criteria

- 18-50 years old
- Self-reported sleep disturbances on 2 of 3 inventories:
  - Pittsburgh Sleep Quality Index ≥6
  - Insomnia Severity Index ≥15
  - Epworth Sleepiness Scale ≥11

Exclusion criteria

- Unwillingness to provide informed consent
- Presence of a metal implant or medical device which poses a safety risk for magnetic resonance imaging or transcranial magnetic stimulation
- Self-reported past or present medical diagnosis of sleep- or breathing-related disorders
- Travel outside the time zone within 1 week prior to the enrollment visit or while active during the study
- Self-reported major medical or neurological problems
- Self-reported past or present history of cardiovascular disease
- Self-reported past or present history or first-degree family history of any seizures or seizure disorders
- Self-reported underlying acute or chronic pulmonary disease
- Self-reported history of fainting spells or syncope
- Self-reported past or present psychiatric problems
- Self-reported suicidal ideation
- Self-reported current use of prescription medications
- Self-reported current use of supplements that affect sleep
- Self-reported caffeine use in excess of 300 mg per day on average
- Self-reported regular nicotine use
- Self-reported or suspected heavy alcohol indicated on the Alcohol Use Disorders Identification Test (AUDIT) as greater than or equivalent to 14 drinks a week for male individuals and 7 drinks a week for female individuals
- Self-reported use of illicit drugs
- Speaking English as a nonprimary language
- Less than a ninth-grade education
- Engaged in overnight shift work
- Female individuals only: positive urine pregnancy test
- Female individuals only: self-reported current breast-feeding or collecting breast milk

Study Activities

Enrollment and Baseline Assessment (Visit 1)

Eligible participants were invited for an in-person screening and baseline data collection session lasting approximately 2-3 hours. After participant consent was obtained by trained study staff members, the participants underwent a baseline assessment, including measurement of intellectual capacity with the Wechsler Abbreviated Scale of Intelligence by a certified administrator, subjective sleep assessment including the Pittsburgh Sleep Quality Index and Insomnia Severity Index, and other cognitive assessments.

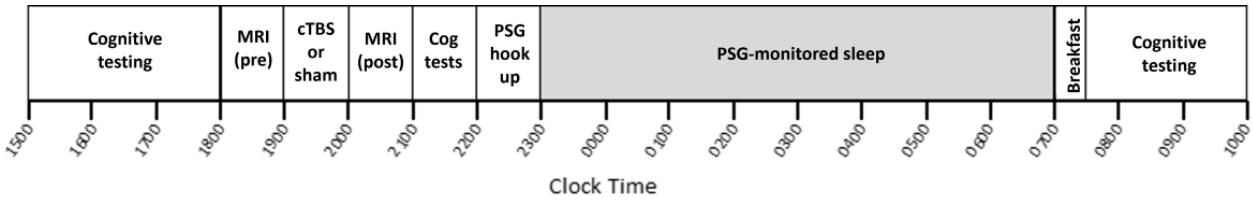
At-Home Actigraphy Week

Upon the completion of the enrollment visit, participants were fitted with a wrist actigraphic sleep monitor that they wear for at least 5 days prior to returning for the in-laboratory assessment sessions and continued to wear the device during the intervening washout week between the 2 in-residence laboratory stays. Participants also completed a web-based sleep diary each morning. Throughout the entire period of enrollment, participants were required to maintain a regular sleep schedule and were not permitted to use caffeine products for 48 hours prior to the in-laboratory overnight stays.

Overnight In-Residence Laboratory Sessions (Visits 2 and 3)

Participants completed 2 overnight in-residence laboratory stays according to a double-blind counterbalanced crossover design, with each session separated by at least 5 days. Figure 2 provides a graphical overview of the in-residence laboratory activities.

Figure 2. Timeline of the in-residence laboratory testing for the pilot randomized controlled trial. Participants arrive at the lab at 1500 and undergo cognitive testing followed by a preintervention MRI scan. The intervention is administered between 1900 and 2000 and is randomly assigned as either active cTBS stimulation or an identical appearing sham condition. After stimulation, participants complete a postintervention series of MRI scans, followed by a brief cognitive testing battery. At 2200, they are escorted to the sleep lab and PSG electrodes are applied. Lights out occur at 2300 and the participant is provided with an 8-hour undisturbed period for PSG-monitored sleep. Following wake-up at 0700 the next morning, the participant is provided a light breakfast and completes a final battery of cognitive tests. This procedure is repeated on separate weeks for the active cTBS and placebo conditions. cTBS: continuous theta burst stimulation; MRI: magnetic resonance imaging; PSG: polysomnography.



Cognitive Testing Block

Participants arrived at 3 PM and completed approximately 3 hours of cognitive testing with a trained and certified administrator, including the 10-minute psychomotor vigilance testing (PVT) and Karolinska Sleepiness Scale (KSS) at 3 time points separated by an hour, in addition to the Visual Analog Mood Scale, State-Trait Anxiety Inventory-State only (STAI-S), Beck Depression Inventory (BDI-II), California Verbal Learning Task 3 (CVLT3), go/no-go task (GNG), repeatable battery for the assessment of neuropsychological status (RBANS) symbol digit test, RBANS digit span, RBANS story memory test, and Glasgow Content of Thoughts Inventory (GCTI).

Prestimulation Neuroimaging

MRI scans were collected on a Siemens MAGNETOM Skyra 3T scanner (Siemens) using a 32-channel head coil. Participants completed a series of scans that included structural (magnetization-prepared rapid gradient-echo), functional (10-min eyes open) resting state, and proton magnetic resonance spectroscopy (^{1}H MRS) scans, with voxels placed in (1) the anterior cingulate gyrus and (2) posterior cingulate or precuneus. Functional MRI data will be preprocessed with standard neuroimaging packages, including statistical parametric mapping 12, FSL, and the functional connectivity toolbox (CONN v17f or later; focusing on DMN network connectivity) following standard published pipelines [44].

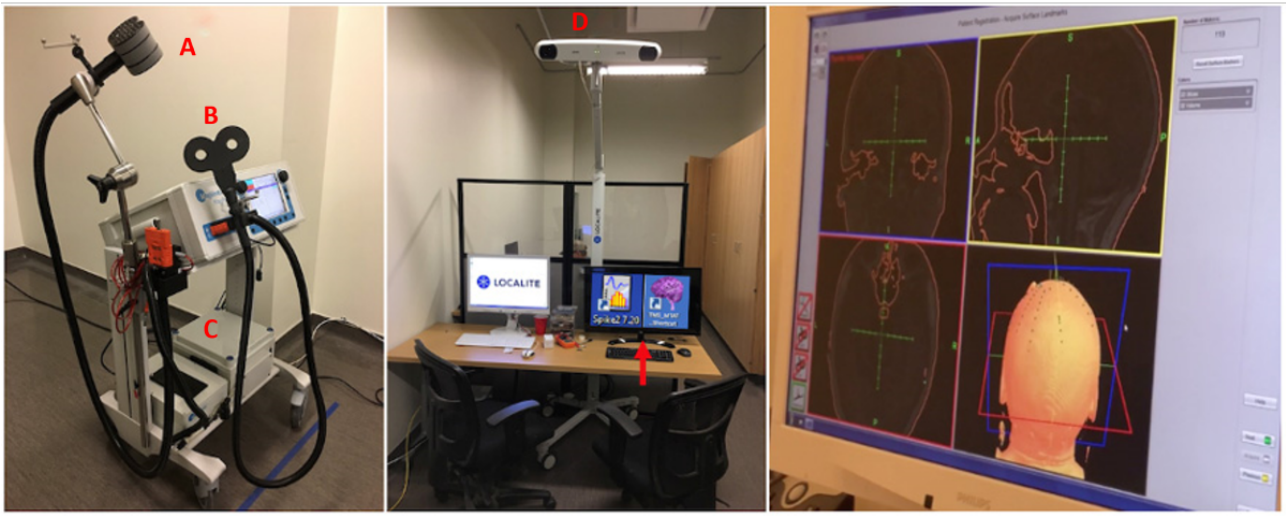
Intervention: cTBS Versus Sham

Following the first MRI scan, participants exited the scanner and underwent either cTBS stimulation or sham stimulation according to their preassigned double-blinded condition. The stimulator was preprogrammed prior to the start of the session and the participants and technicians that administered the stimulation procedure were blind to the administered condition. Each individual was expected to have a different sensitivity to the magnetic fields generated by the stimulation coil, and the stimulation intensity was adjusted based on each individual's resting motor threshold (RMT). The real-time, motor-evoked potential of muscle contraction is provided to ensure consistent force production. Once the RMT was identified, the stimulation intensity for TBS was set to 70% of each participant's RMT.

For primary rTMS stimulation, we located a predetermined node in the inferior parietal lobe, localized by coregistering the participant's head, structural T1-weighted MRI image, and TMS coil in the same space using a TMS 3D Neuronavigation System. Once coregistration was complete, the Neuronavigation system provided real-time feedback on the TMS coil location and recorded the coil position and orientation relative to the head. The cTBS was applied using a figure-of-8 coil with an active cooling system connected to the MagPro magnetic stimulator (MagVenture Cool-B65). The same coil has 2 sides, 1 designed for active TMS stimulation, and the other is equipped with a magnetic shield that effectively blocks any stimulation and is used for the sham condition. The rTMS setup is shown in Figure 3.

For this project, we selected an easily accessible node of the DMN located on the left lateral parietal (LLP) cortex. The exact spatial location for stimulation is based on the Yeo et al [45] probability atlas. We downloaded this atlas into the Mango 4.1 visualization program (and identified the centroid of the LLP node of the DMN at the MNI coordinates of x (–48), y (–61.5), and z (32.5). These coordinates are converted into the same stereotaxic space as the participant's brain to allow precision localization of the LLP node as the target for stimulation. Once this site was localized for the participants, a 40-second cTBS stimulation train (600 stimuli/session) or identically matched sham stimulation was administered using a MagVenture MagPro X100 stimulator (MagVenture Inc) connected with a figure-of-8 magnetic coil with active cooling.

Figure 3. Transcranial magnetic intervention system set-up for the pilot randomized controlled trial. Left: (A) the continuous theta burst stimulation is administered with a MagVenture Cool-B65 stimulator that included an active and sham side; (B) the resting motor threshold was determined using a MagPro X100 stimulator with a figure-of-8 coil; (C) the transcranial magnetic stimulation system is maintained at a constant temperature using an active cooling system. Middle: the stimulation is directed by a computerized system that detected the orientation of the head in space using (D) an antenna camera and correlate it with the individual's coregistered magnetic resonance imaging scan. Right: An image showing the Neuronavigation system used to administer the transcranial magnetic stimulation to the precise default mode network locations.



Poststimulation Neuroimaging

Immediately following the cTBS or sham stimulation period, each participant underwent a second neuroimaging session that was identical to the prestimulation MRI session previously described.

PSG Recording

Participants slept undisturbed in a light- and temperature-controlled private bedroom while continuously monitored by a trained technician with a Nihon Kohden JE-921 PSG recording system using standard 10-20 electrode placement. Data from PSG were scored using Polysmith software according to the standard Rechtschaffen and Kales approach by a trained and certified sleep technician who was blind to the participant's condition and status. The primary outcome metrics include sleep onset latency (SOL), latency to N1, N2, N3, and REM, total sleep time (TST), sleep efficiency (SE), wake after sleep onset (WASO), and number of awakenings and arousals, as well as time and percentage of time spent in each sleep stage.

Monitoring

Participants were assessed both prior to stimulation and after receiving stimulation for any adverse somatic, cognitive, or physical symptoms. Any presence of symptoms was logged in a HIPAA-compliant server and the participant was assessed by the study physician to determine if enrollment needed to be discontinued. All adverse events were reported to both IRB and OHRO. All study activity was subject to independent, random auditing from the Department of Psychiatry at the University of Arizona and study sponsors.

Data Management

All collected data were deidentified and stored within HIPAA-compliant, password-protected servers immediately after collection. Study data were only accessible to IRB-approved study staff. All data were checked and double-entered by study personnel no more than 1 week after data collection. Data quality checks were conducted every quarter by staff members for additional data assurance. Any data collected after participants' consent were included in the study database for both compliant and noncompliant participants. However, following a per-protocol analysis, we are only using data from participants who fully completed the study due to within-subjects analysis.

Primary Outcomes: FC Changes in the DMN

We hypothesize that active cTBS will disrupt the within-network and between-network connectivity of the DMN. This hypothesis will be assessed from a 10-minute resting-state FC scan and analyzed using standard procedures in the CONN (v17f or higher). Standard pipelines for preprocessing will be used. Within-network connectivity will be determined by first conducting an independent components analysis of the intrinsic activation patterns across the brain. Twenty independent components will be extracted. Mean activation clusters from each component will be examined for intercorrelation to determine within-network connectivity. Additionally, between-network, region-to-region, and seed-to-voxel analyses will be conducted to compare changes in FC between the 2 stimulation conditions.

Analysis Plan

FC Changes to the DMN

First-level whole brain connectivity analyses will be undertaken in CONN for each subject at each of the 4 sessions (ie, active prestimulation, active poststimulation, sham prestimulation, and sham poststimulation). This will result in an FC map for each participant at each session, indicating the magnitude and direction of intrinsic correlation between each seed region (eg, lateral parietal cortex of the DMN) and all other voxels in the brain. For our primary analysis, we will estimate the effects of active cTBS on FC within the DMN using multimodal neuroimaging data including resting state FC. Raw NifTI images

will be preprocessed using standard functional preprocessing pipelines in CONN [46].

The first-level connectivity maps will be combined in subsequent second-level analyses in CONN to explore the effects of cTBS stimulation on brain connectivity to include (1) independent components analysis, (2) seed-to-voxel analyses, and (3) region of interest to region of interest analyses [44]. Statistically significant differences in FC of the DMN between sham and active conditions will be the minimal important change to confirm the primary hypothesis. Next, PSG parameters measuring sleep stage duration and onsets, arousals, and awakenings will be added as covariates of FC change from before to after stimulation, comparing sham and active cTBS conditions.

PSG Analysis

We will assess the effects of active cTBS on sleep and whether participants demonstrated greater sleep quality during their active cTBS session compared with their sham stimulation session. Analyses will be conducted on sleep variables including total sleep time; N1 latency; N2 latency; N3 latency; REM latency; SOL; persistent SOL; SE; WASO; total number of awakenings; spontaneous arousals; wake duration; and stage duration for N1, N2, N3, and REM. Analyses will include repeated measures ANOVA controlling for covariates. Statistically significant difference between sham and active conditions will be the minimal important change to confirm this hypothesis.

Exploratory Analysis

We will examine the effects of active cTBS on secondary outcomes of cognitive performance, mood, and side effects compared with sham stimulation using repeated measures ANOVAs and nonparametric tests accordingly.

Results

Our study was funded in September 2020 by the Department of Defense (W81XWH2010173). We completed the enrollment of our target population of 20 participants in October 2022. As of July 2023, we will initiate extensive neuroimaging data analysis and anticipate that the full results of the study will be published by 2024.

Discussion

Study Rationale

With a growing number of people reporting greater sleep disturbances, identifying effective nonpharmacological interventions is an important step in providing more innovative and noninvasive approaches for improving sleep outcomes. While the sample size for this study is small, this is the first study to investigate cTBS effects on the DMN to improve sleep outcomes.

Experimental Clinical Design Rationale

Double-blind randomized controlled trials are the gold standard for scientific inquiry. Therefore, each participant will serve as their own control in a counterbalanced crossover design. Implementing a crossover design in which every participant receives both active and sham cTBS stimulation permits comparison of intraindividual differences in DMN connectivity and sleep quality parameters, as each participant acts as their own control. Because the goal was to examine the effects of cTBS on individuals with sleep problems, no healthy control samples were recruited or necessary to test our hypotheses. Blinding study personnel to the TMS condition also reduces systematic differences in the administration of the stimulation interventions and ostensibly reduces the influence of expectations about treatment effects.

Brief cTBS of the LLP Lobule

Continuous theta burst was selected as the intervention based on its previously demonstrated inhibitory effects on the cortex [47]. A single 40-second cTBS session inhibits, or suppresses, neural excitability in the cortex for up to 50 minutes or longer [47]. Stimulation of a single node of the DMN is expected to inhibit local activity, with further suppression of cortical excitability propagating throughout the network overall. Inhibition of the left inferior parietal lobule was selected for two primary reasons: (1) prior research showed reduced metabolic activity in this region when individuals were falling asleep and (2) this region facilitates an easy-to-access node of the posterior DMN [48].

The localization of specific brain regions requires prestimulation imaging to account for individual variability in brain structure. For this reason, a critical element of that project was to show that stimulation of a single, easily accessible surface node of the larger DMN could lead to significant alterations in FC within this network. Prior investigations using cTBS have focused primarily on the stimulation of brain regions associated with the prefrontal areas of the DMN. Sleep-related parameters have rarely been collected as outcome measures for cTBS. One prior study examining rTMS effects on the right parietal cortex showed reduced anxiety and insomnia symptoms [49]. However, that study used a stimulation session (of three 1-Hz stimulations every 10 minutes) spread across 10 days. The presently proposed cTBS protocol is aimed at establishing initial research outcomes of the effects of a single burst of cTBS on disrupting network connectivity of the DMN to improve sleep. Thus, only a single stimulation session of both active cTBS and sham is needed to identify the intraindividual effects of cTBS on sleep outcomes.

Limitations and Future Directions

Targeting a single node of the DMN and conducting only 1 stimulation session are limitations of this protocol to sufficiently answer the research questions and aims proposed regarding DMN and insomnia improvement. Future work could determine the most effective stimulation sites within the DMN and the optimal number of pulses and administrations to optimize this potential intervention for sleep problems. Larger samples are also needed than the small pilot sample collected for this protocol to examine the effects of sex observed in previous studies [38].

Summary and Conclusions

Insomnia symptoms linked with many other psychiatric and physiological morbidities have become an increasingly prevalent

and important health care and societal concern. Noninvasive neuromodulation can be inexpensive and is a technique accessible to many types of treatment providers. The protocol presented here unifies the prominent aspects of insomnia—physiological and psychological hyperarousal—by targeting a unique neural network, known to be associated with proposed mechanisms of insomnia [8,50].

Acknowledgments

This study was funded by the United States Army Medical Research and Development Command (W81XWH2010173; primary investigator: WDSK).

Authors' Contributions

LH carried out the data collection, data management, wrote the initial draft of the manuscript, and contributed to revisions. AH contributed equally to the initial drafting of the manuscript, provided revisions, and contributed to the ongoing statistical analysis of the study. ND assisted with the study design and executed data collection. SJ and KHA contributed to data collection, data management, and regulatory reporting, and reviewed drafts of the manuscript. CT, YCC, and YHC provided training in transcranial magnetic stimulation (TMS), provided the TMS study equipment, and oversaw TMS data collection. WDSK was responsible for the initial conceptualization and design of the project, obtaining the research funding, providing oversight of the study, contributing to ongoing statistical analysis and interpretation of the findings, and contributing to initial drafting and revisions of the manuscript.

Abstract

Background: Cerebral palsy (CP) is a prevalent nonprogressive disorder that leads to impaired movement (ie, spasticity), posture, and balance, which affects functions such as walking and upper extremity tasks. Current medical treatments show efficacy in improving motor performance but have considerable side effects. Emerging off-label use of central nervous system (CNS) medications for improving motor performance has shown promising results in children with CP and other populations.

Objective: The aim of this study is to describe a protocol for a pilot randomized controlled trial (RCT) to examine the safety, tolerability, and efficacy of methylphenidate (MPH) and modafinil on spasticity and motor performance in children with CP.

Methods: This will be a protocol study for a pilot, triple-masked, placebo-controlled RCT (a class I trial following the American Academy of Neurology criteria) with blinded patients, outcome assessors, and intervention delivery team. Eligible children should be diagnosed with CP levels I or II based on the Gross Motor Function Classification System and be aged between 7 and 12 years. Thirty-six children with CP will be randomized into 3 groups to receive (1) MPH (2.5 mg of MPH + 100 mg placebo), (2) modafinil (100 mg modafinil + 2.5 mg placebo), or (3) a placebo (2.5 mg placebo + 100 mg placebo), in addition to physical therapy for 12 weeks. Primary outcomes include the Gross Motor Function Measure–66 and the Modified Ashworth Scale. Secondary outcomes include the Timed Up and Go test, 5 Time Sit to Stand test, Modified Clinical Test for Sensory Interaction of Balance, and 10-Meter Walk Test.

Results: The protocol has been accepted by Kuwait University (VDR/EC-225) and the Ministry of Health of Kuwait (2022/2157). The inclusion of participants will start in June 2024.

Conclusions: The combination of CNS stimulant medications and controlling for rehabilitation has not been studied yet. The findings of this study may determine if using CNS stimulant medications is beneficial for the reduction of spasticity and improvement of physical function in children with spastic CP.

Trial Registration: ClinicalTrials.gov NCT05675098; https://clinicaltrials.gov/study/NCT05675098

Introduction

Background

Cerebral palsy (CP) is a group of disorders that cause permanent, nonprogressive damage to the developing brain [1], leading to impairments in movement and posture, as well as balance deficits [2,3]. These impairments could affect gross motor skills [4], such as gait [5], upper limb tasks (eg, reaching) [6], and oral motor function (eg, eating and swallowing) [7], which could contribute to limitations across a variety of life domains, including self-care, education and work, and recreational activities [8].

CP is one of the leading causes of disability [2], affecting about 1 in 500 children, with estimated prevalence of 17 million individuals globally [9]. CP can be classified into different categories based on motor impairments, including spasticity (increased muscle excitability) [10], dyskinesia (uncontrollable random movement) [11], ataxia (impaired coordination) [12], or mixed movement disorders [3].

Spastic disorders are the most common type of CP that affects motor activities essential for activities of daily living (ADL) [3]. Treatment of CP spastic disorders includes pharmacological medications (oral and injected), surgical therapy, and nonpharmacological therapy (ie, rehabilitation or constraint-induced movement therapy [13,14]). Pharmacological medications with different mechanisms of action can be used to reduce spasticity in children with CP. For instance, using botulinum toxin type A (BoNT-A) injections is efficacious in reducing spasticity of the upper extremities (UEs) [15] and lower extremities (LEs) [16], which helps in improving the overall motor function in children with CP [17]. BoNT-A inhibits acetylcholine production from the presynaptic terminal, causing a decrease in muscle excitability [17]. Based on the current CP clinical practice guidelines, BoNT-A is considered a safe and effective intervention for spasticity in children and adolescents with CP [18-21]. However, BoNT-A effects are peripheral, targeting specific muscles, and have a temporary influence on spasticity [15,16]. Importantly, BoNT-A has been criticized due to its potential to induce muscle weakness in a condition that is characterized by motor impairments [17].

Other pharmacological medications can reduce spasticity in children with CP, such as baclofen (tablets or intrathecal injections) and diazepam (tablets) [20]. These medications reduce spasticity by improving the affinity of gamma-amino butyric acid (GABA) on its receptors, which in turn blocks excitatory neurotransmitters [22,23]. Notably, these medications have shown effectiveness in both reducing spasticity and improving motor performance in children with CP [24,25]. Nevertheless, baclofen and diazepam have potential side effects that could impact their use, including drowsiness and potential muscle weakness [20]. These medications counter a key factor in improving motor performance by decreasing the rate of motor firing [20]. Therefore, there is a critical need to explore the effects of medications that could both improve motor performance and reduce spasticity but also exhibit minimal side effects in children with CP.

In the past 2 decades, central nervous system (CNS) stimulants such as methylphenidate (MPH) have been reported to improve motor performance when used in children with attention-deficit/hyperactivity disorder (ADHD) [26,27]. Furthermore, a case report documented that a woman aged 44 years with CP (mixed type—choreoathetosis with spasticity) consumed another CNS stimulant (amphetamine) recreationally and observed a remarkable reduction in her spasticity, which encouraged her physician to prescribe MPH for spasticity reduction [28]. This woman had a considerable long-term decline in spasticity and choreoathetosis with MPH use [28]. Another CNS stimulant (modafinil) showed improvements in gait and spasticity among children with CP [29-31]. Nevertheless, the effects of modafinil on spasticity and motor improvement have been inconsistent [32]. Consequently, potential CNS stimulants such as MPH and modafinil are hypothesized to reduce spasticity and improve motor performance in children with CP due to alteration in neurochemicals in the brain (ie, changes in neuroplasticity) [33].

Rehabilitation interventions for children with CP produce changes in neuroplasticity [34], which could lead to long-term improvements in motor function. Specifically, early interventions for spasticity and motor function may be associated with improved motor performance due to enhancement of sensory feedback plasticity [35]. Sensory feedback is an essential modifiable factor for motor learning by iteration, which alters

connections between primary motor and somatosensory cortices [36,37]. Therefore, the use of CNS stimulants, in addition to rehabilitation interventions, could offer long-term improvements in spasticity and motor performance in children with CP. Using CNS stimulants may offer advantages over existing pharmacological treatments, primarily because they do not induce muscle weakness [17]. Given the limited studies that have examined the effects of CNS stimulants on motor performance, with or without rehabilitation, in children with CP, a pilot experimental research study is warranted.

Objective

We designed a triple-masked pilot randomized controlled trial (RCT) that aims to examine the safety and tolerability of MPH and modafinil (aim 1) as well as to assess trends in changes in gross motor function and spasticity with the use of MPH and modafinil in children with CP (aim 2). In this placebo-controlled study, participants will be randomized into 3 groups that will receive MPH, modafinil, or placebo tablets. We hypothesize that using MPH or modafinil will be tolerable and safe for children with CP. We also hypothesize that there will be trends toward improvement in gross motor function and spasticity in children with CP.

Methods

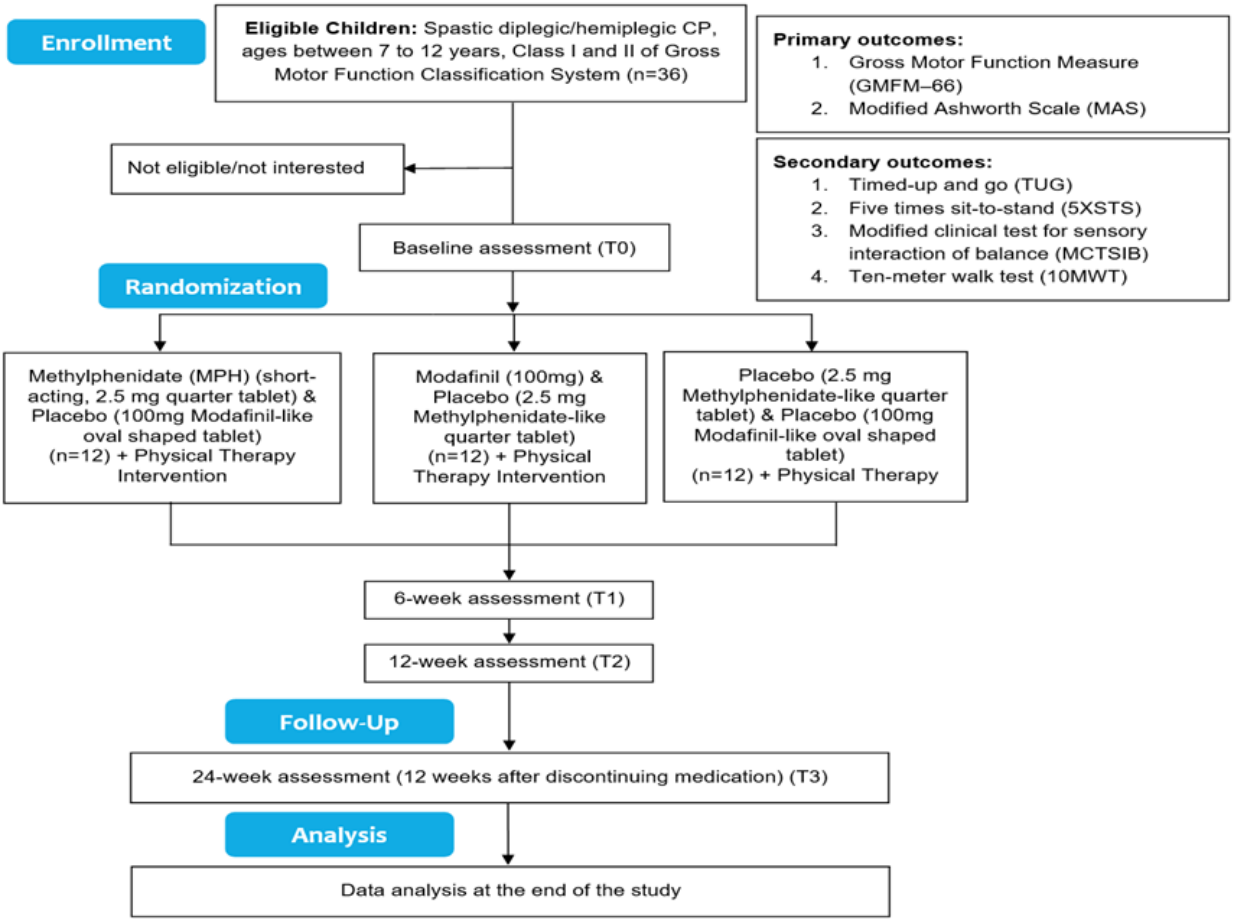
Ethical Considerations

Ethical approval for this study has been obtained from Kuwait University (VDR/EC-225) and the Ministry of Health of Kuwait (2022/2157). Prior to initiation of this study, participants and their legal guardians will be informed about the study and written consent and assent will be obtained from each participant. We followed the SPIRIT (Standard Protocol Items: Recommendation for Interventional Trials) guidelines for the preparation of this protocol [38]. The SPIRIT guidelines are a 33-item checklist that allows researchers to draft and plan high-quality RCTs and describe elements of the content of the RCT. The protocol of this study has been registered at ClinicalTrials.gov (NCT05675098).

Study Design

This study will be a single-center, prospective, triple-masked, placebo-controlled pilot RCT. The study design is informed by the American Academy of Neurology (AAN) criteria for evidence classification as a class I study [39]. To meet these criteria, this study will (1) be triple-masked (blinded) to minimize the risk of bias (ie, patients and legal guardians, treatment providers, and outcome assessors will be blinded), (2) use the intent-to-treat principle to account for dropouts, (3) have only 2 primary outcomes (the Gross Motor Function Measure [GMFM] and Modified Ashworth Scale [MAS]), (4) have a prespecified minimal clinical detectable change in the primary outcomes, and (5) use a powerful method to correct for multiple comparisons for secondary outcomes. This study will also use a placebo-control group as an active control; this is due to the fact that there are no medications that possess CNS-stimulant qualities that have been tested for the purpose of the study. This study will examine the effects of a 12-week administration of MPH, modafinil, or placebo with the GMFM and MAS, with a testing session in the middle of the study period (ie, at the 6-week mark). This is integral, as it will allow for monitoring changes in the primary outcomes at multiple time points. The study will also examine the long-lasting effects of these medications (MPH and modafinil) at 12 weeks after the conclusion of the intervention (ie, at 24 weeks) to assess if any detected trends of improvement last beyond the period of the intervention. This study will be guided by the CONSORT (Consolidated Standards of Reporting Trials) guidelines for recruitment (Figure 1).

Figure 1. Consolidated Standards of Reporting Trials (CONSORT) flowchart of the proposed randomized controlled trial.



Recruitment

Participants

Formal power calculation will not be carried out because this is a pilot study. Children with CP (N=36) aged 7 to 12 years will be enrolled (ie, 12 children per group). Children will be recruited from hospitals around Kuwait using several advertisement methods, including flyers, email notifications to health care providers, and social media advertisements (eg, on X, formerly known as Twitter). Additionally, we will use the snowball recruitment method for this study. The study will be conducted at Jaber Al-Ahmad Hospital, Kuwait.

Inclusion Criteria

Children will be screened and considered for eligibility if they are diagnosed with spastic diplegic or hemiplegic CP by a pediatric neurologist with at least 5 years of experience with this population, aged 7 to 2 years, male or female, classified as level I or II on the Gross Motor Function Classification System (GMFCS), (ie, they are able to walk independently with or without limitation) [40], and have received physical therapy for at least 3 months. GMFCS level will be determined by the treating therapist of the participant according to the expanded and revised version of the GMFCS [41]. If eligible, participants will only follow the rehabilitation intervention described in this protocol. Medicine management will continue as prescribed by the treating physician.

Exclusion Criteria

Children will be excluded if they have had a seizure in the past 6 months, have been diagnosed with ADHD, have had any surgery within the last 6 months, use medications that interfere with spasticity (eg, baclofen), are unable to follow simple commands, or have LE (hip, knee, and ankle) contractures determined by the passive range of motion (ROM). Contracture measurement will follow the CP Follow-up Program (CPUP) measurement manual, based on the guidelines of Norkin and White [42]. Measurements will be done using a universal goniometer and in standardized positions. Decreases in passive ROM are considered contractures if they fall within the red level of the “traffic light” system of the CPUP [42]. For the hip joint, abduction and extension ROM will be measured with the Ely test [43]. For the knee joint, extension along with popliteal angle will be measured [44]. Finally, for the ankle joint, dorsiflexion with knee flexed and extended along with plantarflexion will be measured. Assessors will be consistent across data collection points (screening, baseline, at 6 weeks, at 12 weeks, and at 24 weeks). Interrater reliability will be measured on 25% of the sample, chosen randomly to ensure consistency among assessors.

Randomization

Match or pair randomization will be used in this study to control for confounding effects of sex and GMFCS level. Children will be allocated to the MPH, modafinil, or placebo group using a concealed centralized electronic allocation application. Children

will be matched for sex (male or female) and GMFCS (level I or II).

Sample Size

This study will include 12 children in each group (N=36). Due to the design of the study (ie, a pilot trial), power calculation will not be performed to estimate the sample size. Upon the completion of this study, our findings will provide effect sizes that are essential for future studies to conduct a power analysis.

Blinding Procedures

This study will be triple-masked (blinded), where treatment providers, outcome assessors, and participants (children and their legal guardians) will be unaware of the study group allocation. Two pharmacists and 1 study coordinator will be the only personnel exposed to the group allocation. The 2 pharmacists will carry out the randomization process and prepare the medication using a concealed nontransparent envelope and send it to the nursing staff, who will provide the treatment approximately 90 minutes before the physical therapy session. The study coordinator will track group allocation and deliver the prescriptions to the nursing staff before the administration of the drug. Physicians who prescribe MPH, modafinil, or placebo will use a customized sham form to ensure blinding. All primary and secondary outcomes will be collected by 2 physical therapists (PTs), who will be also blinded to the group allocation.

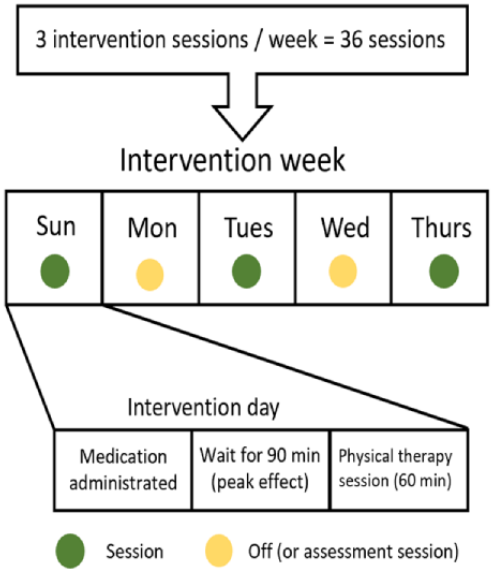
Intervention

Medication

Participants will receive 2 medications based on their group assignment. The MPH group will receive a quarter tablet of short-acting MPH (2.5 mg) and an oval-shaped placebo (100 mg) tablet that looks like a modafinil tablet. The modafinil group will receive a modafinil (100-mg) tablet and a circle-shaped quarter tablet of placebo that looks like an MPH tablet (2.5 mg). The placebo group (the active control) will receive 2 placebo tablets (a circle-shaped quarter tablet of MPH placebo and an oval-shaped tablet of modafinil placebo). All delivered medications (MPH, modafinil, and placebo) will be administered approximately 90 minutes before the physical therapy session, to use the peak medication effect to augment the outcomes of physical therapy [45]. The medication will be administered by a registered nurse and will be controlled by the pharmacy department at Jaber Al-Ahmed Hospital. The medication will be only prescribed on the day of a physical therapy session, which means that children will receive 3 medication doses per week over 12 consecutive weeks (the duration of the study). Since children need to receive the medication 90 minutes before their PT session, appointments will be scheduled on Sundays, Tuesdays, and Thursdays during the daytime (ie, from 8 AM to 1 PM; Figure 2). Any missed appointment will be documented, and the prescribed medication will be returned to the pharmacy. After 12 weeks of medication administration, participants will stop receiving the prescribed medication in this study, whether it was the active agent or placebo. A follow-up assessment session will be performed 12 weeks after the discontinuation of medication to examine the potential for long-lasting benefits from the received medication. Further analysis will be done to compare compliant versus noncompliant children.

All MPH (Ritalin, 10 mg; Novartis), modafinil (Provigil, 100 mg; Apotex), and placebo (circle-shaped MPH placebo, 10 mg; oval-shaped modafinil placebo, 100 mg; Kuwait Saudi Pharmaceutical Industries Co) bottles that will be used in this study will adhere to labeling requirements to ensure traceability and accountability, containing the following information: (1) the full name of the supplier of the medication and placebo bottles, (2) the batch number, and (3) the manufacturing and expiration dates. In addition, the medication and placebo tablets will be extracted from their original bottles and secured in individual containers with the aforementioned information and a patient identifier. The study coordinator is responsible for ensuring compliance with these labeling requirements, which will be recorded and will be made available for inspection upon request.

Figure 2. Illustration of the timing of the administration of the medication and physical therapy sessions.



Physical Therapy Intervention

The physical therapy intervention will include therapeutic exercises that target different domains of the International Classification of Functioning, Health, and Disability (ICF), including body structure, activity, and participation. The dose of the physical therapy intervention will be as follows: (1) the frequency will be 3 sessions per week for 12 weeks; (2) the session time will be 60 minutes; (3) the type and intensity will be treatment activities that focus on joint ROM and muscle strength (body structure domain), locomotion training (body structure [endurance], activity [gait training], and participation [locomotive abilities] domains), reaching training (activity and participation domain), and motor control and motor learning training (activity and participation domain) (Table 1). A detailed manual will be provided to the treating PTs to ensure consistency in the treatment delivered to each child. After 12 weeks of receiving the physical therapy intervention, participants are entitled to enroll into any other rehabilitation program. At week 24, participants will complete an assessment session and provide information on whether they received rehabilitation after stopping the medication, if any, including duration of the session per day, frequency of sessions per week, and compliance to these sessions in the past 12 weeks.

Table 1. Detailed physical therapy plan.

ICF[a] domain and type	Details
Body structure and function	
Joint range of motion	• Active and passive stretching (eg, squats and stepping up)
Muscle strength	• Active and resistive training (85% of 1-repetition maximum—build up to 3 sets of 10 repetitions)
Activity	
Locomotion training	• Treadmill walking—build up to 1.2 m/s with a 0.2 m/s increase per week or as tolerated • Overground walking—over and around obstacles for 10 m or as tolerated
Reaching training	• Bimanual activities—reaching in all directions (with both hands or switching between hands)
Postural control	• Equilibrium reaction training— moving from a stable to an unstable surface with eyes open, then repeated with eyes closed
Participation	
Motor control and learning	• Training for activities of daily living—standing progression, walking progression, and higher function progression (stair climbing, running, and jumping)

[a]ICF: International Classification of Functioning, Health, and Disability.

Implementation of the Intervention

Data collection sessions (assessment data points) will be held on Sundays, Tuesdays, and Thursdays during the daytime (ie, 8 AM to 1 PM). Two PTs will be assigned to deliver physical therapy interventions throughout the study. Each PT will treat a range of 3 to 6 children per intervention period (n=36 intervention sessions). Two experienced investigators will supervise the physical therapy treatment and track the participants' compliance. The expected time commitment for each child for each session is about 2 to 2.5 hours, with the first hour waiting for the medication's peak effect and the remaining time for the physical therapy intervention.

Outcomes

Primary Outcomes

After obtaining the consent and assent forms, caregivers will complete a questionnaire on demographic information, followed by a body weight and height assessment of each child. The primary outcomes of this study will be the GMFM-66 and MAS scores for the LEs and UEs to assess changes in functional motor performance and spasticity, respectively. The assessment session will be done by a trained PT who is different from the PTs that will deliver the intervention. There will be 4 examination sessions (baseline, at 6 weeks, at 12 weeks, and at 24 weeks) that will last approximately 2 hours—for both primary and secondary outcomes. These assessment sessions will be scheduled separately from the intervention sessions. The GMFM-66 is designed to examine gross motor activities in five domains: (1) lying and rolling, (2) sitting, (3) crawling and kneeling, (4) standing, and (5) walking, running, and jumping [46]. The GMFM-66 scores range between 0 to 3, where 0 corresponds to "does not initiate," 1 corresponds to "initiates," 2 corresponds to "partially completes," and 3 corresponds to "completes" [46]. Items that a child refuses to perform or that are not administered are scored as "not tested" [46]. Scoring will be done using the Gross Motor Ability Estimator (GMAE), where each score is entered and then converted into an internal level to calculate the total score for each child's gross motor function. The GMFM-66 is a valid and reliable tool to assess gross motor function in children with CP [47]. In addition, we will use the MAS for the LE (hip extensors and adductors and ankle plantar flexors) and UE (shoulder internal rotators and flexors and elbow flexors) musculature as the second primary outcome. The MAS scores range from 0 (no increase in resistance to stretch) to 4 (complete rigidity) [48]. Children will lay supine on a flat bed with their head at midline and the arm beside the trunk [48]. Each extremity will be examined

separately. The examiner will rapidly move the child's extremity throughout the range within 1 second [48]. The examiner will determine the MAS score after applying 3 passive movements [48]. This MAS has been shown to have a good intrarater reliability for the LEs (intraclass correlation [ICC]=0.644; Cohen κ=0.488) [49]. The minimum clinically important differences (MCIDs) for the GMFM-66 are 1.7 and 1.0 for GMFCS levels I and II, respectively [50].

Secondary Outcomes

The secondary outcomes will include the Timed Up and Go (TUG) test, 5 Times Sit to Stand (5XSTS) test, Modified Clinical Test for Sensory Interaction of Balance (MCTSIB), and 10-Meter Walk Test (10MWT). For the TUG, participants will stand up from a 45-cm height armchair, walk at their typical, comfortable pace around a cone that will be placed 3 meters away from the chair, then walk back to the chair and sit down. Time(s) to complete the task will be recorded as the score of this test using a stopwatch. The TUG has excellent test-retest reliability in children with CP (ICC=0.91-0.99) and MCIDs of 0.36 and 0.87 for GMFCS levels I and II, respectively (ie, a large effect size) [51].

For the 5XSTS, participants will stand up from a 45-cm armchair and sit down as fast as they can. Time(s) will be used for scoring this test. This test has excellent test-retest reliability in children with CP (ICC=0.91) [52]. Of note, MCID data are not available for children with CP; however, the minimal detectable change for this test is 0.06 seconds [53].

The MCTSIB measures balance in 4 conditions, measured for a maximum of 3 trials of 30 seconds for each condition: firm floor with eyes open, then closed; and foam (unstable surface) with eyes open, then closed [54]. This test has excellent test-retest reliability (ICC=0.91) [54].

For the 10MWT, participants will be instructed to walk at their comfortable pace for 10 meters; time(s) will be recorded as the score of this test. This test is to measure gait speed and variability and has fair test-retest reliability (ICC=0.81) [55].

Statistical Analysis

SPSS (version 29; IBM Corp) will be used to conduct all the data analyses in this study. For changes in the primary outcomes, we will use a repeated-measures ANOVA to examine changes in the GMFM-66 between the 3 intervention groups across all testing time points (ie, baseline, at 6 weeks, at 12 weeks, and at 24 weeks). To examine changes in MAS between the 3 intervention groups, we will use Kruskal-Wallis *H* test because MAS is an ordinal scale. Finally, we will use multivariate linear mixed models to determine changes in the associated secondary outcomes between the 3 intervention groups.

Adverse Events

At the beginning of each intervention week, a questionnaire will be administered by the PTs inquiring about adverse effects. Any adverse events will be addressed immediately by the research team. Any potential risks of using CNS medications will be recorded in the informed consent and assent forms and will be explained to the caregiver of each child. In case of an adverse event, we will refer the participant directly to the emergency department to receive medical care and record the incident of the adverse event. Additionally, we will notify the institutional review board office at Kuwait University and the Ministry of Health of Kuwait about any potential incidents. Finally, should we encounter 2 or more incidents per medication group, we will stop the intervention for that specific group and document it in our records.

Data Collection and Management

Data collection will be performed at baseline (before randomization), 6 weeks, and 12 weeks, as well as at 24 weeks (as a test of long-lasting effects) after starting the intervention. A data monitoring committee (DMC) will be assigned that will include a research assistant and a pharmacist. Members of the DMC will be exposed to the randomization process and will manage adverse events throughout the protocol. Compliance to medication and physical therapy will be collected every session by the PTs, using an online Google form; Microsoft Excel sheets and participant ID numbers will be used to identify each participant. Only the DMC members will have access to this sheet, in which no identifiable information of participants will be included.

Confidentiality

All identifiable data of participants will be protected and decoded in the data collection sheet. After agreement to participate, signed consent and assent forms will be stored in a locked locker at the principal investigator's office. All other study documents (eg, data collection sheet, randomization and mediation prescriptions, and demographic data questionnaires) will use a participant ID number that will replace the name of the child.

Ancillary and Posttrial Care

Due to the pilot nature of this study, the results will not provide definite findings regarding the effectiveness of CNS stimulant medications in reducing spasticity and improving motor function in children with CP. Therefore, we are unable to recommend the prescribing of any CNS medication for children with CP until the findings of advanced phases of this project indicate their efficacy and effectiveness.

Results

The protocol has been accepted by Kuwait University (VDR/EC-225) and the Ministry of Health of Kuwait (2022/2157). The inclusion of participants will start in June 2024. The findings of this study are intended to be disseminated at several scientific meetings, including the American Academy of Cerebral Palsy and Developmental Medicine and the AAN annual meetings. Additionally, the findings of this study will be submitted for publication to scientific journals specialized in the field of CP and developmental medicine.

Discussion

Principal Findings

This study protocol details the background and design of a pilot RCT to determine changes in motor performance and spasticity

as a result of the use of CNS stimulant medications in children with CP. We expect the findings of this study to document the safety and tolerability of using these medications in children with CP. We also expect that there will be a trend of improvements in the GMFM-66 and MAS in the CNS stimulant groups (ie, MPH and modafinil) compared to the placebo group. We anticipate that these changes will impact quality of life and the overall function of children with CP, demonstrated by improvement trends in secondary outcomes, where these improvements could document positive effects of CNS stimulants in improving the health of patients with CP.

The findings of this study will be shared and disseminated through multiple scientific mediums, including annual conferences and scientific meetings, as well as peer-reviewed scientific journals. The functional and motor improvements that could result from using CNS stimulants in this population could reduce the consequences of impairments associated with CP. Therefore, using CNS stimulants could help in reducing the financial burden associated with treating CP functional impairments on the health care system.

Limitations

The complexity of CP and the heterogeneity of motor impairments may contribute to variations in response to medication in this study. However, we limited participation in this study to participants with GMFCS levels I and II to minimize the effect of severe motor impairments. Although not an issue in pilot studies, dropout across the study groups may occur. Nevertheless, this concern could be mitigated by providing physical therapy sessions to all groups in addition to medications. Regardless, CP motor treatment is valued across parents of children with CP and could help in reducing attrition. Finally, information obtained from the physical therapy intervention will be important for revising the conceptual model for the intervention and will inform the next step of the trial.

Conclusions

Evidence suggests promising results of using CNS stimulant medications for reducing spasticity and improving physical function in children with spastic CP. The combination of CNS stimulant medications and controlling for rehabilitation has not been studied yet. The findings of this study may suggest positive effects of using CNS stimulant medications for reducing spasticity and improving physical function in children with spastic CP.

Acknowledgments

The authors extend their appreciation to the Deanship of Scientific Research at Northern Border University, Arar, Saudi Arabia, for funding this research work through project NBU-FFR-2024-2508-02.

Data Availability

Data sharing is not applicable to this article as no data sets were generated or analyzed during this study.

Authors' Contributions

M Alotaibi and ABA conceptualized the idea and methodology and contributed to manuscript preparation and revision. SA and NA improved the methodology, provided an overall framework, and revised the manuscript. AA, M Alharbi, and AT managed the pharmacological planning and placebo design in accordance with the study requirements and revised the manuscript. BA, LV, and MMA helped refine the protocol and provided critical feedback for improving the quality of this protocol. All authors have read and approved the manuscript.

Conflicts of Interest

Abstract

Background: Obesity is an established, modifiable risk factor of multiple myeloma (MM); yet, no lifestyle interventions are routinely recommended for patients with overweight or obesity with MM precursor conditions. Prolonged nightly fasting is a simple, practical dietary regimen supported by research, suggesting that the synchronization of feeding-fasting timing with sleep-wake cycles favorably affects metabolic pathways implicated in MM. We describe the design and rationale of a randomized controlled pilot trial evaluating the efficacy of a regular, prolonged nighttime fasting schedule among individuals with overweight or obesity at high risk for developing MM or a related lymphoid malignancy.

Objective: We aim to investigate the effects of 4-month prolonged nightly fasting on body composition and tumor biomarkers among individuals with overweight or obesity with monoclonal gammopathy of undetermined significance (MGUS), smoldering multiple myeloma (SMM), or smoldering Waldenström macroglobulinemia (SWM).

Methods: Individuals with MGUS, SMM, or SWM aged ≥18 years and a BMI of ≥25 kg/m^2 are randomized to either a 14-hour nighttime fasting intervention or a healthy lifestyle education control group. Participants' baseline diet and lifestyle patterns are characterized through two 24-hour dietary recalls: questionnaires querying demographic, comorbidity, lifestyle, and quality-of-life information; and wrist actigraphy measurements for 7 days. Fasting intervention participants are supported through one-on-one telephone counseling by a health coach and automated SMS text messaging to support fasting goals. Primary end points of body composition, including visceral and subcutaneous fat (by dual-energy x-ray absorptiometry); bone marrow adiposity (by bone marrow histology); and tumor biomarkers, specifically M-proteins and serum free light-chain concentrations (by gel-based and serum free light-chain assays), are assessed at baseline and after the 4-month study period; changes therein from baseline are evaluated using a repeated measures mixed-effects model that accounts for the correlation between baseline and follow-up measures and is generally robust to missing data. Feasibility is assessed as participant retention (percent dropout in each arm) and percentage of days participants achieved a ≥14-hour fast.

Results: The PROlonged nightly FASTing (PROFAST) study was funded in June 2022. Participant recruitment commenced in April 2023. As of July 2023, six participants consented to the study. The study is expected to be completed by April 2024, and data analysis and results are expected to be published in the first quarter of 2025.

Conclusions: PROFAST serves as an important first step in exploring the premise that prolonged nightly fasting is a strategy to control obesity and obesity-related mechanisms of myelomagenesis. In evaluating the feasibility and impact of prolonged nightly fasting on body composition, bone marrow adipose tissue, and biomarkers of tumor burden, this pilot study may generate hypotheses regarding metabolic mechanisms underlying MM development and ultimately inform clinical and public health strategies for MM prevention.

Introduction

Multiple myeloma (MM) is the second most common hematologic malignancy in the United States and is preceded by well-defined precursor conditions called monoclonal gammopathy of undetermined significance (MGUS) and smoldering MM (SMM) [1,2]. MGUS and SMM are asymptomatic conditions that have an annual progression rate to overt MM of 1% and 10%, respectively, but can be as high as 58% in 20 years in certain risk groups [3,4]. Despite the increasingly strong interest in intervening at the precursor stage for the early interception and prevention of MM, safe and cost-effective interventions are lacking. Although clinical trials have shown that earlier initiation of anti-MM therapies at the precursor stage (eg, lenalidomide-based regimen for high-risk SMM [5]) may alter the natural disease course and improve survival [5,6], early treatment remains highly controversial due to high costs and toxicity risks to patients, limiting its use to only a subset of patients at the highest risk strata [7-10].

Lifestyle interventions targeting excess adiposity and metabolic health in precursor patients may have an important role in MM prevention. Obesity is a well-established, potentially modifiable risk factor of MM [11], and there is accumulating evidence that obesity may also increase the risk of MGUS and its progression to overt MM [12-14]. Although current dietary and weight control guidelines for cancer prevention focus largely on calorie restriction and optimizing intake of specific food groups [15], challenges related to their integration into individuals' daily lives for a sustained period of time remain a consideration [16-19]. Time-restricted feeding, a form of intermittent fasting whereby ad libitum energy consumption is constrained to a window of time (typically between 4 and 12 hours daily), may be a simple, feasible alternative for weight loss and cancer risk reduction [16,20]. When food intake timing occurs during the wake phase of the 24-hour day, time-restricted feeding may benefit metabolic health and cancer risk by synchronizing feeding-fasting regimens with daily circadian rhythms, which, in turn, improve oscillations in the circadian clock expression of numerous genes important for glucose metabolism and overall cellular homeostasis (eg, autophagy and DNA damage repair) [16,21,22].

The PROlonged nightly FASTing (PROFAST) study is a randomized controlled pilot trial investigating the clinical benefit of a 4-month prolonged nightly fasting regimen in individuals with overweight or obesity with MGUS, those with SMM, and those with smoldering Waldenström macroglobulinemia (SWM). The intervention is supported by evidence that prolonged nighttime fasting is not only a simple and sustainable behavior change [16,23] but also improves metabolism and body weight regulation [24-29]. Here, we describe the study design, rationale, and framework for assessing the potential clinical significance of a low-risk, cost-effective lifestyle intervention in patients with MM precursor conditions.

Methods

Design of PROFAST

PROFAST is a pilot randomized controlled trial of our 4-month prolonged nightly fasting intervention in patients with overweight or obesity with MGUS, SMM, or SWM. The goal of the trial is to acquire preliminary outcome data for the efficacy of prolonged nightly fasting on body composition and clinical markers of disease progression in precursor patients. Participants are randomly assigned to (1) a theory-based intervention designed to promote a 14-hour fast during the nighttime hours or (2) the healthy lifestyle education control group.

Ethical Considerations

All study procedures and materials have been approved by the institutional review board at the Dana-Farber Cancer Institute (22-071).

Participants and Eligibility

Eligible participants are at least 18 years old, have a BMI of ≥25 kg/m^2, and have a documented diagnosis of MGUS, SMM, or SWM via the review of their electronic medical records. As shown in Textbox 1, inclusion criteria include individuals who (1) are currently fasting for <14 hours per night as assessed via

self-report and using 24-hour food recalls and (2) own a cell phone and are capable of sending and receiving SMS text messages comfortably. Exclusion criteria are patients with (1) overt MM; (2) other cancers requiring active therapy; (3) diabetes mellitus, which may increase the risk of hypoglycemia with a prolonged fast, unless the physician who manages their clinical care provides consent that they may enroll; or (4) any other condition or circumstance that, in the investigators' judgment, would be a contraindication to nightly fasting or interfere with trial participation (eg, night shift work, night eating syndrome, taking weight loss medication, and participation in another weight loss program). Participants are primarily recruited from the Dana-Farber Cancer Institute Center for Early Detection and Interception of Blood Cancers, a clinic focused on evaluating patients diagnosed with precursor conditions of hematologic malignancies and which works with patients to manage their risk of disease progression.

Textbox 1. Study eligibility criteria.

Inclusion criteria

- Age ≥18 years
- BMI ≥25 kg/m^2
- Diagnosis of monoclonal gammopathy of undetermined significance, smoldering multiple myeloma, or smoldering Waldenström macroglobulinemia
- Currently fasting for <14 hours per night, as assessed by 24-hour food recalls
- Owns a cell phone capable of sending and receiving SMS text messages comfortably
- Ability to understand and willing to sign a written informed consent document

Exclusion criteria

- Diagnosis of overt multiple myeloma
- Diagnosis of another malignancy requiring active therapy
- Diagnosis of diabetes mellitus, unless consent from the patient's physician managing the participant's clinical care
- Any medical or lifestyle condition contraindicated in or would interfere with study intervention (eg, night eating syndrome and night shift work)
- Currently taking medications intended for weight loss or participating in other weight loss programs

Clinic Visits and Randomization

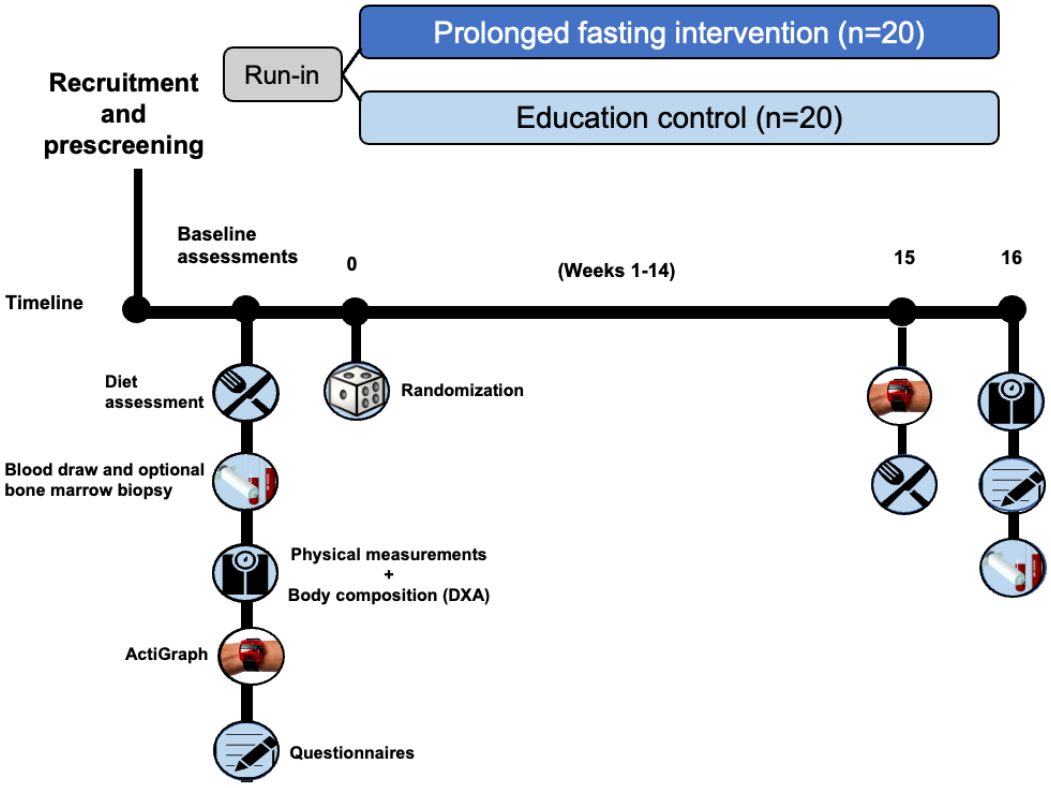
On completion of the consent form, participants attend a baseline clinic visit that includes laboratory, self-report, and physical assessments, as shown in Figure 1. In particular, participants have their height and weight measured and receive a dual-energy x-ray absorptiometry (DXA) scan to evaluate body composition. Participants provide biospecimen samples (ie, blood and bone marrow aspirate or biopsy). For each blood draw, approximately 30 to 60 mL of blood per participant is collected into EDTA and serum separator tubes for immediate plasma and serum preparation, respectively, and aliquots of plasma and serum in 1.8-mL cryovials are placed in a –80 °C freezer for storage. As for bone marrow samples, approximately 20 mL of bone marrow is collected into EDTA tubes for immediate processing, and the processed samples are placed in cryovials in a slow freezing cryostorage for 1 to 7 days before moving to storage in a liquid nitrogen tank.

Participants' current diet and lifestyle patterns are characterized through two 24-hour dietary recalls: (1) questionnaires ascertaining demographic, comorbidity, lifestyle, and quality-of-life information; and (2) the wearing of an ActiGraph accelerometer (GT3XP-BTLE; ActiGraph Corp) on their wrists for 7 days for baseline assessment of sleep, physical activity, and circadian rhythm.

Within 28 days of completing baseline assessments, participants are randomized in a 1:1 manner to either the nighttime 14-hour fast intervention group or the healthy lifestyle education comparison group. Once randomized, participants initiate the intervention or control condition ideally no later than 28 days of baseline screening assessments.

A clinic visit is scheduled 4 months after initiating and ideally within 7 days of completing the intervention or control condition. At this final visit, participants' weight, biospecimens and clinical labs, DXA scan, and self-reported outcome measures are reobtained.

Figure 1. Schematic of the study design. Timeline of participant recruitment, baseline visit, randomization to intervention or control arm, and end-of-study visit, with assessments that include tumor biomarkers, body composition, 24-hour food recalls, quality-of-life and lifestyle survey, and ActiGraph.



Details of the Intervention

The intervention's goal is to achieve a 14-hour nightly fast. Fasting goals during the initial weeks of the study are individualized, allowing participants to gradually adopt a 14-hour fasting duration on or before the third week of study. A 14-hour window was selected because it has been demonstrated to be an achievable intervention target in other populations of adults with chronic health conditions, and studies to date suggest that it is a sustainable intervention target [29,30]. Specifically, previous interventions have reported elective continuation of the intervention beyond the intervention period, resulting in sustained health benefits including weight loss [29,30]. The overnight fasting period is defined as the longest interval of time overnight in which no calorie-containing foods or beverages are consumed. Given prior findings that fasting may be more beneficial when aligned with the biological night [26], participants are encouraged to begin their nightly fast by 8 PM. To maximize acceptability and adherence to the intervention protocol, participants are allowed to consume noncaloric beverages including water, plain coffee, plain tea, zero-calorie sodas, and calorie-free sweeteners.

The intervention delivery consists of one-on-one telephone counseling by a health coach and an SMS text messaging system to support this target. Participants are supported through telephone counseling during the initial phase (weeks 1-3) of the interventional period and gradually transition to activities that promote self-reliance for behavioral maintenance from week 4 until the end of the study. The intervention incorporates a number of theory-based behavior change strategies in its design [31-33], including those grounded in social cognitive theory and its central tenet of self-efficacy [31].

SMS Text Messaging System

An SMS text messaging system was developed in collaboration with Mosio, Inc, and is introduced to participants during week 3 of the study for the purpose of self-monitoring, tracking adherence, and encouraging maintenance of prolonged nightly fasting. Participants are asked to text the study team to indicate when they began and ended their overnight fast. Participants receive an automated response to their SMS text messages, with positive reinforcement if the fasting goal was successfully achieved or corrective tools, such as a behavioral strategy, that may help them achieve a longer fast. The messages sent back to participants also contain feedback about their cumulative adherence to the prolonged overnight fasting pattern, calculated as the percentage of the successful overnight fasts during the past week. Participants also receive an SMS text message each day to remind them of their target end time of the overnight fast as well as encouraging SMS text messages to promote adherence that are customized to past performance. An example of SMS text messages sent to and received from participants through the automated SMS text messaging system is provided in Table 1.

Table 1. Example of an interaction in which a participant in the intervention arm submits SMS text messages to indicate the beginning and end of overnight fast and, in turn, is provided with automated, encouraging messages promoting cumulative adherence and achievement of the fasting goal.

Time stamp	Message status	Message content
February 17, 2013, 6:00 PM	Sent	Remember: Calories break a fast! Once you start, you need be calorie-free
February 17, 2013, 7:28 PM	Received	FAST
February 17, 2013, 7:29 PM	Response	Thanks! You are now running calorie free! Check back in the morning for your end time.
February 18, 2013, 7:00 AM	Sent	Your fast ends at 9.28 am. You can do it!
February 18, 2013, 9:55 AM	Received	EAT
February 17, 2013, 10:05 AM	Response	Congratulations! Your success rate is 100%. Nice work!

Healthy Lifestyle Education Control

Participants in the control arm receive educational information regarding healthy lifestyle to enhance retention of participants randomized to this group. At baseline, control participants receive an educational session with the health coach and a workbook containing brief information about topics about a healthy lifestyle (eg, sun safety, sleep, hydration, and sitting less). It is notable that research indicates that a single education session has only modest and temporary impacts on behaviors among most individuals [34,35]. To support sustained engagement throughout the 4-month study period, control group participants also receive 1 email and 1 SMS text message per week by the same SMS text messaging system used for participants in the interventional arm. These SMS text messages contain a mixture of educational information and potential personalized touch points to help participants feel valued.

Primary End Points

A challenge in assessing the clinical benefit of short-term interventions in MGUS, SMM, and SWM is that precursor patients are expected to have a relatively small number of progression events over months to years, limiting the ability to evaluate these events as the outcome. In this study, we focus on body composition, bone marrow adipose tissue, and biomarkers of tumor burden, which are accessible outcome measures in evaluating the efficacy of our lifestyle intervention.

Body Composition and Bone Marrow Adiposity

Most investigations evaluating the association of obesity and MGUS and MM have used BMI as a surrogate measure of obesity [12,13,36,37], and although BMI is a convenient, inexpensive measurement [38], it has low specificity for identifying excess adipose tissue and does not account for the type and distribution of fat (visceral and subcutaneous fat) [39,40]. These shortcomings of BMI limit our understanding of the relationship between obesity and the development of MM, as different adipose tissue compartments are known to have differential influences on obesity-related diseases [41-43]. For example, visceral fat is a metabolically active tissue type that releases fatty acids and proinflammatory substances and, in comparison with subcutaneous tissue, is more strongly associated with components of metabolic syndrome [41-43]. Thus, in our study, DXA scan (Horizon W DXA; Hologic, Inc) is used to measure body composition, differentiating not only fat mass from lean mass but also among adipose tissue types (visceral and subcutaneous fat). Furthermore, bone marrow adipose tissue is an understudied adipose depot with endocrine and paracrine signaling functions linked with the proliferation of nearby MM cells [44]. In our study, total marrow lipid content is quantified in bone marrow aspirate samples. Adipocyte-lipid content is analyzed using histology, flow cytometry, and lipidomics on adipocyte-enriched fractions. By measuring and comparing these adiposity measures between baseline and end of study, our study is able to evaluate whether prolonged nightly fasting possibly improves the body composition profile of participants.

Clinically Available Tumor Biomarkers

Serum protein electrophoresis supplemented by immunofixation (SPEP/IFX) and serum-free light chains (SFLCs) are the most commonly used clinical tests used to monitor patients at all stages of the disease continuum (MGUS, SMM, and MM). Monoclonal immunoglobulin (M-protein) and light-chain concentrations, as measured by SPEP/IFX and SFLCs, correlate with overall tumor burden and importantly decrease after treatment with a range of mild and aggressive MM therapies [45-47]. These biomarkers are sensitive and measurable variables of tumor response to treatment [48] and, therefore, serve as clinically relevant disease end points for our lifestyle-related intervention pilot study.

Other End Points

Metabolomics

Metabolomics—the high-throughput identification and quantification of small-molecule metabolites—is the study of metabolic changes in biological systems and provides the small-molecule fingerprints that reflect the complex relationships among diet, lifestyle (obesity), genes, and disease processes [49]. Metabolomics can yield novel insights into pathogenesis and risk of cancer and chronic disease [49,50]. Particularly important categories of metabolites in cancer and metabolic disease are metabolites of glycolysis and the tricarboxylic acid cycle [51,52]. These are of interest to this study because of their critical role in tumor growth and because they have been shown to be related to obesity [53]. Metabolomics-based data of MGUS, SMM, and MM are limited to only a small number of studies, including one by Ludwig et al [54] that identified 25 bone marrow metabolites that differed between 10 patients with MGUS and 10 patients with MM [55-59]. Of all molecular entities in the body (eg, genes, transcripts, proteins, and metabolites), metabolites as the final products of biochemical processing have the closest relationship

to expressed phenotype [60]. Thus, we believe that metabolomics offers a unique lens to study progression of MM precursors.

Quality of Life

Given the high rates of anxiety and distress document in individuals with MGUS and SMM and lack of evidence-based risk reduction strategies available for preventing disease progression to MM [61,62], we aim to evaluate the psychosocial benefits of offering a low-risk lifestyle intervention to this patient population as an exploratory objective. Quality of life is assessed using the well-validated PROMIS (Patient-Reported Outcomes Measurement Information System) global health survey [63-65]. Cancer worry is assessed using a 4-item scale adapted from Lerman et al [66].

Baseline Dietary and Lifestyle Assessment

Participants undergo two 24-hour dietary recalls to assess food and beverage consumption (ideally for 1 weekday and 1 weekend day), which are conducted through the Behavioral Measurement and Interventions Shared Resource at the University of Arizona Cancer Center. Participants also complete a baseline survey querying sociodemographic variables (eg, age, sex, race, ethnicity, highest level of education attained, and annual family income), medical comorbidities (eg, hypertension, hyperlipidemia, and diabetes mellitus), and lifestyle factors (eg, smoking, physical activity, sleep impairment, and disturbance) measured by well-validated instruments [67-72]. Finally, participants are asked to wear an ActiGraph accelerometer (GT3XP-BTLE; ActiGraph Corp) on their wrists for 7 days for a baseline assessment of physical activity, sleep, and circadian rhythm parameters [73-75].

Feasibility, Acceptability, Fidelity, and Safety

Feasibility is assessed as participant retention (percent dropout in each arm) and percentage of days participants achieved a ≥14-hour fast. Acceptability is assessed as perceived effectiveness of intervention components, plans to continue to engage in a prolonged nightly fast, elements of intervention liked or disliked, and satisfaction with program delivery and staff. Items are rated on a scale from 1 to 5. Finally, fidelity is assessed as percentage of days participants recorded fasting duration via the SMS text messaging system, percentage of SMS text messages read, and percentage of calls with the health coach.

Safety is monitored and assessed by the number and severity of adverse events, according to the revised National Cancer Institute Common Terminology Criteria for Adverse Events (CTCAE) version 5.0. Individuals with any medical or lifestyle condition (eg, diabetes mellitus) that is deemed to elevate their risk of adverse events from the intervention are excluded from the study (Textbox 1). Participants are informed of expected side effects related to fasting (eg, lightheadedness, headaches, restlessness, irritability, and low blood glucose), and adverse events that vary in nature, intensity, and frequency from what is expected are reported.

Analysis Plan

The key outcomes evaluated in this trial are changes in body composition (with a focus on visceral and subcutaneous adiposity), M-protein concentrations, and bone marrow adiposity. Changes in these end points are evaluated from baseline to follow-up in the 2 groups using a repeated measures mixed-effects model that accounts for the correlation between baseline and follow-up measures and is generally robust to missing data. The baseline values of the dependent variables (eg, weight and M-protein level) and disease subtype are included as covariates in the regression models. Group-by-time interaction terms are included as fixed effects in the regression model. Model fit is assessed using standard methods.

Results

The PROFAST Study was funded in June 2022. Participant recruitment commenced in April 2023, after developing and testing the text messaging system. As of July 2023, a total of 6 participants consented to the study. The study is expected to be completed by April 2024, and data analysis and results are expected to be published in the first quarter of 2025.

Discussion

The PROFAST study provides important preliminary data regarding the impact of prolonged nightly fasting on body composition, bone marrow adipose tissue, and biomarkers of tumor burden (SPEP/IFX and SFLCs) in patients with MM precursor conditions, thereby generating hypotheses on how targeting obesity-related mechanisms of carcinogenesis may help prevent MM development.

Obesity is a well-established, potentially modifiable risk factor of MM [11], and there is accumulating evidence that obesity may also increase the risk of MGUS and its progression to overt MM [12-14]. A study of 3 large prospective cohorts of US-based adults followed over 5 million person-years observed a 17% increase in MM risk per 5 kg/m^2 increase in BMI [36]. In another study of 7818 patients with MGUS in the US Veterans Health Administration database, being overweight and obese were associated with an increased risk of transformation to MM (hazard ratio [HR] for overweight 1.55, 95% CI 1.16-2.06; HR for obesity 1.98, 95% CI 1.47-2.68) [12]. Concordant with these findings, a more recent analysis of patients with MGUS identified through a population-based screening study in Olmstead County, Minnesota, between 1995 and 2003 observed that having a BMI ≥25 was also associated with increased progression to MM or other plasma cell or lymphoid disorders in univariate analysis (HR 2.14, 95% CI 1.05-4.36) and in a multivariable model accounting for clinical factors [13].

These epidemiological studies are supported by mechanistic evidence that obesity may lead to chronic low-grade inflammation and dysregulation of endogenous growth factors linked to myelomagenesis [76,77], together suggesting that weight control may be an effective MM prevention strategy. Indeed, according to a compelling 2016 consensus statement, an expert panel convened by the International Agency for Research on Cancer concluded that there is sufficient

mechanistic evidence that a preventative relationship has been established between the "absence of body fatness" and MM [76]. In obesity, adipose tissue, including adipocytes in the bone marrow, is altered in ways that may promote carcinogenesis, including by creating an unfavorable tumor microenvironment in which MM can engraft and grow [44,78]. Notably, the adipose tissue of obese individuals leads to excess free fatty acids as well as altered levels of proinflammatory cytokines (eg, tumor necrosis factor α and interleukin 6), adipokines (eg, adiponectin and leptin), and metabolic peptide hormones (eg, insulin and insulin-like growth factor 1) [44,78,79]. Dysregulated levels of these biological compounds may fuel tumor initiation and influence the genetic characteristics of MM cells in ways that increase cell proliferation [80], reduce apoptosis [81], and contribute to immune cell evasion [82,83]. The implication of these factors is that weight loss may curb the contribution that excess adiposity-associated chronic inflammation and metabolic dysregulation have on MM development.

Beyond weight loss, the PROFAST study tests the hypothesis that "when we eat," not just "what or how much we eat," is relevant to cancer prevention [24,25,84,85]. There is evidence suggesting that chronic exposure to circadian rhythm disturbances may lead to metabolic dysregulation, upregulation of proinflammatory cytokines, and abnormal cell proliferation [21,86]. As food intake contributes to the setting of circadian clock rhythms in peripheral organs, such as by inducing changes in body temperature and through the action of hormones such as insulin and nutrient-sensing enzymatic and nuclear receptor signaling systems [21,87], the synchronization of feeding-fasting patterns with circadian rhythms may be important for preventing chronic diseases [24,26,27]. This hypothesis is supported by a large prospective study of patients with early-stage breast cancer, which observed that a short nightly fasting duration (<13 hours per night), compared with a nightly fasting of ≥13 hours, was associated with an increased risk of breast cancer recurrence [25]. In that same study, each 2-hour increase in the nightly fasting duration was associated with lower hemoglobin A_{1c} levels and a longer duration of nighttime sleep [25]. These findings are consistent with the results of population-based studies [24,26,27], including a large case-control study in Spain that observed that diurnal eating patterns, specifically in maintaining longer time intervals between the last meal of the day and initiation of sleep, were inversely associated with risk of breast and prostate cancer [27]. Similarly, two US-based studies of 2009-2010 National Health and Nutrition Examination Survey data evaluating biomarkers of breast cancer risk observed that a longer duration of nighttime fasting was associated with improved measures of glycemic control and systemic inflammation [24,26], aligning with pathophysiological mechanisms underlying cancer risk [76].

Results from these human observational studies are consistent with rodent studies demonstrating that mice subjected to a time-restricted (16-hour) fasting regimen of a high-fat diet during the sleep phase were protected against weight gain, abnormal glucose metabolism, and inflammation, all of which were associated with cancer outcomes [22,88-91]. Notably, protective effects were observed despite these mice having the same caloric intake as those that had ad libitum access to food and ate frequently throughout day and night [22], suggesting that the beneficial effects of this fasting regimen were partly mediated through mechanisms independent of calorie restriction. Together, these data provide a strong basis of our intervention aimed to curb the inflammatory and metabolic mechanisms shown to contribute to myelomagenesis [44,77].

Finally, and importantly, prolonged nightly fasting represents a lifestyle modification that is safe, practical, and acceptable for patients who otherwise are managed by a "watchful waiting" strategy. Patients with MM precursor conditions are reported to have diminished quality of life, increased comorbidities, and heighted anxiety and a sense of loss of control regarding their MM risk [61,62,92,93]. There is, therefore, a need to identify lifestyle-based interventions that patients can safely and practically adopt into their daily lifestyles and ultimately help curb disease progression. Fasting, as a practice, developed independently among different people groups and religions (eg, Ramadan in Islam) around the world [94], and intermittent fasting has become one of the most common dietary patterns reported in the United States [95]. Prolonged nightly fasting is attractive because of its simplicity and feasibility, as supported by evidence from clinical trials of time-restricted eating strategies [16,23], and, thus, may be a potentially effective disease prevention strategy at the population level [16].

The limitations of this study include the relatively small sample size of the study and the potential lack of sociodemographic and geographic diversity of participants due to recruitment occurring at a single academic institution, thus, possibly impacting generalizability of findings. Also, participants willing to participate in a 4-month prolonged overnight fasting intervention may not be representative of the general population of patients with overweight or obesity with MM precursors, and selection bias for patients who are motivated to participate in PROFAST could increase the study adherence rate. Furthermore, although participants in the intervention group are prescribed solely a prolonged overnight fasting regimen with no other recommendations regarding lifestyle patterns, it is theoretically possible that participants may change their dietary, physical activity, and sleep habits due to paying closer attention to the timing of their eating and evaluations of their body composition before and after the intervention. These changes may also impact outcomes.

In summary, the study described herein serves as an important first step in exploring the premise that prolonged nightly fasting is a practical, effective strategy to control obesity and intercept disease progression in individuals with MM precursor conditions. By evaluating the impact of this lifestyle intervention on relevant biomarkers of excess adiposity and myeloma tumor burden, this pilot study may generate hypotheses and inform further investigations in identifying clinical and public health strategies for MM prevention.

Abstract

Background: Weight gain following smoking cessation is a well-documented concern, often attributed to the absence of nicotine's metabolic influence. The adoption of Electronic Nicotine Delivery Systems (ENDS) has been used to achieve smoking cessation, with claims of aiding weight control. However, existing reviews present conflicting conclusions on ENDS' impact on weight status, necessitating a rigorous evaluation.

Objective: We aim to conduct a systematic review with meta-analysis to assess the actual impact of ENDS on weight status in individuals who have ceased or reduced conventional smoking. The primary goal is to provide clinicians with evidence-based insights into the potential effects of ENDS use as a smoking substitute on weight control.

Methods: Adhering to PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols) guidelines, our systematic review will analyze randomized and nonrandomized controlled trials, clinical trials (quasi-experimental), and prospective or retrospective cohort studies on the weight status effects of ENDS among individuals who have either quit or reduced smoking. Searches will include PubMed, Scopus, and Cochrane Library, covering the period from 2010 to January 2024. A gray literature search and supplementary searches will be performed. Data will be extracted independently by 2 reviewers and quality assessments will be conducted concurrently. Quality assessments will use Joanna Briggs Institute tools, 2020 version, along with bias assessments for internal validity and reporting bias based on the Catalogue of Bias. The included studies will be examined for any internal data reporting discrepancies by using Puljak's checklist. Meta-analysis and subgroup analyses (ie, general ENDS usage, ENDS use coupled with a reduction in smoking exceeding 50%, and exclusive ENDS use for achieving smoking cessation) are planned. Certainty of evidence will be evaluated using the Grading of Recommendations Assessment, Development, and Evaluation (GRADE) framework.

Results: The protocol has been registered in PROSPERO (CRD42023494974) and the entire systematic review is expected to be completed by April 2024. The main goal of this review is to retrieve all current human research studies investigating the influence of ENDS on weight management among individuals who have quit or reduced smoking. Furthermore, the review will assess the quality of these studies and examine potential biases to identify the most dependable evidence available. Dissemination strategies will include traditional journal publications, social media announcements, and a white paper. The latter, available for download and distributed at conferences, aims to reach a broad audience, including clinicians and ENDS users.

Conclusions: The review will address the importance of informing health care professionals and patients about the current and robust evidence regarding the effects of transitioning to ENDS for smoking cessation on weight status.

KEYWORDS

Electronic Nicotine Delivery Systems; body weight; smoking cessation; tobacco harm reduction; systematic review; meta-analysis

Introduction

Background

The phenomenon of weight gain following smoking cessation is a well-documented concern in scientific research [1]. Typically, individuals who quit smoking experience an average weight increase ranging from 4.67 to 4.8 kg after 1 year, with more than 10% experiencing a rise exceeding 10 kg [2,3]. This weight gain can primarily be attributed to the lack of nicotine's influence on metabolic processes, which includes appetite suppression and alterations to both lipolysis and lipogenesis [4,5].

In the past few years, there has been a notable increase in the adoption of Electronic Nicotine Delivery Systems (ENDS), commonly known as e-cigarettes, among individuals attempting to cease tobacco use [6]. Some who use ENDS do so for weight loss or weight management. The use of ENDS for weight loss was most prevalent among individuals with eating disorders, at 32% (n=178) [7]. This usage drops considerably in the general ENDS-using population. In the United States, 15% (13/84) of college students and 13.5% (62/459) of adults reported using ENDS for weight control [8,9]. Among US military recruits, 5.1% (11/223) of males and 6.0% (4/61) of females have used ENDS for this purpose [10]. In England, the figure stands at 4.6% (18/394) of current ENDS users [3].

Observational studies have also noted the practice of using vaping as a dietary substitution, where individuals vape flavored liquids to mitigate food cravings. This behavior, while less prevalent in England [3], has been reported in various surveys and interviews conducted in the United States [11,12].

Commercial entities have recognized these consumer patterns, resulting in the development and marketing of vaping products that claim to support weight loss. Numerous patents have been filed globally, and several companies have marketed vapor devices that propose to offer benefits such as fat burning, appetite suppression, and rapid weight loss [13,14]. These claims, often promoted through online sites and aggressive marketing strategies [13,15], are claims that have not been verified.

Previous Reviews

Recent reviews assert that there is insufficient evidence to draw definitive conclusions on the impact of ENDS on weight control in people who have ceased or reduced conventional smoking. The systematic review of Hod et al [16] of human and in vitro studies concluded that ENDS use is prevalent among the obese, although the authors state that causality cannot be determined due to the cross-sectional design of human studies. Moreover, the data are conflicting, with in vivo studies suggesting weight loss effects, but in vitro studies do not support this claim Thus, the authors underlined the need for further investigation to determine the impact of ENDS on weight control [16]. Another review by Hartmann-Boyce et al [17] found 2 ENDS studies, 1 involving ENDS as an adjunct to nicotine replacement therapy and the other comparing them to varenicline, both with wide CIs at all measurement time points. The CIs of weight change (kg) at the end of the treatment and 12 months encompassed both clinically significant weight loss and weight gain [17]. Therefore, the authors stated that "data are needed on whether using e-cigarettes to quit smoking affects post-cessation weight change" [17].

Research Question

Given the rise of ENDS as an alternative to traditional smoking, and their associated perceived benefits for weight control, we aim to rigorously evaluate the actual impact of ENDS on weight status in individuals who have ceased or reduced conventional smoking. For this purpose, we intend to conduct a systematic review with meta-analysis to analyze human clinical studies that provide longitudinal data on body weight among participants who have replaced cigarette smoking with ENDS use.

Population, Intervention, Comparator, and Outcomes Criteria

The research strategy follows the Population, Intervention, Comparator, and Outcome (PICO) approach as follows: population—adults who smoke cigarettes, intervention—complete or partial substitution of ENDS for cigarettes, comparator—within-subject changes baseline to the end of the study, and outcomes—changes in body weight.

Objectives

We will conduct a systematic review with a meta-analysis to critically assess and synthesize available human studies on the weight status effects of ENDS among individuals who have either quit or reduced smoking. Our goal is to critically evaluate and synthesize the available evidence to offer clinicians high-quality insights into the potential effects of ENDS use as a substitute for smoking, specifically concerning weight control. Thus, our aim is to equip clinicians with robust evidence to enhance their treatment recommendations and strategies for individuals who smoke, aiding them in making informed decisions and plans.

Methods

Overview

In adherence to the PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols) requirements

[18], this protocol is registered with PROSPERO (CRD42023494974), and any deviations will be transparently reported within the review. The review team (GRMLR, MAQ, LF, EA, and RP), led by RP, has substantial expertise in conducting literature reviews and an expert background in tobacco control, tobacco harm reduction, and ENDS.

Database Search and Secondary Searches

The databases to be included are PubMed, Scopus, and CENTRAL Cochrane Library. Using the keywords specific to each database (ie, weight, BMI, "body mass index," "electronic cigarette," "e-cigarette," and "electronic nicotine"), searches will be performed in the title and abstract fields in PubMed, and in the title, abstract, and keywords in Scopus. Cochrane Library will be searched for trials. The search will include the period from 2010 to January 2024, in line with the date of the first peer-reviewed research studies on ENDS. Language restrictions will not be applied. In compliance with PRISMA-P, the search strategy example is detailed in Multimedia Appendix 1. Retrievals will be downloaded into EndNote (Clarivate), and duplicates will be removed.

A secondary search of the existing reviews, conducted independently by 2 reviewers, will be conducted to identify any additional studies. Next, the references of the included studies will be scrutinized to identify additional studies. Finally, the included studies will be citation chased (ie, snowball search) through Google Scholar. The studies excluded during the thorough full-paper review will be documented.

The list of selected studies will be forwarded to 2 medical experts to validate that all pertinent studies have been included. In addition, a comprehensive gray literature search will be conducted on the websites of 16 weight-related medical organizations (Multimedia Appendix 1).

Inclusion and Exclusion Criteria

The selected study designs will include randomized and nonrandomized controlled trials, clinical trials (quasi-experimental), and prospective or retrospective cohort studies. The initial exclusion will be based on titles and abstracts reviewed. Exclusion criteria will be by publication types (ie, editorials, letters, commentaries, protocols, narrative reviews, conference abstracts, and dissertations), study designs (ie, vitro, animal studies, inhalation toxicology, biomarker studies, surveys, and qualitative studies), adolescent populations, and studies lacking baseline or follow-up weight data. A total of 2 reviewers will independently conduct the exclusion process, with any discrepancies resolved through discussion.

The next process will involve a thorough review of full papers, guided by 3 inclusion criteria, including study designs, availability of data before and after testing participants who substituted ENDS for smoking, and outcome data on weight. All 3 criteria will have to be satisfied for a study to be included.

Review team members will undergo training on the inclusion criteria through analysis of 3 included studies. Two independent reviewers will then conduct the inclusion and exclusion assessments on the studies, resolving any disparities through discussion. The objective is to attain a high level of agreement between reviewers on the study selection process. The project leader will make the final decision regarding the inclusion and assessment of the studies.

Data Extraction

Using a standardized form derived from Joanna Briggs Institute (JBI) and Cochrane Collaboration inventories [19,20], data extraction will be conducted by 2 reviewers independently, followed by cross-checking for accuracy. The full data extraction form is provided in Multimedia Appendix 1. The data extraction form includes bibliographic details, study population demographics, intervention descriptions, and weight measurements. The form will be pilot-tested and revised as necessary.

In cases where the published data are insufficient or absent, an email requesting additional details will be sent to the corresponding author. Findings from the included studies will be reported in a dual format. First, individual studies will be summarized with a concise narrative description. Second, study tables will be formulated incorporating elements derived from the data extraction and quality assessments (refer to the subsequent section).

Quality Assessment and Risk of Bias

Quality assessments will use JBI tools, 2020 version [21], along with bias assessments for internal validity and reporting bias based on the Catalogue of Bias [22] (Multimedia Appendix 1). Examination of studies for any internal data reporting discrepancies will be conducted using the checklist proposed by Puljak et al [23] (Multimedia Appendix 1). The data extraction forms will be pilot-tested and revised if necessary. The comprehensive evaluation of study quality will involve calculating an overall rating through a rubric that integrates the JBI score and biases checklist. The overall study quality will be categorized according to the Cochrane guidelines—low risk of bias, some concerns, and high risk of bias [20]. Quality assessment will be conducted concurrent with the data extraction, and 2 reviewers will independently perform assessments. Discrepancies will be resolved through discussion or decided by the project leader.

No studies will be excluded on the basis of their quality assessment or bias. Studies deviating from the JBI quality assessment criteria or exhibiting biases will be documented in the study table. These limitations will be explicitly identified during the data analysis and referenced in the discussion section of the review.

Data Analysis and Synthesis

Studies will be categorized by risk of bias, and summaries will include study design, participant and intervention characteristics, and main findings. A meta-analysis of change scores is planned, where the change score is defined as mean kg at the end of the study minus mean kg at the baseline. Three subgroup analyses will be performed, focusing on (1) general ENDS usage, (2) ENDS use coupled with a reduction in smoking exceeding 50%, and (3) exclusive ENDS use with the goal of smoking cessation. Publication bias will be assessed if a minimum of 10 studies are included.

Grading of Recommendations Assessment, Development, and Evaluation

Certainty of evidence will be evaluated using the Grading of Recommendations Assessment, Development, and Evaluation (GRADE) framework [24].

Results

The protocol has been registered in PROSPERO (CRD42023494974) and the entire systematic review is expected to be completed by April 2024. The primary objective of this review is to compile all existing human research studies concerning the impact of ENDS on weight control in people who ceased or reduced smoking. In addition, the review will rigorously evaluate the quality of these studies and scrutinize potential biases to emphasize the most reliable and available evidence. The planned review will also identify studies that may exhibit reporting bias, thereby enabling a more accurate representation of the effects of ENDS on weight control within the ongoing discourse on tobacco harm reduction.

Discussion

Principal Findings

This protocol is intended to provide the methodological framework for a systematic review and meta-analysis of the actual impact of ENDS on weight status in individuals who have ceased or reduced conventional smoking.

Many research protocols lack comprehensive planning for dissemination and knowledge translation activities beyond the conventional approach of publishing the review in a peer-reviewed journal and presenting findings at conferences. Naturally, this review will be disseminated through these traditional channels. Following an approach previously described [25], some additional strategies will be adopted. Briefly, upon acceptance, the project protocol will be published in JMIR Research Protocols and the final review with meta-analysis will be published in a peer-reviewed journal. In addition, efforts will be made to translate the review's abstract into several languages. To enhance visibility, the availability of the review will be disseminated via social media platforms.

A white paper will be produced and made available for download on a dedicated website, and we anticipate disseminating it to medical associations and distributing it at conferences. The goal is to ensure the widespread of findings among clinicians and individuals currently using or considering ENDS. Given that a significant number of physicians and health care providers harbor misconceptions regarding the health impacts of nicotine [26,27], the white paper will incorporate a dedicated section focusing on nicotine. Infographics drawn from the white paper will be disseminated to current and potential ENDS users via user advocacy organizations [25]. Traditional review publication methods may not effectively reach the stakeholders who will benefit from clear and accessible updated sources of information. The objective of these activities is to ensure broad dissemination of the review findings to multiple audiences.

It is crucial to acknowledge the potential limitations arising from both the number and the quality of the studies that will be included in this systematic review. The limited quantity of available studies can restrict the scope and depth of conclusions drawn, leading to gaps in understanding and potentially biasing the overall assessment. Furthermore, the quality of the studies significantly impacts the reliability of the review's conclusions. If the included studies exhibit methodological flaws, biases, or insufficient rigor, the overall evidence may be weakened, resulting in tentative or inconclusive findings.

Conclusions

In conclusion, tobacco consumption constitutes a significant public health burden. Electronic cigarettes may represent a viable option for those attempting to quit smoking. Furthermore, there is a growing interest in these devices due to their potential benefits for weight control, especially for counteracting the short-term weight gain associated with smoking cessation. Therefore, it is essential to inform both patients and health care professionals about the most current and robust evidence regarding the effects of switching to electronic cigarettes for smoking cessation on weight status. This review, including meta-analysis, aims to contribute to this objective.

Acknowledgments

This investigator-initiated study was sponsored by ECLAT srl, a research-based spin-off company of the University of Catania, with the help of a grant from the Foundation for a Smoke-Free World, Inc a US nonprofit 501(3)(c) private foundation and a bursary from the Dipartimento di Medicina Clinica e Sperimentale at the University of Catania Italy (Bando N 1355 2020 Borsa di Ricerca). Abstract

Background: Syphilis in pregnancy and congenital syphilis are growing public health issues worldwide. Several factors can influence their occurrence in the population. Therefore, understanding the epidemiology of this condition and the factors that influence its occurrence is fundamental for decision-making by clinicians and health managers. However, so far, no systematic review has summarized and analyzed data on the incidence, prevalence, and predictors of these diseases in Brazilian cities, considering different sociocultural, demographic, economic, sanitary, and spatial-temporal characteristics presented across locations.

Objective: We propose a systematic review protocol to gather and analyze data on the incidence, prevalence, and risk or associated factors of syphilis in pregnancy and congenital syphilis in Brazil, taking into account different local or regional contexts.

Methods: Searches will be conducted in CINAHL, MEDLINE, LILACS, Embase, and Web of Science databases. We will include observational studies (ie, cross-sectional, longitudinal, or case-control studies), analyzing the incidence, prevalence, and risk or associated factors of syphilis in pregnancy and congenital syphilis in Brazil from primary data. The diagnosed syphilis will be assessed based on direct pathogen detection tests or through immunological, treponemal or nontreponemal tests, following Brazilian protocols for diagnosing syphilis. The studies are currently undergoing screening in the databases, and after this step, 2 reviewers will perform all identified documents. The Newcastle-Ottawa Scale and the GRADE (Grading of Recommendations, Assessment, Development, and Evaluations) system will be used to assess methodological quality and quality of evidence of studies, respectively. The Kappa coefficient will assess the agreement between researchers in each study stage. Cochran Q test will assess the heterogeneity among studies. Then, a random-effects meta-analysis will be performed.

Results: Results will be discussed based on subgroup analysis, which is as follows: (1) type of syphilis (in pregnancy or congenital), (2) type of study (case-control and cross-sectional studies for analysis of associated factors and longitudinal studies for risk factors), and (3) contextual factors (ie, region of country, socioeconomic and demographic characteristics, and year of study). This systematic review is expected to be completed by December 2023, and our results will be disseminated through publication in peer-reviewed journals and scientific events.

Conclusions: This systematic review aims to assist health care managers and professionals in their decision-making to control these diseases in Brazil, considering location heterogeneity. Furthermore, countries with health systems and demographic and socioeconomic contexts similar to those of Brazil may benefit from this information.

KEYWORDS

sexually transmitted diseases; epidemiology; prevalence; incidence; Brazil; syphilis; pregnancy; sociocultural; economic; congenital syphilis; heterogeneity; decision-making

Introduction

Syphilis is a sexually transmitted infection caused by *Treponema pallidum* and is a major public health issue worldwide [1]. Despite the efforts of health care professionals to control this infection in Brazil, cases of syphilis have increased in recent years [2-4], impacting public and private health care systems and highlighting the need to improve disease surveillance [5,6]. Globally, 2 million out of 36 million syphilis infections occur in pregnant women [7], resulting in congenital syphilis (infection of the fetus) and adverse events (eg, early fetal death, stillbirth, premature birth, low birth weight, and neonatal death) [8,9].

Recently, an outbreak of syphilis has been observed among men and women in more economically developed countries, which can be explained by changes in the sexual behavior of individuals and increased exposure to the risk of infection due to a false sense of security stemming from new treatments and an increased search for sexual partners over the internet [10]. In this context, understanding the epidemiology and control of this disease becomes more complex and difficult.

Syphilis in pregnancy and congenital syphilis can be controlled with health care measures, such as access to prevention services, early diagnosis, and treatment [4,11,12]. Conversely, these measures require the analysis of epidemiological data and predictors [4,11]. Although studies in Brazilian cities analyzed the incidence, prevalence, and predictors of syphilis in pregnancy and congenital syphilis [13-17], each city presented different sociocultural, demographic, economic, sanitary, and spatial-temporal characteristics, hindering data extrapolation to the national territory.

Summarizing and analyzing the incidence, prevalence, and risk or associated factors of syphilis in pregnancy and congenital syphilis must take into account location heterogeneity. This type of analysis enables a broader understanding of the problem, improves control strategies and equity in disease management, and establishes reference data to help disease screening efforts in Brazil. Despite the relevance of the theme, no systematic review has been conducted to date on the epidemiological data of gestational and congenital syphilis or its predictors, subgrouping and analyzing this information from different contexts.

Thus, we propose a systematic review protocol to gather and analyze data on the incidence, prevalence, and risk or associated factors of syphilis in pregnancy and congenital syphilis in Brazil, taking into account different local or regional contexts.

Methods

Study Design

This systematic review protocol was developed according to PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) [18], which will also guide the systematic review. The protocol has been registered in PROSPERO (CRD42022329329).

Eligibility Criteria

Observational studies whose sample comprised cases of syphilis in pregnant women or newborns in Brazil will be included in the systematic review. Table 1 [2,19,20] presents the eligibility criteria used in the review.

Table 1. Eligibility criteria for the systematic review.

Variables	Inclusion criteria	Exclusion criteria
Study design	• Cross-sectional, longitudinal, or case-control studies conducted in Brazil • Studies based on primary data	• Reviews, opinion articles, editorials, or publications without primary data or not peer-reviewed • The most complete and recent data will be used if studies report the same data in multiple sources [19,20].
Population and location	• Studies in which the sample involved pregnant women or newborns with syphilis • Studies with residents in Brazil	• Studies with samples involving other populations (non-pregnant women or men)
Outcomes	• Studies reporting the prevalence or incidence of Treponema pallidum (syphilis) infection or its risk or associated factors in pregnant women or neonates • Studies that diagnosed syphilis based on direct pathogen detection tests or through immunological, treponemal, or non-treponemal tests, in accordance with Brazilian protocols for diagnosing syphilis [2]	• Studies presenting the incidence or prevalence of combined infections (ie, syphilis with other sexually transmitted infections) and not allowing isolated analysis
Language	—[a]	• No restriction regarding language or year of publication
Time frame	—	• No restriction regarding to year in which the study was carried out or published

[a]Not applicable.

Study Selection

Textbox 1 presents the search strategy. Searches will be conducted in the CINAHL, MEDLINE, LILACS, Embase, and Web of Science databases. Grey literature will be also searched using the reference lists of relevant studies in addition to using databases such as Open Gray and Google Scholar. Further, reports with epidemiological data on syphilis in the country will be screened in the electronic database of the Brazilian Ministry of Health.

Two researchers will independently search, identify potentially eligible studies, and remove duplicates. Then, inclusion and exclusion criteria will be applied to titles and abstracts, eligible studies will be read in full, and reasons for exclusion will be recorded. Disagreements between researchers will be resolved by discussion or with a third researcher. The flowchart of the study selection is described in Figure 1.

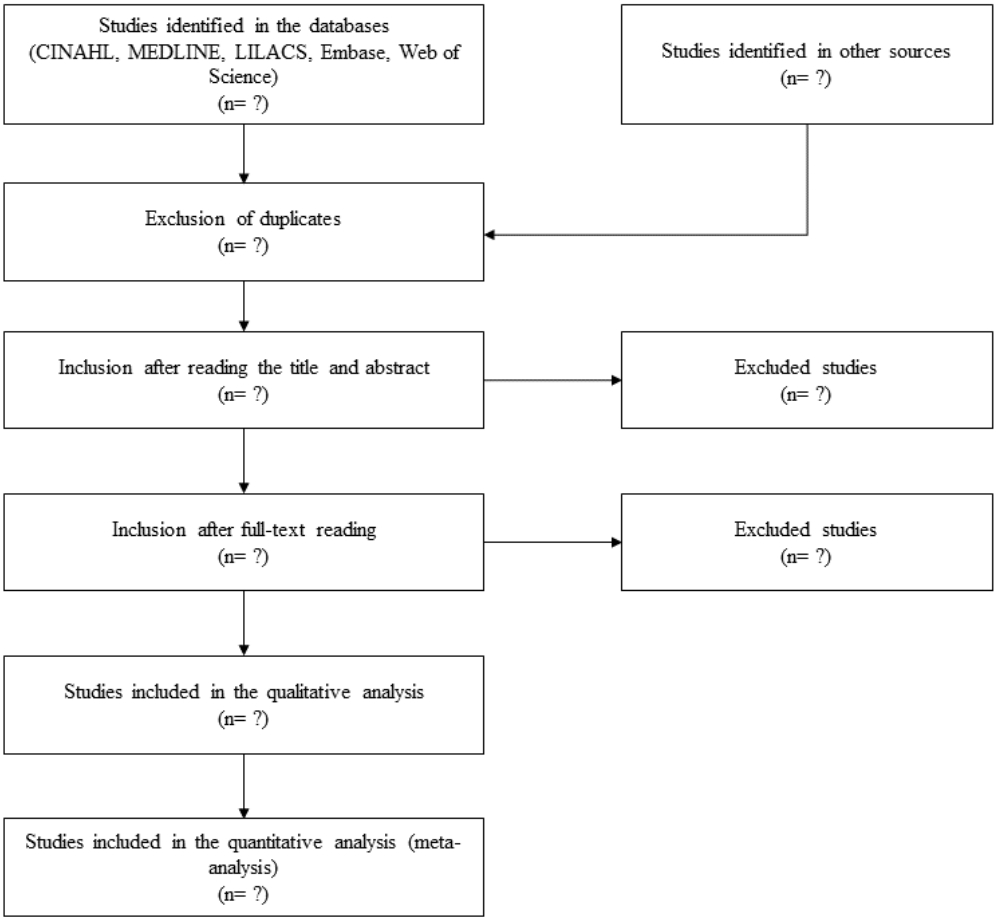
Figure 1. Flowchart of the study. The numbers are to be confirmed.



Assessment of Methodological Quality and Quality of Evidence

The Newcastle-Ottawa Scale will be used to assess the methodological quality of studies [21]. This scale includes 8 items categorized into 3 domains (ie, selection, comparability, and outcome or exposure) to assess the risk of bias in nonrandomized studies. The Newcastle-Ottawa Scale has specific tools for cohort and case-control studies. Thus, adaptations will be made to allow the proper assessment of the potential sources of bias in cross-sectional studies. In addition, quality of evidence will be analyzed using the GRADE (Grading of Recommendations, Assessment, Development, and Evaluations) system, which classifies evidence as high, moderate, low, and very low [22,23].

Data Extraction and Synthesis

The following data will be extracted and entered into a Microsoft Excel spreadsheet: first author, year of publication, type of study (eg, longitudinal, cross-sectional, or case-control), type of syphilis (eg, in pregnancy or congenital), the diagnostic method used, study location (eg, city and state), participants (eg, sample size, age, type of population, and presence of co-infection), population setting (eg, community, health care centers, schools, neighborhoods, and the environmental context of the participants), date of data collection, sampling method, and main results (eg, incidence, prevalence, and risk or associated factors).

After summarizing the studies, results will be discussed based on subgroup analysis, as follows: (1) type of syphilis (eg, in pregnancy or congenital), (2) type of study (eg, case-control and cross-sectional for analysis of associated factors and longitudinal for risk factors), and (3) contextual factors (eg, region of country, socioeconomic and demographic characteristics, and year of study).

Statistical Planning

Kappa coefficient will assess the agreement between researchers [24]. The unadjusted incidence or prevalence and the standard error will be recalculated based on the numerator and denominator values presented in each study. Furthermore, the prevalence or incidence may be reported using the direct method of standardization, adjusted for the variables of age, study location, and presence of co-infection. If the study does not provide data for calculating adjusted incidence or prevalence, the researchers will request this information from the study authors.

Additionally, a meta-analysis will be performed using a random-effects model due to the potential heterogeneity among studies. The random-effects model is applied when the aim is to combine several studies that have similar objectives but are conducted in different ways (ie, exhibiting methodological

heterogeneity) [25]. Moreover, the Freeman-Tukey double arcsine transformation will stabilize variances to maintain the estimates of individual effects of each study [26]. Cochran Q test will assess the heterogeneity among studies [27]. I^2 values of 25%, 50%, and 75% will represent low, medium, and high heterogeneity, respectively [28].

Studies will undergo a subgroup analysis using clustering variables (eg, study location, study population, method of syphilis diagnosis, mean sample size, year of data collection, sampling methods, and methodological quality) to investigate possible sources of heterogeneity [20].

Analyzes will be performed using the Review Manager (RevMan) software (version 5.4; Cochrane Collaboration) and the R software (R Core Team), considering a 95% CI.

Results

The protocol has been registered in PROSPERO (CRD42022329329). The screening of the studies in the databases has already started, and the entire systematic review is expected to be completed by December 2023. The results of the study will provide evidence that can support decision-making regarding strategies to control syphilis in Brazil and countries with similar health, demographic, and socioeconomic profiles. Results will be disseminated through publication in peer-reviewed journals and presentation at scientific events.

Discussion

Expected Results and Practical Implications

After a preliminary search, we found studies in Brazilian cities that analyzed epidemiological data and predictors of syphilis in pregnancy and congenital syphilis [13-17,29]. However, no study has organized and summarized data to perform a broader analysis of this public health issue.

Summarizing local studies will allow the analysis and discussion of epidemiology and risk or associated factors of syphilis in pregnancy and congenital syphilis, considering sociocultural, demographic, spatial-temporal, economic, and sanitary differences in each location. Thus, this systematic review will help in the decision-making of health care managers and professionals to control these diseases in Brazil according to location heterogeneity.

Limitations

Some limitations that may compromise the quality of evidence can be found in the systematic review, such as heterogeneity among studies, wide CIs, and uncertainty of estimated effects.

Acknowledgments

The authors would like to thank Probatus Academic Services for providing scientific language translation and revision.

Abstract

Background: Blockchain has been proposed as a critical technology to facilitate more patient-centric research and health information sharing. For instance, it can be applied to coordinate and document dynamic informed consent, a procedure that allows individuals to continuously review and renew their consent to the collection, use, or sharing of their private health information. Such has been suggested to facilitate ethical, compliant longitudinal research, and patient engagement. However, blockchain-based dynamic consent is a relatively new concept, and it is not yet clear how well the suggested implementations will work in practice. Efforts to critically evaluate implementations in health research contexts are limited.

Objective: The objective of this protocol is to guide the identification and critical appraisal of implementations of blockchain-based dynamic consent in health research contexts, thereby facilitating the development of best practices for future research, innovation, and implementation.

Methods: The protocol describes methods for an integrative review to allow evaluation of a broad range of quantitative and qualitative research designs. The PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) framework guided the review's structure and nature of reporting findings. We developed search strategies and syntax with the help of an academic librarian. Multiple databases were selected to identify pertinent academic literature (CINAHL, Embase, Ovid MEDLINE, PubMed, Scopus, and Web of Science) and gray literature (Electronic Theses Online Service, ProQuest Dissertations and Theses, Open Access Theses and Dissertations, and Google Scholar) for a comprehensive picture of the field's progress. Eligibility criteria were defined based on PROSPERO (International Prospective Register of Systematic Reviews) requirements and a criteria framework for technology readiness. A total of 2 reviewers will independently review and extract data, while a third reviewer will adjudicate discrepancies. Quality appraisal of articles and discussed implementations will proceed based on the validated Mixed Method Appraisal Tool, and themes will be identified through thematic data synthesis.

Results: Literature searches were conducted, and after duplicates were removed, 492 articles were eligible for screening. Title and abstract screening allowed the removal of 312 articles, leaving 180 eligible articles for full-text review against inclusion criteria and confirming a sufficient body of literature for project feasibility. Results will synthesize the quality of evidence on blockchain-based dynamic consent for patient-centric research and health information sharing, covering effectiveness, efficiency, satisfaction, regulatory compliance, and methods of managing identity.

Conclusions: The review will provide a comprehensive picture of the progress of emerging blockchain-based dynamic consent technologies and the rigor with which implementations are approached. Resulting insights are expected to inform best practices for future research, innovation, and implementation to benefit patient-centric research and health information sharing.

Introduction

Rationale

Blockchain has been proposed as a critical technology to advance patient engagement and facilitate a shift toward improved patient centricity in health research [1]. For instance, in addition to being used as a means to enhance the integrity and transparency of data in clinical trials [2,3], research indicates that it can be applied to coordinate and document dynamic consent for patient-centric health information sharing [4,5] in which patients' needs, wants, and perspectives are optimally considered [6].

Dynamic consent is a procedure that allows patients and research participants to continuously review and renew their consent to use their private health information. Compared to conventional one-time obtainment and documentation of informed consent, dynamic consent strives to give individuals greater control over their data and to ensure their preferences are respected throughout their participation [7,8]. Moreover, dynamic consent can facilitate ongoing engagement for the secondary use of data (ie, for purposes other than the initial purposes for which consent was given). Thus, dynamic consent may open up novel opportunities for ethical and compliant research, data sharing, and longitudinal researcher-patient engagement beyond the scope of the original agreement [9].

Blockchain technology offers functionality and efficiencies that are difficult to achieve with traditional data systems. First, it can be applied to facilitate dynamic consent by establishing a privacy-preserving, universally verifiable, and immutable record of the consent process [9]. The decentralized nature of blockchain ensures that these records cannot be altered by a single party, safeguarding the integrity of the participant's documented consent independent of any 1 system or device. Moreover, blockchain offers means for mathematical and privacy-preserving verification of (consent) records and associated user identities, with no dependence on trusted intermediaries for reliable recordkeeping [10]. Such can be used for decentralized authentication and authorization, bolstering individual autonomy. In addition, using blockchain in dynamic consent can enhance the transparency of the process. Research participants can track how their data are used and can be provided with means to readily revise their consent [11]. The use of dynamic consent can inspire more people to participate in clinical research by fostering trust between participants and researchers [8]. Additionally, dynamic consent allows for continuous engagement and communication with research participants throughout and after a study, registry, or repository participation [12]. Last, blockchain technologies are currently used to automate downstream researcher access to data based on individuals' preferences without the burden and expense of manual curation [9].

While promising, dynamic consent based on blockchain technology is a relatively new concept, and it is unclear how well it functions in real-world health research environments. Although numerous studies and pilot projects have been conducted to describe the potential application of blockchain technology to facilitate dynamic consent capabilities [13-15], it is necessary to critically evaluate the articles' scientific methodology and results. Further, there are few best practices published about implementation methodology for blockchain-based dynamic consent. Moreover, there is a need for critical appraisal of approaches that capitalize on blockchain's abilities to empower individuals in managing their digital data and identities. For example, self-sovereign identity (SSI) seems particularly pertinent for ongoing authentication and authorization in patient-centric research collaborations [16].

Yet, as of December 2022, the authors could not locate any published systematic or scoping review to examine the current state of blockchain-based dynamic consent features and implementations. Additionally, no reviews of blockchain-based dynamic consent are currently registered as "in progress" with PROSPERO (International Prospective Register of Systematic Reviews), the systematic review registry [17]. Therefore, there is a need for a systematic review to capture a wide range of literature to establish the scope and quality of evidence for blockchain-based dynamic consent features and implementations in clinical settings.

Objectives

We aim to conduct a systematic integrative research review to synthesize a wide range of evidence regarding blockchain-based dynamic consent solutions, thereby informing future innovation research and practice in this domain. The goal is to identify blockchain-based dynamic consent implementations, the technology's impact, and potential best practices for research, innovation, and implementation.

Research Questions

The following research questions (RQs) will be used to guide the analysis and critical appraisal:

- RQ1: What are the current implementations of dynamic consent involving blockchain and their objectives for health information sharing and health research? What empirical evidence is provided for these implementations?
- RQ2: What are the risks, challenges, and opportunities of applying blockchain-based dynamic consent for health information sharing and health research?
- RQ3: What are the technical, spatial, and temporal aspects of SSI for different blockchain-based dynamic consent systems for health information sharing and health research?
- RQ4: What are the future research directions for research, innovation, and implementation of blockchain-based dynamic consent systems for health information sharing and health research?

A summary of how RQs are addressed by the various research methods is provided in Table 1.

Table 1. Research questions and methods to address them.

Research questions	Associated research methods
RQ1: What are the current implementations of dynamic consent involving blockchain and their objectives for health information sharing and health research? What empirical evidence is provided for these implementations?	• Include only publication years since 2016 (current), and only Technology Readiness Level 6 or higher (actual implementations). • Use integrative design that considers different sources and varied research methodologies. • Perform systematic data extraction and evaluation on implementations' development status and empirical evidence.
RQ2: What are the risks, challenges, and opportunities of applying blockchain-based dynamic consent for health information sharing and health research?	• Perform systematic data extraction and evaluation on implementations' effectiveness, efficiency, satisfaction, compliance, challenges, and limitations.
RQ3: What are the technical, spatial, and temporal aspects of self-sovereign identity for different blockchain-based dynamic consent systems for health information sharing and health research?	• Perform systematic data extraction and evaluation on implementations' consideration of self-sovereign identity standards and capabilities.
RQ4: What are the future research directions for designing, implementing, and validating blockchain-based dynamic consent systems for health information sharing and health research?	• Systematic data extraction and evaluation of articles' future research suggestions and description of best practices regarding design, implementation, and validation. • Critical appraisal and synthesis of collected data from RQ1-4 into best practices for research and innovation.

Methods

Protocol and Registration

This protocol demonstrates a priori development of the research plan. It was registered at PROSPERO on February 15, 2023 (registration number CRD42023396983) [18], before initiating literature review activities. In addition, a timestamped and immutable cryptographic record of the protocol was generated using blockchain-anchoring technology by Triall (Clinblocks BV), allowing for indisputable and independent verification of the protocol and its exact contents at the registered time.

The PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols) checklist [19,20] was referenced to prepare this protocol.

Study Design

The review will accumulate and synthesize the global published literature about blockchain-based dynamic consent, including quantitative, qualitative, and mixed methods research articles. We will use integrative research review methodology for a comprehensive review of diverse literature [21]. Specifically, integrative reviews aim to provide a comprehensive and holistic understanding of a particular phenomenon or problem by synthesizing evidence from diverse research methodologies. For example, an integrative review may include case studies, observational studies, mixed methods, and qualitative methods that inform theory. By synthesizing a combination of diverse research methodologies, an integrative review allows researchers to develop new theories or models as well as identify gaps in the literature that need to be addressed by future research [22,23]. We plan to identify literature gaps and suggest methods for strengthening future research designs accordingly [24]. By critically appraising current implementations of blockchain-based dynamic consent, we also plan to inform best practices for future innovation and implementation.

To ensure precision, we will adopt the following definitions:

A blockchain is a decentralized, distributed ledger that records information about transactions or activities across a network of computers. Blocks consist of interconnected, encrypted groups of records [25].

Dynamic consent is a method of electronic consent that is flexible, configurable, and can honor an individual's consent preferences across a spectrum of choices over time [7,8].

The protocol is organized to use the integrative review methodology proposed by Whittemore and Knafl [21] and augmented by the PRISMA-P checklist [19,20].

Problem Identification

To progress with blockchain-based dynamic consent, it is critical to advance high-quality research and establish guidance for innovation and implementation. However, most papers to date

have concentrated on theoretical applications and proofs of concept. Despite the acknowledged requirement for high-quality data and scientific rigor [26], evidence collection has received little attention.

Literature Search

The integrative review will focus on published articles about blockchain-based dynamic consent. Databases selected to search the indexed peer-reviewed academic literature include CINAHL, Embase, Ovid MEDLINE, PubMed, Scopus, and Web of Science (all databases). Gray literature (which is described in various ways but typically includes nearly everything not published in a peer-reviewed journal [27]) will be included in the literature review because a significant portion of relevant research and innovation in this fast-moving field takes place outside of academia. Further, gray literature allows for a more comprehensive assessment of the field's progress [28]. While gray literature can be captured in some of the indices listed above, additional search engines selected to identify gray literature include Electronic Theses Online Service, ProQuest Dissertations and Theses, Open Access Theses and Dissertations, and Google Scholar.

Eligibility Criteria

Eligibility criteria reflect PROSPERO questions and requirements [29]. Not all PROSPERO data fields are pertinent for this integrative review. The eligibility criteria are summarized and presented in Textbox 1.

Textbox 1. Article inclusion and exclusion eligibility criteria.

Inclusion criteria

- Original research articles (architecture, system designs, framework, scheme, model, platform, approach, protocols, test results, and algorithms)
- Any type of research methodology, including quantitative, qualitative, mixed methods, and descriptive narratives
- Describes an actual blockchain-based dynamic consent system (technology readiness level 6 or higher)
- Solutions are implemented in, or intended for, human health-oriented care or research contexts
- Publication years since 2016
- English language articles

Additional sources of gray literature for inclusion criteria

- Scientific or government reports
- Books and book chapters
- Conference papers or proceedings
- Theses

Exclusion criteria

- Review articles that summarize a body of existing literature (although review articles will be examined to perform backward literature tracking)
- Abstracts only
- Letters to the Editor
- Non-English articles
- Secondary research where an author describes work from another publication
- Articles discussing only proposed, potential, or theoretical applications of blockchain-based dynamic consent
- Articles unrelated to the topic

Additional sources of gray literature for exclusion criteria

- Magazine publications
- Interviews
- White papers
- Patents
- Preprints self-posted by the author

Types of Articles to Be Included

Inclusion and exclusion criteria reflect academic and gray literature sources to capture a vast body of literature for the integrative review. These criteria are deliberately broad because few empirical studies are available for inclusion. Therefore, we will include quantitative, qualitative, mixed methods, and descriptive articles from various sources. Further, review articles are included to permit backward citation tracking. A population,

intervention, control, and outcomes format was used to guide the article selection criteria as follows.

Participants and Population

Articles must feature participants who would use a blockchain-based dynamic consent solution. Populations may include—but are not limited to—patients, research participants, providers, staff members, and research administrators. Some studies may not assess the actual users.

Interventions and Exposures

Rather than a health intervention, participant exposure involves interaction with a dynamic consent solution. The blockchain-based dynamic consent solution must demonstrate sufficient development progress for evaluation. We evaluated the technology described in each article using a modified Technology Readiness Level (TRL) framework that includes technology descriptions from both the US Government Accountability Office [30] and the US Department of Defense [31]. TRL frameworks provide guidelines about the nature of evidence and progress expected for each level of technology development on a scale of 1 (idea formulation and review of scientific literature) to 9 (ready for full-scale production and commercialization). Government Accountability Office guidelines allow consideration and early negotiation with vendors whose products meet the criteria of TRL 6 (representative model or prototype in a relevant environment) or higher. Therefore, for this integrative review, descriptions of dynamic consent solutions must meet the criteria for TRL 6 or higher for inclusion. Our preliminary examination of the full-text articles has confirmed a sufficient body of literature with blockchain-based dynamic consent products at and above this threshold.

Comparators and Control

While we would like to capture comparisons of blockchain-based systems to other comparator systems, we are unaware of any published head-to-head comparisons. Therefore, we included studies without comparators if they meet all other eligibility criteria.

Context

The studies must apply to a health research context, which is, they must describe intended or actual application to the sharing and use of health information for research purposes. Publication years must be 2016 or later to capture the modern implementations of blockchain in this context.

Main Outcome

The review is intended to capture evidence of progress with blockchain, and dynamic consent technology related to health research. Several components will be collected about the implementation or commercialization stage, effectiveness, efficiency, satisfaction, regulatory compliance, and methods of managing identity.

Search Terms

The search strategies were determined through team discussion and were reviewed by an experienced academic librarian at the University of Colorado Denver Auraria Library.

The blockchain-based dynamic consent search strategy includes 2 primary blocks of search terms: “blockchain” and “dynamic consent” within a health care or health research setting. The blocks of terms include synonyms and related concepts, such as using the search term “distributed ledger” for “blockchain.”

Because exact terms, such as “dynamic consent,” may not be used in the desired articles, a list of synonyms was generated for “dynamic,” including: “progressive,” “personalized,” “customized,” “interactive,” “modify,” “modifiable,” “revocation,” “revocable,” and “revoking.” These synonyms will be searched within the proximity of other pertinent terms. For example, we propose using synonyms of “dynamic” within 5 words of terms representing “consent” as a verb or noun, including: “consent,” “permission,” “grant,” “authorize,” “authorization,” “allow,” “agree,” and “agreement.”

Search strategies used character substitutions, such as “decentrali?ed,” to capture American and British English spelling variations (eg, decentralized and decentralised, respectively). Further, word truncations were used to capture related word endings, such as “consent*,” to capture “consent,” “consents,” and “consenting.” The search strategy was customized for each index or database’s unique syntax and capabilities. The complete search terms and syntax are presented for a sample MEDLINE search in Multimedia Appendix 1.

Additional scientific articles were identified using manual backward and forward citation tracking of review articles obtained during the search. Backward citation tracking, also referred to as “backward chaining,” “footnote chasing,” and “reference list searching,” is an umbrella term for finding articles directly or indirectly from the reference section of articles being reviewed [28]. Forward citation tracking, also called “forward chaining,” aims to identify additional literature among the articles that cite one of the selected articles [32]. These additional abstracts were obtained and reviewed for inclusion.

Several gray literature articles were incidentally identified using the search process described above. Theses and dissertations were identified with iterations of the search terms to augment the gray literature search process. Google Scholar was searched using the advanced search screen and Boolean operators. Forward citation tracking was facilitated by clicking the “cited by” option.

Article Selection and Screening

Search results were imported and deduplicated using Covidence Systematic Review Management software (Veritas Health Innovation Ltd). A total of 2 reviewers (WMC and MBW) independently reviewed titles and abstracts (and keywords, when applicable) to determine potential eligibility for inclusion in the review. Any abstracts considered too ambiguous or where reviewers disagreed were resolved by a third reviewer (JF) or by examining the full text.

To facilitate full-text review and abstraction, Covidence automatically imported the open-access articles, and the remaining articles were manually imported. The articles selected for abstraction were also imported into EndNote (version X9; Clarivate) citation management software to facilitate manuscript preparation.

Full-Text Review

A total of 2 reviewers (WMC and MBW) will independently review the publications to verify that eligibility criteria are met. While the articles do not specify a TRL level, the reviewers will attempt to discern whether the blockchain-based dynamic consent technologies described in the articles meet the criteria for TRL 6 or higher. Any reviewer disagreement will be resolved by a third reviewer (JF) or by discussions between reviewers.

Data Extraction and Evaluation

Although integrative reviews do not typically include a quality appraisal, we have elected to use the validated Mixed Method Appraisal Tool (MMAT) [33] to capture data on the studies' quality. This aligns with established guidelines for organizing and synthesizing a wide range of literature [22,23]. Moreover, we recognize that there is an increased risk of bias in articles where the authors describe their own products with the goal of future commercialization. The MMAT is brief (only 5 yes or no questions per article) and is designed to assess the methodological strength of studies with diverse designs, consistent with an integrative review. Questions pertain to methodological quality, interpretations, and risks of bias. This tool has been assessed and updated for reliability [34] and content validity [35]. A total of 2 reviewers (WMC and MBW) will independently address the MMAT quality appraisal questions of the eligible literature and will extract all pertinent information from each article. A third reviewer (JF) will integrate the reviews from the 2 reviewers or request collaborative discussions among all reviewers.

The remaining data extraction questions were developed by WMC and MBW and refined by the other team members. Questions were programed into Covidence and tracked with an audit trail. Key information planned for extraction includes: (1) article characteristics: author or authors, year of publication, title, and journal; (2) context and setting for actual or intended blockchain-based dynamic consent implementation: country of intended implementation, setting of implementations (eg, hospital, clinic, or research organization), and intended users; (3) details about blockchain-based dynamic consent solution: name given to the technology (if any), stated purposes or objectives of the product, blockchain platform used (if specified), capabilities of integrations with other data sources, maturity of the technology, stated compliance with regulations, SSI capabilities; (4) evidence about the blockchain-based dynamic consent solution: comparisons with other technologies, evaluation with patients or research participants, nature, and scope of evidence presented; and (5) additional questions about scientific integrity and future research: descriptions of challenges and limitations, whether evidence is presented objectively, descriptions of best practices, and recommendations for future research.

Data Synthesis

Categorical data will be summarized by the percentage of articles or blockchain-based dynamic consent products by category.

Information pertaining to the research questions will be organized using qualitative summary narratives—comparing and contrasting blockchain-based dynamic consent approaches [36]. If necessary, a coding manual will be developed to increase the consistency of coding categorization and the synthesis of subthemes [37,38]. The interpretations will consider article quality, representativeness, and bias or objectivity [36].

Results

Article Selection and Screening

Using the search strategies and databases described above, 637 articles were identified. A total of 145 duplicates were removed, resulting in 492 articles eligible for preliminary screening. Title and abstract screening removed 312 articles. A total of 180 articles are available for full-text review against inclusion criteria, confirming a sufficient body of literature for project feasibility.

Presentation

The review will present data as a narrative, supported by tables and graphs to display the characteristics of included articles and implementations of blockchain-based dynamic consent. The structure of the narrative synthesis will reflect the objective and research questions. The flow of information through the review phases will be generated by Covidence and displayed as a PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 flow diagram [39].

Discussion

Key Findings

While the results will not be known until we complete the integrative review, we plan to interpret the findings and their implications in the context of the 4 research questions. In discussing findings and implications, we will refer to the subthemes synthesized by evaluating data extracted from the articles.

Potential Impact of the Review

Individual patients and research participants are increasingly given more rights to control the uses of their data through privacy regulations [40-42] and health information interoperability requirements [43,44]. In addition, patient-centric research initiatives are considered by industry, academia, and regulatory stakeholders globally as a promising means to overcome clinical research and development delays, inefficiencies, and high failure rates [45]. Therefore, technologies that facilitate patient-centricity, such as blockchain-based dynamic consent, are increasingly relevant for health care and health research organizations. It underscores the importance of rigorously reviewing these technologies and their impact, elevating scientific rigor, and establishing best practices for research, innovation, and implementation.

Elucidating Technology Benefits

Extant studies that suggest blockchain-based technologies for health care settings typically involve prototypes, proof-of-concept technologies, or minimum viable products, where nearly all purported results are theoretical [46]. This protocol and subsequent integrative review publication highlight

the relevance and methods for evaluating technology readiness and empirical evidence. Similarly, some studies promote blockchain products and possible benefits but do not explain how products are designed to address specific problems. For example, Durneva et al [47] performed a systematic review of blockchain-based systems for health care and examined how well-proposed solutions aligned with organizational goals. In their review, the authors noted that only 10% (7/70) of products were designed to reduce inefficiencies. As organizations publish more literature about these technology developments, this protocol provides methodology that facilitates critical appraisal of studies and presented evidence.

With the recognition that it is necessary to manage users' identities for a digital consent solution used over time [48]—and possibly across multiple devices—we believe this literature review will also shed light on the identity management features that blockchain could underpin.

Elevating Scientific Rigor

This work can inform and improve future research designs on blockchain-based dynamic consent. In 2019, Treiblmaier [26] noted that the quality of blockchain research was lagging, and he offered guidelines for designing and publishing case studies to improve evidence quality. Years later, authors still emphasize that blockchain research must have more scientific rigor for the work to be respected [49-51]. When addressing blockchain-based dynamic consent literature quality, we will offer deeper insight into gaps, weaknesses, and ways to address these.

Offering Best Practices

This integrative review is expected to identify optimal approaches to implementing and evaluating the effectiveness of blockchain-based dynamic consent technologies. While blockchain products are being developed for health research environments, few implementation models exist [52]. Additionally, few articles describe their products' limitations or weaknesses, contributing to narrow and unrealistic perspectives [53]. Based on the data, we plan to discuss how blockchain-based dynamic consent solutions must be designed to address specific issues in health information sharing and health research. This review will aggregate all information from the articles about strengths and weaknesses—plus draw from our real-world experience—to offer best practices for blockchain technology implementation in this domain. To enhance understanding and practical relevance, we intend to discuss these best practices in an exemplary implementation case, for example, blockchain-based dynamic consent for collecting and exchanging health information and managing informed consent across research centers in the context of longitudinal cardiovascular research projects with extensive and diverse participant cohorts.

Limitations

This integrative research review has several limitations. First, we acknowledge that this is a relatively new area of research and innovation. As a result, the literature base is still relatively small and may not facilitate a comprehensive understanding of the technology and its potential applications. Another limitation is that many published studies on blockchain-based dynamic consent describe early stages of development rather than being based on real-world implementations [14]. This means that they may not reflect the challenges and limitations encountered in practical applications of the technology. Last, some published studies on blockchain-based dynamic consent may be based on small-scale or pilot projects, which may not represent how the technology would perform in a larger, more complex health research setting [47]. To mitigate these limitations, we have conducted a preliminary full-text examination of eligible articles to confirm a sufficient body of literature on implementations at a sufficiently progressed technology readiness level (ie, TRL 6 or higher). The quality of studies and their focal implementations will be appraised systematically using the MMAT. Besides, the early stages of this research arguably increase the relevance of critically evaluating current approaches and synthesizing best practices for future research, innovation, and implementation.

Conclusions

The review will provide a comprehensive picture of the progress of emerging blockchain-based dynamic consent technologies and the rigor with which implementations are approached. Resulting insights are expected to inform best practices for future research, innovation, and implementation to benefit patient-centric research and health information sharing.

Acknowledgments

The authors gratefully acknowledge the support and assistance of Geoff Johnson at the University of Colorado Denver Auraria Library for assisting with the literature search strategies and syntax.

Abstract

Background: There has been an increasing interest in the use of digital health lifestyle interventions for people with prediabetes, as these interventions may offer a scalable approach to preventing type 2 diabetes. Previous systematic reviews on digital health lifestyle interventions for people with prediabetes had limitations, such as a narrow focus on certain types of interventions, a lack of statistical pooling, and no broader subgroup analysis of intervention characteristics. The identified limitations observed in previous systematic reviews substantiate the necessity of conducting a comprehensive review to address these gaps within the field. This will enable a comprehensive understanding of the effectiveness of digital health lifestyle interventions for people with prediabetes.

Objective: The objective of this systematic review, meta-analysis, and meta-regression is to systematically investigate the effectiveness of digital health lifestyle interventions on prediabetes-related outcomes in comparison with any comparator without a digital component among adults with prediabetes.

Methods: This systematic review will include randomized controlled trials that investigate the effectiveness of digital health lifestyle interventions on adults (aged 18 years or older) with prediabetes and compare the digital interventions with nondigital interventions. The primary outcome will be change in body weight (kg). Secondary outcomes include, among others, change in glycemic status, markers of cardiometabolic health, feasibility outcomes, and incidence of type 2 diabetes. Embase, PubMed, CINAHL, and CENTRAL (Cochrane Central Register of Controlled Trials) will be systematically searched. The data items to be extracted include study characteristics, participant characteristics, intervention characteristics, and relevant outcomes. To estimate the overall effect size, a meta-analysis will be conducted using the mean difference. Additionally, if feasible, meta-regression on study, intervention, and participant characteristics will be performed. The Cochrane risk of bias tool will be applied to assess study quality, and the GRADE (Grading of Recommendations Assessment, Development and Evaluation) approach will be used to assess the certainty of evidence.

Results: The results are projected to yield an overall estimate of the effectiveness of digital health lifestyle interventions on adults with prediabetes and elucidate the characteristics that contribute to their effectiveness.

Conclusions: The insights gained from this study may help clarify the potential of digital health lifestyle interventions for people with prediabetes and guide the decision-making regarding future intervention components.

Introduction

Diabetes is a major global health care challenge. In 2021, an estimated 10.5% of the world's population aged between 20 and 79 years had diabetes, and the prevalence is expected to increase to 12.2% by 2045 [1]. Type 2 diabetes (T2D) is the predominant form of diabetes, representing approximately 90% of diabetes cases worldwide, and is one of the most common metabolic disorders [1,2]. T2D results in abnormally high levels of plasma glucose due to insulin resistance and gradual impairment of pancreatic beta-cell function [2,3]. Continuously high levels of plasma glucose can lead to several micro- and macrovascular complications, such as retinopathy, nephropathy, and cardiovascular diseases, increasing the risk of premature mortality, morbidity, and reduced quality of life [2,3]. This poses a major economic burden to the health care system and society [3-5].

The development of T2D is affected by both environmental and genetic factors but living with overweight and having a sedentary lifestyle are prominent risk factors [2,6]. Before the diagnosis of T2D, an intermediate stage of elevated plasma glucose usually exists [7,8]. This intermediate stage, where a person has abnormally high glucose levels but not high enough to be diagnosed with T2D, is called prediabetes [1,9]. Prediabetes is characterized by impaired fasting glucose (IFG), impaired glucose tolerance (IGT), or elevated hemoglobin A_{1c} (HbA_{1c}) levels [9,10]. Depending on the organization, diagnostic test, and cutoff criteria used, different definitions of prediabetes exist, which makes global prevalence estimates challenging and varying [8,11]. According to the International Diabetes Federation, an estimated 10.6% of the global population aged between 20 and 79 years had IGT in 2021 and an estimated 6.2% of adults had IFG, based on the criteria established by the World Health Organization. The global prevalence of IGT and IFG is expected to increase to 11.4% and 6.9%, respectively, by 2045 [1].

Most people with prediabetes are unaware of the condition, as it is frequently asymptomatic [10]. People with prediabetes are at increased risk of developing T2D. Approximately 70% of people with prediabetes will develop T2D during their lifetime and about 25% will progress to T2D within 3-5 years [10,11]. Additionally, elevated plasma glucose in the range of prediabetes leads to an increased risk of developing micro- and macrovascular complications usually associated with T2D [12-14]. Several studies have demonstrated that progression from prediabetes (mainly IGT) to T2D, as well as complications, can be prevented and delayed through intensive lifestyle interventions that focus on diet and physical activity [15-18]. These studies have found that intensive lifestyle interventions reduced the risk of progression to T2D by 28%-58% over a 2.5- to 6-year period [15-18]. Prediabetes thus represents a time of opportunity to prevent or delay progression to T2D, potentially slowing down the increase in the prevalence of people with T2D [10,11,19].

Despite the effect of resource-intensive lifestyle interventions observed in clinical trials, these interventions may not be scalable and accessible in clinical practice because of restricted health care resources [8,20,21]. Digital health interventions have the potential to reduce the resources of intensive lifestyle interventions and thereby make them more scalable and accessible in clinical practice [21-23]. Digital health defines the use of digital technologies in support of health care and includes technologies such as mobile apps, videos, websites, and wearable devices [24,25]. Previous reviews have demonstrated that digital health interventions are effective in reducing body weight among people with overweight or obesity [26,27] and reducing HbA_{1c} among people with diabetes [28-30]. These findings indicate that digital health interventions have the potential to improve various health-related outcomes. However, more research is still required to determine whether digital health lifestyle interventions can effectively improve prediabetes-related outcomes (eg, weight loss and glycemic status) to clarify their potential for people with prediabetes. In addition, an evaluation of characteristics associated with effects on outcomes is crucial to guide the development of future interventions and inform decision-making on intervention components.

Previous systematic reviews have investigated the effect of digital health lifestyle interventions on people with prediabetes [20,21,31-33]. However, the reviews had limitations. They focused on specific types of digital interventions [32], including a relatively small number of data sources [32,33], lacking a meta-analysis [20,21,33], or pooling results from different study designs [31]. Furthermore, previous meta-analyses did not include a broader subgroup analysis exploring the association between intervention characteristics and effects on outcomes [31,32]. As a result, the specific characteristics that are associated with effects on prediabetes-related outcomes remain relatively unknown. Additionally, given the rapid development of digital interventions, several new research papers have likely emerged since the conduct of previous reviews.

The considerations mentioned above indicate the need for an updated and comprehensive systematic review, meta-analysis, and meta-regression in the field to synthesize and evaluate the effectiveness of digital health lifestyle interventions on people with prediabetes.

Methods

Study Design

The conduct and reporting of this review will follow the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [34]. The review process will

be conducted based on this review protocol, which adheres to the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) checklist [35]. The protocol was registered on PROSPERO (International Prospective Register of Systematic Reviews) on July 5, 2023 (CRD42023426919), in accordance with the PRISMA guidelines.

Objective

The objective of this systematic review, meta-analysis, and meta-regression is to systematically investigate the effectiveness of digital health lifestyle interventions on weight loss and other prediabetes-related secondary outcomes in comparison with any comparator without a digital component among adults with prediabetes.

Review Questions

This systematic review, meta-analysis, and meta-regression is guided by the following research questions: What is the effectiveness of digital health lifestyle interventions on weight loss and other prediabetes-related outcomes among adults with prediabetes, and how do variations across study, intervention, and participant characteristics contribute to differences in the observed effect?

Inclusion Criteria

Participants

Studies including adults aged 18 years or older meeting criteria indicative of prediabetes will be considered for inclusion in this systematic review, meta-analysis, and meta-regression. The criteria for meeting prediabetes will be defined by the presence of IFG, IGT, or raised HbA_{1c}. According to the criteria of the American Diabetes Association, IFG is defined as fasting plasma glucose levels between 5.6-6.9 mmol/L, IGT as 2-hour plasma glucose (75-gram oral glucose tolerance test) between 7.8-11.0 mmol/L, and raised HbA_{1c} as HbA_{1c} levels between 39-47 mmol/mol [9].

Studies that are restricted to adults with T2D, type 1 diabetes, or gestational diabetes will be excluded. In addition, studies that investigate the effect of a combined lifestyle and pharmacological intervention will be excluded. Studies that examine combined age groups (eg, adults and adolescents) will also be excluded unless the data for the adult population are reported transparently and separately. Similarly, studies that do not report separate data when considering prediabetes in conjunction with any type of diabetes (eg, T2D) or metabolic syndrome will also be excluded.

Interventions

Studies that examined the effectiveness of digital health lifestyle interventions (diet or physical activity interventions) on adults with prediabetes will be considered for inclusion. These studies may encompass both independent digital solutions and interventions that combine in-person meetings with a digital component. The digital component may include different technologies such as SMS text messaging, smartphone apps, email, automated phone calls, mobile phones, websites, computer-based programs, and video. Studies will be deemed ineligible for inclusion if the intervention does not incorporate a digital component.

Comparators

This systematic review, meta-analysis, and meta-regression will examine studies that compare digital health lifestyle interventions to any comparator without a digital component.

Settings

Studies investigating the effectiveness of digital health lifestyle interventions on adults with prediabetes will be considered without any restrictions on the setting.

Outcomes

Studies that report the effectiveness on relevant outcomes related to prediabetes (eg, weight loss, glycemic status, and incidence of T2D) will be considered in this systematic review, meta-analysis, and meta-regression. The primary outcome will be a change in body weight (kg). Secondary outcomes will include changes in the following variables: (1) glycemic status, (2) body composition, (3) incidence of T2D, (4) markers of cardiometabolic health (eg, blood pressure and lipids), (5) patient-reported outcomes (eg, quality of life), and (6) feasibility outcomes (eg, differential retention rate, adherence, and acceptance).

Study Types

Randomized controlled trials with a parallel design will be eligible for inclusion in the systematic review, meta-analysis, and meta-regression. Additionally, studies will be eligible for inclusion if the researchers assess that the study was conducted using a parallel randomized controlled trial design, regardless of whether the paper itself describes the design using a different terminology. Systematic reviews or meta-analyses will be excluded but inspected for potentially eligible studies. Only full-text studies that have undergone peer review and are available in English, Norwegian, Danish, or Swedish will be included. The present review will not impose any restrictions on the publication year of included studies, as older as well as more recent interventions will be evaluated to offer valuable insights.

Search Strategy

The systematic search will be conducted by the first author (TFH) across various databases with the aim of systematically identifying studies investigating the effectiveness of digital health lifestyle interventions for adults with prediabetes. The following bibliographic databases will be searched: Embase, PubMed, CINAHL, and CENTRAL (Cochrane Central Register of Controlled Trials). Assistance in the performance of the systematic search will be provided by a research librarian experienced in systematic review searching.

To identify search terms of relevance, encompassing controlled vocabulary and keywords, an initial limited search will be conducted in PubMed and Embase. The systematic search will involve the identification and incorporation of related terms and synonyms associated with the identified search terms. Additionally, a series of search functions, such as truncation and phrase search, will be used, and the identified search terms

will be combined using Boolean operators. The systematic search approach will be tailored and adjusted to suit each database included in the study. The complete search strategy for PubMed is presented in the Multimedia Appendix 1. If relevant, for example, in case of inaccessibility of a study or questions during the selection process, the authors of the study in question will be contacted.

Reference search and citation tracking of eligible studies will be performed to identify additional potentially relevant studies. Citation tracking will be conducted in Web of Science and SCOPUS.

A follow-up search will be conducted in each included database before final submission to prevent selection bias and to ensure that all newly published papers are included.

Study Selection

The identified studies will be collected and imported into RefWorks. First, any duplicate studies will be removed in RefWorks. Second, the titles and abstracts of remaining studies will be screened for inclusion against the review eligibility criteria by the first author. Third, the studies that meet eligibility criteria, as well as those where uncertainty persists, will undergo full-text screening. The first author will assess their inclusion against the predetermined eligibility criteria with assistance from a coauthor. In case of any disagreement between the reviewers regarding study selection, the reviewers will engage in discussion to resolve the issue. If necessary, a third coauthor will be involved to reach a consensus. Data extraction, quality assessment, and, if feasible, statistical analysis will be conducted for all eligible studies.

A PRISMA flowchart [34] will be used to demonstrate the screening process for each stage and the results of the systematic search, as depicted in the Multimedia Appendix 2. The PRISMA flowchart will also comprise exclusion reasons of full-text studies.

Risk of Bias Assessment

The Cochrane risk of bias tool will be applied to facilitate the quality assessment of the included studies by the first author with assistance from a coauthor. In case of disagreements, the reviewers will resolve them through discussion, and a third coauthor may be involved if needed. If necessary, for example, if items are missing or unclear for the risk of bias assessment, the authors of the studies in question will be contacted.

Data Extraction

A standardized spreadsheet in Excel (Microsoft Corporation) will be used to extract data from included studies, facilitating data synthesis and analysis while ensuring consistent data extraction. The first author will perform the data extraction with assistance from a coauthor. In case of any disagreement between the reviewers regarding data extraction, the reviewers will engage in discussion to resolve the issue. If necessary, a third coauthor will be involved to reach a consensus.

The data items that will be extracted include the following four categories:

1. Study characteristics, including first author, year of publication, study design, and country.
2. Baseline characteristics of study participants, including sample size of each group, percentage male participants, ethnicity, age, body weight, BMI, HbA_{1c}, and fasting plasma glucose.
3. Outcomes of the study intervention and control group, including primary and/or secondary outcomes when available.
4. Characteristics of the digital health lifestyle intervention, including duration of follow-up, setting, resources used, intervention components, mode of delivery, provider, contact type (eg, face-to-face, fully automated, or remote), and frequency of contact.

Data Synthesis

A statistical meta-analysis will be conducted using Stata (version 17; StataCorp 2021) by pooling data from included studies to estimate the overall effect size of digital health lifestyle interventions on adults with prediabetes. The mean difference between the digital intervention group and the comparator group will be used to present the effect size for continuous data, along with a 95% CI. Primary outcomes presented in other units will be scaled to the same unit if possible (eg, a change in body weight reported as percentage or in pounds will be transformed into kilograms). Standardized mean difference will be used to present the effect size for secondary outcomes presented in different units unless it is possible to scale them to the same unit. Traditional methods will be used to convert results reported as medians and interquartile ranges into means and SDs [36]. For dichotomous data, the effect size will be presented as an odds ratio with a 95% CI. In cases where statistical pooling is impossible, the results will be presented narratively, accompanied by tables and figures where applicable. Feasibility outcomes will also be summarized narratively, eventually supported by tables and figures.

Both qualitative and statistical assessments will be conducted to evaluate the heterogeneity of the included studies. Qualitative assessment will involve comparing the characteristics of the studies, while the I^2 test will be used for statistical analysis. If heterogeneity is present, as determined by an I^2 value of more than 50%, a random-effects model will be used to statistically pool the data. Otherwise, a fixed-effect model will be used. The results of the meta-analysis will be presented in a forest plot. If possible, meta-regression on study characteristics (eg, variations across countries), intervention characteristics (eg, human-to-human interventions vs fully automated interventions), and participant characteristics (eg, gender) will be conducted to uncover common patterns among effective interventions and identify knowledge gaps within the research field. If conducting a meta-regression is impossible due to data limitations, alternative subgroup analyses based on study-, intervention-, and participant characteristics will be performed.

To visually evaluate the potential presence of publication bias, a funnel plot will be created and included in the presentation of the results. If the number of studies included in the meta-analysis is more than 10, a statistical test (Egger test) will be performed to detect funnel plot asymmetry.

Certainty of Evidence Assessment

The certainty of evidence will be assessed using the GRADE (Grading of Recommendations Assessment, Development and Evaluation) approach [37]. The assessment will consider the risk of bias, inconsistency, indirectness, imprecision, and publication bias. Based on these considerations, the evidence will be classified as high, moderate, low, or very low certainty. A summary of findings table will be generated using the web-based software GRADEpro Guideline Development Tool to summarize the strength and reliability of the evidence [38].

Results

The results of this review intend to provide insights into both the overall effectiveness of digital health lifestyle interventions and the characteristics that contribute to their effectiveness. The results will undergo peer review and be submitted for publication.

Discussion

This systematic review, meta-analysis, and meta-regression will review current evidence to address a lack of comprehensive research within the field of digital health lifestyle interventions for people with prediabetes.

As this publication represents a preliminary stage of the systematic review, specific comparisons with key studies are currently lacking. However, the protocol emphasizes conducting a comprehensive review of relevant literature to allow for meaningful comparisons once the results are obtained. Furthermore, the forthcoming discussion aims to assess the applicability of the findings in clinical practice and their potential implications for real-world implementation. Evaluating the resources used in the included interventions may be crucial for this assessment, considering their potential limitations in expanding digital health lifestyle interventions into real-world settings.

The insight gained from this study may help clarify the potential of digital health lifestyle interventions in the management of prediabetes and offer guidance for future development decisions. The planned systematic evidence assessment, using the GRADE methodology, is expected to indirectly inform and guide future recommendations and development decisions for digital health solutions [39]. These recommendations will be enriched by insights obtained from the meta-regression or subgroup analysis. We intend to explore these aspects in the forthcoming discussion.

However, it is crucial to acknowledge the anticipated limitations within this review. Studies investigating digital health interventions are expected to vary in factors such as mode of delivery, intervention type, population, and duration, resulting in notable heterogeneity among the included studies. This diversity might complicate the comparison and statistical pooling of results. Moreover, the upcoming discussion intends to highlight additional limitations and knowledge gaps identified during the review, with the aim of informing and enhancing further work in this field.

Acknowledgments

The authors would like to express their gratitude to research librarian Conni Skrubbeltrang for competent assistance with the search strategy and the literature search. No specific funding will be allocated to support this systematic review, meta-analysis, and meta-regression.

Authors' Contributions

The protocol was drafted by TFH. TFH and SH constructed the search strategy in collaboration with a research librarian experienced in systematic review searching. All authors contributed to the developed eligibility criteria and data extraction strategy. FWU provided statistical expertise. All authors contributed to the final manuscript by reading it, providing feedback, and critically revising it for important intellectual content. The final protocol was approved by all authors.

Conflicts of Interest

KF and BJvS are full-time employees and own shares at Novo Nordisk A/S (joint-stock company). MHJ owns shares at Novo Nordisk A/S. No conflicts of interest were declared by the remaining authors.

Abstract

Background: Chatbots have the potential to increase people's access to quality health care. However, the implementation of chatbot technology in the health care system is unclear due to the scarce analysis of publications on the adoption of chatbot in health and medical settings.

Objective: This paper presents a protocol of a bibliometric analysis aimed at offering the public insights into the current state and emerging trends in research related to the use of chatbot technology for promoting health.

Methods: In this bibliometric analysis, we will select published papers from the databases of CINAHL, IEEE Xplore, PubMed, Scopus, and Web of Science that pertain to chatbot technology and its applications in health care. Our search strategy includes keywords such as "chatbot," "virtual agent," "virtual assistant," "conversational agent," "conversational AI," "interactive agent," "health," and "healthcare." Five researchers who are AI engineers and clinicians will independently review the titles and abstracts of selected papers to determine their eligibility for a full-text review. The corresponding author (ZN) will serve as a mediator to address any discrepancies and disputes among the 5 reviewers. Our analysis will encompass various publication patterns of chatbot research, including the number of annual publications, their geographic or institutional distribution, and the number of annual grants supporting chatbot research, and further summarize the methodologies used in the development of health-related chatbots, along with their features and applications in health care settings. Software tool VOSViewer (version 1.6.19; Leiden University) will be used to construct and visualize bibliometric networks.

Results: The preparation for the bibliometric analysis began on December 3, 2021, when the research team started the process of familiarizing themselves with the software tools that may be used in this analysis, VOSViewer and CiteSpace, during which they consulted 3 librarians at the Yale University regarding search terms and tentative results. Tentative searches on the aforementioned databases yielded a total of 2340 papers. The official search phase started on July 27, 2023. Our goal is to complete the screening of papers and the analysis by February 15, 2024.

Conclusions: Artificial intelligence chatbots, such as ChatGPT (OpenAI Inc), have sparked numerous discussions within the health care industry regarding their impact on human health. Chatbot technology holds substantial promise for advancing health care systems worldwide. However, developing a sophisticated chatbot capable of precise interaction with health care consumers, delivering personalized care, and providing accurate health-related information and knowledge remain considerable challenges.

This bibliometric analysis seeks to fill the knowledge gap in the existing literature on health-related chatbots, entailing their applications, the software used in their development, and their preferred functionalities among users.

KEYWORDS

artificial intelligence; AI; bibliometric analysis; chatbots; health care; health promotion

Introduction

Chatbots are software applications that use computerized algorithms to simulate conversations with human users through text or voice interactions [1,2]. Since their inception in the 1960s, chatbots have found applications in various settings, such as airlines, banks, hotel chains, and information technology companies, serving as digital agents to handle and streamline customers' queries and needs [3]. Compared to human agents, chatbots can efficiently respond to a large number of users simultaneously, conserving human effort and time while still providing users with a sense of human interaction [4]. Due to this advantageous feature, chatbots have been implemented in health care settings to automatically resolve or deflect repetitive calls, thereby reducing waiting times for health care consumers and enabling health care professionals to focus on more complex cases. Driven by the evolution of Industry 4.0, characterized by the integration of digital technologies, data, and automation to create more efficient and responsive societal systems, the future of high-quality health care hinges on the automation and digitalization of data exchange. Against this social-technological backdrop, artificial intelligence (AI) chatbots, also known as conversational AI, hold substantial promise as innovative tools for advancing our health care systems [5].

AI chatbots have been developed to automate and streamline various tasks for health care consumers, including retrieving health information, providing digital health support, and offering therapeutic care [6]. The literature reveals that AI chatbots commonly fulfill roles such as assisting individuals in scheduling medical appointments, identifying health clinics, and providing health educational information [7,8]. Research has also shown that health care professionals, patients, and families exhibit favorable attitudes toward the use of chatbot technology to enhance health outcomes [7,9-12].

While AI chatbots hold considerable potential to drive significant advancements and improvements in health care [13,14], their application in health care is still in its early stages. A significant barrier to the deployment of chatbot technology in health care systems is the lack of sophisticated AI algorithms capable of facilitating precise and personalized human-chatbot interactions to meet the expectations of health care providers or fulfill the needs of health care consumers [11]. For instance, in the United States, health-related chatbots have been developed to monitor the health status of patients with chronic heart failure [15], screen for osteoporosis in menopausal women [16], and detect colorectal cancer in the general population [17]. However, their effectiveness in clinical trials was found to be limited when compared to health professional assessments. To fully realize the potential of chatbot technology in health care systems, more studies are needed to develop more sophisticated AI algorithms that are culturally tailored, theoretically informed, and trained based on clinical needs [18-21]. Creating such sophisticated AI chatbots presents a challenge for both health scientists and chatbot engineers, necessitating iterative collaboration between the 2 [22]. Specifically, after chatbot engineers develop a chatbot prototype, health scientists evaluate it and provide feedback for further refinement. Chatbot engineers then upgrade the chatbot, followed by health scientists testing the updated version, training it, and conducting further assessments. This iterative cycle can impose significant demands in terms of time and funding before a chatbot is equipped with the necessary knowledge and language skills to deliver precise responses to its users.

Bibliometric analysis is a quantitative research method to discern publication patterns within a specific timeframe [23]. Scholars use this type of analysis to elucidate the intellectual structure of a particular area within the realm of existing literature [24]. Despite the increasing popularity of health-related chatbots, no bibliometric analysis has been conducted to examine their application. Studies on the coverage of health-related chatbot research have predominantly been conducted in the form of scoping or systematic reviews [19,25,26]. The current body of research papers lacks the breadth of a comprehensive scientific performance mapping analysis. Hence, this bibliometric analysis aims to identify the current status and emerging trends in chatbot technology research, serving as an initial stride for researchers worldwide to gain a comprehensive understanding on the landscape of health-related chatbots. This overview will facilitate the identification of areas for improvement and promote the integration of chatbot technology into health care systems.

Chatbot technology should be promoted in the health care system because many digital health interventions have proven effective but are not implemented in real clinical settings, as they often require high-intensity and sustained human inputs. For example, they often require researchers to regularly and manually send personalized reminders, provide real-time guidance, and initiate referrals [27,28]. To bring population-level effects, digital health intervention needs to be automating personalized messages, modifying them based on responses, and providing new outputs in real time [29]. AI chatbots have the potential to achieve these goals. For example, our previous formative research indicates a high level of acceptance toward the use of chatbot technology among vulnerable populations who are at high risk for HIV [2]. Additionally, we have conducted beta testing for chatbot technology in promoting HIV testing and prevention and found that participants believed chatbot technology provided them with a platform to protect their safety and privacy. This was particularly important in

environments where stigma and discrimination toward HIV exist, and where same-sex behaviors are criminalized. Compared with the conventional health care use model, where people need to face stigma and discrimination from health care providers, chatbots can provide them with a safe platform to ask questions and receive consulting services. Therefore, promoting chatbot technology holds significance for enhancing the current health care system and an anonymous user setting in chatbots is necessary to protect health consumers' privacy [2].

Methods

Bibliographic Search

We will conduct searches in the following databases: CINAHL (EBSCOHost), IEEE Xplore (IEEE), PubMed, Scopus (Elsevier), and Web of Science (Clarivate) to ensure a comprehensive coverage of research on health-related chatbots. We have identified a set of consensus search keywords related to chatbots and health care through a review of previous systematic reviews [18-21] and consultations with university librarians who possess expertise in informatics and digital health. Our search strategy includes keywords such as "chatbot," "virtual agent," "virtual assistant," "conversational agent," "conversational AI," "interactive agent," "health," and "healthcare." A retrieval search string, including the keywords with Boolean operators listed in Multimedia Appendix 1, will be used.

Selection of Studies

We will include papers on chatbots that are used to promote health outcomes. All interventional and observational studies published as journal papers or conference proceedings will be included. To offer a holistic view of the evolving usage of chatbots in health care, we will not set restrictions on the year of publication. Moreover, we will not exclude papers published in non–English language to incorporate research findings from low- and middle-income countries [30]. Studies that do not discuss the use of chatbots to promote health or wellness will be excluded. Systematic reviews pertaining only to chatbot designs and development, purposes, or features will be excluded. Papers such as editorials, dissertations, preprints, and letters to the editor will also be excluded.

Search results from each database will be imported into Covidence (Veritas Health Innovation Ltd), a systematic review management software. Duplicate papers will be identified and removed. Five researchers will independently screen the titles and abstracts of all papers and categorize them as either "include," "exclude," or "unsure" based on the following inclusion criteria related to (1) chatbot and (2) health promotion. To provide a comprehensive overview of the current research on health-related chatbots, we will include papers about chatbots designed for various populations, including patients, clinicians, policy makers, or the general population. We will not exclude papers based on their study design. Papers marked as "unsure" will be downloaded and assessed for eligibility. The eligibility assessment will be performed by 2 authors (VB and VT) who are an AI consultant and a clinician. In the event of disagreements, the 2 authors will discuss in team meetings with the corresponding author (ZN) to reach a consensus.

Data Extraction

Selected studies will be downloaded from Covidence and imported into VOSViewer (version 1.6.19; Leiden University), a Java-based bibliometric analysis visualization software application. We will use VOSViewer to analyze data related to chatbot publication patterns, encompassing the number of annual publications, the distribution of countries and institutions involved in chatbot research, the number of annual grants that supported chatbot research, the number of funders, the number of journals publishing chatbot research, the number of journal citations, the most prolific authors in the field of chatbots, author network maps, and the most frequently used keywords related to chatbots. Additionally, using Excel (Microsoft Corp), we will manually extract data regarding the number of interventional and observational studies, the methodologies used in creating chatbots, the number of chatbots deployed worldwide, and the usage of chatbots.

Data Analysis

Research Characteristics

In this bibliometric analysis, we will analyze the characteristics of chatbot research based on the topics of the selected studies, identified through their reported keywords, such as primary functions and disease domains. We will report the frequency and percentage of the top keywords and topics by following the framework in previous research to measure the centrality of a keyword using its frequency scores [31].

Publication Patterns

We will report the trend of yearly number of publications and showcase the growth rate of publication by computing the monthly publication rate each year from the earliest publication selected to the latest. To control for the "publication noise," a surge in publications following the releases of ChatGPT, we will stratify the data by publication date before and after the emergence of ChatGPT and conduct sensitivity analyses to distinguish between the direct impact of ChatGPT and other trends in chatbot research. This approach will help to ensure that our findings reflect the broader trends in chatbot technology research and are not disproportionately influenced by the recent increase in publications related to a single event or development. We will calculate the frequencies and percentages of publications for each journal and country in each publication year, whereby we identify the countries and institutions associated with the publication based on the affiliations of the corresponding authors. We will report the trend of research support by identifying the number of grants and funders as reported under each study's source of funding. Moreover, we will compute the distribution of the following two indicators including (1) the methodology used to create chatbots and (2) the implementation of health chatbots.

Research Hot Spot and Connectedness

We will use the number of journal citations to construct bursts, whereby clusters will be sorted by the keywords used by the study. We will further report the most prolific authors based on a combined metric of the number of publications and citation frequency. We will present 2 author network maps using author names and research institutions affiliated with the listed authors.

Authors and affiliated institutions will be the nodes within each network connected by edges representing the coauthorship of publications [32]. Edges will be weighted by the number of coauthorships between the same listed authors and their affiliated institutions.

Ethical Considerations

This analysis does not involve recruiting human participants or providing interventions; therefore, ethical review and consent forms are not required. We hope that the findings from the manuscript will aid researchers, engineers, health professionals, funders, and policy makers in their future implementation of chatbot technology to facilitate innovative and efficient health care systems.

Results

The preparation for the bibliometric analysis began on December 3, 2021, with the initial steps involving the research team familiarizing themselves with VOSViewer and CiteSpace, followed by digital consultations with 3 librarians from Yale University. Tentative searches in the databases yielded a total of 2340 papers. The official search phase began on July 27, 2023. Our goal is to complete the screening of papers and perform the analysis by February 15, 2024. We anticipate a significant increase in chatbot research following the emergence of ChatGPT.

Discussion

AI chatbots hold strong potential to transform the field of health care. For example, ChatGPT, an AI chatbot developed by OpenAI, has sparked numerous discussions within the health care industry regarding the impact of AI chatbots on human health [13,14,33-38]. Our team has been developing an AI chatbot since June 2019, and we have discovered that developing a sophisticated AI chatbot capable of precise interaction with health care consumers, delivering personalized care, and providing accurate health-related information and knowledge remains a considerable challenge. One of the major obstacles faced by health scientists interested in chatbot research is their lack of familiarity with chatbots' underlying technologies, such as the computational systems, software platforms, and underlying algorithms that train chatbots and enable their automation and individualization. Similarly, chatbot engineers may have limited insight into the challenges faced by patients and health care providers in real-world clinical settings, making it difficult for them to fully grasp the nuances and directions of chatbot technology. Such information asymmetry in interdisciplinary collaboration hinders health-advancing chatbot technology from reaching its full potential. More literature that can offer diverse stakeholders, ranging from health scientists, health care providers, to chatbot developers, insights into a holistic roadmap to creating effective chatbots to meet health care needs is thus urgently needed to facilitate such interdisciplinary endeavors.

Chatbot technology holds immense potential to enhance health care quality for both patients and professionals through streamlining administrative processes and assisting with assessment, diagnosis, and treatment. Used for health information acquisition, chatbot-powered search, as we anticipate, will become an important complement to traditional web-based searches. This trend is primarily driven by the convenience of chatbot-powered search for users, as it eliminates the need for users to manually sift through search results as required in traditional web-based searches. However, no recognized standards or guidelines have been established for creating health-related chatbots. We believe that with theory-informed and well-trained algorithms, chatbots can also be used as health care digital assistants to provide consumers and patients with quick, precise, and individualized answers. As demonstrated by the widespread adoption of ChatGPT in recent times, it is reasonable to anticipate that the development and implementation of AI chatbots will substantially enhance the efficiency and convenience of health care consumers' information search. Existing studies have also shown that AI chatbots can increase health appointment volume by automating the scheduling process for health care consumers, achieved through a user-friendly platform that enables appointment scheduling, verification, and cancellation with ease, further leading to reduced no-show rates. For example, Weill Cornell Medicine reported a 47% increase in appointments booked digitally through the use of AI chatbots [39]. Moreover, chatbot technology can enhance the work efficiency of nurses, physicians, and other health care professionals by delivering prompt responses to inquiries related to clinical practice standards, eliminating the need to navigate prolonged websites or extensive clinical guidelines for specific information.

Despite the obvious benefits of chatbot technology in health care, several potential risks of using chatbots exist, including breaching privacy, providing misinformation, and generating systematically biased responses [2,7-9]. These risks are relevant to the nature of chatbot technology, in which chatbot developers need to maximize a personalized experience and enable chatbots to provide users with precision answers through training chatbots [12]. However, training chatbots requires chatbot technology to have access to a wealth of users' personal data. This poses a major threat to using chatbots in health care. To address privacy issues, chatbot developers and researchers must ensure that users' data are protected using encryption during human-chatbot interactions or when a chatbot needs to retrieve backend data [2]. Second, misinformation originates from the immature or flaws of the chatbot algorithms. Training a chatbot is an iterative process that demands a large data set and vetting of the outputs by researchers. During a chatbot creation, the earlier versions of the chatbot often provide redundant and impersonalized information that may prevent users from using the chatbot. To increase chatbot usability, a chatbot must be precise enough in its communications with users or can connect users to a human agent if necessary [11,12]. Third, even well-trained chatbots can provide biased responses or solutions to users [13]. This is particularly true if the data sets used to train chatbots are biased. To minimize these risks of using chatbots in health care, it is necessary for researchers to validate chatbot outputs and reduce biases in the data sets used to train a chatbot. Only by adopting this approach, quality chatbots with high usability can be used to promote health care.

To fully realize the potential of chatbot technology in improving health outcomes for everyone, sustained collaborative efforts from an interdisciplinary research team comprising chatbot engineers and health scientists are essential. To the best of our knowledge, this is the first study aimed at summarizing the current status and future trends of chatbots in the health care field. This study will provide a broad overview of publications on health-related chatbot research and bridge the knowledge gap in the existing literature, including software used for chatbot development, popular functionalities, and chatbots' applications in health care. This study includes papers published since the inception of the chatbot and is not confined by the language of publication. Consequently, it offers a global perspective on the evolution of chatbots within the health care domain. One limitation of this study is its nature as a bibliometric analysis, which does not explore topics in the same depth as a systematic review.

Acknowledgments

This work was supported by grants from the National Institutes of Health (R21TW011663 and R33TW011663 for ZN and FLA; and D43TW011324 for FLA and RS) and faculty research funds from Yale University School of Nursing for ZN.

We extend our sincere thanks to Janene Batten and other librarians at Yale University for their invaluable assistance and guidance in preparing for this bibliometric analysis

Data Availability

Data sharing is not applicable to this article as no data sets were generated or analyzed during this study.

Authors' Contributions

ZN, VT, MLP, and VB conceived the study and wrote the first draft of the manuscript. MLP and VB helped to develop the bibliographic search and bibliometric analysis. All authors contributed to the development of the study protocol, revised the subsequent version of the manuscript, and approved the submitted version.

Conflicts of Interest

None declared.

Abstract

Background: Mild cognitive impairment (MCI) is the stage between cognitive decline due to physiological aging and the severity of decline seen in neurodegenerative disorders like Alzheimer disease (AD), which is among the most prevalent neurodegenerative disorders characterized by cognitive impairment. People with MCI are at increased risk of developing AD. Although MCI and AD are incurable, nutritional interventions can potentially delay or prevent their onset. Consequently, effective interventions used to decelerate or alleviate the progress of cognitive impairment in older people are a significant focus in geriatric care. Given the synergistic effects of nutrition on health, assessing the effectiveness of nutritional supplements or dietary composition in preventing MCI or AD is essential for developing interventional strategies.

Objective: Our study aims to assess the effectiveness of various nutritional interventions, including special dietary types, dietary patterns, specific foods, nutritional intake, and nutritional supplements, in preventing cognitive decline among patients diagnosed with MCI or AD. To achieve this, we will use a comprehensive approach, including network meta-analysis, pairwise meta-analysis, and systematic review of randomized controlled trials (RCTs).

Methods: The review will follow the Population, Intervention, Comparison, Outcome (PICO) model and the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) guidelines. Two investigators will independently search PubMed electronically. Data extraction will follow the inclusion criteria, and data will be assessed for risk of bias using a revised tool. Additionally, evidence quality will be evaluated using the Grading of Recommendations, Assessment, Development and Evaluation (GRADE) framework. The outcomes of interest are assessing the cognitive outcomes in patients with MCI or AD. A systematic literature search will be conducted, identifying randomized controlled trials that investigate the impact of these nutritional interventions on cognitive function decline in individuals with MCI and AD. Network meta-analyses (random-effects model) and pairwise meta-analyses will then estimate the relative effectiveness of different nutritional interventions.

Results: We included 51 studies, published between 1999 and 2023 (27 studies for AD and 24 studies for MCI) and involving 8420 participants. We completed data extraction for all 51 studies by December 2023. Currently, we are actively engaged in data analysis and manuscript preparation. We plan to finalize the manuscript and publish the comprehensive results by the end of 2024.

Conclusions: Our study holds significant clinical relevance given the rising prevalence of AD and the potential influence of nutritional interventions on cognitive function in individuals with MCI and AD. By investigating this relationship, our research aims to inform evidence-based decision-making in the development of prevention strategies for MCI and AD. The outcomes are

expected to contribute to the establishment of reliable recommendations for MCI or AD management, providing substantial support in the field.

Introduction

Cognitive decline, particularly associated with mild cognitive impairment (MCI) and Alzheimer disease (AD), represents a significant and growing public health concern worldwide [1]. As the aging population continues to increase, the prevalence of MCI and AD is also on the rise, leading to substantial personal, societal, and economic burdens [2]. One study indicated that the occurrence of MCI was higher than 22.5 per 1000 person-years among people aged 75 years and older [3]. Patients with MCI are also at a high risk of developing AD [4,5]. Therefore, identifying effective interventions to prevent or delay cognitive decline in individuals with MCI and AD is of utmost importance.

Currently, MCI and AD are incurable; however, delay and prevention of MCI or AD are possible [6]. Modifiable factors such as metabolic conditions (eg, diabetes), vascular issues (eg, hypertension), mental health concerns (eg, depression), social factors (eg, isolation), and lifestyle choices (eg, nutritional intake [7], dietary type [8], and physical inactivity) have been frequently linked with the risk of MCI and AD [9]. As such, it is critical to understand how modulating health and lifestyle factors may prevent cognitive decline. In recent decades, nutritional interventions have gained attention as potential strategies for cognitive decline prevention [10,11]. Various nutrients, dietary patterns, and dietary supplements have been investigated for their potential benefits in cognitive function and neuroprotection. Multiple types of intervention have been applied to these populations to reduce the decline of cognitive function, such as the Mediterranean diet and the ketogenic diet as well as the regulation of fatty acids, antioxidants, vitamins, and micronutrients [12-15]. Andrews et al [16] conducted a systematic review and meta-analysis of randomized controlled trials (RCTs) to evaluate the effect of dietary patterns, food, and nutritional supplements on cognitive function in individuals with MCI. The findings of this review demonstrated that few nutritional interventions convincingly improved the cognition of individuals with MCI [16]. Vlachos et al [17] conducted a systematic review and found folate, vitamin E, omega-3 fatty acids, and certain multinutrient formulations have shown some preliminary promising results [17]. However, the evidence regarding the effectiveness of different nutritional interventions remains inconclusive, with conflicting findings reported across individual RCTs.

To address the limitations of traditional pairwise meta-analyses and provide a comprehensive synthesis of the available evidence, we propose conducting a network meta-analysis (NMA). An NMA is a type of meta-analysis that extends beyond regular meta-analyses [18,19]. By using this approach, we aim to provide more precise and robust estimates of the effects of different nutritional interventions on cognitive decline in patients with MCI and AD. In this protocol, we outline the methodology for conducting an NMA of RCTs on nutritional interventions for the prevention of cognitive decline in patients with MCI and AD.

Methods

Experimental Approach

This protocol was developed following the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) 2015 checklist [20]. This protocol has been registered with the PROSPERO database (CRD42022331173).

Inclusion and Exclusion Criteria

The inclusion and exclusion criteria will be determined according to the principle of the Population, Intervention, Comparison, Outcome (PICO) design. The inclusion and exclusion criteria are presented briefly in Table 1.

Table 1. Inclusion and exclusion criteria for studies in the meta-analysis.

Variables	Inclusion criteria	Exclusion criteria
Study design	RCTs[a] reported as comparing one nutritional intervention with another or a placebo	Non-RCTs
Participants	Participants with MCI[b] or AD[c] older than 50 years	Participants with vascular dementia; Parkinson disease–related dementia; delirium; depression and other mental illnesses; congenital brain function hypoplasia, such as Down syndrome; or subarachnoid hemorrhage
Diagnosis of MCI or AD	Diagnosis according to NINCDS-ADRDA[d] DSM[e] or assessed by MMSE[f] with scores between 10 and 26	N/A[g]
Nutritional intervention assessment	Any type of nutritional intervention, such as special dietary type, dietary pattern, food, nutritional intake, and nutritional supplements at all doses or ingested amounts with a duration of more than 12 weeks	No definitive preventative impact was evaluated, or the effects were evaluated for less than 12 weeks.
Outcome measurement	The primary outcome will be assessed by the MMSE. The secondary outcomes will be assessed with other scales like the ADAS-Cog[h], CDR[i], and WAIS-R[j] scores.	N/A

[a]RCTs: randomized controlled trials.

[b]MCI: mild cognitive impairment.

[c]AD: Alzheimer disease.

[d]NINCDS-ADRDA: National Institute of Neurological and Communicative Disorders and Stroke and the Alzheimer's Disease and Related Disorders Association.

[e]DSM: Diagnostic and Statistical Manual of Mental Disorders.

[f]MMSE: Mini-Mental State Examination.

[g]N/A: not applicable.

[h]ADAS-Cog: Alzheimer's Disease Assessment Scale cognitive subscale.

[i]CDR: Clinical Dementia Rating Scale.

[j]WAIS-R: Wechsler Adult Intelligence Scale-Revised.

Inclusion Criteria

Type of Study

All RCTs that compared one nutritional intervention with another or a placebo for the prevention of cognitive decline in patients with MCI or AD will be included.

Participants

Participants with MCI or AD older than 50 years, regardless of gender, ethnicity or race, geography, dwelling, or chronic diseases, will be included in the analysis.

Inclusion of Patients With Different Degrees of MCI or AD

Participants will be considered as having AD by fulfilling the requirement of the National Institute of Neurological and Communicative Disorders and Stroke and the Alzheimer's Disease and Related Disorders Association (NINCDS-ADRDA) or the Diagnostic and Statistical Manual of Mental Disorders (DSM) [21,22]. Participants will be evaluated for MCI using the Mini-Mental State Examination (MMSE) [23].

Nutritional Interventions Assessment

Experimental interventions included any type of nutritional intervention, such as special dietary type, dietary pattern, food, nutritional intake, and nutritional supplements at all doses or ingested amounts. Interventions lasted more than 12 weeks and were with or without medication as cointervention. The control group received a placebo intervention.

Outcome Measurements

Both the primary outcome and secondary outcomes involve the assessment of the cognitive function. The primary outcome will be assessed by the MMSE and the Alzheimer's Disease Assessment Scale cognitive subscale (ADAS-Cog). The secondary outcomes will be assessed using other scales, such as the Clinical Dementia Rating Scale (CDR), and the Wechsler Adult Intelligence Scale-Revised (WAIS-R). The standard mean difference (SMD; Cohen *d*) will assess the effect sizes of the continuous variables. A small-sample (n<20) correction will be applied to SMD, leading to an effect size called Hedges *g*.

Exclusion Criteria

The following studies were excluded:

- Studies were non-RCTs or in the form of a letter, editorial, commentary, or case report.
- There was no definitive preventative impact evaluated, or the effects were evaluated for less than 12 weeks.
- Participants had vascular dementia; Parkinson disease–related dementia; delirium; depression and other mental illnesses; congenital brain function hypoplasia, such as Down syndrome; or subarachnoid hemorrhage.

Search Strategy

Two investigators (QH and KCHW) will independently perform the search strategy, and disagreements will be resolved by discussion or by a third investigator (JYZ). We will search for all the relevant citations published from the date of the respective database onset until Dec 31, 2023, in 3 English databases (ie, PubMed, Embase, and Cochrane Library). We will establish search strategies that combine keywords and indexed terms indicative of MCI or AD, nutritional intervention, and RCTs. Furthermore, the reference lists of the listed papers will be manually examined to seek new studies that are related. Any controversies will be resolved through dialogue. Multimedia Appendix 1 includes the search techniques.

Data Extraction

Two investigators (QH and KCHW) will independently extract the data from all eligible studies published in English using standardized spreadsheets that are predefined. Any discrepancies will be resolved through consensus by discussion between the 2 investigators or, if necessary, arbitrated by a third investigator (JYZ). The following information will be extracted from every study: first author, publication year, detailed trial information (ie, randomization, sequence concealment, blinding, nutritional intervention protocols, number of treatment arms, as well as the dose and frequency of interventions), the diagnosis criteria, characteristics of the patient (eg, age, gender, race, and baseline MMSE or ADAS-Cog scores), sample size, follow-up MMSE or ADAS-Cog scores, number of completed interventions, as well as the duration of the intervention and follow-up. We will contact the authors via email to obtain the raw data when the data on outcomes are incomplete in the original article; otherwise, we will not include studies lacking such data. At last, 2 investigators will cross-check all retrieved data to verify their accuracy.

Quality Assessment

The quality of the included studies will be evaluated by the Version 2 of the Cochrane risk-of-bias tool for randomized trials (RoB2) [24]. Various biases, such as selection bias (randomized sequence generation and allocation concealment), performance bias (blinding of participants and personnel), detection bias (blinding of outcome assessment), attrition bias (dealing with incomplete outcome data), reporting bias (selective reporting), and overall biases will be assessed in our study. The trials will be categorized into 3 types: low risk of bias, unclear risk of bias, and high risk of bias. Assessment of bias of the trials will be conducted by 2 investigators (QH and KCHW), and disagreements will be resolved through discussion with a third investigator (JYZ). Moreover, we will contact the authors asking for detailed allocation concealment and other characteristics when they are not available in the study.

Statistical Synthesis

Characteristics of Included Studies and Information Flow in the Network

For the eligible trials included in our analysis, we will generate descriptive statistics to provide a comprehensive overview of the population characteristics and key variables across all trials. These descriptive statistics will encompass factors such as age, disease subtype, and other relevant risk factors that may impact the outcomes of interest. To visually represent the network of evidence, we will construct a network diagram. The edges connecting different interventions will be depicted with widths proportional to the inverse of the variance of the summary impact for each direct treatment comparison. The size of the nodes in the diagram will correspond to the quantity of evidence accumulated for each treatment, represented by the total number of studies contributing to that node. In addition, we will use a contribution matrix to explore the direct comparisons that have a substantial influence on the relative effects within the network [21,22]. This matrix will help identify the specific comparisons that contribute significantly to the overall findings.

Assessment of the Transitivity Assumption

The transitivity assumption will be assessed by evaluating the distribution of modifiable variables, such as age and mean baseline cognitive function, between the intervention and the control group [23].

Pairwise Meta-Analyses and Network Meta-Analyses

By conducting the pairwise meta-analysis, we can quantitatively assess the effectiveness of interventions that have direct evidence. This analysis allows for a comparison of the treatment effects within individual studies, providing valuable insights into the efficacy of each intervention. To ensure transparency and facilitate interpretation, we will present the results of the pairwise meta-analysis using forest plots.

The NMA will be conducted using a Bayesian framework, pooling data from all included studies [24]. To provide a visual representation of the network of evidence, we will generate network plots, which summarize the geometry of the network. These plots will help illustrate the connections between different interventions and highlight the available evidence for each comparison. For the estimation of effect sizes, we will use contrast-based methods within the NMA framework. The surface under the cumulative ranking curve will be used to estimate the relative rank of the different nutritional interventions [25].

All data will be analyzed using the R 4.0.3 (R Core Team) software, specifically using the gemtc package. Estimates will be reported as SMDs and 95% credible intervals (CrIs). We will use 3 Markov chains with 100,000 iterations after an initial thinning of 10,000 and a thinning of 10. The convergence of the model will be estimated by checking trace plots and the Brooks-Gelman-Rubin statistical value.

A systematic review will be considered when studies are scarce, typically involving less than 2 available studies. Additionally, if the heterogeneity observed among the included studies is exceptionally high, typically exceeding 95%, a systematic review approach will be adopted.

Assessment of Inconsistency for Network Meta-Analysis (NMA)

Consistency refers to the statistical manifestation of transitivity while a lack thereof is known as inconsistency [26]. Inconsistency suggests a disagreement between these estimates and indicates potential issues with the consistency of evidence

across the network of studies. We will use the node-splitting method to assess inconsistency [27,28]. The presence of inconsistency between different estimates using direct and indirect evidence can be evaluated by assessing the *P* value. Inconsistency in the network is indicated by $P<.05$.

Assessment of Heterogeneity and Sensitivity Analyses

To quantify between-study heterogeneity, we will calculate the I^2 statistics with 95% CrI and τ^2 to convey the heterogeneity. τ^2 represents the variability in intervention effects across studies, while I^2 quantifies the proportion of total variability that is due to heterogeneity rather than chance. If I^2 >50%, it will be considered as moderate to substantial heterogeneity; in such cases, the effect sizes will be estimated using a random-effects model [29]. Moreover, we will estimate the outlier and influential study when I^2>50%, and then, we will perform the NMA or pairwise meta-analysis again, excluding the outliers and influential studies. Study-specific estimates and 95% CrIs, will be presented by forest plots. Subgroup meta-analyses and meta-regression analysis will be performed to estimate the source of heterogeneity. Subgroup analyses by different groups allow us to test specific hypotheses and describe why certain types of studies produce lower or higher effects than others. Performing subgroup analysis would help estimate if the interventional effects for the primary outcomes are robust. Meta-regression analysis could help quantify the effects by including covariates in the network meta-analysis models, if suitable. Then we will run subgroup and meta-regression with the following criteria: cognitive dysfunction severity at baseline, study year, sample size, risk of bias, duration of intervention, and number of recruiting centers (ie, single-center or multicentric studies).

Sensitivity analyses will be conducted to assess the robustness of the primary outcome results in the meta-analysis. These analyses will involve examining the impact of outliers, influential studies, risk of bias, and sample size by using the leave-one-out method. Specifically, each study will be systematically removed from the meta-analysis, and the pooled effect will be re-evaluated both in pairwise meta-analysis and NMA for each iteration. Studies with changes in the effect size exceeding 10% will be noted.

Assessment of Publication Bias

The comparison-adjusted [26] and contour-enhanced funnel plots [30] will be used to find out whether the results in imprecise trials differ from more precise trials. In addition, network meta-regression models and the Egger test will be performed to detect the effects between study size and effect size and to assess the asymmetry of the funnel plot, respectively.

Results

The initial search yielded 30,269 citations, of which 248 articles were identified as potentially eligible and will undergo evaluation for eligibility. Among these, a total of 197 articles were excluded for various reasons. This exclusion consisted of 3 duplicates, 39 articles without full-text availability, 45 articles lacking an assessment of cognitive function, 40 articles not meeting the criteria of being RCTs, 28 articles not in English, and 42 articles unrelated to the study objective. Ultimately, 51 studies meeting the inclusion criteria were included in our NMA. These studies, published between 1999 and 2023, consisted of 27 studies focusing on AD and 24 studies focusing on MCI. In total, these studies involved 8420 participants. We completed data extraction for all 51 studies by December 2023. Currently, we are actively engaged in data analysis and manuscript preparation. We plan to finalize the manuscript and publish the comprehensive results by the end of 2024.

Ethical approval was not required in the meta-analysis. Our study is merely based on the published literature, for which ethical approval has been obtained. To disseminate the evidence obtained, we will publish our results in an international peer-reviewed journal to improve preventive applications with scientific evidence.

Discussion

The global phenomenon of population aging has led to a significant increase in the prevalence of cognitive impairment, particularly AD and MCI [31]. This demographic shift has garnered substantial attention from health care providers, researchers, and policy makers due to the immense personal, societal, and economic implications [32]. As the current treatments for MCI and AD are limited and primarily focused on symptom management, identifying effective preventive strategies is of paramount importance [15]. The potential benefits of nutritional interventions for cognitive health have been a subject of considerable interest [2]. Various nutrients, dietary patterns, and dietary supplements have been investigated for their potential neuroprotective effects and cognitive function improvement. Therefore, through this study, we aim to consolidate the available evidence and provide a rigorous and comprehensive synthesis using the NMA approach. Moreover, identifying the most effective interventions will help guide future research efforts and resource allocation toward the most promising strategies.

It is important to acknowledge the limitations of this study. Although an NMA provides a robust statistical framework for synthesizing evidence, it is reliant on the quality and availability of data from included RCTs. Furthermore, potential sources of bias and heterogeneity among the studies may affect the robustness of the results.

In conclusion, the findings of this study will have significant implications for clinical practices as well as for informing public health strategies and policy making.

Acknowledgments

The authors would like to thank Dr Qing Xia and Yubo Ma for their helpful advice on this protocol.

This work is supported by the City University of Hong Kong New Research Initiatives Support from Central (APRC; grant 9610401).

Authors' Contributions

QH and KCHW participated in the study design and data collection; they also analyzed the data and wrote the manuscript. ANB participated in the discussion of the study design and data analysis; he also edited the manuscript. JYZ participated in the independent quality checking of all data included in the analysis. KHKC conceived the study, designed and coordinated the study, and revised the manuscript.

Conflicts of Interest

Abstract

Background: The global obesity pandemic among adolescents is becoming a public health issue throughout the world. Telehealth use has significantly increased during and after the COVID-19 pandemic, including its application in adolescent obesity prevention and treatment.

Objective: This review aims to synthesize the evidence on the effectiveness of telenutrition in improving dietary behavior and physical activity in adolescents with obesity.

Methods: The PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analysis Protocols) guideline will be used to structure this protocol. The focus of the systematic review is guided by the population, intervention, comparator, and outcome (PICO) framework. A systematic search of Science Direct, PubMed, Cochrane, Embase, JMIR, ProQuest, and Google scholar databases will be conducted. Two authors will screen the titles and abstracts of identified studies independently and select studies according to the eligibility criteria. The full-text reading will be done independently by 2 reviewers to assess final eligibility. Any discrepancies will then be discussed and resolved. The Cochrane Collaboration Risk of Bias tool was used to assess the risk of bias; a descriptive analysis will summarize the effectiveness of the telenutrition or any type of telehealth intervention used.

Results: The systematic review is expected to be completed by the end of March 2024. The ongoing screening and review of the articles are currently being conducted.

Conclusions: This systematic review aims to summarize the effectiveness, features, design process, usability, and coherence of a telenutrition intervention using behavior change theory to improve dietary patterns and physical activity among adolescents with obesity. It will identify areas for improvement and best practices, informing the development of more useful and engaging telenutrition interventions for adolescents.

Trial Registration: PROSPERO CRD42023458336; http://tinyurl.com/cp46fjj9

KEYWORDS

telehealth; obesity; telenutrition; adolescent; behavior change; virtual counseling; teenager; young adult; food intake; dietary pattern; intervention

Introduction

The global obesity pandemic is becoming a public health issue, particularly among children and adolescents aged 5 to 19 years [1]. Between 2013 and 2018, the trend of adolescent obesity nearly doubled in Indonesia [2,3]. Obesity is caused by unhealthy lifestyles, such as most adolescents not meeting the daily fruit and vegetable recommendation and engaging in less physical activity; additionally, approximately 65% of adolescents skip breakfast, and 56% of adolescents aged 15-19 years have regular daily consumption of sugar-sweetened beverages [4,5].

To address this issue, various programs and interventions have been implemented. Nutrition literacy interventions combined with behavior change communication interventions in a school-based setting have shown to be promising for improving BMI and reducing unhealthy food choices. The school environment has been identified as a strategic channel for health promotion among school-age adolescents [6,7]. However, certain gaps have been identified that explain why health and nutrition programs in school settings in Indonesia have not been as effective as desired. Some schools encountered competing priorities in supporting the program, such as a lack of teachers and time due to teaching constraints. Additionally, 21% of adolescents were not going to school, compounded by insufficient parental support [8,9].

Telehealth is an alternative method for increasing access to adolescents, as the target population, and their parents. A previous systematic review revealed that there is great potential in digital platforms for universal health promotion, especially among school-age children and adolescents [10]. Digital nutrition literacy combined with a behaviour change program delivered via a telehealth platform could be a promising solution to bridge the gap. The International Organization for Standardization defines telehealth intervention for children as "the use of telecommunication techniques for the purpose of providing telemedicine, medical education, and health education over a distance" [11]. A review was carried out to assess the use of digital health interventions, such as websites, short-text messages, gamification, social media, and multidigital component interventions, aimed at improving adolescent diet and physical activity. The review revealed that website interventions can influence behavior change in adolescent diet and physical activity. However, due to variability in engagement, these changes often are not sustained in the medium or long term [12]. Meanwhile, there is less evidence supporting the effectiveness of other digital platforms, such as apps, text messages, and social media [12].

During and after the COVID-19 pandemic, there has been an increase in evidence supporting the impact of telehealth interventions in improving health [13,14]. This medium provides more engagement features compared to other forms of digital intervention. Therefore, a systematic review is required to address the following:

- Synthesize the evidence on the effectiveness of telenutrition in improving dietary behavior and physical activity in adolescents with obesity.
- Identify specific intervention components that characterize the more successful telenutrition intervention, particularly in adolescent populations.

Methods

Overview

We will use the population, intervention, comparator, and outcome (PICO) framework to identify appropriate Medical Subject Headings (MeSH) terms for the literature search. Meanwhile, the PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analysis Protocols) 2015 guideline will be used as the standard reporting protocol guideline checklist. The PRISMA-P 2015 guideline will aid in describing the rationale, hypothesis, and planned methods of the review [15]. The checklist is provided in Multimedia Appendix 1.

This systematic review will comprise a literature search, article selection, data extraction, quality appraisal, data analysis, and data synthesis. The protocol of this systematic review was prospectively registered on PROSPERO (CRD42023458336).

Eligibility Criteria

The PICO framework presented in Table 1 is derived from the research questions previously mentioned.

Table 1. The eligibility criteria based on the population, intervention, comparator, and outcome (PICO) framework.

Criteria	Detailed information
Population	Adolescents or young adults aged 13-18 years with overweight or obesity.
Intervention	Any digital health promotion intervention with any type of telehealth (including but not limited to either educational or personalized feedback or monitoring services).
Comparator	Other digital health promotion interventions delivered by other methods, such as social media, websites, and short-text messengers or studies with control groups without an intervention.
Outcomes	Healthy behavior and nutritional outcome, such as changes in dietary behavior, physical activity level, and BMI.

Search Strategy

We will search the following databases: Science Direct, PubMed, Cochrane, Embase, JMIR, ProQuest, and Google Scholar. Key terms relating to telehealth and telenutrition were extracted from an initial review of the literature. Specific search terms, such as "obesity," "adolescent," "dietary behaviors," and "physical activity," were identified in a preliminary scan of the literature and chosen in consultation with a medical librarian. Search terms will include MeSH terms and related keywords and are grouped into 3 themes presented in Table 2. All the MeSH terms and Keywords are included in Table 2 with the following structure: Obesity (MeSH OR keywords) AND Adolescent (MeSH OR keywords) AND Telenutrition (MeSH OR keywords). To broaden the scope of the article collection, we will not limit the publication period or language of publication in our search strategy. In addition to exploring these databases, a manual search will be performed to identify the reference lists of included studies. Authors of conference and poster abstracts selected for inclusion will be contacted to see if a full text is available to be included.

Table 2. Search terms.

Number	Category	MeSH[a] terms and keywords in titles or abstracts
1	Obesity	"Obesity"[Mesh] OR "Pediatric Obesity"[Mesh] OR "overweight"[MeSH Terms] OR "overweight"[All Fields]
2	Adolescent	("Adolescent" OR "Adolescent Behavior" OR "Adolescent Health" OR adolesce*)
3	Telenutrition	("Telenutrition" OR "Mobile Health" OR "mHealth" OR "Telehealth" OR "eHealth" OR "Short Message Service" OR "SMS" OR "Text Messag*" OR "cell phone" OR "telephone" OR "smartphone" OR "cellular" OR "mobile" OR "social media" OR "social network")
4	All categories	1 AND 2 AND 3

[a]MeSH: Medical Subject Headings.

Inclusion Criteria

Only human intervention studies, either quasi-experimental studies or randomized controlled trials, will be included in this review. This review will evaluate original research articles using digital health promotion interventions delivered via any type of telehealth and involving adolescents aged 13-18 years with overweight or obesity. Overweight and obesity among adolescents aged 5-19 years are defined by their BMI per age *z* score, as outlined in the World Health Organization growth chart references [16]. We will include any study that categorizes participants with a BMI per age *z* score >1 SD as overweight and those with a BMI >2 SD as obese.

Exclusion Criteria

The review focused mainly on the changes in healthy behaviors and nutritional outcomes, including dietary behavior, physical activity levels, and BMI. Any outcomes other than these will be excluded from our review. In addition, articles for which full texts cannot be obtained despite requests to the corresponding authors will be excluded.

Screening and Article Selection

All articles found through database searches will be saved in the citation and article management software Mendeley and Rayyan AI, which will be used to eliminate duplicates and screening. The titles and abstracts of all studies will be reviewed independently by 2 reviewers. Studies that do not meet the eligibility criteria will be excluded, and any disagreements will be discussed until a consensus is reached. The full text of the remaining studies will then be examined by 2 reviewers independently to determine final eligibility, with any disagreements resolved by a third and fourth reviewer. A PRISMA flow diagram will be used to record the details of the screening and selection process so that the study can be replicated.

Data Extraction and Management

One reviewer will read the full text of all the papers included in the final selection to extract the predetermined outcomes, which will be validated by a second reviewer. The outcomes will be extracted into a standard extraction form, which will be designed in Covidence (Veritas Health Innovation). The detailed extraction custom-built form is summarized in Table 3. Disagreements will be resolved through discussion, and if consensus cannot be reached, a third and fourth reviewer will be consulted. Missing data will be considered in the risk of bias assessment, but due to time constraints, authors will not be contacted.

Table 3. Summary of the data extraction template.

Information	Detail extraction
General study information	• Year of publication • Study setting (including the time frame before or after the COVID-19 pandemic, if available) • Analyzing the sample size • Sample demographics (including age, gender, and target population) • Intervention design information (including type, duration, and follow-up periods, if any)
Behavioral and nutrition literacy intervention	• Target health behaviors and intervention focus • Theory of the intervention • Behavior change technique
Telehealth and telenutrition	• Area of health care used • Name of the platform • Developers • Media platform • Design process or steps • Component and design features (ie, gamification, families' involvement, and SMS reminder)
Evaluation	• The outcomes measured • Any kind of effectiveness measurement • Participant health outcomes • Participant engagement or adherence rates (including participation or drop-out rates) • Feasibility and usability • Challenges and limitations (including ethical concerns and barriers during the experiment)

Quality Appraisal and Risk of Bias Assessment

Following the final selection of studies, 2 reviewers will independently assess the risk of bias in all papers included in the final selection. If there is a disagreement in judgment, the reviewers will discuss it before consulting the third and fourth reviewers. The Cochrane Collaboration Risk of Bias tool will be used to assess the randomized controlled trials included in the review and assign low, unclear, or high risk to the studies for each of the potential biases [17]. Studies will be classified as low risk if the identified bias is unlikely to significantly alter the results, and they are classified as high risk if the bias clearly has the potential to significantly alter the results. Unclear risk occurs when the bias imposes some doubt on the outcome. The risk of bias assessment will cover 6 domains: selection, performance, detection, attrition, reporting, and other bias [17].

Meanwhile, ROBINS-I (Risk Of Bias In Non-randomized Studies of Interventions) will be used for evaluating the risk of bias in estimates of the comparative effectiveness of interventions from studies that did not use randomization to allocate units to comparison groups [18]. A table will be created that summarizes the quality of all included studies.

Data Analysis and Synthesis

A meta-analysis is unlikely to be conducted due to the expected diversity of study aims, methods, and reported outcomes. As a result, we will conduct a descriptive analysis to summarize the extracted data. Each outcome will be coded as having no (0), some (+), or significant evidence (++) of effectiveness in both outcomes. Significant evidence will be coded only when the intervention (ie, nutritional literacy and behavior change communication via telehealth delivery) outperforms a comparator or control. The intervention will be considered to have some evidence of effectiveness if there is a significant difference over time but not between groups or a significant improvement in only a subgroup of the population. Studies will be grouped by target health behavior (eg, dietary pattern only, physical activity only, or both) and analyzed together to describe the effectiveness of telehealth or telenutrition interventions in general for both those target behaviors; in particular, the analysis will focus on either dietary pattern or physical activity. The discussion will synthesize the data to describe specific intervention components that characterize a successful telenutrition intervention, such as the type of digital platform, engagement features, theory, method, and behavior change strategy used. The theory, method, and behavior change strategy will be analyzed and presented based on the intervention mapping approach and its taxonomy, as described by Bartholomew et al [19] and Kok et al [20]. Furthermore, the information regarding the identified barriers and challenges of telehealth interventions will be summarized to give directions for future research and development.

Ethical Considerations

There will be no involvement from patients or the public in this study. This study synthesizes data from studies that were already peer reviewed and published. Thus, no ethical approval will be required.

Results

The systematic review is expected to be completed by the end of March 2024. The ongoing review and data extraction of the articles is currently being conducted. The findings of this study will be outlined in the following subsections: (1) study selection,

(2) study characteristics, (3) synthesis of results (behavior change strategy and method or telehealth development and intervention), as well as (4) impact and evaluation, including challenges and barriers of study implementation.

Discussion

A systematic and transparent review of the literature will provide a better understanding of the current state-of-the-art telehealth or telenutrition approaches, how they are used, and their effectiveness. Strengths, limitations, and implications for the interaction of technology and behavioral health management will help inform and improve the development, acceptability, and effectiveness of future telehealth approaches in managing adolescent obesity for clinicians, telehealth providers, and relevant stakeholders. Based on the data, we will outline the conclusions, the strengths and limitations of our systematic review, and important directions for future research. Telehealth has grown over the past decade, with its popularity increasing during the COVID-19 pandemic. In addition, our review aims to differentiate findings between before and after the COVID-19 pandemic, if possible. Furthermore, the findings will be interpreted carefully, taking into consideration the potential scalability to other areas or countries with similar contexts. Our study has some potential limitations due to limited resources; we were unable to conduct manual searching and identification of reference lists of included studies. The review also could not provide a clear effect estimate between the telehealth intervention and health outcomes, as a meta-analysis could not be conducted.

Acknowledgments

The authors would like to thank the Faculty of Medicine, Public Health and Nursing of the Universitas Gadjah Mada and the Faculty of Public Health of the Universitas Ahmad Dahlan, Indonesia, for their support of this study. Our special thanks goes to Herman Herman, PhD, from the Faculty of Information and Technology at Universitas Ahmad Dahlan for the useful discussion during our protocol design.

Authors' Contributions

MRA and FSTD conceived the study topic and designed the review protocol. MRA and NK performed article screening, reviewed by AAPP and FSTD. MRA prepared the first draft of the protocol, and revisions were made by NK, AAPP, and FSTD. The manuscript was submitted after all authors reviewed and agreed to it.

Conflicts of Interest

None declared.

Abstract

Background: Chronic pain is a highly prevalent condition that requires multidisciplinary treatment. However, in the United Kingdom, access to specialist pain clinics where patients can receive medical multidisciplinary treatment is limited, and provision varies between health boards. As such, self-management of chronic pain using digital tools has been gaining traction recently, but evidence of its effectiveness from clinical-based trials focuses mainly on quantitative outcomes.

Objective: This systematic review aims to identify, appraise, and synthesize qualitative evidence on patients' experiences with digital health interventions (DHIs) for the management of chronic pain.

Methods: This systematic review will consider qualitative and mixed methods studies that explore the experience of patients (aged 18 years and older) with chronic pain engaging in DHIs to manage their pain. MEDLINE Ovid, PubMed, Embase, CINAHL, PsycINFO, and Scopus databases will be searched for published studies. The systematic review will be conducted in accordance with the ENTREQ (Enhancing Transparency in Reporting the Synthesis of Qualitative Research) guidelines. Following the 3-step thematic synthesis methodology of Thomas and Harden, titles and abstracts will be screened by 2 independent reviewers (AM and HM), and a third reviewer (MI or FM) will resolve any conflict that arises before the full-text screening. The Critical Appraisal Skills Programme checklist tool will be used to critically appraise the included studies. The extracted data will be imported to NVivo (QSR International), where thematic synthesis will be used to derive analytical themes from the included studies.

Results: Themes that encapsulate the patient experience will be identified from qualitative evidence, and these themes will shed light on the perceived benefits and disadvantages, usability, acceptability, and the overall impact digital tools can have on the lives of those with chronic pain.

Conclusions: This systematic review will identify, appraise, and synthesize the overall experience of patients engaging in DHI to manage a diverse range of chronic pain conditions. By elaborating the patient experience through qualitative analysis, the findings from this review will enhance our current understanding of the experiences of patients with chronic pain using digital tools for the self-management of their pain and highlight what person-centered elements are essential for future DHI development.

Introduction

Background

Chronic pain is a major public health condition affecting more than 30% of the world's population [1]. Defined as pain that persists beyond the expected recovery period of 12 weeks [2], chronic pain is a complex phenomenon, and the root causes are only partially understood [3]. Following recent developments, the *International Classification of Diseases* has adapted its definition of chronic pain to encompass both primary and secondary chronic pain. Chronic secondary pain is initially regarded as a symptom caused by an underlying condition or disease (such as cancer, rheumatoid arthritis, or endometriosis), whereas in chronic primary pain, pain emerges without any history of an injury or operation (eg, fibromyalgia, headache, and musculoskeletal pain) [2].

Chronic pain is a complex condition pertaining to biological, psychological, and social components [4]. A UK-based population study found that of 28 million adults affected by chronic pain, around 12% of people described their pain to be moderately or severely disabling [5]. In addition to the physical burden, psychological challenges are frequently associated with chronic pain with many individuals reporting a significantly deteriorated quality of life [6]. Chronic pain can also have a considerable socioeconomic impact, with pain impacting work effectiveness, which in many cases leads to unemployment [7].

To successfully manage the multifaceted nature of chronic pain, a multidisciplinary treatment approach is required. Substantial evidence supports that combining approaches across disciplines is the most effective treatment in addressing the biopsychosocial nature of chronic pain [8-12], although access to evidence-based multidisciplinary treatment is not always readily available [13]. Many patients with chronic pain rely on their general practitioner for advice [14], and those who do get referred to specialist pain clinics can wait months to years for assessment and treatment [13].

A means of overcoming the barriers of accessibility to multidisciplinary health care could be the delivery of self-management strategies using digital tools, which have become more prevalent than ever since the COVID-19 pandemic. Digitization has transformed the health care landscape by offering more accessible alternatives to conventional medical treatment [15]. Digital health interventions (DHIs) use a range of digital tools, such as smartphone apps, websites, and social media campaigns, to deliver self-management programs remotely [16]. Self-management strategies for chronic pain management include symptom tracking, physical activity, education, relaxation techniques, and cognitive behavioral therapy [17-20]. According to the Office of National Statistics, approximately 90% of private UK households have computers and mobile phones in 2022; therefore, digital health is accessible to almost everyone [21].

Research regarding the impact of digital tools has grown exponentially in recent years. A number of systematic reviews have evaluated the effectiveness of digital tools in areas such as chronic pain in general [16,22], specific chronic pain conditions [23,24], the impact of individual modalities such as smartphones [25,26], and specific age groups [27]. It is widely considered that such tools are effective in improving clinical outcomes such as pain intensity, pain interference, and improvements in quality of life [28].

Although there is substantial evidence on the positive effect digital tools can have on chronic pain patients' symptoms, most research focuses on quantitative outcomes. Quantitative research is essential in supporting evidence-based practice, which emphasizes findings from well-designed research to provide high-quality patient care [29]. However, it has been argued that quantitative evidence from clinical trials does not take into account patients' individual experiences, thus overlooking the complex nature of chronic pain [30]. In response to standard evidence-based practice, there has been a shift to person-centered care, which has transformed the health care system. Person-centered care was first described as "understanding the patient as a unique human being" [31], where the sole focus is on the individual, and treatment can be tailored to a patient's needs. The World Health Organization (WHO) guidelines advise person-centered care as a core element of good quality health care [2], and studies have shown that person-centered care significantly improves clinical outcomes [32].

A systematic review of qualitative studies by Fernandes et al [33] evaluated enablers and barriers to telehealth interventions for individuals with musculoskeletal pain, and Svendsen et al [34] explored engagement strategies, facilitators, and barriers to the use of DHIs for low back pain management. However, both qualitative reviews focus on barriers and facilitators to DHI engagement rather than overall patient experience, and both studies target a specific condition as opposed to a diverse range of chronic pain conditions. Despite the abundance of qualitative literature exploring the experiences of patients with chronic pain with DHIs, the evidence that encapsulates the experience as a whole has yet to be synthesized.

To address this gap in the research, this review will identify, appraise, and synthesize qualitative data, through a thematic synthesis approach, to provide a detailed account of how patients with chronic pain experience DHIs, and if and why they experience changes and improvements in patient-reported outcomes. Thematic synthesis was developed to address questions concerning intervention need, appropriateness, and acceptability and can produce results that have the potential to inform the design and practice of interventions [35]. Descriptive explanations of patients with chronic pain views could uncover a better understanding of DHI lived experiences from the point of view of the end user—for whom the treatment is designed. Therefore, the findings from this review could have the potential

to enhance our understanding of how DHIs impact patients with chronic pain and emphasize what patient-centered aspects are important for future DHI development.

Objectives

This review aims to identify, appraise, and synthesize existing qualitative evidence on patients' experiences with a DHI for the self-management of chronic pain.

Methods

Overview

The proposed review will be conducted in accordance with "ENTREQ (Enhancing Transparency in Reporting the Synthesis of Qualitative Research) guidelines [36].

Search Strategy

The search strategy and eligibility criteria will be based on the SPIDER (Sample, Phenomenon of Interest, Design, Evaluation and Research) framework [37]. This framework was deemed the most suitable for answering the research question as it has been adapted for clarity in nonquantitative research by outlining key characteristics of qualitative research questions [37].

Keywords used in the search strategy adhere to each of the key characteristics of the SPIDER framework. These include chronic pain as the sample ("fibromyalgia" and "rheumatoid arthritis"), DHIs as the phenomenon of interest ("mHealth" and "telemedicine"), qualitative methods as the design and research type ("qualitative" and "thematic analysis"), and patient experience as the evaluated outcomes ("patient satisfaction" and "patient attitudes").

The search strategy will involve an initial search of electronic databases, followed by the analysis of keywords in the titles and abstracts of each database search. The search will then continue to the reference lists of selected articles to identify additional studies not located through the electronic database search. The strategy will aim to locate published articles—gray literature and unpublished articles will be excluded from the review. Due to the rapidly evolving nature of digital technology, the search will be limited to articles published within the last 10 years in order to capture the most relevant literature (2013-2023). The search will also be limited to articles published in the English language. The search strategy will be adapted for each electronic database. A detailed search strategy for each database is presented in Multimedia Appendix 1.

Information Sources

A literature search for qualitative and mixed methods studies will be conducted on the following electronic databases: Embase, MEDLINE, PubMed, CINAHL, PsycINFO, and Scopus. These databases have been chosen as they encompass nursing, medicine, social sciences, and psychology literature, which are deemed the most appropriate for answering the research question concerning patient experience and chronic pain.

Eligibility Criteria

Inclusion criteria will follow the SPIDER [37] framework. Textbox 1 shows the list of inclusion and exclusion criteria.

Textbox 1. Inclusion and exclusion criteria based on the SPIDER (Sample, Phenomenon of Interest, Design, Evaluation and Research) framework.

Inclusion criteria

- Papers reporting on participants (aged ≥18 years old) with a diagnosis of chronic pain
- Papers that report on digital health interventions to deliver self-management strategies for chronic pain
- Qualitative studies and mixed methods studies with a qualitative component
- Papers that report on patient experience of participating in a digital health intervention through qualitative data
- Papers published in the English language

Exclusion criteria

- Papers reporting on participants <18 years old
- Papers that have not specified that the participants have a chronic pain diagnosis
- Papers that include participants with chronic pain that does not exceed 12 weeks
- Papers that report on digital health interventions that incorporate external involvement
- Quantitative studies, quantitative components from mixed methods studies, gray literature, protocols, dissertations, and other reviews
- Papers that report data from participants who did not actively participate in the intervention
- Papers published in a language other than English

Sample

The review will include studies that involve patients older than age of 18 years with a diagnosis of chronic pain, who have participated in a DHI that delivered self-management strategies. Studies exploring the experience of children, adolescents, clinicians, or health professionals will be excluded. The definition of chronic pain will be aligned with the revised *International Classification of Diseases, 11th Revision* classification: pain that persists or recurs for more than 3 months [2], including both primary and secondary chronic pain. The included conditions are based on the National Institute for Health

and Care Excellence guidelines for assessing and managing both primary and secondary chronic pain [3].

Phenomenon of Interest

The phenomenon of interest explored in this review will be DHIs that deliver self-management strategies for chronic pain. Digital interventions regardless of platform (eg, telephone, web-based smartphone app, and social media) or self-management strategy (eg, exercise, education, relaxation, and meditation) will be included. Due to the terminological inconsistency existent in the current literature, the review will not distinguish among telehealth, telemedicine, eHealth, mobile health, or other similar terms. This review will use the term "digital health" to encompass all related terms.

Design and Research Type

The review will consider studies that explore patients' experiences of participating in a DHI. Qualitative data regarding patient experience collected through surveys, questionnaires, focus groups, group and individual interviews, and observational data will be examined, and this may have been collected remotely or face-to-face or in a group or one-to-one setting. Mixed methods studies with a qualitative component will be included; the quantitative data from these studies will not be used in this review. Protocols, dissertations, gray literature, and other reviews will be excluded.

Evaluated Outcomes

The outcome evaluated in this review will be patients' experiences of participating in DHIs. This will be in the form of qualitative data collected via questionnaires, focus groups, surveys, observational data, and interviews. Patients must have participated in the intervention either entirely or partially, for example, patients who started a digital intervention and followed through until completion, and patients who started a digital intervention and did not complete it in its entirety. Studies exploring patients' opinions or perceptions of what an intervention should involve without active participation will be excluded.

Data Extraction

Articles identified from the database search will be uploaded to EndNote (version 20; Clarivate), and any duplicates will be removed. Two independent reviewers (AM and HM) will then screen the titles and abstracts in Rayyan for papers that meet the inclusion criteria. The data extracted will adhere to the SPIDER tool, specifically outlining the sample, phenomenon of interest, and outcomes of significance to the objective of this review [37]. Any uncertainty between reviewers will be resolved by discussion, and if necessary, a third reviewer (MI or FM) will be requested to resolve any disagreements that persist. This process will be repeated for the papers included for full-text screening. Subsequently, the remaining papers will be included in the review. Each paper will be uploaded to NVivo (version 12) as this will facilitate the researcher's ability to perform data synthesis systematically and rigorously. The full data extraction table will include the author, year of publication, country design, data collection method, participant characteristics, type and description of the intervention, and potential themes.

Strategy for Data Synthesis

The results and discussion section of each included paper will be imported verbatim to NVivo, where a 3-step thematic synthesis approach based on the methodology described by Thomas and Harden will be used [38].

1. The first step will involve line-by-line coding of the results and discussion sections to identify contextual information on patient experiences with DHIs for the self-management of chronic pain.
2. Subsequently, similarly coded data will be clustered together to generate "descriptive themes." Descriptive themes will be based on verbatim data from the selected studies. Reviewers will reassess these codes to ensure the data are captured accurately.
3. Consequently, using inductive reasoning to make inferences from previous codes, reviewers will identify "analytical themes" about the experiences captured in the descriptive themes. These themes will be relevant to the key aim of this meta-synthesis. These themes are comprised based on inferences made from the data and, therefore, will be conducted independently by 1 reviewer (AM).

Risk of Bias or Critical Appraisal for Included Studies

The Critical Appraisal Skills Programme (CASP) checklist tool will be used to assess the methodological quality of the included studies. The CASP tool was deemed appropriate for the context of this review as it is endorsed by Cochrane and the WHO [39] and is the most frequently used tool for quality appraisal in health-related qualitative evidence syntheses [40]. Two reviewers (AM and HM) will assess the quality of the included papers independently, and any discrepancies that arise between reviewers will be resolved through discussion. If an agreement is not met, an additional reviewer (MI or FM) will be consulted until a consensus has been reached.

Ethical Considerations

Ethical approval is not required for conducting the systematic review as the research does not directly involve human participants or access to personal or identifiable data. The findings from this review will be disseminated to a broad range of stakeholders, including academics, clinicians, and policy makers. The findings will also be published in accredited peer-reviewed journals. This protocol is part of a larger PhD project; therefore, the findings will also be included as part of the thesis.

Results

This review will synthesize qualitative literature on patients' experiences of participating in a DHI for the self-management of chronic pain. Using thematic synthesis, an adapted version of Braun and Clark's thematic analysis developed for the purpose of secondary data synthesis [38,41], analytical themes will be derived from the included studies. We anticipate that the results from this review will characterize the patient experience of DHIs for the self-management of chronic pain and explain the impact digital tools have on the lives of those with chronic pain. These findings will emphasize what patient-centered aspects are essential for future DHI

development, such as how they engaged with DHIs, perceived advantages and disadvantages, which aspects of DHIs they felt worked well and which could be improved, and insights on acceptability and usability. Evidence-based practice emphasizes evidence from well-designed research. However, it has been argued that this approach does not value individual experience and subsequently does not effectively represent the complexity of the chronic pain experience [38]. The results of this qualitative systematic review will enhance our understanding of the way patients experience DHIs for the self-management of chronic pain by emphasizing individual experience from a person-centered approach.

Discussion

Principal Findings

Previous systematic reviews have demonstrated the effectiveness of DHIs in improving patients' outcomes across various health conditions, including chronic pain in general [16,22] as well as specific chronic pain conditions like musculoskeletal pain [23]. However, there is a lack of research evaluating qualitative studies that explore how patients with chronic pain experience such improvements in DHIs. A qualitative exploration of experiences has the potential to generate an in-depth, representative, conceptual understanding of how patients exhibit such improvements in outcomes. Themes that characterize the patient experience of participating in DHIs for the self-management of chronic pain will be identified to capsulate the impact DHIs have on individuals living with chronic pain.

Strengths and Limitations

The comprehensive systematic approach to the current review is a major strength of this research. The search strategy and inclusion criteria are based on SPIDER, a framework adapted for clarity in qualitative research by defining crucial characteristics of qualitative research questions [37]. The search strategies for each database were developed with the help of 2 specialist librarians (see Multimedia Appendix 1), and search terms regarding chronic pain were taken from the National Institute for Health and Care Excellence guidelines for the management of chronic pain [3]. The review will be guided by the ENTREQ checklist to ensure a rigorous systematic approach is taken to synthesize the qualitative evidence [36]. The quality of included studies will be assessed using the CASP checklist tool, which has been endorsed by Cochrane and the WHO [39]. Following the 3-step thematic synthesis approach based on the methodology described by Thomas and Harden, extracted data will be reviewed by 2 independent researchers (AM and HM), and a third reviewer (MI or FM) will be consulted to resolve any issues that arise.

Limitations of this review include the exclusion of studies published in a language other than English, as well as gray literature, both of which could have valuable contributions to the research outcomes. Furthermore, although thematic synthesis is a powerful method that can draw overall conclusions on a specific topic, the raw data from each included study are not analyzed, which could undermine the richness of the data from each primary study.

Conclusions

This systematic review will be the first to synthesize the overall experience of patients engaging in DHIs to manage a diverse range of chronic pain conditions. The in-depth analysis provided by qualitative data will enhance our current knowledge, representing the point of view of the end user—for whom the digital interventions are designed to treat. By elaborating the patient experience through qualitative analysis, the findings from this review have the potential to inform the future development of DHIs by highlighting which person-centered aspects are crucial to effectively manage symptoms of chronic pain.

Acknowledgments

The authors thank the University of Strathclyde librarians Elaine Blair from the Faculty of Science and Sarah Kevill from Humanities and Social Sciences for their support in developing the search strategies for this review. This systematic review is part of a PhD studentship funded by the Dr David Stirling Health Research Fund to support research into Chronic Pain.

Abstract

Background: Artificial intelligence as a medical device (AIaMD) has the potential to transform many aspects of ophthalmic care, such as improving accuracy and speed of diagnosis, addressing capacity issues in high-volume areas such as screening, and detecting novel biomarkers of systemic disease in the eye (oculomics). In order to ensure that such tools are safe for the target population and achieve their intended purpose, it is important that these AIaMD have adequate clinical evaluation to support any regulatory decision. Currently, the evidential requirements for regulatory approval are less clear for AIaMD compared to more established interventions such as drugs or medical devices. There is therefore value in understanding the level of evidence that underpins AIaMD currently on the market, as a step toward identifying what the best practices might be in this area. In this systematic scoping review, we will focus on AIaMD that contributes to clinical decision-making (relating to screening, diagnosis, prognosis, and treatment) in the context of ophthalmic imaging.

Objective: This study aims to identify regulator-approved AIaMD for ophthalmic imaging in Europe, Australia, and the United States; report the characteristics of these devices and their regulatory approvals; and report the available evidence underpinning these AIaMD.

Methods: The Food and Drug Administration (United States), the Australian Register of Therapeutic Goods (Australia), the Medicines and Healthcare products Regulatory Agency (United Kingdom), and the European Database on Medical Devices (European Union) regulatory databases will be searched for ophthalmic imaging AIaMD through a snowballing approach. PubMed and clinical trial registries will be systematically searched, and manufacturers will be directly contacted for studies investigating

the effectiveness of eligible AIaMD. Preliminary regulatory database searches, evidence searches, screening, data extraction, and methodological quality assessment will be undertaken by 2 independent review authors and arbitrated by a third at each stage of the process.

Results: Preliminary searches were conducted in February 2023. Data extraction, data synthesis, and assessment of methodological quality commenced in October 2023. The review is on track to be completed and submitted for peer review by April 2024.

Conclusions: This systematic review will provide greater clarity on ophthalmic imaging AIaMD that have achieved regulatory approval as well as the evidence that underpins them. This should help adopters understand the range of tools available and whether they can be safely incorporated into their clinical workflow, and it should also support developers in navigating regulatory approval more efficiently.

KEYWORDS

AIaMD; artificial intelligence as a medical device; artificial intelligence; deep learning; machine learning; ophthalmic imaging; regulatory approval

Introduction

Overview

There is a growing capacity-demand mismatch within ophthalmology, increasing the risk of sight loss from treatment delays [1,2]. Artificial intelligence (AI) has the potential to help address these challenges. AI's strength lies in its ability to produce high-throughput analyses and glean meaningful insights from complex multimodal and multidimensional data sets through pattern recognition. This is well aligned with ophthalmology services, where disease diagnosis and management depend heavily on multimodal imaging [3]. AI therefore has the potential to help improve speed and access to care at reduced costs.

However, despite the exponential increase in the number of AI as a medical device (AIaMD) being developed and receiving regulatory approval, relatively few have been seamlessly integrated into routine clinical practice [4-6]. This so-called "AI chasm" limits the deployment of AIaMD to achieve patient benefit at scale [7]. This AI chasm results from a wide range of interdependent factors at the policy, organizational, and individual levels [8-13]. Key elements include ensuring adequate clinical evaluation to support regulatory decisions, such that the evidence base underpinning such tools is aligned with their intended use and is safe for the target population, and also clarifying how these regulatory requirements align with commissioners' needs.

The evidential requirements for software (including AIaMD) may be more ambiguous compared to more established interventions, making it more difficult for AI developers to explicitly understand the nature and extent of evidence they need to generate to gain regulatory approval. Attempts to study regulator approved AIaMD are impeded by the usability of public databases as well as the private nature of much of the information submitted by applicants, making it difficult for researchers, clinicians, or commissioners attempting to understand the evidence underpinning approved AIaMD. A review of Food and Drug Administration (FDA) approvals in the United States found that few submissions included comparisons between AI and human performance and that only a small proportion reported prospective data [14]. The reporting of sample size and number of sites in the validation studies was generally poor. The review did not assess whether participant characteristics such as gender and ethnicity were reported. Although guidelines for performing and presenting AI studies have been developed [15-18], there is no clear "best practice" for providers to ensure the safety and effectiveness of the AIaMD they adopt [14].

Review Objectives

This scoping review will focus on AIaMD that contributes to clinical decision-making (relating to screening, diagnosis, prognosis, and treatment) using ophthalmic imaging as an input. The aim is to identify and characterize AIaMD for ophthalmic imaging, which have received regulatory approval in 4 countries with established regulatory pathways for clinical use, in order to support providers in procurement decisions and developers in generating evidence to support applications to regulators.

The objectives are as follows:

1. To identify regulator-approved AIaMD for ophthalmic imaging in Europe, Australia, and the United States
2. To report the characteristics of those AIaMD and the regulatory approvals granted to them
3. To report the available evidence for the effectiveness and efficacy of approved AIaMD

Methods

Protocol Registration and Reporting

The protocol and subsequent review will adhere to the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) [19] and PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) [20] reporting guidelines, respectively (note that PRISMA-AI [21] is still in development). The protocol was registered with the Open Science Framework's website.

Eligibility Criteria

This review will focus on AIaMD for ophthalmic imaging that helps inform clinical management. All AIaMD for ophthalmic

imaging where the AIaMD or its manufacturer are recorded in the US FDA, Medicines and Healthcare products Regulatory Agency (MHRA), European Database on Medical Devices (EUDAMED), or Australian Register of Therapeutic Goods (ARTG) databases will be included. All 4 countries are members of the International Medical Regulators Device Forum and have a track record of admitting AIaMD to their markets. No restrictions will be placed on the type of ophthalmic imaging modality involved or the intended use of the AIaMD.

The AIaMD will have a partial or fully data-led mechanism (eg, regression modeling, random forest, or convolutional neural networks). Any AIaMD that exclusively uses rule-based mechanisms (eg, a priori decision trees, best practice alerts, and normal or abnormal threshold alerts) will be excluded.

With regard to the evidence underpinning each AIaMD, only original research that comprises a clinical evaluation of the AIaMD in human participants will be included. This may include randomized controlled trials or prospective or retrospective observational studies. Systematic reviews and meta-analyses, case series, case reports, commentaries, and expert opinions will not be eligible. No date or language restrictions will be applied to the electronic search.

Search Strategy and Sources of Information

To identify potentially eligible AIaMD, the FDA (United States), ARTG (Australia), MHRA (United Kingdom), and EUDAMED (European Union) regulatory databases will be searched through a snowballing approach [22]. This will involve an exhaustive review of the product class codes and predicate devices (if applicable) with which each known eligible device is associated. This strategy has been adopted due to limitations in the search functionality of these databases. No AI tools will be used to assist the search.

The snowball search will commence with a list of 15 AIaMD for ophthalmic imaging (Textbox 1). This represents the sum of the authors' awareness of regulated products and a pragmatic search of relevant academic literature [23].

Textbox 1. Initial list of ophthalmic imaging artificial intelligence as a medical device (AIaMD) used in snowball search.

Ophthalmic imaging AIaMD

- LumineticsCore (previously known as IDx-DR), Digital Diagnostics
- Eyeart, Eyenuk Inc
- RetmarkerDR, Retmarker SA
- SELENA+, eyRIS Pte Ltd
- Automated Retinal Disease Assessment, Verily Life Sciences
- Medios AI, Remidio
- OphtAI, Evolucare, ACDIS
- RetCAD, Thirona Retina B.V.
- DeepDee AI, DeepDee
- MONA DR, MONA
- Eyetelligence, Eyetelligence Pty Ltd
- CARA, Diagnos
- RetinaLyze, RetinaLyze System A/S (Ltd)

Next, PubMed, ClinicalTrials.gov, and the International Clinical Trials Registry Platform will be systematically searched for each eligible AIaMD and its manufacturer by combining both search terms with an "OR" Boolean operator. These searches will be limited to relevant ophthalmology-specific studies using relevant key terms such as "retin*" for AIaMD relating to diabetic retinopathy screening.

In addition, manufacturers' websites will also be reviewed for any peer-reviewed publications. The manufacturers of all eligible AIaMD will be contacted directly for clarification and as an additional source of peer-reviewed publications and ongoing studies. A preliminary scoping search highlighted that not all studies mention the AI device name or manufacturer, and some devices undergo a name change from one version to the next. Hence, this additional search will ensure that the data captured are as comprehensive as possible.

Study Selection

Two authors will search the regulatory databases independently. They will come to a consensus decision about the eligibility of any AIaMD identified. Any unresolved disagreements will be arbitrated by a third author. There may be instances where an AIaMD's eligibility or its regulatory approval status cannot be determined with publicly available evidence, as eligible devices may use proprietary AI that is kept confidential. If this is the case, correspondence with the manufacturer will be undertaken to seek clarification. If further clarification is not possible, the ambiguity about the AIaMD's eligibility and the rationale for including or excluding it will be recorded.

The search for evidence will be undertaken by an independent author. After deduplication, the titles and abstracts will be independently screened by 2 authors to assess their relevance to the eligible AIaMD. Discrepancies will be resolved by discussion and by arbitration with an additional author if

necessary. The full texts will be screened, and a further round of arbitration will take place as needed.

Data Extraction

Data extraction will be undertaken in 2 phases, using standardized data extraction forms designed and piloted for the purposes of this review.

Phase 1

The characteristics of each eligible AIaMD for ophthalmic imaging with regulatory approval in Europe, Australia, and the United States at the time of the search will be obtained. Where available, this will include:

1. Type of regulator approval and date of approval
2. Class assigned under FDA, TGA, UK MDR (Medical Devices Regulations 2002) and/or EU MDR (Regulation (EU) 2017/745)
3. Intended use statement
4. Ophthalmic imaging modality
5. Model type and architecture (eg, deep learning with machine learning)
6. Recall indications on the regulatory databases, as available

Some AIaMD may be approved in 2 or more jurisdictions, and the data will be extracted accordingly. Google searches will be used to supplement data extraction if the required data are unavailable from the FDA, EUDAMED, MHRA, or ARTG databases.

Phase 2

Published evidence underpinning the effectiveness and efficacy of each eligible AIaMD will be obtained. The following data will be extracted from each included study:

1. Study characteristics: title, author name, publication status, funding source, conflicts of interest, and author affiliations with manufacturers
2. Study methodology: study duration, study design (randomized, prospective observational, and retrospective observational), etc
3. Validation: external validation, reference standards, and comparison between AI and humans
4. Data set or cohort details: source of data set, size of data set or number of participants, setting, number of countries, number of centers, and participant demographics (age, gender, and ethnicity)
5. Model performance: metrics including sensitivity, specificity, area under the curve, etc, with 95% CIs; clinical outcomes as described

Assessment of Methodological Quality

Two review authors will independently assess the methodological quality of each included clinical validation study. Appropriate quality assessment tools will be used for each study type, for example, the QUADAS-2 tool for evaluating the risk of bias and applicability of primary diagnostic accuracy studies [24], the Cochrane risk of bias-2 tool for randomized controlled trials [25], and the ROBINS-I (Risk of Bias in Nonrandomized Studies of Interventions) tool for nonrandomized studies [26]. QUADAS-AI (quality assessment tool for artificial intelligence-centered diagnostic test accuracy studies) [27] and PROBAST-AI (Prediction Model Risk of Bias Assessment Tool for Artificial Intelligence) [28] are under development at the time of writing but will be used where appropriate if available. Any disagreements will be resolved through discussion or by involving a third reviewer where consensus cannot be reached.

Data Synthesis

Study-Level Data

The extracted data will be synthesized using narrative and tabular approaches. A summary of the findings will be presented, using descriptive statistics to describe the characteristics of the included studies. For example, mean and SD will be used to describe continuous variables, while percentages will be used to describe proportions. If appropriate, a meta-analysis of AIaMD diagnostic accuracy will be considered, but this may not be feasible if there is significant heterogeneity in study methods and AI methodology.

AIaMD-Level Data

The data for each AIaMD will be synthesized to give an overview of the characteristics of its regulatory approval or approvals and its clinical validation studies, again through narrative and tabular approaches.

Ethical Considerations

Ethical approval is not required, as this is a protocol for a systematic scoping review. All relevant data have been published, and no primary or proprietary data will be collected. This decision has been verified with the Newcastle University Ethics Committee.

Results

Preliminary searches were conducted in February 2023, and screening is underway. Data extraction, data synthesis, and assessment of methodological quality commenced in October 2023. We anticipate that the scoping review will be completed and submitted for peer review by April 2024.

Discussion

This will be the first review to examine and synthesize evidence on AIaMD for ophthalmic imaging. The key aim is to better understand the landscape of AIaMD for ophthalmic imaging on the market and the level of evidence that supports their regulatory approval.

Strengths and Limitations

Due to the limited and variable functionality of regulatory databases, it was not possible to conduct searches with standard systematic review methodologies based on research databases. This has necessitated several design considerations. We have sought to minimize publication bias and improve the completeness of the search process by undertaking a snowballing approach informed by expert knowledge, in combination with a database search. This was necessitated by limitations in the search functionality of the regulatory databases, but we

acknowledge that this approach facilitates the mitigation rather than the removal of these limitations. In addition, our PubMed search strategy may be hampered by incomplete reporting or no mention of the AI device's name or manufacturer. We have attempted to mitigate this by supplementing our search with reviewing manufacturers' websites, corresponding with manufacturers, and performing adjunct searches of major clinical trial registries in order to ensure that our search is as comprehensive as possible.

Strengths include the international scope of the review. We recognize that there may be differences in regulatory requirements across territories (and in the transparency of reporting of data supporting those applications) and have therefore included 4 major jurisdictions. We have also assembled an international team of authors with representation from the United States, Europe, and Australia to support the interpretation of the data. The inclusion of critical appraisal to identify any methodological variations or shortcomings of existing clinical validation studies is a further strength not common to previous regulatory reviews of AIaMDs, and will help guide any future improvements.

Conclusion

We describe the protocol for a systematic scoping review that seeks to map and examine AIaMD for ophthalmic imaging that has received regulatory approvals for commercial use. We anticipate that our findings may be of interest to ophthalmic professionals, AI model developers, health care commissioners, and policy makers, with the overall aim of improving transparency to help inform safe AIaMD implementation, thereby optimizing patient care.

Data Availability

Data sharing is not applicable to this article, which is a protocol for a scoping review, as no data sets were generated or analyzed.

Conflicts of Interest

HDJH is funded by the National Institute for Health Research through a doctoral fellowship award (NIHR301467) and is on the advisory board for Siloton, an optical coherence tomography imaging equipment manufacturer. PAK has received personal fees from AbbVie, Google Health, Roche, Apellis, Novartis, RetinAI, Bitfount, and nonfinancial support from Bayer outside the submitted work. The remaining authors do not have any conflicts of interest or financial disclosures to declare.

Abstract

Background: Vaccine hesitancy is a growing concern in Saudi Arabia, impacting even well-educated parents. The decision-making process involves various factors such as accessibility, trustworthy information, and the influence of social networks, reflecting a complex interplay of emotional, cultural, social, spiritual, and political dimensions.

Objective: This review seeks to evaluate the prevalence and trends of vaccine hesitancy, identify contributing factors, and explore potential solutions to enhance immunization rates. This review aligns with global concerns, as the World Health Organization has identified vaccine hesitancy as a top global health threat.

Methods: Our systematic review will follow the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines and PICOS (Population, Intervention, Comparison, Outcomes, and Study) criteria for comprehensive assessment. We will conduct a thorough search across various databases, encompassing a wide range of vaccines, and pay special attention to vaccination campaigns and refusals. Inclusion criteria involve descriptive, observational, and analytical studies focusing on factors influencing vaccine acceptance or hesitancy. The study will use the Crowe Critical Appraisal Tool for quality assessment and perform a narrative synthesis to summarize findings thematically.

Results: This systematic review is expected to unveil the prevalence and trends of vaccine hesitancy in diverse populations in Saudi Arabia, shedding light on cultural, religious, and social factors contributing to hesitancy. It aims to assess the effectiveness of implemented strategies, enable regional and global comparisons, and provide implications for tailored vaccination policies. Additionally, the review may pinpoint research gaps, guiding future investigations to address and mitigate vaccine hesitancy effectively.

Conclusions: The findings are expected to have direct policy implications and guide interventions to strengthen vaccination programs and improve public health outcomes.

Introduction

Vaccines have consistently proven to be among the safest and most effective methods for preventing a wide range of infectious diseases [1,2]. Despite the proven safety and effectiveness of vaccines, vaccine-preventable diseases continue to persist in various parts of the world. In recent years, there have been outbreaks of infectious diseases, even when effective vaccines are available to combat them. One significant contributing factor to this phenomenon is “vaccine hesitancy” [3,4]. Vaccine hesitancy is defined as a reluctance or delay in accepting or agreeing to receive vaccines, even when vaccination services are readily available. Vaccine hesitancy is a complex and multifaceted phenomenon influenced by a wide range of factors. These factors encompass cognitive, psychological, sociodemographic, political, and cultural elements, among others. Moreover, the specific factors contributing to vaccine hesitancy can vary significantly across different populations and communities [5]. The reasons for vaccine hesitancy are intricate and can vary over time, across different locations, and depending on the specific type of vaccine in question. Similarly, vaccine hesitancy arises from a multitude of factors, including religious beliefs, geographic barriers, the quality of the parent-provider relationship, concerns about adverse events of immunization, limited knowledge about vaccination, and perceptions of disease risk [6].

In 2019, the World Health Organization (WHO) identified vaccine hesitancy as one of the top 10 global health threats [7]. Vaccine hesitancy refers to the reluctance of certain individuals or communities to accept vaccines, and it poses a substantial challenge to public health efforts. This reluctance is influenced by various factors, including misinformation, distrust in health care systems, personal beliefs, and a perceived low risk of vaccine-preventable diseases [7,8]. Vaccine hesitancy is not a recent challenge in disease prevention. It has been a significant issue for years, and examples of it can be found in the context of seasonal influenza vaccination and the response to the 2009 H1N1 pandemic [9-11]. Recent research in the literature over the past decade has indicated a concerning trend: vaccine hesitancy appears to be on the rise among various populations, including health care workers [12,13]. According to Olive et al [14], a social movement opposing public health vaccines has been gaining traction in the United States. This movement, among various other factors, has played a role in the increasing percentage of the population in both the United States and Europe that is refusing vaccination efforts in recent years [14]. Vaccine hesitancy indeed poses a substantial challenge to public health experts as it leads to significantly reduced vaccination rates within populations. This challenge becomes even more critical in the context of combating infectious diseases [1]. According to a survey conducted by the WHO and UNICEF (United Nations Children’s Fund), vaccine hesitancy started to emerge as a significant concern approximately a decade ago [15]. This trend of vaccine hesitancy has been observed in several countries around the world, including the United Kingdom, the United States, and India [16,17]. Vaccine hesitancy across Gulf Cooperation Council countries varied between 11% and 71%, with notable discrepancies observed based on the type of vaccine, with the highest reported hesitancy recorded for the COVID-19 vaccine at 70.6% [18].

Vaccine hesitancy has also become a concern in Saudi Arabia. According to Alabbad et al [19], 17% of their study population expressed hesitance to receive the influenza vaccine. Additionally, Alsubaie et al [20] found that vaccine hesitancy among Saudi parents reached 20%. Even well-educated parents have the same behavior. Alzahrani and Alghamdi [21] reported a vaccine hesitancy rate 20%-27 % against COVID-19 immunization [21]. A study conducted by Thabit et al [22] determined that factors such as the convenience of receiving the vaccine, the availability of trustworthy information from authorities, and the positive influence of family and friends played significant roles in motivating the public to get vaccinated. Al-Mohaithef and Padhi [23] reported that concerns about vaccine safety (17%), worries about potential side effects (35%), and perceptions of receiving too many injections (28%) are critical factors contributing to vaccine hesitancy. Alaamri et al [24] conducted a cross-sectional study in Saudi Arabia, which stated that decision-making for vaccination is a multifaceted process that encompasses emotional, cultural, social, spiritual, and political dimensions. These various aspects can significantly influence an individual’s or a community’s choice regarding vaccination. In-depth literature analysis reveals the current absence of a systematic review on vaccine hesitancy factors specific to Saudi Arabia. This review aims to (1) assess

the prevalence and trends of vaccine hesitancy, (2) identify factors contributing to vaccine hesitancy, and (3) explore potential solutions to enhance immunization rates.

These findings will be instrumental in shaping a comprehensive vaccination policy for Saudi Arabia.

Methods

Basic Strategy

This systematic review will adhere to the quality standards outlined in the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) reporting guidelines [25,26] and will be structured according to the PICOS (Population, Intervention, Comparison, Outcomes, and Study) criteria for comprehensive and transparent reporting [27], as given in Textbox 1 and Table 1. Before conducting this review, the protocol will be submitted to PROSPERO (the International Prospective Register of Systematic Reviews) for approval [28,29].

A comprehensive search will be conducted across multiple databases, including Cochrane, PubMed (MEDLINE), Web of Science, Google Scholar, Scopus, Science Direct, and Springer Links, to identify peer-reviewed literature. The search will not be limited by a specific time period because no previous review on the factor has been conducted. If it is time-limited, there is a chance of missing some factor that may affect the prospective work. It will also encompass literature with search terms present in the title, abstract, and full text. Furthermore, the search will be restricted to publications available in the English language.

Textbox 1. Title and checklist items for the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) checklist.

Title

- Determine whether the report is categorized as a systematic review, a meta-analysis, or a combination of both.

Background: objectives

- The research inquiry encompasses elements such as comparators, interventions, outcomes, and participants.

Methods: eligibility criteria

- Criteria for inclusion are based on the characteristics of the study and the report.

Methods: sources of information

- The databases that were searched and the dates of those searches.

Methods: potential for bias

- Methods for evaluating the potential for bias in research studies.

Results: studies inclusion

- The quantity and nature of incorporated research studies, the participants involved, and pertinent attributes of these studies.

Results: report of findings

- Summary of primary results, ideally with a breakdown of the number of studies and participants for each outcome.

Results: description of the effect

- The direction of the impact (ie, which group benefits) and the magnitude of the effect expressed in terms that are meaningful to health care professionals and patients.

Discussion: limitations and strengths of available evidences

- Concise overview of the advantages and drawbacks of the evidence, including factors like inconsistency, imprecision, indirectness, or risk of bias, along with any corroborating or conflicting evidence.

Discussion: interpretation

- Overall interpretation of the findings and significant implications.

Table 1. PICOS (Population, Intervention, Comparison, Outcomes, and Study) inclusion and exclusion criteria.

PICOS criteria	Inclusion criteria	Exclusion criteria
Participants	The community of Saudi Arabia	Research studies will intentionally exclude certain subgroups, such as those with comorbidities, complex patients, or health care providers
Intervention	The qualitative and quantitative studies and randomized controlled trials	Studies pertaining to other topics and those involving statistical, mathematical, or predictive methods will not be covered in this context
Comparison	When applicable, this comparison of specific subgroups may also extend to studies conducted in multiple cities or locations	N/A[a]
Outcomes	To assess the factors that influence individuals' decisions regarding vaccine acceptance or vaccine hesitancy	Studies that do not aim to identify or analyze the factors influencing vaccine acceptance or hesitancy
Study design	Observational or descriptive and analytical studies conducted at a national level, or those with an adequately justified sample size and calculations	Pilot studies for tool assessment or improper sampling

[a]N/A: Not applicable.

Searching Approaches

To optimize search results and ensure comprehensive coverage, a combination of medical subject headings and natural language keywords will be used. Boolean and proximity operators will also be used to refine search queries and uncover relevant studies. Additionally, truncation (*) and wildcards ($) will be used to account for variations in search terms and enhance the chances of identifying a wide range of relevant literature.

The search strategy has been configured to align with the specific vocabularies and indexing systems used by each database, ensuring that the search is optimized for each platform's unique structure and content. This approach enhances the precision and relevance of search results within each database.

The search strategy will be formulated using the vocabularies and indexing systems specific to each database. This tailored approach ensures that the search is optimized for the unique characteristics and content of each database. The terms "vaccine," "immunization," "vaccine hesitancy," "vaccine trust," "vaccine resistance," "vaccine concern," "vaccination," "vaccine intervention," "vaccine side effects," "vaccine confidence," "vaccine impact," "vaccine strategy," "vaccine hesitant," "vaccine refusal," "adverse effect of vaccines," and "vaccine rejection" will be applied alone or combined as operators.

Eligibility Criteria

While conducting our search for vaccine hesitancy, we will take into account universally recommended vaccines for individuals across various age groups, including children, adolescents, and adults. These vaccines encompass a range of preventable diseases and include: "seasonal influenza vaccine," "hepatitis B vaccine," "tuberculosis (Bacillus Calmette-Guerin [BCG] vaccine)," "measles, mumps, and rubella (MMR) vaccine," "diphtheria-pertussis-tetanus (DPT) vaccine," "Haemophilus influenzae type b (Hib) vaccine," "human papillomavirus (HPV) vaccine," "poliomyelitis vaccine," "oral polio vaccine," "varicella vaccine," "meningococcal vaccine," "pneumococcal vaccine," and "COVID-19 vaccine." These vaccines are typically recommended as part of immunization programs to protect individuals from various infectious diseases. In addition, we will pay particular attention to the results of vaccination campaigns aimed at promoting and expanding vaccination programs in Saudi Arabia. This will also involve a detailed examination of the various campaigns, their objectives, strategies, and outcomes, as well as their impact on increasing vaccine coverage and public health in the region.

In this review, we will include both descriptive and analytical studies that provide insights into the impact of strategies aimed at addressing vaccine hesitancy. These studies should offer a clear description of the strategies used and their effects on vaccine hesitancy.

However, we will exclude studies that are opinion-based or studies that do not primarily focus on populations eligible to receive vaccines or their parents. Additionally, studies that do not allow for the extraction of relevant information related to vaccination will also be excluded from our analysis.

Selection of Studies and Critical Appraisal

Our research review process should be robust, and it should be designed to ensure the quality and relevance of the studies included in the analysis [30]. The following sections provide a summary of the key steps.

Initial Screening

A total of 2 researchers will independently review the titles, abstracts, and keywords of the identified studies. This step will ensure the segregation of eligible studies from those that are not relevant.

Full-Text Retrieval and Screening

After the initial screening, studies that pass this stage will have their full texts retrieved and reviewed. This allows for a more detailed assessment of their eligibility.

Data Extraction

A total of 2 researchers will independently perform data extraction from the selected studies. This process involves extracting relevant information and data from the studies.

Consensus on Unmatched Studies

In cases where there is a disagreement between the 2 researchers regarding the inclusion or exclusion of a study, a third researcher will be involved to reach a consensus. This ensures that the final selection of studies is based on consensus and reduces bias.

This screening process, along with independent data extraction and consensus resolution, will help to enhance the reliability and validity of our research findings. It also minimizes the potential for bias in the selection and extraction of data from the identified studies.

Quality Assessment

This study will undergo quality assessment using the Crowe Critical Appraisal Tool (CCAT) [31,32]. This tool focuses on 8 domains for evaluating quality, encompassing preliminaries (title, abstract, and text), introduction (background and objective), design (research design, intervention, treatment, exposure, outcome, output, predictor, measure, and bias), sampling (sampling method, sample size, sampling protocol), data collection (collection method, collection protocol), ethical considerations (participant ethics, researcher ethics), results (analysis, integration, interpretation method, essential analysis, outcome, output, predictor analysis), and discussion (interpretation, generalization, and concluding remarks). The CCAT tool will be used to evaluate the quality of all the included articles across these 8 domains. A cumulative score will be computed for each article and then converted into a percentage. The percentage scores will be categorized into three groups: (1) high quality (≥80%), (2) medium quality (60%-79%), and (3) poor quality (<60%). This assessment of quality will be carried out independently by the authors, with any disagreements being resolved through consensus.

Analysis and Synthesis

According to the methodological nature of our systematic review, conducting a narrative synthesis of the results will be a suitable approach. A narrative synthesis will involve summarizing and interpreting the findings of the included studies. This approach is common when the included studies are diverse in terms of methodology, outcome measures, or data presentation [33].

Thematic Analysis

We will organize the findings thematically. Focus on the common themes, patterns, or trends across the studies. We will create categories, themes, and subthemes that capture the key aspects of vaccine hesitancy and the impact of strategies.

Narrative Description and Synthesis

We will describe the findings of each study within the context of the identified themes that provide a clear and concise summary of each study. We will synthesize the findings by drawing connections between different studies and themes.

Results

We can anticipate potential results that may emerge from this systematic review.

Prevalence and Trends of Vaccine Hesitancy

The review is expected to reveal the prevalence and trends of vaccine hesitancy among different populations. It may show whether vaccine hesitancy rates have been increasing or decreasing over time and how this compares to global trends.

Factors Contributing to Vaccine Hesitancy

Identification of specific factors contributing to vaccine hesitancy in the Saudi Arabian context. Insights into cultural, religious, and social influences on vaccine hesitancy within Saudi Arabia.

Impact of Strategies on Vaccine Hesitancy

Evaluation of the effectiveness of strategies implemented to address vaccine hesitancy and the identification of successful interventions and areas where improvements are needed.

Regional and Global Comparisons

Discover potential comparisons between vaccine hesitancy factors and strategies in Saudi Arabia and those in other countries, particularly within the Middle East region, and understand whether Saudi Arabia faces unique challenges or shares common issues with other nations.

Implications for Vaccination Policy

The review is likely to have implications for public health policy in Saudi Arabia and provide recommendations for tailored vaccination strategies to improve acceptance rates and combat vaccine hesitancy.

Identifying Research Gaps

The review may identify gaps in the existing literature on vaccine hesitancy in Saudi Arabia and highlight areas where further research is needed or not to address vaccine hesitancy.

Discussion

Impact

Vaccine hesitancy poses a substantial threat to public health worldwide [34], and Saudi Arabia is no exception [19-24]. Understanding the prevalence and factors contributing to vaccine hesitancy in Saudi Arabia is crucial for developing targeted interventions to increase vaccination rates and prevent outbreaks of vaccine-preventable diseases [35,36]. Moreover, the causes of vaccine hesitancy and its consequences will be helpful to mitigate [37].

Like the United States, the findings will help tailor an individualized educational program for vaccine-hesitant parents [38]. Alternatively, childhood vaccination will increase, as it is reported to be very low in Saudi Arabia [39-41]. Delays in vaccination were influenced by factors such as parental education, nutrition preferences, and vaccine-related beliefs, while prematurity was associated with a decreased likelihood of delays. As a mandatory requirement, children in Saudi Arabia are expected to be fully vaccinated before starting school at the age of 6 years [42].

In Saudi Arabia, the vaccination program commenced in 1979 with the administration of DTP vaccines, and it has since been

expanded to encompass a broader range of vaccines [20]. The Saudi National Immunization Program advises administering several vaccines within the first 24 months of life. These vaccines include the hepatitis B vaccine at birth, as well as the pneumococcal conjugate, rotavirus, inactivated poliovirus vaccine (IPV), meningococcal vaccine (MCV), diphtheria, tetanus, polio, Hib vaccine, BCG vaccine, MMR vaccine, and hepatitis A vaccines [20,42].

According to the WHO, vaccination coverage rates in Saudi Arabia have shown significant variation in recent years. In 2019, the coverage rate for BCG vaccination was reported to be 52%, a notable decrease from the 98% coverage rate observed in 2018 [42,43]. While in 2022, it was similar to 2022 [44]. On the other hand, the coverage rates for DPT and MMR vaccines remained high, with rates of 98% and 96%, respectively. Despite the generally high immunization rates, there were concerning numbers of reported cases in 2019. Measles, for instance, had 1035 reported cases, mumps had 187 reported cases, pertussis had 326 reported cases, and rubella had 62 reported cases. These figures indicate that, despite high vaccination coverage rates for some vaccines, there are still significant challenges in preventing these vaccine-preventable diseases in certain populations or regions within Saudi Arabia [42,43].

The study aligns with global concerns about vaccine hesitancy, which the WHO identified as a top 10 global health threat [7]. By exploring vaccine hesitancy in Saudi Arabia, this research contributes to the global understanding of this phenomenon and may shed light on whether Saudi Arabia faces unique challenges or shares common issues with other nations [45,46].

By analyzing the predictors from different stakeholders [47-51], the study's findings are likely to have direct policy implications. Tailored vaccination strategies can be developed based on the identified factors contributing to vaccine hesitancy [41-43,52]. Policy recommendations can help improve acceptance rates and strengthen vaccination programs in Saudi Arabia, ultimately enhancing public health outcomes. Identifying specific factors contributing to vaccine hesitancy in Saudi Arabia is essential for designing targeted interventions. For instance, if religious beliefs are a significant factor [53,54], interventions may involve engaging religious leaders to promote vaccination [55].

Conclusions

This systematic review will investigate Saudi Arabia's vaccine hesitancy, examining prevalence, trends, and contributing factors across diverse populations. It evaluates the effectiveness of implemented strategies and draws regional and global comparisons, shedding light on unique challenges or shared issues within the Middle East. The findings hold implications for Saudi public health policy, suggesting tailored vaccination strategies to combat hesitancy. Additionally, by identifying research gaps, the review provides direction for future studies, pinpointing areas where further investigation is crucial for a comprehensive understanding of vaccine hesitancy in Saudi Arabia.

Abstract

Background: Long wait times in the emergency department (ED) are a major issue for health care systems all over the world. The application of artificial intelligence (AI) is a novel strategy to reduce ED wait times when compared to the interventions included in previous research endeavors. To date, comprehensive systematic reviews that include studies involving AI applications in the context of EDs have covered a wide range of AI implementation issues. However, the lack of an iterative update strategy limits the use of these reviews. Since the subject of AI development is cutting edge and is continuously changing, reviews in this area must be frequently updated to remain relevant.

Objective: This study aims to provide a summary of the evidence that is currently available regarding how AI can affect ED wait times; discuss the applications of AI in improving wait times; and periodically assess the depth, breadth, and quality of the evidence supporting the application of AI in reducing ED wait times.

Methods: We plan to conduct a living systematic review (LSR). Our strategy involves conducting continuous monitoring of evidence, with biannual search updates and annual review updates. Upon completing the initial round of the review, we will refine the search strategy and establish clear schedules for updating the LSR. An interpretive synthesis using Whittemore and Knafl’s framework will be performed to compile and summarize the findings. The review will be carried out using an integrated knowledge translation strategy, and knowledge users will be involved at all stages of the review to guarantee applicability, usability, and clarity of purpose.

Results: The literature search was completed by September 22, 2023, and identified 17,569 articles. The title and abstract screening were completed by December 9, 2023. In total, 70 papers were eligible. The full-text screening is in progress.

Conclusions: The review will summarize AI applications that improve ED wait time. The LSR enables researchers to maintain high methodological rigor while enhancing the timeliness, applicability, and value of the review.

Introduction

Background

Extended emergency department (ED) wait times are a major health care system problem worldwide [1-4]. Long wait times in the ED can threaten patients' well-being, leading them to depart the ED without receiving the essential care they require. Additionally, this situation contributes to overcrowding within the ED and fosters a sense of dissatisfaction among both patients and ED personnel [2]. Previous studies have investigated many initiatives to reduce ED wait times. Among them, a new approach is the use of artificial intelligence (AI) [3,4].

AI is one of the most important technological advancements of the Fourth Industrial Revolution [5]. AI refers to the use of technology and computers to mimic human-like critical thinking and intelligent behavior. In 1956, the word AI was first used by John McCarthy to refer to the science and engineering of creating intelligent machines AI refers to the use of technology and computers to mimic human-like critical thinking and intelligent behavior. As mentioned by Amisha et al [6], John McCarthy used the word AI for the first time in 1956 to refer to the science and engineering of creating intelligent machines. Recent years have seen exponential growth in the technological and scientific aspects of AI as well as machine learning, one of its main subcategories [7]. Notable benefits include increased productivity and innovation. Significant progress has been made to date in several fields, including computer vision, natural language processing, audio analysis, smart sensing, and many more [8]. Therefore, modeling based on AI is the key to creating automated, intelligent, and smart systems that meet today's needs. Different forms of AI, including analytical, functional, interactive, textual, and visual AI, can be used to improve an application's intelligence and capabilities to solve problems in the real world [5]. Although many of AI's practical applications are still in the early stages and require further research and development, the technology has the potential to revolutionize medicine in ways that have not yet been considered [6].

Harnessing the power of AI holds promising potential to improve the quality of care within EDs by effectively tackling challenges such as overcrowding by offering advanced clinical decision-making tools [9,10]. By developing an AI-assisted module, a significant reduction in wait times for outpatient services was demonstrated in the ED, according to a retrospective cohort study [4]. Furthermore, a prospective study revealed a notable decrease in the wait time for receiving care services through digital automation [11].

All AI methods that enable computers to learn from data without explicit programming are included in machine learning [12]. An Italian study used 2 large data sets of EDs to test several machine learning methods using predictive analytics. The findings demonstrate the viability of a real-time performance monitoring system that supports operational decision-making and has major practical implications for EDs and hospitals [13]. An Australian study showed that wait time forecasts for low-acuity ED patients assigned to the waiting room were improved through machine learning techniques and a wide range of queuing and service flow features. Machine learning models surpass the best rolling average in terms of mean absolute prediction error using queuing and service flow characteristics along with knowledge of daily fluctuations, and quantile regression lowers the proportion of patients with significantly underestimated wait times [14].

Deep learning is a subclass of machine learning defined primarily by neural network models with more layers and, in general, more neurons than typical machine learning neural networks. Additionally, deep networks, relative to traditional neural networks, achieve increased performance with increasingly large amounts of data, becoming practically realizable due to modern advances in computing power [15]. In a study conducted in Saudi Arabia, deep learning was used to forecast the length of time patients would wait in the ED's queue system. The findings of this study demonstrated the applicability of deep learning models for predicting patient wait times in the ED [16].

By looking at current developments in ED operations and clinical patient management, the authors of a review paper summarized the applications of AI in emergency medicine. They came to the view that the areas of prehospital emergency management, patient acuity, triage, and disposition, prediction of medical diseases and conditions, and ED management are where AI applications in ED are most prevalent [2]. Another systematic review study sought to show how AI was applied in ED and how it changed how ED practitioners' work was organized. Most AI applications, according to the study's findings, involved AI-based tools to support clinical judgment and reduce the pressure on overburdened EDs. Additionally, AI support was primarily provided during triage, the decision-making stage that determines a patient's course, and there is strong evidence that AI-based apps could enhance clinical decision-making [10].

Based on our understanding of the literature, the systematic reviews that encompassed studies involving AI applications in the context of EDs were comprehensive and addressed diverse aspects of AI implementation. However, these reviews were limited in their usefulness due to the absence of a plan for regular updates on AI progress, rendering them less applicable across some contexts. It is crucial to recognize that AI development is a revolutionary field with a rapidly evolving landscape. As such, reviews in this domain must undergo frequent updates to stay relevant. As a result of AI, computer programs can answer questions intelligently and infer facts based on real-world data. AI will become a core component of all contemporary decision-making in the immediate future. To keep up with the ongoing changes and revolutions in this field, we plan to conduct living systematic reviews (LSRs). Our

review will be regularly updated. We will incorporate relevant new evidence when it is available.

Study Goals and Objective

The study aims to summarize the available evidence on how AI can impact ED wait times; describe the applications of AI in reducing wait times; and examine the depth, breadth, and quality of evidence related to the application of AI in reducing wait time in the ED.

Methods

Rationale for LSR

LSR enables researchers to maintain high methodological rigor while enhancing the timeliness, applicability, and value of the review. Our strategy involves conducting continuous monitoring of evidence, with biannual search updates and annual review updates. Upon completing the initial round of the review, we will refine the search strategy and establish clear schedules for updating the LSR.

Type of Review

This will be an integrative review. Integrative reviews stand out as the most exhaustive form of systematic review methodology. They offer the flexibility of diverse sampling strategies and a broad scope of objectives, enabling them to provide a comprehensive representation of complex ideas, theories, or significant health care issues [17]. We selected this type of review since we aimed to examine the full breadth of techniques, methods, algorithms, and modalities of AI used to improve wait time in EDs from various academic sources. As mentioned by Hopia et al [18], according to Whittemore and Knafl's methodological steps, the integrated review method can use diverse data sources, thereby creating a comprehensive understanding of the topic of interest by presenting the state of the science and contributing to theory development. Whittemore and Knafl [17] approach consists of 5 stages and is based on Cooper's theoretical framework, which is one of the methodological approaches used in integrative reviews. These steps generally include problem identification, literature search, data evaluation, data analysis, and presentation [17].

Systematic Review Team

Research team members participating in the systematic review include researchers, physicians, and nurses with expertise in emergency medicine, librarians, learners, patients, AI specialists, and review methodologists.

Patient Engagement

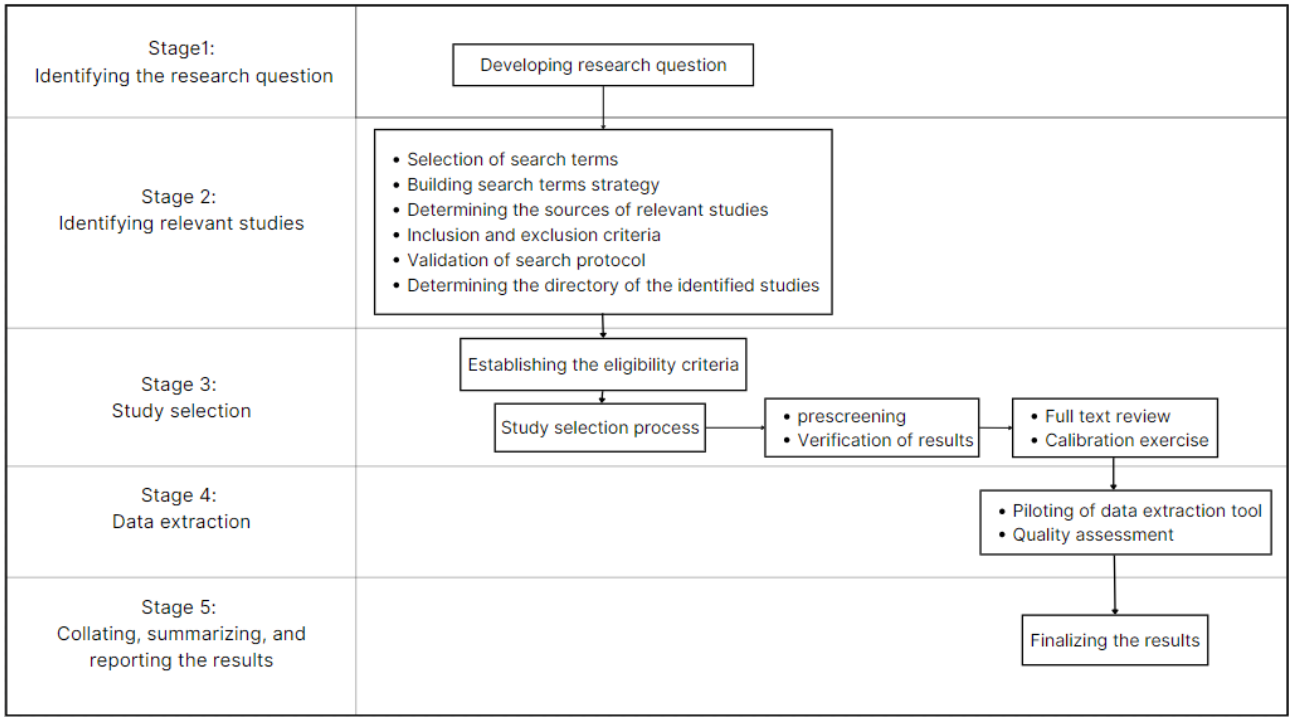
Our research plan and related materials will be showcased to SurgeCon's [19] patient engagement working group, comprising individuals from diverse backgrounds, including people of different gender identities residing in urban and rural areas of Newfoundland and Labrador. This approach aims to comprehensively gather the needs, desires, and firsthand experiences of those who stand to gain from the implementation of AI in improving ED wait times.

Protocol of the Integrative Review

Overview

Our designed integrative review protocol will include 5 stages summarized in Figure 1, which will be explained in the following. Furthermore, to ensure transparent and accurate reporting, we will use PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines in this review [20].

Figure 1. Visual representation of the 5 key stages in an integrative review protocol.



Stage 1: Identifying the Research Question

Our research questions will be developed and refined by a team of researchers and clinicians, including physicians and nurses with expertise in emergency medicine, patients, and librarians. "How does the application of AI reduce ED wait times, as supported by evidence from current literature?"

Stage 2: Identifying Relevant Studies

Selection of Search Terms

The search terms will be developed by content experts and patients. These terms include general variations on "ED," "wait times," "AI," "machine learning," "deep learning," and any more specific terms related to algorithms and methods used in the field of AI and indicators related to wait times in the ED. Once completed, the research question's key terms will be chosen by relevant stakeholders, which will be compiled alongside a list of potential synonyms or other terms identified by a librarian. The optimal search phrases will be determined by searching for Medical Subject Heading (MeSH) terms, the MeSH tree, and related words in keywords and references.

Building Search Terms Strategy

A librarian will assist in exploring various word combinations in databases to discover the most effective search method. When searching relevant literature, search phrases are iteratively improved by evaluating various terms, merging new terms, and finding new relevant citations. The MeSH and keywords will be combined in the search. For other data sets, different search techniques will be applied as needed.

Sources of Relevant Studies

We initiate the review process by conducting a comprehensive examination of peer-reviewed papers cited in electronic databases. This meticulous approach allows us to identify and encompass all relevant, available information sources. A librarian will provide support in completing the search for research studies in the following databases for studies that were published between January 1, 1946, and August 17, 2023: Embase, MEDLINE via Ovid, CINAHL, Cochrane, and Scopus. The search strategy for MEDLINE is available in Multimedia Appendix 1.

Inclusion and Exclusion Criteria

During our search for relevant research papers, we will incorporate peer-reviewed papers and published PhD dissertations from reputable repositories. Studies that focus on AI-related concepts, including AI algorithms and techniques, in the context of EDs to improve wait times will undergo a full-text review. We have categorized all the AI-related concepts and terminology we want to explore in reducing ED wait times in Multimedia Appendix 2. Since AI and its applications are evolving, we will reevaluate the inclusion and exclusion criteria in the next review to ensure new terminologies for AI will be included in our research. Our inclusion criteria will consist of studies that specifically concentrate on the application of AI techniques in the ED to decrease wait times. These studies must include wait times as an outcome measure and present relevant results. We will exclude studies that do not directly address the use of AI or do not primarily focus on reducing wait times in the ED. Additionally, master theses and conference abstracts will also be excluded from our selection.

Validation of the Search Protocol

The gold standard papers and journals recommended by subject matter experts will be used to test the search methodology and calibrate our search technique. The eligibility requirements will be changed as necessary. The search strategy for this LSR will be iteratively revised, and new search terms may supplement future searches if required.

Directory of Identified Studies

Covidence software (Veritas Health Innovation) will be used to manage the review and build a directory of publications.

Stage 3: Study Selection

Overview

The process of inclusion studies will be iterative and involve searching the literature, adjusting the search strategy, determining eligibility, prescreening, reviewing the full text of the literature for inclusion, and keeping only studies that discuss the use of AI to reduce ED wait times.

Eligibility Criteria

Members of our team who are knowledgeable about AI and ED and who will be blinded to the study results in question will make decisions about the review process methodology. Inclusion criteria will ensure a wide range of literature from various sources.

We will include patients, regardless of gender or age, who have been analyzed by AI algorithms. Audits or anecdotal information, planning-stage research, pilot studies, undergraduate dissertations, book reviews, gray literature, such as unpublished theses and reports from relevant websites, and policy assessments are among the exclusion criteria. We will look at both qualitative and quantitative studies. If the paper is a systematic review, all included studies in the review will be examined, and the related ones will be included in our review. In addition, we will conduct backward and forward citations of all studies eligible for data extraction in our review.

Study Selection Process

Prescreening

Papers will be digitally stored and managed in Covidence software, and duplicates will be removed by Covidence software. After training team members, they will independently review the titles and abstracts of all publications found through database searches to determine eligibility. Conflicts will be resolved through a discussion between the 2 reviewers (BA and AG); a third team (SA) member will provide feedback when necessary. If studies or abstracts do not address the topic of the search, or if the studies are commentaries or editorials, they will be deemed unrelated and excluded.

Verification of Results

One of the 2 reviewers (BA and AG) will then reevaluate a random sample of 5% (n=875) of the papers that were rejected based on title and abstract to make sure that all pertinent studies were considered. All excluded papers will be reexamined if

more than 5% (n=44) of the sample is determined to be relevant. We will also provide reviewers with retraining as needed.

Full-Text Review

Two research team members (BA and AG) will independently review all full texts. Only English papers are subject to full-text reviews, although the total number of studies considered appropriate by title, abstract, and full text will be noted for future use.

Calibration Exercise

We will conduct a calibration exercise before the process begins and then continue the calibration exercise throughout the review. Five percent of the listed citations will be randomly chosen. Two reviewers (BA and AG) will independently assess the full text against the eligibility criteria provided in Covidence. They will then discuss their rationale for including or excluding each article, and a third team member (SA) will provide feedback if necessary. Using an iterative process, if the level of agreement between the 2 reviewers is low (0.5), the eligibility criteria for screening and full-text review and the exclusion criteria for full-text review will be revised on Covidence. Then, the remaining citations will be evaluated by the reviewers (BA and AG), and a third reviewer (SA) will settle any disagreements. Furthermore, we will schedule biweekly team meetings to assess the review process. We will examine the reviewers' understanding of the eligibility criteria during these meetings and provide training if needed. The reviewers need to maintain a 0.8 agreement during the process.

Stage 4: Data Extraction

Overview

A data extraction tool for systematic data gathering from the indicated studies will be prepared in Excel (Microsoft Corporation). The tool will be made to extract data based on citation type (eg, original research), country, study date, study methodological features, study design, study population, sample size, AI techniques used, input variables, wait time metrics, outcomes measured, results performance, performance measure, and any limitations or challenges reported by the authors.

Piloting of the Data Extraction Tool

The team evaluates the data extraction tool by using a random sample of 5% (2) of the included studies. If required, the data extraction tool will also undergo frequent revisions. The data will be reviewed and extracted separately by 2 independent reviewers (BA and AG).

Quality Assessment

A scoring system for systematic reviews of mixed research will be used to evaluate the quality of primary studies (both quantitative and qualitative) [21]. The goal of the quality assessment is to determine the overall caliber of the studies in the sample rather than to identify or reject weaker studies. The quality of the screened studies will be reported.

Stage 5: Collating, Summarizing, and Reporting the Results

We will use a complex strategy to understand and combine the results of many studies for an interpretive synthesis. A descriptive summary of the identified and relevant studies will be reported. The frequency of research with study designs that match the criteria included in the data extraction tool will be provided [22]. In addition to collecting results, we seek to uncover underlying meaning, patterns, and relationships in the data. The framework developed by Whittemore and Knafl [17] is a useful resource for accomplishing this interpretative synthesis. Detailing the documented outcomes of AI interventions and the kinds of AI methods used by our data extraction tool's specifications will be part of the interpretive synthesis. We aim to identify commonalities or patterns in the studies by categorizing their results according to their impact on various wait time metrics. We will classify the findings of the identified research according to how they affect different wait time metrics in the ED using interpretive synthesis. These metrics include length of stay, number of patients leaving without being seen by a physician or their delegate, time to the initial physician assessment, and others. We will list the reported effects of AI interventions and the types of AI techniques implemented based on the criteria included in our data extraction tool. For an in-depth visual representation, the outcomes of the interpretative synthesis will be presented using descriptive tables, frequency tables, and diagrams. To develop a combined estimate of the effectiveness of AI initiatives in lowering ED wait times, the integrative review will evaluate the included papers' suitability for conducting a meta-analysis. If the selected studies show sufficient homogeneity in their methods and findings, a meta-analysis could be possible and provide a quantitative synthesis of the findings. We improve the breadth and clarity of this study's results by integrating these components into our interpretive synthesis approach, offering a robust analysis of the effect of AI interventions on ED wait times.

Knowledge-User Consultation

The review will be carried out using an integrated knowledge translation strategy, and knowledge users will be involved at all stages of the review to guarantee applicability, usability, and clarity of purpose. This strategy aims to engage content experts and the community advisory committee within our team through multiple consultations. The objective is to actively involve them in shaping the study's outcomes, action plan, and research agenda while also fostering opportunities for knowledge exchange [22,23]. We will organize regular meetings with the knowledge users' group to provide an opportunity to receive their feedback throughout the review. In addition, we will regularly update the progress of the review to notify them. By adopting these strategies, we can ensure that feedback from consultations is systematically integrated into the integrative review process, enhancing the relevance and applicability of the study outcomes. This team includes researchers and clinicians, including physicians and nurses with expertise in emergency medicine, learners, patients, AI specialists, and review methodologists. A practical understanding of the difficulties and possible advantages of applying AI to reduce wait times can be gained by speaking with ED physicians, nurses, administrators, and other health care workers who have firsthand experience working in the ED. Speaking with those in charge of planning the ED system and allocating resources

can give us an understanding of the broader effects of using AI in the ED. They can provide viewpoints on financing priorities, legislative considerations, and the viability of incorporating AI solutions into current health care systems. Speaking with professionals involved in the development and application of AI in similar contexts will help us comprehend the technical facets and capabilities of AI systems on a deeper level. These professionals can offer perceptions of the promise of AI technologies, the difficulties in putting them into practice, and factors to consider for successful integration into the ED environment. This LSR aims to provide updated information on the application of AI to improve ED wait times. Initial review findings will be regularly communicated to our team to validate our conclusions and help direct the completion of the review [22]. In addition to scientific papers and academic presentations, a summary of potential clinical practice implications will be created using the study's findings, including any areas that might call for medium- or long-term action. The summary will be distributed in our biweekly meetings with ED stakeholders to generate ideas, formulate research questions, and decide on suitable approaches for the SurgeCon ED wait time improvement team in Newfoundland and Labrador, Canada.

Results

The literature search was completed by September 22, 2023. We identified 17,569 studies. The title and abstract screening was started independently by 2 reviewers (BA and AG) on September 23, 2023, and ended on December 9, 2023. The full-text review phase started with 70 eligible papers on January 22, 2024, and is in progress.

Discussion

Recognizing the dynamic nature of AI research and its impact on health care decision-making in emergency medicine, we propose the use of LSRs. The major goal of LSRs is to keep our reviews up-to-date and relevant by including new information and revolutions in the field of AI as they become available. Using LSRs, we propose a methodological innovation that maintains rigor and assures that reviews remain relevant and applicable over time, reflecting the continual progress of AI applications in EDs.

Our research aimed to analyze the published studies examining AI applications in EDs, with a particular emphasis on reducing wait times. The analysis of the literature found that studies of AI applications in EDs to improve wait times cover a wide range of topics in emergency medicine [4,9,11,13,14,16]. We also found a few systematic reviews showing that scholars and specialists in the field have been proactive in synthesizing the available knowledge [2,10]. Despite their comprehensiveness, these systematic assessments have 1 significant limitation: no plan for regular updates. Since the field of AI is characterized by rapid change and continual progress, this issue jeopardizes the use of these studies in future settings. AI technologies are continually improving, and their applications in health care, including EDs, are no exception.

The study has several limitations. Implementing an LSR strategy may necessitate changes to existing review procedures as well as potential challenges in gathering and synthesizing constantly emerging data. Furthermore, the feasibility and practicality of conducting living reviews must be carefully considered. In addition, like other types of systematic reviews, the LSR is prone to publication bias, and the quality of the synthesis could be affected by the quality of the included studies.

In conclusion, our study illuminates the current state of AI applications in EDs and addresses a crucial gap in systematic review methods. LSRs emerge as a timely solution to the challenge of obsolescence amid rapid AI growth and advancements. Embracing LSRs ensures timely information for health care decision makers and sets a precedent for enhancing review techniques in the dynamic realm of AI research. As major technological shifts loom, our study highlights the methodological evolution needed to fully harness AI's potential in health care.

Acknowledgments

The work outlined in this protocol is supported by the Canadian Institutes of Health Research and provincial sponsors, including the Newfoundland and Labrador Provincial Government (Department of Industry, Energy and Technology), Newfoundland and Labrador Health Services, and the Trinity Conception Placentia Health Foundation. We acknowledge the use of ChatGPT (GPT-3.5, August 2023) for cross-validating a list of AI-related concepts and terminology. The original ChatGPT transcript is made available in Multimedia Appendix 3. Furthermore, we used AI-powered writing assistant tools, QuillBot for document editing and grammar checking, and Grammarly for proper referencing and improving readability. We thank Aswathy Geetha Manukumar for her role as one of the two reviewers in the in-progress integrative living review.

Abstract

Background: Quality improvement (QI) interventions are designed to resolve the recurring challenges of care for older individuals, such as working conditions for staff, roles of older individuals in their own care and their families, and relevant stakeholders. Therefore, there is a need to map the impacts of QI interventions in older adult care settings and further improve health and social care systems associated with older adults.

Objective: This review aims to compile and synthesize the best available evidence regarding the effectiveness of policy and practice QI interventions in older adult care. The secondary aim is to understand the care of older individuals and QI intervention-related experiences and perspectives of stakeholders, care providers, older individuals, and their families.

Methods: The mixed methods review will follow the standard methodology used by Joanna Briggs Institute. The published studies will be searched through CINAHL, MEDLINE, PsycINFO, ASSIA, and Web of Science, and the unpublished studies through Mednar, Trove, OCLC WorldCat, and Dissertations and Theses. This review included both qualitative and quantitative analyses of patients undergoing older adult care and any health and care professionals involved in the care delivery for older adults; a broad range of QI interventions, including assistive technologies, effects of training and education, improved reporting, safety programs, and medical devices; the experiences and perspectives of staff and patients; the context of older adult care setting; and a broad range of outcomes, including patient safety. The standard procedure for reporting, that is, PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines, will be followed.

Results: A result-based convergent synthesis design will be used in which both quantitative and qualitative studies will be analyzed separately, and the results of both syntheses will be then integrated during a final (convergent) synthesis. The integration will compare the findings of quantitative and qualitative evidence using tables in light of the results of both syntheses.

Conclusions: This comprehensive review is expected to reflect on the insights into some QI interventions and their impact, outline some common challenges of quality for older adult care, and benefit both the practical usefulness of care service activities and the society at large.

KEYWORDS

patient safety; acceptability; accessibility; appropriateness; timeliness; equitability; social care

Introduction

Overview

Quality improvement (QI) intervention has been defined as "a systematic and continuous approach that designs, tests and implements changes using real-time measurements to improve the safety, effectiveness and experience of care" [1]. There are QI interventions designed to illuminate and resolve the current challenges in the care of older individuals that arise within health care and social care systems. This may include the challenges regarding working conditions for staff and the organization as a whole [2]; the roles of older individuals in their own care, including support from their relatives and families [3]; and the roles of clinical and public health researchers, academics, engineers and planning experts [4-7] to make changes in improving health and social care systems for older adults [4,8]. For the readers' convenience, the definition of QI will be used throughout this protocol to indicate the care of older individuals associated with health and social care systems.

The older population worldwide is growing with increased life expectancy and improving public health. These individuals are expected to live longer with multiple needs and circumstances [9]. Despite the challenge regarding adequate funding, care for older individuals in Sweden has been established because everyone should have equal access to care services [10]. Over 18% of the Swedish population is 65 years or older, and this number is expected to grow and be over 20% by the year 2030 and 25% by 2040 [11]. Sweden's health and care burden was moved to homecare in 1992 by implementing the ÄDEL reform, which focuses on minimizing complications for older adult care. Even though this strategy turned out to be a success for the Swedish health and social care system, achieving better accessibility by providing home health services to 90% of the aging population [10,12], the challenges around older adult care still remain. For example, a Swedish study found that while government agencies were very positive about the implementation of new technology in older adult care, the unstructured implementation process (without proper planning) and incoherent evaluation model (without compatible designing) indicated inequality of access to such new technology [13,14].

Several QI programs have shown promising results in improving the aging population's health and social care quality. For example, the QI program, that is, Acute Care for Elders, improved the outcomes for older adults, that is, significant reductions in cost and length of stay with greater comorbidity scores [15]. Other QI interventions, such as education sessions/toolkits, improved the impact of accurate and suitable medicines supply to the residents of residential aged-care facilities [16]. A discharge planning intervention increased the feasibility and effectiveness of facilitating the transition of older adults from hospitals to their homes [17]. An intervention comprising technical and social components reduced preventable harm in care homes [18,19]. Such QI programs may also involve collaboration between geriatricians and primary care physicians, further reducing hospitalization risk and total health and care costs among vulnerable older adults [20].

The review will consider various dimensions of care quality, such as accessibility, appropriateness, safety, efficacy, effectiveness, timeliness, patient-centeredness, and equitability [21,22]. Each subsection will also be covered to obtain a comprehensive insight into health and care quality. For example, the 5 dimensions of accessibility, that is, approachability, acceptability, availability and accommodation, affordability, and appropriateness, will be considered and explored [23,24]. This is because the care provided should be adequate for all these dimensions, that is, 1 or more missing aspects of the care do not complete the entirety of the quality [25,26]. For instance, providing inappropriate or ineffective care should be unacceptable even if it is safe and provided in a timely manner [27,28].

A recent comprehensive or mixed methods systematic review of QI interventions in the radiology setting has demonstrated expected results, that is, improvements in outcomes, such as improved workflow efficiency, report turnaround time, and teamwork and communication [29,30]. We believe that a similar review in the setting of older adult care would develop new knowledge for the health and social care system as well as for older individuals and care providers. Therefore, the findings of the review will generate insights that have wider relevance in creating a model for improved older adult care systems and to meet today's societal challenges.

Several systematic reviews have been performed for older adult care focusing on health and care quality and its dimensions, such as patient safety [31], appropriateness [32], and accessibility [23], including recent reviews on the interventions of eHealth [33] and training [34]. However, none of these reviews constitutes a comprehensive systematic review focusing on both quantitative and qualitative studies for looking through multiple lenses into the health and social care system of older adult care with broader perspectives that would further facilitate analyzing the issues and devising recommendations. A preliminary search has been performed on Campbell Systematic Reviews, the Cochrane Database of Systematic Reviews, PROSPERO (International Prospective Register of Systematic Reviews), and Joanna Briggs Institute (JBI) evidence synthesis, and we have not identified any systematic reviews on QI interventions in older adult care settings using either qualitative or quantitative methodology.

Aim and Review Questions

The primary purpose of this review is to compile and synthesize the best available evidence regarding the effectiveness of QI interventions in older adult care. Provided that QI initiatives ultimately target the beliefs and perspectives of clinicians, in a broader sense, the organization and its resources, the secondary objective of this review is to understand the experiences and perspectives of care providers, older individuals and their families, and relevant stakeholders undergoing a QI initiative. Specifically, the review questions are as follows:

- What kind of QI interventions have been used to improve the quality of older adult care?
- How effective are interventions in relation to policy and practice that target improvements in the quality of older adult care?

- What are the experiences and perspectives of care providers, older individuals and their families, and relevant stakeholders about these interventions?

Methods

The proposed scoping review will be conducted in accordance with the JBI methodology for systematic (mixed methods) reviews [35].

Search Strategy

Databases will be searched for both published and unpublished studies. The approach to searching for studies for a scoping review will follow the standard 3-step method. The first step will be an initial limited search of a selection of relevant databases, followed by an analysis of text words in the title and abstract and the index terms used to describe the article. The search for published studies will include a 2-way search strategy. One is to search the journal and reference databases, such as CINAHL, MEDLINE, PsycINFO, ASSIA, and Web of Science. Another is to search article-based (journal) databases, such as ACM digital library, IEEE Xplore, and BMJ Journals. The search for unpublished studies (gray literature) will include Mednar, Trove, OCLC WorldCat, and Dissertations and Theses. A second search using all identified keywords (see Textbox 1) and index terms will be undertaken across all included databases. Additional search strategies, that is, citation search—specific researcher or article (for example, gold-standard article), and chain search—review reference list of the systematically selected articles will be included to complement the search for published and unpublished papers. Studies, such as reviews (systematic, scoping, umbrella) and editor letters, will be excluded. Any studies that lack ethical concerns will also be excluded.

Textbox 1. A list of keywords for search strategy.

Participants: Old people (patient), older people (patient), elderly people (patient), elderly people (patient), elderlies, aging population, geriatricians, social workers, and domiciliary workers (Using OR Boolean operator).

Context: elderly care, aged care, primary care, private hospital, public hospital, clinic, geriatric ward, old-age home, nursing homes, domiciliary care, and home care (Using OR Boolean operator).

Interventions: Technology, training, education, staff arrangement, incident reporting, peer review, clinical audit, teamwork intervention, communication intervention, team training, safety checklist, local governance, and quality improvement intervention. (Using OR Boolean operator).

Outcomes: Patient safety, incident, event, near miss, adverse event, safety culture, safety effectiveness, timeliness, patient-centeredness, equitability, decision-making, communication, teamwork, leadership, report turnaround, patient experience, patient perspective, staff experience, and staff perspective. (Using OR Boolean operator).

Types of Studies: Randomized controlled trials, cluster randomized controlled trials, quasi-experimental, controlled before and after trials, interrupted time series analysis, qualitative, grounded theory, ethnography, phenomenology, case study, narrative model, and historical model (Using OR Boolean operator).

Studies published in English will be considered. Studies published from 1990 onward (when the first substantive patient safety research study, "Harvard Medical Practice," was published) [36,37] will be considered for inclusion in this review. The search strategy results will be depicted through the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram [38].

Inclusion Criteria

Research Background

The inclusion criteria of this review will follow the mnemonics of PICO (for quantitative studies) and PICo (for qualitative studies)—which stands for Population, Phenomena of Interest, and Context. These mnemonics are used as a guide (not policy); therefore, the inclusion criteria of this systematic review will include a detailed description of types of participants/population, types of interventions, phenomena of interest, context, outcomes, as well as types of studies, search strategies, assessment of methodological quality, and synthesis of results.

Types of Participants/Population

This review will include studies of older individuals (65 years or older) undergoing older adult care irrespective of gender and diversity, including age, ethnicity, socioeconomic status, and disability, and any health and care professionals (care providers) and stakeholders involved in the care delivery for older individuals, such as nurse practitioners, registered nurses, enrolled nurses, specialist nurses, and geriatricians.

Types of Interventions

The included studies should concentrate on the implementation of a QI intervention, that is, defined as the systematic and continuous approach that designs, tests, and implements changes using real-time measurements to improve the safety, effectiveness, and experience of older adult care. Given the complexities of the health and social care system, a range of QI interventions will be included in this review. The interventions will include but not are limited to ton technology; training and education; improved reporting and management; safety programs; changes in staffing arrangements (staffing levels, and skill, grade and qualification mix); improved regulation; peer review; and revalidation, clinical audit, and changes to local governance.

Phenomena of Interest

The phenomena of interest will be the effects on outcomes and workflow processes and the experiences and perspectives of care providers and older individuals undergoing or being exposed to the QI interventions. These experiences or perspectives included descriptions of the quality and safety concerns, the contexts and cultures of the workplaces (including factors such as conflict and how it was managed, teamwork

behaviors, and the attitudes of care providers), and the management of adverse events and near misses.

Context

The systematic review will consider studies in older adult care settings, such as geriatric wards of primary health care, hospitals or clinics, old-age homes, nursing homes, and home care facilities for older people.

Outcomes

The outcomes will include validated measures of safety culture decision-making, communication, teamwork, leadership, report turnaround time, and timeliness of care. Further outcomes will be patient satisfaction and patients' perceptions of the quality of older adult care [39].

Types of Studies

Quantitative and qualitative studies will be included to report empirical evidence and the human experience. Quantitative studies include randomized controlled trials or Cluster Randomized Controlled trials; nonrandomized controlled trials; quasi-experimental, controlled before-after trials; and interrupted time series studies. Qualitative studies included interpretive work focusing on, but not limited to, designs such as content analysis, phenomenology, grounded theory, ethnography, case study, narrative model, and historical model. Mixed methods and descriptive studies will also be eligible for inclusion.

Assessment of Methodological Quality

Two independent reviewers for methodological validity prior to inclusion will assess selected quantitative and qualitative papers for retrieval, reducing the risk of methodological issues, such as subjective bias. This will be done using the standardized critical appraisal criteria from the critical appraisal instruments by the JBI. Any discrepancies that may arise between reviewers' assessments will be resolved by consensus through discussion.

A critical appraisal of the selected papers will be conducted after screening. The formal process of GRADE (Grading of Recommendations Assessment, Development, and Evaluation) and the GRADE-CERQual (Confidence in the Evidence from Reviews of Qualitative Research) will be used to rate the quality of scientific evidence and confidence to place in findings from systematic reviews of both quantitative and qualitative studies, respectively. For example, 3 grades of quality may be used for each study, based on the score achieved in the critical appraisals: low quality (less than 33% or equal to 33%), medium quality (34%-66%), and high quality (more than 66%).

Data Extraction

Quantitative data will be extracted from papers included in the review using the standardized JBI data extraction tool. Qualitative data will be extracted from papers included in the review using the standardized JBI data extraction tool. The data extracted for quantitative and qualitative studies will include specific details about the interventions, populations, study methods, and outcomes of significance to the review question and specific objectives.

Results

A result-based convergent synthesis design [40] will be used in which quantitative and qualitative studies will be analyzed separately, and the results of both syntheses will be then integrated during a final (convergent) synthesis. The integration will compare the quantitative and qualitative evidence findings using tables in light of the results of both syntheses. This will help us address overall review questions with subquestions (if possible).

Quantitative papers will, where possible, be pooled in a statistical meta-analysis using the appropriate JBI tool. All results will be subject to double data entry. Effect sizes expressed as odds ratio (for categorical data) and weighted mean differences (for continuous data) and their 95% CIs will be calculated for analysis. Heterogeneity will be assessed statistically using the standard chi-square and I-square. It will also be explored using subgroup analyses based on the different quantitative study designs included in this review. Where statistical pooling is impossible, the findings will be presented in narrative form, including tables and figures, to aid in data presentation where appropriate.

Qualitative research findings will, where possible, be pooled using the appropriate JBI tool. This will involve the aggregation or synthesis of findings to generate a set of statements that represent that aggregation through assembling the findings rated according to their quality and categorizing them based on similarity in meaning. These categories are then subjected to a meta-synthesis to produce a single comprehensive set of synthesized findings that can be used as a basis for evidence-based practice. Where textual pooling is impossible, the findings will be presented in narrative form.

Discussion

Principal Findings

Health and social care systems embrace welfare broadly and include institutions, organizations, and resources to maintain or promote health and social care. The resources may consist of funds for the training and education of care providers and welfare technologies used for older adult care services [41,42]. During the COVID-19 pandemic, the quality and safety of care for older individuals have been a top priority [43]. A future pandemic situation can be overcome through sustainable health and social care systems for older individuals by dealing with the challenges found at the system and organizational levels.

This review is designed to be a mixed methods systematic review that will contain evidence of and bring together the results of single-method reviews (including quantitative and qualitative), which has the potential to produce reviews of direct relevance to policy makers and practitioners. As this review covers a wide range of interventions and outcomes and the experiences and perspectives of both care providers and older individuals, the results are expected to reflect on and offer insights into some QI interventions and their impact and some common quality challenges for older adult care. The challenges may include accommodation and availability, the role of the

families, friends, and relatives; working conditions and staffing arrangements; and the practical usefulness of the patients and care service activities and the society at large.

It is essential to cover a diversity perspective in the review; for example, older individuals of different cultural backgrounds may have different needs for QI. As we cover as many health and care quality dimensions as possible, we believe that issues of diverse perspectives will be included in the literature. For example, the dimension of "acceptability" is defined as the relationship between clients' attitudes about personal and practice characteristics of existing providers, including age, sex, location, and type of facility or religious affiliation of the provider or facility, as well as provider attitudes about acceptable personal characteristics of clients, including ethnicity and source of payment [23,24,44].

This review will include studies of individuals undergoing older adult care irrespective of gender, diversity, ethnicity, socioeconomic status, and disability. This review will evaluate if older adult care facilities worldwide are equipped enough to deal with the challenges of gender sensitivity and cultural diversity. For example, the review may cover the issues of gender sensitivity, especially when a family experiences feelings of shame when receiving care from a nonfamily member or the opposite gender [23,45].

Strengths and Limitations of the Review

The results of this systematic review will need to be treated with caution since our search is restricted to language and publication period. To minimize the effect of such limitations, a comprehensive strategy, that is, a standard 3-step method, will be followed. For example, the inclusion of gray literature will provide additional insights into the review findings. There may be other limitations, for instance, the possibility pertaining to the results associated with limited included studies, introducing a layer of bias for the selected studies. The evidence-based practice center methods guide proposed by the Agency for Health Care Research and Quality will be used to risk the risk of bias in individual studies [46].

To ensure the review produces generalizable findings, discussions with older adults and their families and the relevant public will be channeled to support the interpretation and dissemination of the review findings.

Conclusion

No current or underway systematic reviews on the topic were identified. This comprehensive review will uncover the shreds of evidence requiring diligent attention to address the effectiveness of interventions in relation to policy and practice in older adult care settings. The review will also reflect on the insights into the impact of QI interventions, outline some common challenges of quality for older adult care, and benefit both the practical usefulness of care service activities and the society at large.

Acknowledgments

The authors thank the librarians from Linnaeus University and the University of Bradford for their guidance and assistance in this research. This study is being undertaken without external funding. A publishing grant has been received from Linnaeus University as a part of the University Library's research support. No generative artificial intelligence was used in any portion of the manuscript writing.

Data Availability

All data generated or analyzed during this study will be included in this published article and its supplementary information files.

Abstract

Background: There is great potential for delivering cost-effective, quality health care for patients with chronic conditions through digital interventions. Managing chronic conditions often includes a substantial workload required for adhering to the treatment regimen and negative consequences on the patient's function and well-being. This treatment burden affects adherence to treatment and disease outcomes. Digital interventions can potentially exacerbate the burden but also alleviate it.

Objective: The objective of this review is to identify, summarize, and synthesize the evidence of how digital interventions impact the treatment burden of people with chronic conditions.

Methods: The search, selection, and data synthesis processes were designed according to the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) 2015. A systematic search was conducted on October 16, 2023, from databases PubMed, Scopus, Web of Science, ACM, PubMed Central, and CINAHL.

Results: Preliminary searches have been conducted, and screening has been started. The review is expected to be completed in October 2024.

Conclusions: As the number of patients with chronic conditions is increasing, it is essential to design new digital interventions for managing chronic conditions in a way that supports patients with their treatment burden. To the best of our knowledge, the proposed systematic review will be the first review that investigates the impact of digital interventions on the treatment burden of patients. The results of this review will contribute to the field of health informatics regarding knowledge of the treatment burden associated with digital interventions and practical implications for developing better digital health care for patients with chronic conditions.

chronic illness; treatment burden; eHealth; mHealth; digital health; mobile health

Introduction

Background

Digital technologies are now commonly used in daily life, bringing many new possibilities for connecting people and providing services. The use of mobile- and web-based digital health care interventions has increased during the COVID-19 pandemic and has been found to have high efficacy, accessibility, and cost-effectiveness in the self-management of chronic diseases [1-3].

As the global population is growing, the prevalence of chronic diseases has increased significantly [4]. The World Health Organization [4] has estimated that if this trend continues, by 2050 chronic diseases will be the cause of 86% of the 90 million deaths each year. This means a 90% increase in absolute numbers since 2019. Therefore, there is a continuous need for new interventions for the management of chronic diseases.

Chronic diseases often require regular long-term management, which requires patients to not only cope with their symptoms but also navigate services, interact with health professionals, and adhere to treatments, creating a significant burden for many patients [5]. Treatment burden is defined as both the workload required for self-management of disease and the impact treatment regimens have on the patient's function and well-being [5]. Treatment burden can affect many domains: burden of taking medications, traveling to appointments, financial burden, impact on social life and emotions, and burden of accessing health care services [6,7]. A high treatment burden has been associated with poor adherence and worse disease outcomes [6].

The variety of available digital interventions can be tailored to meet the diverse needs of patients. For example, telemedicine and remote visits can reduce the need for traveling to medical appointments [8]. Mobile health apps, wearable technologies, and remote monitoring systems can track patients' health data and alert health care professionals (HCPs) if intervention is required [9,10]. Electronic health records offer a central repository for patients' history to minimize the paperwork and speed up the adherence process [11], while electronic prescription management improves patient safety as well as the efficiency and costs of prescribing medications [12]. Furthermore, patients' portals, web-based support groups, and forums provide emotional and social support for patients [13].

The World Health Organization Classification of Digital Interventions, Services and Applications in Health [14] highlights a variety of digital health technologies for different types of services. In this study, we will focus on the point of service category of digital interventions. The point of service category includes those digital interventions that facilitate and deliver health care services to the patients, making it easier to see the connection between the treatment burden of the patient and the digital intervention. This category includes communication systems, community-based information systems, decision support systems, diagnostics information systems, electronic medical record systems, laboratory information systems, personal health records, pharmacy information systems, and a variety of telehealth systems. These digital interventions can include many different components, such as monitoring tools, decision aids, behavior change support, communication with HCPs, and web-based peer support groups.

Digital interventions may affect the treatment burden in multiple ways. With limited resources, digital interventions may be used to reduce the burden on the health care system, and staff end up offloading the burden to patients [15-18]. Patients may also find digital systems inaccessible or difficult to use [19] and struggle with digital stress [20]. However, digital interventions can expedite and simplify health care processes in a way that patients may receive treatment more efficiently, reducing the treatment burden for patients. For example, they can reduce the need for medical appointments and travel to hospitals [8] and make self-management easier and more motivating for patients [21,22].

Many systematic reviews have been conducted to investigate the treatment burden on patients with chronic conditions [6,7,23-26]. These reviews have provided insights into the definition, prevention, and patient's experience of treatment burden. In addition, recent systematic and umbrella reviews about digital interventions have found that most digital interventions in health care are mobile- or computer-based [27-29]. The findings of the recent research are mostly focused on effectiveness, and the largest targeted condition group is mental illnesses [27,29]. However, we have observed a gap in the literature regarding systematic reviews combining these 3 concepts: treatment burden, digital interventions, and chronic conditions.

Objective

The aim of this review is to identify gaps in the literature and summarize and synthesize currently available evidence of how digital interventions impact the treatment burden of people with chronic conditions. The impact can be a positive or negative effect on any domain of treatment burden. We aim to investigate if the results differ between chronic conditions with different levels of treatment burden or between interventions with different components.

Research Questions

We have two primary research questions: (1) How can digital interventions impact the treatment burden on people with chronic conditions? (2) What kind of support can digital interventions provide for people with chronic conditions with their treatment burden?

Methods

Ethical Considerations

We followed the University of Oulu ethics process as defined in the guidelines from the Ethics Committee of Human Sciences [30]. According to the guidelines, an ethics board review is not needed for this protocol.

Study Design

This protocol is reported according to the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) 2015 [31]. We registered the protocol on the International Prospective Register of Systematic Reviews (PROSPERO CRD42023477605).

The systematic review will use a convergent design for systematic mixed studies reviews [32]. The mixed method approach was selected because qualitative results can help us to understand the phenomenon of treatment burden in the context of digital health care, and quantitative results can be used to generalize the qualitative findings by measuring their magnitude, trends, causes, and effects [33]. The convergent design was

most suitable for this review since the research questions can be answered by both qualitative and quantitative findings.

Information Sources and Search Strategy

A systematic search for papers published between January 1, 2013, and October 16, 2023, was conducted from bibliographical databases PubMed, Scopus, Web of Science, ACM, PubMed Central, and CINAHL. The following search string was used: ("Chronic illness" OR "chronic disease" OR "chronic diseases" OR "chronic illnesses" OR "chronically ill" OR "diabetes" OR "asthma" OR "cancer" OR "cystic fibrosis" OR "epilepsy" OR "rheumatoid arthritis" OR "HIV" OR "patient") AND ("Digital" OR "Remote" OR "Mobile" OR "smartphone" OR "smartwatch" OR "smart ring" OR "smart device" OR "smart devices" OR "app" OR "mHealth" OR "eHealth" OR "web-based") AND ("Treatment burden" OR "Burden of treatment" OR "Treatment impact" OR "Treatment workload" OR "Treatment inconvenience" OR "Treatment acceptability" OR "Illness burden" OR "Burden of illness" OR "Medication burden"). To identify relevant papers, a search strategy was conducted in an iterative way. The creation of the search strings for treatment burden was informed by previous systematic reviews on the topic [23,24]. Scoping searches were conducted in several potential databases focusing on health and biomedicine, information technology, nursing, psychology, or multiple disciplines (PubMed, Scopus, Web of Science, ACM, PubMed Central, CINAHL, IEEE, and APA PsycINFO). Scoping searches were conducted on October 15, 2023, in CINAHL and on October 12, 2023, in other databases. Searches conducted on IEEE and APA PsycINFO databases revealed no relevant results, so databases were excluded from the search strategy. Including only certain chronic conditions, for example, epilepsy or neurological conditions, was considered, but there was a limited number of studies found during the initial scoping searches. For example, in the scoping search for epilepsy conducted on October 12, 2023, only 3 relevant papers were identified. Therefore, we decided to keep the scope wide and include all chronic conditions in the search string.

The MeSH term "chronic disease" and search terms "coronary heart disease," "heart disease," "MS," and "multiple sclerosis" were tested during a scoping search in PubMed, but they brought no new results and therefore were removed from the search terms. A supplementary search will be conducted from the citations contained in systematic literature reviews and scoping reviews that were found during the literature searches.

Inclusion Criteria

We have included original publications written in English and accepted in peer-reviewed journals or conference proceedings. Qualitative, quantitative, and mixed method studies are included. The studies can be clinical trials, nonrandomized controlled trials, cross-sectional studies, longitudinal studies, observational studies, case studies, and other types of qualitative studies. Study design will be classified based on the tool from Grimes and Schulz [34]. Conference proceedings are included, but reviews, protocols, and book chapters are excluded.

We limited our search to publications after 2013 to include the last 10 years of research. Although digital health technology has developed quickly in recent years, the use of digital interventions in health care for chronic conditions goes farther than 10 years [35]. To the best of our knowledge, there are no previous systematic reviews relating to both digital health and treatment burden. However, studies before 2013 referred mostly to apps created only for research purposes, which were not available to the public at that time. Therefore, we decided to include papers published after 2013 to cover all relevant publications.

The study population in the included publications must consist of patients who have a chronic condition, their caregivers, or HCPs treating patients with chronic conditions. All ages and ethnicities are included. Only studies with outcomes regarding treatment burden for the patients are included. Studies that do not specifically mention the phrase "treatment burden" or "burden of treatment" but still discuss the impact of health care on the workload and burden for patients are also included. Only studies regarding a digital intervention that facilitates and delivers health care services to patients with chronic conditions are included.

Selection of Studies

After the searches, all titles and abstracts from search results were uploaded to a web-based Covidence screening tool (Veritas Health Innovation), where duplicate records will be removed. All titles and abstracts were screened and selected for inclusion independently by 2 authors (MP and PK or OK). Full-text papers from the selected papers will also be screened and selected for inclusion independently by 2 authors (MP and PK or OK). Disagreements will be resolved by discussion.

Data Extraction

Data on population characteristics, study design, aims, intervention characteristics, measures, and main results will be extracted using a predefined data extraction form in Covidence. Study design will be classified based on the tool from Grimes and Schulz [34]. Before proceeding with data extraction, MP will pilot the data extraction form with 5 papers to identify possible adjustment needs. Data extraction will be performed independently by 2 reviewers (MP and PK or OK). Disagreements will be resolved by discussion.

Risk of Bias

The quality of the included studies will be assessed using Joanna Briggs Institute Critical Appraisal tools. Two reviewers (MP and PK or OK) will assess the quality of each included study independently. Based on the design of the eligible studies, we will use Joanna Briggs Institute checklists designed for randomized controlled trials, quasi-experimental studies, analytical cross-sectional studies, case-control studies, case series, and qualitative studies.

Data Synthesis

A convergent integrated approach to synthesis and integration will be used [32]. This involves converting quantitative data into qualitative data followed by integration of the qualitative and quantitative evidence [36].

Results

Currently, we have performed searches in the 6 selected databases, and 241 studies have been identified. Screening based on title and abstract excluded 192 studies. Overall, 69 studies have been included in the second round of study selection, which is ongoing. The review is expected to be completed in 2024.

Discussion

This systematic review is performed to investigate the impact of digital health care on the treatment burden of patients with chronic conditions. This review is important because the world is currently facing increasing amounts of chronic diseases, and digital solutions are needed to improve the management of chronic diseases, which pose a significant burden on both health care systems and the patients themselves. However, it is essential to design the digital interventions in a way that helps patients to deal with their existing treatment burden and avoids further increasing the treatment burden. To the best of our knowledge, this will be the first review that covers the impact of digital health care on the treatment burden of patients with chronic conditions. The outcomes are expected to cover the positive and negative impacts of digital interventions on treatment burden and the different types of support digital interventions can provide to people with chronic conditions struggling with treatment burden. We aim to categorize different types of interventions and their components and find potential differences between interventions with different components and chronic conditions with different levels of treatment burden.

For the limitations of this review, the findings will depend on the number of eligible studies we will be able to identify and the quality of these studies. In addition, the studies identified for this review may be heterogeneous in terms of design, interventions, participant groups, and outcomes. Furthermore, our search will be restricted to peer-reviewed studies published in English.

Authors' Contributions

MP developed the initial research questions; design of the review, search, and selection strategies; and drafted the paper. PK and OK contributed to the refining of the research questions; design of the review, search, and selection strategies; and writing and editing of the paper. WB and MI contributed to the editing and approved the final paper.

Conflicts of Interest

None declared.

Abstract

Background: The learning process in clinical placements for health care students is a multifaceted endeavor that engages numerous actors and stakeholders, including students, clinical tutors, link teachers, and academic assessors. Successfully navigating this complex process requires the implementation of tasks and mentorships that are synchronized with educational and clinical processes, seamlessly embedded within their respective contexts. Given the escalating number of students and the rising demand for health care services from the general population, it becomes imperative to develop additional tools that support the learning process. These tools aim to simplify day-to-day clinical practice, allowing a concentrated focus on value-based activities. This paper introduces a project funded by the European Commission that involves 5 European countries. The project's objective is to comprehensively outline the entire process of development and ultimately implement mobile technology in practice placements. The project tackles the existing gap by constructing tailored mobile apps designed for students, teachers, tutors, and supervisors within each participating organization. This approach leverages practice-based learning, mobile technology, and technology adoption to enhance the overall educational experience.

Objective: This study aims to introduce mobile technology in clinical practice placements with the goal of facilitating and enhancing practice-based learning. The objective is to improve the overall effectiveness of the process for all stakeholders involved.

Methods: The "4D in the Digitalization of Learning in Practice Placement" (4D Project) will use a mixed methods research design, encompassing 3 distinct study phases: phase 1 (preliminary research), which incorporates focus groups and a scoping review, to define the problem, identify necessities, and analyze contextual factors; phase 2 (collaborative app development), which involves researchers and prospective users working together to cocreate and co-design tailored apps; and phase 3, which involves feasibility testing of these mobile apps within practice settings.

Results: The study's potential impact will primarily focus on improving communication and interaction processes, fostering connections among stakeholders in practice placements, and enhancing the assessment of training needs. The literature review

and focus groups will play a crucial role in identifying barriers, facilitators, and factors supporting the integration of mobile technology in clinical education. The cocreation process of mobile learning apps will reveal the core values and needs of various stakeholders, including students, teachers, and health care professionals. This process also involves adapting and using mobile apps to meet the specific requirements of practice placements. A pilot study aimed at validating the app will test and assess mobile technology in practice placements. The study will determine results related to usability and design, learning outcomes, student engagement, communication among stakeholders, user behavior, potential issues, and compliance with regulations.

Conclusions: Health care education, encompassing disciplines such as medicine, nursing, midwifery, and others, confronts evolving challenges in clinical training. Essential to addressing these challenges is bridging the gap between health care institutions and academic settings. The introduction of a new digital tool holds promise for empowering health students and mentors in effectively navigating the intricacies of the learning process.

Introduction

Background

Practice-based learning encompasses the educational process in which students acquire knowledge within a service delivery environment tailored to their educational level and competencies. Health profession students, such as nurses, physicians, and physiotherapists, cultivate skills through hands-on experience in various settings. Learning occurs through observation and subsequent participation in clinical tasks.

Conceptually, learners in practice settings acquire "knowledge-in-action" [1] through interaction with experienced professionals, patients/clients, and their peers. For health profession students, practice-based learning provides an opportunity for direct engagement with "real" patients in authentic settings where actual health care is delivered. Health profession students cannot grasp the full complexity of the health care environment until they acquire the specific knowledge, skills, and attitudes that demonstrate competency in their area of practice [2].

The learning process in clinical placements typically involves a diverse array of individuals, including tutors, supervisors, mentors, teachers, and students. Throughout this intricate process, tasks and mentorships must be implemented in a manner that aligns with both educational and clinical processes and is well-embedded in the respective contexts [3].

The learning process, connecting the academic environment with health care centers, encompasses a broad variety of scenarios and contexts. Numerous factors are involved in this complex and challenging practical training for health profession students, affecting both the respective actors and institutions. These factors can result in an inefficient process, causing dissatisfaction and frustration. Much of the effort is directed toward coordinating the involved parties rather than focusing on the learning process itself and its quality.

The interplay between learning and education at the university, along with practical training in placements, constitutes core elements of health care degree programs at universities, such as nursing or medicine [4]. The purpose of education in practice placements is to equip future professionals with the ability to manage their learning, make decisions that enable effective action in their future professional practice, and enhance the quality of care provision [5]. To attain these objectives, practice-based learning becomes indispensable as it necessitates students to scrutinize and assess their patient care, evaluate and integrate scientific evidence, and consistently enhance patient care through ongoing self-evaluation. Students are expected to cultivate skills and habits that enable the practical application of clinical and transversal competencies acquired at the university.

Practice-based learning in health care settings is defined and characterized by several key aspects [6]. These include the contexts in which practices occur [7], their purpose or objective [8], the methods used to assess students [9], the overall commitment within health care degree programs, the practice education model [10-13], and the various actors involved [3,14].

Elements of Practice Placement in Health Care Education

According to Jokelainen et al [15], the 2 fundamental aspects of mentorship in practice placement involve establishing a supportive learning environment and addressing aspects related to the mentorship process itself. Delving into the establishment of learning support environments, 2 elements are identified as facilitators of learning and indicators of clinical practice environments. These elements are (1) the preparation of the practice setting for learning, which involves planning the training and practice placement, ensuring the implementation of training in the practice setting, and providing opportunities for individualized support during placement; and (2) the organization of interpersonal learning practices, encompassing becoming familiar with the workplace as a work environment, promoting equal participation in practices through teamwork, and collaborating with other stakeholders involved in training.

In delving into the mentorship process within a practice placement, 2 elements that serve as facilitators of learning and indicators of clinical practice placement are recognized. These are (1) facilitating student learning by establishing a supportive

learning environment and fostering individualized learning processes; and (2) enhancing the professionalism of students by encouraging the development of professional attributes and identity, ultimately improving the attainment of professional competence.

Furthermore, Thomson et al [16], in a qualitative phenomenological study, identified 5 significant aspects of the experience in tutoring and follow-up in nursing student practice environments. These mentoring and follow-up aspects were (1) being more independent, (2) receiving support, (3) a sense of belonging to the profession, (4) feedback on the learning process, and (5) anticipatory anxiety.

In this intricate scenario involving various actors, institutions, placement contexts, and mentoring approaches, among others, numerous processes are undertaken, requiring substantial resources and time investments. Given that the primary goal of practice-based learning is student learning and the enhancement of their clinical practice, it becomes crucial to develop innovative approaches that can enable more efficient resource management. In this context, the integration of mobile technology in practice settings has the potential to support and enhance students' learning process while concurrently reducing the resources required for administrative processes in practice placements.

Introducing Mobile Technology in the Learning Process

Contemporary health systems are shifting toward more integrated and person-centered care models [17], with the use of technology becoming increasingly common in various processes related to care provision. Within this context, health care higher education institutions are incorporating technology into their degree programs with the goal of equipping students with essential skills in digital health [18] and preparing them for their future workplaces. The integration of mobile technologies, coupled with advancements in digital literacy, is expected to empower professionals to confront the intricate challenges presented by contemporary health systems [19]. Additionally, these technologies should facilitate student learning, particularly during clinical practice periods. The education of health students is grounded in the preparation of future professionals capable of navigating this evolving context. Therefore, a key objective of training and learning is the transition from acquiring established knowledge to educating for an unknown future. This shift in learning necessitates the adoption of new approaches and the utilization of innovative teaching and learning technologies [20]. Hence, the utilization of information and communication technologies and Web 2.0 environments in the context of learning during practice placements plays a pivotal role in preparing for this uncertain future in education. Technology-enhanced learning encompasses the application of technology to support any learning-related activity, concentrating on various pedagogical domains that leverage technology [21-23].

The evolution of the Web 2.0 concept has seen a shift in learning from eLearning to mobile learning (mLearning). mLearning is characterized as learning that occurs in diverse contexts, involving social interactions and content consumption, using personal electronic devices as a means of distance education. In this approach, mLearners (students) use educational technology through mobile devices [24] at their convenience [25]. The application and utilization of mLearning in education are contingent on the specific learning needs, context, and objectives to be accomplished [26,27].

In practice placements, where the learning needs involve reinforcing and applying competencies acquired at the university, mLearning serves as a valuable tool for consulting reference materials. Its accessibility virtually anywhere and anytime allows students to enhance their understanding. Furthermore, students can share experiences and knowledge gained in the practice setting with mentors and peers, enabling instant feedback and suggestions. This highly interactive process has demonstrated a 22% reduction in abandonment rates in technical environments, accompanied by an increase in evaluation scores from the 50th percentile to the 70th percentile [28]. In the context of mobility, mLearning facilitates student movement, offering excellent content portability by replacing traditional books and notes with small, personalized devices filled with learning materials. Its convenience stems from its accessibility from almost anywhere.

To effectively tackle current issues in teaching and learning, integrate technologies into their respective practices, and enhance user acceptance, mLearning solutions must be collaboratively designed with all stakeholders. This includes researchers, teachers, students, and administrative staff. Achieving a sustainable digitization and transformation of higher education demands a human-centered approach [29,30] that fosters adoption and ensures a lasting impact on practices. Applying this approach to the digitization and transformation of practice-based learning in health care can aid in comprehending the determinants and factors contributing to the successful introduction of mLearning in practice placements. To bridge the gap between the various actors in these learning contexts (university and clinical practice placement) and enhance the overall experience in practice-based learning in health care settings, it becomes essential to implement mLearning approaches in practice placements and gain insights into their tangible benefits and optimal usage strategies.

This paper outlines the protocol for a study focused on the implementation of mobile technology in practice placements. The study protocol aligns with the research vision of an innovation project in higher education known as the "4D in the Digitalization of Learning in Practice Placement" (4D Project; Multimedia Appendices 1 and 2), involving participants from 5 European countries, namely, Spain, Germany, The Netherlands, Austria, and Poland [31] (Multimedia Appendix 3).

The project aims to fill this gap by creating personalized mobile apps for students, teachers, tutors, and supervisors in each participating organization. This will be achieved through the integration of practice-based reflective learning, mobile technology, and the adoption of technology. The aims are as follows:

- To determine the key factors (barriers, facilitators, and solutions) to introduce mobile technology in practice placements.
- To cocreate design learning practices, materials, and adapt or adopt mLearning technology in practice placements using various co-design methods. This approach aims to respect users' core values and address their needs.
- To test and assess the introduction of this mobile technology in practice placements in 3 different health institutions in European countries.

Methods

Study Design and Methodological Framework

The research will follow a mixed methods research design, incorporating 3 distinct study phases, each utilizing different methodologies.

In phase 1, the focus is on comprehending the facilitators and barriers associated with the integration of mobile technology into clinical education during practice placements for medical and health care students. The goal is to identify potential strategies and approaches to overcome the identified barriers.

During phase 2, the emphasis is on collaborative creation and design with users, involving various design methods. The objective is to cocreate and co-design an mLearning technology specifically tailored for practice placements. This phase aims to incorporate user input and preferences into the development process.

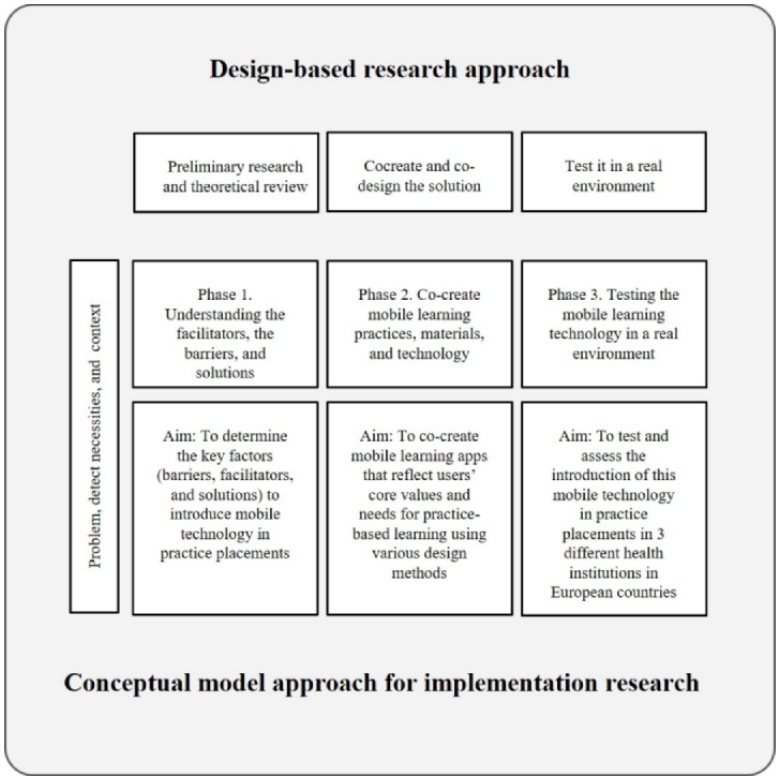
In phase 3, the research moves to the practical testing of the mLearning technology in a real-world environment. The focus is on evaluating the impact, usability, design effectiveness, interactive learning features, and overall user satisfaction. This phase involves assessing how well the developed technology performs in a real setting and gathering feedback to refine and improve its functionality.

Theoretical Framework

The study will be guided by a design-based research framework, which aligns with the principles of design-based research [32-34]. This framework acknowledges that initial research and theoretical review are essential for understanding the problem, identifying needs, and analyzing the context (as seen in phase 1). Subsequently, during the next phase, researchers actively engage in the cocreation of the solution using various design methods (as in phase 2). The final phase involves testing the solution in a real-world environment to assess its impact on students' learning (as in phase 3). This iterative process allows for the continuous refinement and improvement of the developed solution. The study includes a reflecting phase that directs researchers to reflect on the outcomes and use this reflection to redesign the solution. The iterative research process involves designing, testing, evaluating, and reflecting, leading to a new research cycle aimed at refining and redesigning the solution [35] (Figure 1). This cyclical approach allows for continuous improvement and adaptation based on the insights gained from each iteration.

The following sections detail methodological considerations for each phase:

Figure 1. 4D Project conceptual model approach for implementation research [35].



Phase 1: Understanding the Facilitators, the Barriers, and Solutions

Overview

During this initial phase, the primary objective is to comprehend the facilitators and barriers associated with the integration of mobile technology into clinical education during practice placements for medical and health care students. The focus is on identifying potential solutions to overcome the identified barriers, laying the foundation for subsequent phases of the research.

Aim

The aim of this phase is to determine the key factors (barriers, facilitators, and solutions) to introduce mobile technology in practice placements. We describe 3 research questions to ensure and support the objective's consecution:

- What are the facilitators for introducing mobile technology into clinical education in the practice placement of medical and health care students?
- What are the barriers to introducing mobile technology into clinical education in the practice placement of medical and health care students?
- What are the solutions to overcome barriers for introducing mobile technology into clinical education in the practice placement of medical and health care students?

Research Design

To carry out the assessment, we will use 2 methods. First, a scoping literature review will analyze and synthesize existing research evidence. Simultaneously, focus groups will be conducted to capture the perspectives of undergraduate health profession students and stakeholders on the barriers and facilitators associated with the introduction of mobile devices in practice placements. The scoping literature review adheres to the recommendations of the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) statement [36]. The review process follows the framework established by Arksey and O'Malley [37], further refined by Levac and colleagues [38], encompassing the following stages: (1) identification of research questions; (2) identification of relevant studies; (3) selection of studies; (4) data charting; and (5) collation, summarization, and reporting of results.

Focus groups will be conducted to analyze the barriers, facilitators, and needs associated with introducing mobile technology in practical training for future health care students. This qualitative data collection method aims to offer an in-depth understanding of the phenomena. The findings will be reported following the guidelines outlined in the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist [39]. The content for the focus groups will be collaboratively developed through consensus among the research team and subject matter experts. Research questions have been formulated in alignment with the research's purpose by experts representing all partners involved in the 4D Project. This collaborative approach ensures a comprehensive and well-informed set of questions for the focus groups.

Sampling Procedures of Focus Groups

Participants for the focus groups will include undergraduate health care students and stakeholders from Tecnocampus, Pompeu Fabra University, the Medical University of Lublin (Poland), the University of Duisburg Essen (Germany), and the Germans Trias i Pujol University Hospital (Spain). The selection of participants will be carried out using purposive sampling with the aim of achieving maximum variation. Students eligible for participation should be enrolled in degree programs such as nursing, medicine, physiotherapy, or midwifery. Stakeholders will also be included based on the following criteria: involvement in the practical training of future nurses, midwives, physiotherapists, or doctors in roles such as clinical mentors; link teachers; practical training coordinators; hospital ward managers; or staff in the nursing, midwifery, and medical fields.

In each country, we have scheduled 2 focus groups with 8-10 participants each. Overall, we plan to conduct 3 focus groups with undergraduate students (nurses, physiotherapists, midwives, or medical students) and 3 focus groups with stakeholders, including clinical mentors, link teachers, practical training coordinators, hospital ward managers, staff, and other relevant stakeholders.

Analysis

In the scoping literature review, the study screening will follow a structured process [40] involving a sequential review by title, abstract, and full text. Two pairs (pair 1: BD and Agnieszka Chrzan-Rodak; pair 2: Cristina Casanovas Cuéllar and Ariadna Huertas Zurriaga) of experienced researchers will participate in this screening process. Initially, study titles will undergo independent screening by paired reviewers to identify studies that meet the inclusion criteria. Subsequently, researchers will assess the abstracts for inclusion, reviewing a distinct group of articles from the previous step. Following this, the researchers will rigorously evaluate the full text of the remaining articles, strictly adhering to the inclusion and exclusion criteria. In each round, a third researcher will scrutinize the work of each reviewing pair for potential errors. In case of any disagreement between the paired researchers, the document will be referred to the next researcher in the process to mitigate deselection bias. The third researcher will additionally assess the level of agreement between review pairs for both the title and abstract phases, aiming for a 95% agreement level.

The analysis of focus group data will adhere to Koole's FRAME (Framework for the Rational Analysis of Mobile Education) model [41]. The FRAME model delineates 3 principal aspects influencing mLearning and specifies factors (device usability, interaction learning, and social technology) that impact the successful integration of these aspects. For this study, the FRAME model will be adapted to encompass all the findings generated throughout the research.

The initial phase of analysis involves 1 of the researchers (BD) reading the transcripts multiple times to gain familiarity with the content and identify initial units of meaning. Subsequently, the texts will be coded using descriptive codes based on their content. These codes will then be organized into categories according to similarities in the codes. At this juncture, the

preliminary results will be discussed within the research group. Through reflective thinking and critical reasoning, adjustments will be made until a consensus is reached. The themes derived from the analysis will be organized under the learning aspects outlined in Koole's original model. Subsequently, the resulting report will be discussed with 2 participants to validate the meaning and coherence of the interpretations. To enhance the trustworthiness of the data, considerations will be given to credibility, dependability, conformability, and transferability [42]. The participants for this discussion will be selected through purposive sampling with maximum variation to bolster credibility. The information from the focus groups will undergo thorough examination by at least two members (SH and CMG) of the research team, and the results will be compared to evaluate dependability. To ensure conformability, all information provided by participants will be presented transparently. For the transferability of the study's data, a comprehensive and detailed description of the data and context will be provided.

Phase 2: Cocreate Mobile Learning Practices, Materials, and Technology

Overview

This phase is dedicated to collaboratively creating mLearning practices, materials, and technology for practice-based learning using various (co-)design methods.

Aim

The objective is to cocreate mLearning apps that align with users' core values and needs for practice-based learning. This involves collaborative design and production of mLearning practices and materials. Additionally, it includes the adaptation and appropriation of existing mobile apps to bridge the gap between the academic and practice contexts in health care practice placements.

Research Design

This section of the study utilizes collaborative design methods to comprehend the core values and needs of health care students and stakeholders. The goal is to develop embedded mLearning apps for practice placements. To facilitate the coordination of the innovation process within the design team and with domain representatives, the university innovation canvas (UIC) is used. The UIC elucidates the key factors fostering digital transformation and sustainable innovation. This will help to plan the selection and application of more specific co-design methods and tools such as the value proposition canvas (VPC), personas, storytelling, and use case definitions.

University Innovation Canvas and Value Proposition Canvas

The UIC draws inspiration from the business model canvas by Osterwalder and Pigneur [43] and the lean canvas by Maurya [44]. While the business model canvas primarily explores the creation of value for businesses, the UIC [30] is designed to reflect how "value" is generated within a university setting. This adaptation aligns the canvas with the specific context and objectives of fostering innovation within the university environment. In our scenario, the aim is to establish a shared understanding of enhancing collaboration between universities and their affiliated practice placement organizations, involving all relevant stakeholders (eg, students, teachers, and nurses). The UIC comprises 11 elements organized into 3 dimensions: the technology-enhanced learning concept (value creation), stakeholder relationships (value delivery), and foundation and scaling (value capture). This framework provides a structured approach to addressing key aspects of innovation and value creation in the university setting. The specific elements and dimensions within the canvas serve as tools for various stakeholders from diverse contexts to refine their collective focus. They facilitate reflection on crucial factors related to planned sustainable innovation, particularly in the context of enhancing practice placements. The canvas provides a structured framework that encourages stakeholders to align their perspectives and contribute to the development of innovative solutions.

To precisely define the value proposition within the UIC and align it with the technologies available for adoption within the consortium, we opted for the VPC [45]. This tool concentrates on how to generate value for all stakeholders involved (eg, students, teachers, nurses), or more precisely, how these stakeholders can benefit from the anticipated learning intervention. The VPC offers a structured approach to articulate and understand the unique value that the proposed innovations bring to each stakeholder. The VPC consists of 2 parts: First, the *stakeholder profile*, which aims at (1) describing the things or tasks they must do during their work; (2) related pains during the work including risks, potential bad outcomes, or obstacles related to their job; and (3) desired gains including the outcomes and benefits they would like to have. Second, the *value map*, which aims at creating value for the stakeholders by identifying the following: (1) pain relievers in the form of an innovation to reduce/eliminate the stakeholder's pains, (2) innovations that could be built around the value proposition, and (3) gain creators that describe how the innovation creates gains for the stakeholders.

Participants

The participants involved in this process are all members of the 4D Project partner teams, particularly those working at universities or in hospitals. This inclusive approach aims to gather perspectives and insights from both the education side at the university and the practice placements, ensuring a comprehensive representation of stakeholders involved in the project.

Procedure and Analysis

The application of the UIC and VPC will follow a 2-step approach, commencing with a "top-down" approach and subsequently transitioning to a "bottom-up" approach. In the initial step ("top-down" approach), the UIC will be distributed to all 4 distinct practice placements. The stakeholders engaged in the practice placements will receive an introduction to the UIC along with a clear explanation of the purpose behind this activity. The objective is to illuminate the addressed problems, identify value propositions and measures, and identify all involved stakeholders from various perspectives. After the completion of the UICs for each of the 4 practice placements,

the analysis will focus on uncovering commonalities across all of them. In the subsequent step (ie, the "bottom-up" approach), 3 of the identified commonalities will undergo a more detailed analysis. Hence, in a face-to-face setting, the pertinent stakeholders will be invited to vote for the most significant commonalities and collaboratively complete the VPC. The objective is to explore, from a value proposition perspective, how potential innovations could assist them in creating value for their stakeholders (eg, students, lecturers, and nurses). After the completion of the VPCs, the input will be analyzed and used to generate new UICs. This process aims to establish a shared understanding of possible solutions that align with all 4 practice placements and to emphasize how such innovations can be applied across all 4 settings. Based on the outcomes, subsequent co-design activities using personas, storytelling, and use case definition will be used to further refine the elicited innovation. This may involve creating mock-ups and developing application scenarios in practice. The process includes collaborative efforts to cocreate mLearning practices, materials, and suitable tools within the consortium and with all stakeholders. The overarching goal is to support the practice-based learning of health care professionals in education through innovative and tailored solutions.

Phase 3: Testing the Mobile Learning Technology in a Real Environment

Overview

This phase is dedicated to testing the mLearning technology in a real environment, evaluating its impact, usability, design, interactive learning, social technology, and overall satisfaction.

Aim

The objective is to test and assess the introduction of this mobile technology in practice placements within 3 distinct health institutions located in Spain, Germany, and Poland.

Research Design

In this phase of the study, the descriptive method, specifically a survey, will be used. The underlying premise is that the primary users, namely, the students and clinical mentors, can provide valuable information on aspects related to the use of mobile devices in a practice placement.

The proposed data collection method involves designing and crafting a questionnaire to ensure a comprehensive exploration of the subject. A self-administered questionnaire will be formulated, comprising distinct sections, including a participant information sheet; consent form; demographics information; and segments focusing on usability, design interaction, learning, social technology, and satisfaction. The questionnaire has been created by the authors of the study and draws upon the insights gained from the literature review [41,46,47] and the outcomes obtained in phase 2. Response options will consist of a 5-point Likert scale (ranging from 5=strongly agree to 1=strongly disagree), short responses, or free-text answer options. To assess the feasibility of the questionnaire, it will undergo a pilot phase with a group of students and stakeholders engaged in clinical education. Subsequently, the questionnaire will be revised, if necessary, based on the feedback received during the pilot testing. All participants will be provided with information about the study, including the study protocol, a digital consent form, and a questionnaire. Only those who agree to participate in the study will be directed to the questionnaire. Participants retain the right to withdraw from the study at any point. The online survey is estimated to take approximately 15 minutes to complete. The collected data will be securely stored on a password-protected computer, with access restricted to designated research staff or other authorized personnel who are obligated to maintain the confidentiality of the information. It is important to note that the data will be anonymized.

Participants

The study sample will consist of participants from Tecnocampus, Pompeu Fabra University (Spain), the Medical University of Lublin (Poland), the University of Duisburg Essen (Germany), and the Germans Trias i Pujol University Hospital (Spain). The questionnaire will be completed by students, teachers, tutors, and supervisors who use the developed apps. Moreover, all other individuals engaged in clinical education (practice placement) will be invited to participate in the study.

Analysis

The survey will be designed and implemented using REDCap (Research Electronic Data Capture), a secure, web-based application specifically designed to facilitate data capture for research studies [48].

The analysis in this phase will use inferential statistics to draw conclusions regarding the integration of mobile technology in practical placements. The statistical package used for this analysis will be SPSS, version 23.0 (SPSS Inc.). However, we do not exclude the possibility of using MS Excel (Microsoft Corporation) to facilitate and expedite the data collection and analysis process.

The methodology for describing and analyzing open free-text answers (unstructured data) will involve the use of Dcipher Studio (Dcipher Analytics), an artificial intelligence–powered tool designed to identify topics and sentiments in free-form text responses [49]. Using sentiment analysis and tonality detection will prove valuable in quantifying the emotional tones expressed in the responses.

The analysis of mobile app usage will involve reviewing computer-generated event logs to identify bugs and security threats, ensuring compliance with regulations, and gaining insights into user behavior.

Ethical Issues

At every stage of the planned research, strict adherence to the ethical principles outlined in the Declaration of Helsinki will be maintained. In research involving individuals, such as students and stakeholders, each partner will submit an application containing a comprehensive description of the research protocol to the relevant Ethics Committee. The focus groups and questionnaire studies will adhere to the principles of voluntary participation, anonymity, and respect for the decision to withdraw from the study at any stage. The gathered data will be used solely for purposes associated with the implementation of the 4D Project.

Ethics Approval

The study has received approval from the ethics committees of the respective institutes in each country: the Bioethical Commission at the Medical University of Lublin in Poland (protocol code KE-0254/152/06/2022 approved on June 30, 2022), the University of Duisburg Essen's Ethics Committee in Germany (protocol code 22-10783-BO approved on October 19, 2022), and the Fundació Tecnocampus Mataró-Maresme's Ethics Committee in Spain (protocol code CEI2/2022 approved on October 7, 2022). Informed consent will be obtained from all study participants.

Results

Phase 1: Understanding Facilitators and Barriers

The scoping literature review commenced in April 2022 and concluded in July 2022, while the focus groups were conducted from October to December 2022. It is anticipated that the outcomes of phase 1 will reveal (1) the identification of factors supporting the successful integration of mobile technology in clinical education for medical and health care students; (2) the acknowledgment of obstacles and challenges impeding the effective use of mobile technology in practice placements; (3) practical solutions proposed to address the identified barriers and challenges, and (4) insights derived from the focus groups, which will provide a deep understanding of the perspectives and experiences of health care students and stakeholders regarding the integration of mobile technology.

Phase 2: Cocreating Mobile Learning Practices

The design process commenced in July 2022 and concluded in November 2023. The outcomes of phase 2 revealed (1) the development of innovative and customized mLearning apps that resonate with the core values and requirements of health care students and stakeholders; (2) the adaptation and proficient utilization of preexisting mobile apps to fulfill the distinct needs of practice placements; and (3) the recognition of how collaboratively crafted mLearning practices can yield value for a diverse range of stakeholders, encompassing students, educators, and health care professionals.

Phase 3: Testing Mobile Learning Technology

The pilot study is set to commence in January 2024. It is anticipated that the outcomes of phase 3 will reveal (1) results pertaining to the usability and design of the collaboratively created mLearning apps obtained through surveys; (2) the impact of mobile technology integration on various aspects including learning outcomes, student engagement, and communication among stakeholders; (3) an examination of the emotional tones expressed by participants in relation to the implementation of mobile technology; and (4) findings from the analysis of computer-generated event logs from mobile apps, providing insights into user behavior, identifying potential issues, and ensuring compliance with regulations.

Discussion

Principal Findings

The primary objective of this study is to bridge the gap in practice-based learning by developing personalized mobile apps tailored for diverse actors and stakeholders. The study aims to assess the integration of mobile technology in practice placements within European health care institutions.

This study aims to showcase the transformative potential of mobile technology in reshaping practice placements within health care education. Through targeted efforts to overcome significant barriers, engaging stakeholders in co-design processes, and integrating mobile apps, the study will concentrate on enhancing both the learning and administrative aspects of practice placement. The overarching goal is to ensure the effective clinical education of health care students in higher education.

Identifying key factors, including barriers, facilitators, and potential solutions, for the introduction of mobile technology in practice placements will unveil a spectrum of elements. Literature reviews and insights from focus groups suggest that factors facilitating the use of mLearning in practice placements may include improved access to clinical resources; enhanced communication and collaboration among health care professionals, students, and stakeholders; and the facilitation of self-directed learning. Barriers to the integration of mobile technology in practice placements are concerns about the design of the product being beyond the control of learners and their teaching staff. Additionally, challenges arise when cultural acceptance and adherence to social norms regarding the use of mobile devices in clinical settings are not taken into account. Moreover, the absence of clear policies further contributes to impediments in this context [50-52].

The co-design of an mLearning app, aligning with users' core values and needs, is crucial for the effective adoption of mobile technology in practice-based learning [53]. The outcomes will offer valuable insights into users' needs, values, and preferences, guiding the design process to ensure a user-centered application [54].

Ultimately, the testing and assessment of mobile technology in clinical practice placements are poised to yield promising results across various dimensions, including usability and design, learning outcomes, student engagement, communication among stakeholders, user behavior, identification of potential issues, and compliance with regulations. The integration of mobile apps holds the potential to have a positive impact on the learning process, streamlining day-to-day clinical practice, and enhancing value-based activities.

The impact of this study underscores the necessity for sustained investment in technology-enhanced learning and the crucial role of user-centered design in health care education. Extending beyond the immediate scope of this study, the findings will emphasize broader implications for health care education, particularly in clinical practice placements.

Limitations

It is important to note that the findings of this study may have limited generalizability beyond the participating European countries due to variations in educational contexts and health care systems. Moreover, the assessment of learning outcomes and intervention effectiveness in complex educational settings poses challenges, potentially impacting the comprehensiveness and quantifiability of our results.

Conclusions

The 4D Project endeavors to address the existing gap between academic contexts and clinical placements in higher education. Its objective is to introduce mobile technology as a solution to enhance the learning process in this context. The project actively supports the examination of communication and interaction processes among various stakeholders within and across different organizations and countries. This is achieved through a meticulous methodology used in the design of a mobile app.

The study will use a multiphase approach. Initially, a systematic review and qualitative methodology involving focus groups will be used to identify barriers and facilitators to the introduction of mobile technology in practice placements. Subsequently, a design-based research methodology will be implemented, enabling the cocreation of mLearning apps that align with users' core values and needs for practice-based learning. Finally, a pilot study using both quantitative and qualitative methods will be conducted to validate and test the mLearning technology in a real-world environment. This phase will evaluate its impact, usability, design, interactive learning, social technology aspects, and user satisfaction.

The long-term benefits of the "4D Project" are centered around improving communication, interaction, and collaboration among the diverse stakeholders engaged in the educational process. By addressing current challenges in practice placements, the project aims to fortify the connection between these stakeholders in the digital era. It seeks to foster new forms of collaboration through the strategic integration of mobile technology.

Health care education, encompassing disciplines such as medicine, nursing, midwifery, and others, encounters ongoing challenges in clinical training. The imperative task of bridging the divide between health care institutions and academic settings is crucial. The introduction of a novel digital tool holds the potential to empower health students and mentors, providing a means to navigate the complexities inherent in the learning process.

Acknowledgments

The authors thank the work and dedication of the 4D Project Consortium. The members of the 4D Project Consortium are Esther Cabrera (Tecnocampus, Pompeu Fabra University, Barcelona, Spain), Carlos Martínez-Gaitero (Tecnocampus, Pompeu Fabra University, Barcelona, Spain), Carles Garcia (Tecnocampus, Pompeu Fabra University, Barcelona, Spain), Sebastian Dennerlein (University of Twente, Enschede, The Netherlands), Beata Dobrowolskaa (Faculty of Health Sciences, Medical University of Lublin, Lublin, Poland), Agnieszka Chrzan-Rodak (Faculty of Health Sciences, Medical University of Lublin, Lublin, Poland), Gilbert Peffer (Kubify BV, Utrecht, The Netherlands), Raymond Elferink (Kubify BV, Utrecht, The Netherlands), Daniel Moreno-Martinez (Germans Trias i Pujol Research Institute, Badalona, Spain), Cristina Casanovas-Cuéllar (Germans Trias i Pujol Research Institute, Badalona, Spain), Ariadna Huertas-Zurriaga (Germans Trias i Pujol Research Institute, Badalona, Spain), Stephanie Herbstreit (Medical Faculty, University of Duisburg-Essen, Duisburg, Germany), Cynthia Szalai (Medical Faculty of the University of Duisburg-Essen, Duisburg, Germany), Daniela Mäker (Medical Faculty of the University of Duisburg-Essen, Duisburg, Germany), and Angela Fessl (Graz University of Technology and the Know-Center GmbH, Graz, Austria). The Know-Center is funded within COMET (Competence Centers for Excellent Technologies) under the auspices of the Austrian Federal Ministry of Transport, Innovation and Technology, the Austrian Federal Ministry of Economy, Family and Youth, and by the State of Styria. COMET is managed by the Austrian Research Promotion Agency FFG. This project has been funded with support from the European Union, Programme Erasmus+ Action Type KA220-HED—Cooperation partnerships in higher education Call 2021 Round 1.

Authors' Contributions

All authors have had substantial intellectual contributions to this protocol. CMG and EC conceptualized this study and wrote the first and final drafts of the protocol. All the authors participated in writing, reviewing, and editing the protocol. All authors have contributed to revising the protocol for intellectual content. All authors have read and approved the final manuscript and given final approval for the manuscript to be published.

Abstract

Background: Digital or eHealth knowledge translation (KT) interventions have been identified as useful public health tools, particularly to advance sexual and reproductive health (SRH) among adolescents. Existing literature reviews on digital health interventions for adolescents' SRH demonstrate limitations, including shortcomings in reporting and comprehensiveness that limit the utility and trustworthiness of findings. However, there is a lack of evidence synthesis on the effectiveness of available digital or mobile health KT tools to promote SRH interventions for adolescents.

Objective: We aim to identify, map, and describe existing empirical evidence on the digital KT tools developed to improve adolescent SRH outcomes globally.

Methods: This study will be conducted using an evidence gap map (EGM) approach to address the objectives, including reviewing relevant literature and a landscape analysis of the outcomes of interest. The following electronic databases will be searched for retrieval of literature: MEDLINE (1946-present), Embase (1974-present), and Global Health (1910-present) via OVID; CINAHL (1936-present) via EBSCOhost; Scopus (1976-present); and Cochrane Library (1993-present) via Wiley. We will include only those studies that focused on adolescents aged 10-19 years and addressed SRH outcomes. We will include experimental studies (randomized or cluster randomized and nonrandomized controlled trials, including quasi-randomized, controlled before-after, and interruptive time series) and observational studies, that is, including prospective cohort and case-control studies. The experimental and observational studies will only be included in the presence of control or comparison arms. Studies with a historical control arm will be excluded. The systematic review software, Covidence (Ventas Health Innovation), will be used to screen and select the studies. Further, 2 independent reviewers will complete the first and second levels of screening of studies and any conflicts arising will be resolved by consensus between the 2 reviewers or by involving the third reviewer. We will conduct the quality assessment of all included studies using the Risk of Bias tool for randomized controlled trials and nonrandomized controlled trials, and AMSTAR2 for systematic reviews.

Results: Papers screening, data extraction, and synthesis will be completed by March 2024. We will use EPPI-Mapper (The International Public Policy Observatory) software to generate an online evidence map and to produce the tables and figures for the descriptive report. This EGM review will identify areas with high-quality, evidence-based digital KT tools (for immediate scale and spread) and areas where few or no KT tools exist (for targeted KT tool development and research or policy prioritization).

Conclusions: This protocol focused on mapping eHealth KT tools that have been used in the literature to address SRH among adolescents. This will be the first EGM exercise to map digital KT tools to promote adolescents' SRH and will incorporate a range of published sources.

KEYWORDS

adolescents; sexual and reproductive health; digital tools; knowledge translation; mobile phone

Introduction

Background

Adolescence is a critical period in the transition from childhood into adulthood, during which young individuals aged 10 to 19 years experience substantial physical, psychological, social, and emotional changes [1]. Adolescents are vulnerable because of their age-related psychosocial and biological changes and the challenges associated with navigating these changes [2]. As part of their physical, psychological, and social development, it is common for adolescents to explore their sexual orientations and feelings through sexual experimentation [3]. Depending on their knowledge about sexuality and social support, some may experience unintended consequences such as unplanned pregnancy and sexually transmitted infections. Neglect of specific adolescents' sexual and reproductive health (SRH) needs can affect their physical and mental health, future employment, economic well-being, and ability to reach their full potential [4-6].

SRH issues pose serious concerns for adolescents including the lesbian, gay, bisexual, transgender, queer, and gender diverse population. Adolescents have the highest rates of contracting sexually transmitted infections, including HIV [7,8]. Approximately 16 million girls aged 15-19 years and 2 million girls younger than 15 years become pregnant each year around the world [9]. Pregnancy-related complications are the second leading cause of death among girls aged 15-19 years [10]. Furthermore, adolescents have less access to information and services. Access to contraception also remains low among females 15-24 years compared to women older than 30 years [11]. This is primarily due to a lack of awareness, social stigma, policies, and procedures inhibiting the provision of contraception and abortion services to girls, and judgmental attitudes of health care professionals [12-14]. Young people have special SRH education needs that remain unmet, and to address these specific SRH needs, innovative and novel approaches are required to ensure access to evidence-based SRH information and acceptable SRH services [13].

To maximize health system resources and improve SRH outcomes for adolescents, it is increasingly important to close the research-practice gap by ensuring that research knowledge translates into action—a process called knowledge translation (KT). KT is the synthesis, exchange, and application of knowledge to improve the health of individuals, provide more effective health information, services, and products, and strengthen health care systems [15]. KT is the process of translating knowledge into action to provide more effective health services and strengthen the health care system [15,16]. The goal of KT is to ensure that individuals, such as patients, health professionals, and policymakers, can access and use research evidence to inform their health-related decision-making [17].

KT is a dynamic process that uses tools and methods to increase the use of evidence in decision-making while considering policy rationales in the process of generating evidence [18]. On the other hand, KT tools are a subgroup of KT interventions that facilitate moving research-based information to clinicians and patients or health care consumers in user-friendly language and formats to provide explicit recommendations or meet knowledge or information needs [16,17,19]. KT tools to transfer health information to health care consumers can be presented using a multitude of formats, including but not limited to videos, infographics, apps, practice guidelines, and decision-aiding tools to aid consumers in the synthesis, dissemination, and implementation of research [19]. Digital KT tools offer a promising approach to improving health literacy and communicating complex health information to health care consumers. Digital KT tools such as mobile phone websites, mobile apps, mobile health (mHealth), SMS text messaging, and social media platforms have been identified as useful public health tools, particularly to promote SRH among adolescents. The use of digital technology for SRH promotion offers privacy [20-25], access to personalized information [20,22,24,26], and convenience [20,25,27] making it a valuable way to provide accurate information about sexual health to adolescents [20-24].

Several research studies tested the effect of technology-based tools on improving adolescents' knowledge, attitudes, and practices regarding sexual health [22-27]. Cornelius and Lawrence [23] used text messaging through mobile phone technology to increase awareness of adolescents to prevent sexually transmitted infections (HIV) and improve safe sexual practices [28]. The study reported that adolescents found text messaging to be an excellent source of information exchange and a reminder to have safe sex practices [27]. Another study evaluated the prevalence and effectiveness of using chatbot (chat agent) inquiries related to sex, drugs, and alcohol use among adolescents. The study reported that adolescents found chatbots a confidential and user-friendly tool to answer their queries related to topics around sex and sexual activities [28]. Additionally, Guse and colleagues [21] conducted a systematic review to summarize evidence on the effectiveness of digital media-based sexual health intervention for adolescents aged 13-24 years [29]. The review included 10 studies in total, while the majority of the included studies were conducted in the United States. The findings of the review study reported the

effectiveness of digital media-based interventions in improving sexual behavior and health among adolescents.

However, despite the availability of digital KT tools, there is a lack of evidence of synthesis on the available digital or mHealth KT tools to promote SRH interventions for adolescents. Not all KT tools are equally effective and trustworthy sources of SRH information. Therefore, this study using an evidence gap map (EGM) exercise aims to synthesize evidence on the usefulness of digital KT tools to improve adolescents' SRH. EGM is an emerging approach to mapping and synthesizing evidence from empirical studies to implement effective strategies and inform policymakers [30]. EGM is a systematic way of gathering scientific evidence and summarizing the evidence in a graphical format for researchers and practitioners to understand what is known and where the gap is in a particular sector. Another key advantage of using the EGM framework is that this guide is designed for nonspecialist audiences to distill key findings and provide implications for practice and policy [30].

Study Purpose and Objective

This review aims to identify, map, and describe existing empirical evidence on the digital KT tools developed to improve adolescent SRH outcomes globally. In this EGM, we will assess and report on empirical studies describing the development, implementation, or evaluation of SRH digital KT tools to identify current aims, processes, methods, frameworks, tools, user roles, disciplinary and geographic domains of application, as well as to document existing knowledge gaps. The specific objectives of this EGM are to, first, identify, assess, and report on empirical studies of any design that describe the development, implementation, or evaluation of adolescent SRH digital KT tools; second, to identify current uses, purposes, and methods in the development of digital KT tools; third, to describe the characteristics of digital KT tools; and finally, to identify research gaps in the literature.

We will conduct an EGM to address the objectives, including reviewing relevant literature and a landscape analysis of the outcomes of interest. The EGM will be presented on a web-based platform and accompanied by a published paper with an analysis of the available evidence. An EGM aims to establish what we know and do not know about the effects of interventions in a thematic area [31]. The map is populated through systematic searching, screening, and data extraction of all relevant completed, and ongoing, impact evaluations and systematic reviews.

Methods

Study Design

This study is conducted in alignment with standard methodologies for the development of EGM [30]. The protocol for this work is registered with PROSPERO (CRD42022373970). We started this review in May 2023 and will complete it by April 2024.

Scope of EGM

The scope of the EGM was determined through a consultative workshop organized by SM to discuss the interventions and strategies to improve the adolescents' SRH and rights and on how to meet the information needs of adolescents related to SRH. We invited the stakeholders from Option for Sexual Health and Action Canada for Sexual Health and Rights to the consultative workshops for research team members of World Universities Network and members of the Contraception and Abortion Research Team. This workshop identified the need for the EGM and informed the general inclusion criteria and the framework of the EGM. We found EGM as the most appropriate and suitable framework for this review as we aim to map the available evidence on the effectiveness of digital interventions in the form of a table or matrix that provides a visual presentation of the evidence [32].

Eligibility Criteria

The eligibility criteria for the evidence map are summarized in Textbox 1 and detailed below:

- *Study types:* We will include experimental studies (randomized or cluster randomized and nonrandomized controlled trials, including quasi-randomized, controlled before-after, and interruptive time series) and observational studies, that is, including prospective cohort and case-control studies. The experimental and observational studies will only be included in the presence of control or comparison arms. Studies with a historical control arm will be excluded. Studies such as cross-sectional studies, case reports and series, editorials, commentaries, and narrative reviews will not be included.
- *Topics of interest:* We will include studies that have reported KT tools on SRH topics such as family planning and contraception use, healthy timings and spacing of pregnancy, teenage pregnancy, abortion, HIV and AIDS and other sexually transmitted infections, intimate partner violence or dating violence, menstruation, feminine hygiene, child marriage, and female genital mutilation associated with the above topics.
- *Population:* We will include primary studies conducted on adolescents aged 10-19 years. Studies and reviews on populations younger and older than adolescents but inclusive of adolescents will be included if they separately report outcomes on adolescents. We will report the studies separately if they do not report outcomes on adolescents separately.
- *Exposure or intervention:* We will include studies assessing digital KT tools for disseminating SRH information to adolescents. If a digital KT tool is meant for dissemination in wider age groups, it will be included, and these KT tools will consist of websites, mobile apps, mHealth, SMS text messaging, pamphlets, and brochures over email, podcasts, mass media such as radio messages or videos on television, and social media such as Instagram, TikTok, Facebook, Twitter, YouTube, and over-the-top platforms.
- *Comparison:* We will include studies comparing the abovementioned KT tools with no interventions, the standard of care, or other interventions.
- *Setting:* We will include studies conducted globally regardless of the settings or context of its conduct.

Textbox 1. Eligibility criteria for the evidence map.

Population

- Adolescents aged 10-19 years

Exposure or intervention

- Digital knowledge translation tools for disseminating sexual and reproductive health information such as websites, mobile apps, mobile health (mHealth), SMS text messaging, pamphlets, and brochures over email, podcasts, radio messages, videos on television, and social media such as Instagram, TikTok, Facebook, and Twitter

Comparison

- Any comparison is eligible

Geography

- Global evidence, that is, studies from high-income and low- and middle-income countries

Topics of interest

- Family planning and contraception use
- Healthy timings and spacing of pregnancy
- Teenage pregnancy
- Abortion
- HIV and AIDS and other sexually transmitted infections
- Intimate partner violence or dating violence
- Menstruation and feminine hygiene
- Child marriage
- Female genital mutilation
- Rights, norms, education, and empowerment associated with the above topics

Study type

- Experimental and observational studies, including systematic reviews

Timeframe

- Studies and reports published from 2010 onwards as internet and digital or social media usage increased from 2010

Language

- English language only given the prominence of the English language in science

Search Strategy

The search strategy for this review will be reported in adherence to the PRISMA-S (Preferred Reporting Items for Systematic Reviews and Meta-Analyses for Searching) extension [33]. The search strategy will be developed by an experienced health sciences librarian (MK) in consultation with the research team. The following databases will be searched individually from inception to present: MEDLINE (1946-present), Embase (1974-present), and Global Health (1910-present) via OVID; CINAHL (1936-present) via EBSCOhost; Scopus (1976-present); and Cochrane Library (1993-present) via Wiley.

The search strategy will be derived from four main concepts: (1) adolescents, teenagers, or young adults; (2) SRH or health services including vocabulary related to contraception, family planning, pregnancy, sexually transmitted infections, and gender-based violence; (3) digital communication tools such as websites, web-based messaging, smartphones, mobile apps, social media, podcasts, television, or digital information; and (4) KT including vocabularies such as information dissemination, research innovation, knowledge transfer, implementation science, research into practice, knowledge into practice, and evidence-based practice. Bibliographic databases will be searched using a combination of natural language (keywords) and subject headings, such as Medical Subject Headings, wherever they are available. Items such as books, book chapters, editorials, conference materials, and opinion pieces will be removed from the results and a publication date limit of 2010 to the present will be applied. A preliminary search for OVID Medline was developed and executed in October 2022 to determine the feasibility of this project and test the scope (see Multimedia Appendix 1 for the MEDLINE search strategy). The systematic review software, Covidence, will be used to manage this review. Covidence will be used for the

deduplication of database search results and will be used to facilitate the title or abstract screening and full-text screening phases.

Screening and Extraction

All the studies identified from the databases will be imported to Covidence (a digital screening software), and 2 independent reviewers will screen the studies in title or abstract and full-text stages. Disagreements, if any, will be resolved by consensus. The reference list of all the included studies will be scanned and searched to include any relevant study that may have been missed during the search of databases. The final list of included studies will be subject to forwarding and backward citation chaining to ensure no relevant eligible papers have been missed. A diagram showing the flow of literature will be produced and reported by PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [33]. For data extraction, we will use a standardized data extraction form to extract descriptive data from all studies meeting our inclusion criteria. Data extracted from each study will include bibliographic details, KT tool types and descriptions, outcome types and descriptions, study design, context or geographical information, and details on the outcome and quality of the KT tool. Further, 2 review authors will independently extract data, and discrepancies will be resolved through discussion until consensus has been achieved or by consulting a third reviewer if required. Attempts will be made to contact the authors of the included studies to obtain clarifications or additional data. We will extract data on the following study characteristics presented in Textbox 2:

Textbox 2. Extraction of data on this study's characteristics.

Publication information

- Journal, publication year, study location, and study setting

Population

- Number of participants, sex, mean age, age range, and sociodemographic status

Digital knowledge translation (KT) tool

- Digital KT tool description, purpose, setting, and any other important detail

Intervention (if studies used digital KT tool as an intervention to improve sexual and reproductive health [SRH] information and outcome of adolescents)

- Intervention description, the composition of the intervention, duration of intervention, a platform for delivery (school-based or community-based, peer-support, mobile health [mHealth]), and comparison group description

Control

- Standard of care or control

Outcomes

- Outcomes specified earlier, time points of outcomes reported, and evaluation methods used

Study design

- Type of study design

Other information

- Funding sources, study limitations, and conflicts of interest

Data Synthesis

Data from the review will be visually synthesized in an EGM using EPPI-Mapper [34] with an accompanying narrative. Rows of the EGM list digital KT strategies and columns components of outcomes and other relevant data coding. Each cell shows the number and quality of evidence for digital KT strategies. We will conduct the quality assessment of the included studies using Risk of Bias for interventional studies including randomized controlled trials and nonrandomized controlled trials and AMSTAR2 tool for systematic reviews [31,35]. The EGM identifies areas with high-quality, evidence-based digital KT tools (for immediate scale and spread) and areas where few or no KT tools exist (for targeted KT tool development and research or policy prioritization) An example of the layout of the evidence map matrix can be found in Multimedia Appendix 2 (developed in consultation and discussion with experts in the area of adolescents SRH).

Patient and Public Involvement

Patients will not be involved in the design, conduct, reporting, or dissemination of the EGM exercise.

Ethical Considerations

No ethical review was required, as we included published data which is accessible and available for the public in this review. We will disseminate findings from the EGM through summary reports and publications; present our findings at conferences to

facilitate research reach; list project descriptions and associated outputs on investigator-affiliated websites and professional web-based accounts; and concurrent dissemination through professional social media accounts. The EGM has the potential to inform researchers and decision makers about user-centered innovation by highlighting current practices and opportunities for further KT tools development. Findings will inform the development of future projects with the principal investigators and coprincipal investigators' research program aimed at developing, implementing, and evaluating digital KT tools and associated projects in various receptive adolescent SRH contexts. Findings will directly inform a concurrent project by the lead investigator (SM) focused on co-designing a mobile app to improve the SRH of immigrant adolescents in Canada.

Results

Overview

Paper screening, data extraction, and synthesis will be completed by March 2024. We will use EPPI-Mapper software to generate a digital evidence map and to produce the tables and figures for the descriptive report. EPPI-Mapper will consist of rows representing digital KT interventions and column components presenting outcomes. Each cell shown within the matrix will present the number and quality of evidence for digital KT strategies. This EGM review will identify areas with high-quality, evidence-based digital KT tools (for immediate scale and spread) and areas where few or no KT tools exist (for targeted KT tool development and research or policy prioritization). This EGM exercise will offer a novel knowledge synthesis tool (a web-based EGM), mapping all of the digital KT tools currently available to promote the SRH of adolescents. The information will be available in a usable format to enable efficient and effective use by multi-stakeholder audiences.

Discussion

Principal Findings

The purpose of this review is to create an EGM to guide multi-sectoral stakeholders regarding digital KT tools to better understand and use the evidence-based digital KT tools to improve the SRH of adolescents. Digital KT tools have the potential to advance the SRH of adolescents, yet there is a dearth of knowledge regarding the quality and uptake of these digital KT tools. Digital technologies have the potential to facilitate innovative, efficient ways of meeting growing global health needs. A global 2019 report [36] indicated that over 5 billion mobile phone users, 4 billion internet users, and 3 billion active social media users, with most accessing the internet through mobile devices. The anonymity, convenience, and accessibility afforded by SMS, web access, and video streaming enhance the potential for SRH interventions to reach persons disconnected from mainstream SRH services.

Existing literature reviews on digital health interventions for adolescents' SRH demonstrate limitations, including shortcomings in reporting and comprehensiveness that limit the utility and trustworthiness of findings. An EGM of digital KT tools is therefore warranted. Innovative ways to deliver sexual health information and services are more important than ever before due to the impact of the COVID-19 pandemic on access to SRH services globally [37]. Interruptions in SRH information and service delivery seriously impact vulnerable adolescents' health and well-being. The absence of adolescent SRH services from "essential" health services during COVID-19 amplifies the potential role of technology in meeting the SRH needs of vulnerable groups like adolescents. Amidst the pandemic, technology has primarily provided the means to support the recalibration of health systems, service provision, and information delivery [38]. Digital health tools play an important role in preserving the continuity of SRH services for adolescents and youth during a crisis. Using digital health tools in the pandemic and climate change context would improve adolescents' access to information which might support them in having the knowledge and motivation to access services.

Guidelines and policies are increasingly focused on adolescents as a specific population for modifying health behaviors [39], and the global community is calling for further research in this area [40]. However, it is important to first map out all the available digital KT tools for improving behavior related to SRH among adolescents. Digital or eHealth KT interventions have been identified as useful public health tools, particularly to advance SRH among adolescents. The use of digital technology for SRH promotion offers privacy [21-26], access to personalized information [21,23,25,27], and convenience [21,26,28] making it a valuable way to provide accurate information about SRH to adolescents [21-26].

Despite the high level of SRH information consumption via a digital platform, evidence of the successful use of SRH digital KT tools is limited. EGM provides a novel knowledge synthesis approach that can accelerate the uptake of digital KT tools to promote adolescent SRH outcomes. This study will map all the digital KT tools currently available and identify the key evidence gaps in digital KT tools that may not be obvious from quick snapshots of the literature. Systematically mapping evidence for digital KT tools will provide valuable insights to inform practice, policy, research, or investment for future adolescent SRH research agendas.

Strengths and Limitations of This Study

This will be the first EGM exercise to map digital KT tools to promote adolescents' SRH and will incorporate a range of published literature sources. An independent dual-reviewer process will be used throughout to reduce the risk of bias and increase the likelihood of comprehensive study identification and inclusion. The 2D matrix of interventions and outcomes will help identify and inform policy and funding agencies for further specific areas of research. Publication bias is a possible limitation as non-English and gray literature will be excluded, which may underrepresent the digital KT tools available and used across geographically diverse contexts.

Conclusions

This project will offer a novel knowledge synthesis tool (a digital EGM), mapping all of the digital KT tools currently available to promote the SRH of adolescents. The information will be available in a usable format to enable efficient and

effective use by multi-stakeholder audiences. This work is timely as innovative ways to deliver SRH information are more important than ever before due to the impact of digital media on accessing SRH information and services globally. In addition, key policies will be enacted to encourage and support research initiatives in underrepresented regions as this would promote a more comprehensive global understanding of SRH among adolescents. This review will report on the gaps identified in the research and quality assessment of included studies and recommendations will be set forth for future robust research studies. We will disseminate the findings of our study, via community symposiums, and public training sessions, and present at academic conferences and publish in open-access, peer-reviewed journals, advancing the body of knowledge on available digital KT tools to promote SRH and the rights of adolescents.

Acknowledgments

Thank you to stakeholders from Option for Sexual Health and Action Canada for Sexual Health for providing their expert feedback in preparing an evidence map matrix for this study. This study is funded through an Endowment Fund for the Future: Support for the Advancement of Scholarship (EFF-SAS) Research Fund (ZLD 23).

Authors' Contributions

SM and ZSL conceptualized this study, including leading the associated grant application and drafting this study's protocol. All authors contributed to the protocol and will be involved in conducting the proposed research. All authors provided final approval of this paper before submission and agree to be accountable for all aspects of this study as described here.

Conflicts of Interest

Abstract

Background: Protected areas are crucial for the maintenance of human health and well-being. They aim to preserve biodiversity and natural resources to secure various ecosystem services that are beneficial to human health. Their ecological characteristics can influence local health literacy. Typically, communities surrounding protected areas have limited economic opportunities due to restriction policies to protect the ecosystem, resulting in socioeconomic disparities. The local community faces obstacles in gaining access to health care facilities and health information due to these limitations. It is difficult for them to locate, comprehend, and apply information and services to make better health-related decisions for themselves and others.

Objective: This study protocol examines the impact of the ecosystem on health literacy among rural communities in protected areas.

Methods: This study comprises 5 phases. In phase 1, we conduct a systematic review to identify the issue of health literacy in protected areas. In phase 2, we will collect data from stakeholders in a protected area of Pahang National Park and analyze the results using Net-Map analysis. In phase 3, we will conduct a survey among the adult community in Pahang National Park related to health literacy, socioeconomic status, health expenditure, and quality of life. In phase 4, informed by the results of the survey, we will determine suitable intervention programs to improve health literacy through a focus group discussion. Finally, in phase 5, we will conduct a costing analysis to analyze which intervention program is the most cost-effective.

Results: This study was funded by Universiti Sains Islam Malaysia (USIM) and strategic research partnership grants, and enrollment is ongoing. The first results are expected to be submitted for publication in 2024.

Conclusions: This is one of the first studies to explore health literacy among rural communities in protected areas and will provide the first insights into the overall level of health literacy in the protected community, potential determinants, and a suitable intervention program with expected cost analysis. The results can be used to promote health literacy in other protected areas and populations.

Introduction

Good health and well-being can be achieved with adequate health literacy [1,2]. Adequate health literacy indicates that the individual can obtain, process, understand, and apply basic health information and services needed to make appropriate health decisions [3]. Higher levels of health literacy allow people to make better health decisions [4], be more committed, and do their jobs more efficiently [5]. Patients must have enough information about their health to leverage it and make well-informed decisions regarding getting health treatments and medicine. In the context of preventive health care, an adequate level of health literacy helps ensure that patients get the most out of their health investments and make the best use of resources [6]. According to the World Health Organization (WHO), people residing in rural areas often experience socioeconomic inequity and lower educational attainment due to imperfect living conditions. These areas are cut off from urban centers and have limited facilities [7,8]. The varying ecosystems within the population may influence different levels of health literacy.

People living in the protected areas often have limited health literacy [9]. The government designates protected areas for conservation purposes. Thus, less emphasis is placed on new land development for farming, housing, and infrastructure [10-12]. As a result, populations encounter challenges in gaining better access to networks, health facilities, the internet, and other resources. This limitation, in turn, adversely affects their quality of life [9]. The health outcomes, living conditions, and education levels of the population residing in rural areas lag significantly behind those living near urban centers. This disparity places people in rural areas at a disadvantage when it comes to making informed health decisions, as they have limited knowledge in this regard.

Accordingly, policy makers are putting in place and advocating for health programs and awareness campaigns to improve the health literacy status among populations in rural and protected areas [13]. However, this strategy is hard to implement in communities that live in protected areas as they have limited educational backgrounds. They struggle to access, obtain, understand, and apply health information in their daily lives. Moreover, they are often unable to access health information when they are sick. Indigenous people often turn to traditional remedies, consult shamans, or opt for inaction with the hopes that the illness will recover on its own [14]. The limited knowledge of hygiene among indigenous people has prompted the government to develop a specialized syllabus for indigenous children at primary school. This curriculum focuses on teaching essential practices, such as washing hands, proper toilet usage, and dental hygiene. Understanding the impact of protected areas on health literacy in local communities is crucial to sustaining their way of life and health. However, the level of health literacy and its response to protected areas varies, depending on factors such as the type of protected area, how policies are planned, and how they are implemented [15].

Research on health literacy among people who live in protected areas is important for understanding their needs for access to health care, disease prevention, health promotion, and health care. It will also help elucidate how to meet these needs in the best and most effective way. Nevertheless, thus far, there has been limited research on health literacy and health issues among people in protected areas considering 4 perspectives (ie, that of government entities, knowledge institutions, civil agencies, and local communities). Accordingly, this paper proposes a study that will examine health literacy and health status of communities in protected areas. The study protocol can serve as a model for similar investigations in protected areas in other countries.

Based on the available evidence, this study aims to (1) conduct a systematic review to understand the health literacy status among rural communities surrounding protected areas; (2) explore stakeholders' perceptions of health literacy status among rural communities surrounding protected areas; (3) determine the health literacy status and its associated factors among rural communities located near protected areas; (4) develop a new health literacy intervention program for rural communities near protected areas; and (5) conduct a cost structure analysis of the new health literacy intervention programs for rural communities surrounding protected areas.

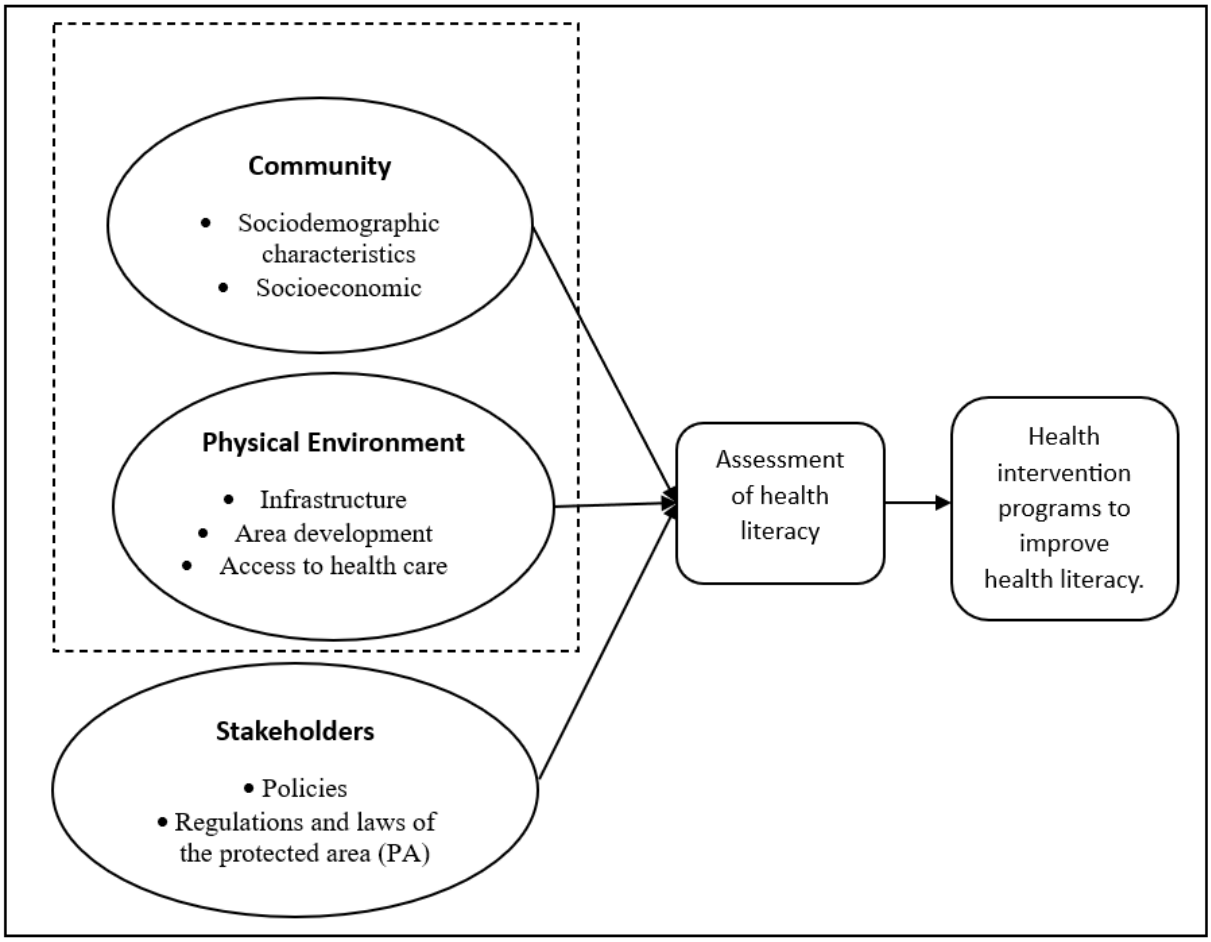
Methods

Background and Conceptual Model

This study adopts a mixed methods approach to investigate health literacy.

Our understanding of health literacy is underpinned by the four core dimensions of the Health Literacy Model [16]: (1) accessing, (2) understanding, (3) appraising, and (4) applying health information. Based on this model, this study will explore the impact of the ecosystem on health literacy among rural communities in protected areas. Figure 1 explains the conceptual model for this study.

Figure 1. Conceptual model of the study.



Study Site

This study comprises one of Malaysia's protected areas, Pahang National Park (PNP). There are 53 national and state parks in Malaysia, with PNP being among the country's most important and best-protected conservation areas. The region has diverse populations, including Malay and indigenous communities. As per the Jabatan Kemajuan Orang Asli (JAKOA; translated to Department of Orang Asli Development) [17], Pahang has the highest number of indigenous communities (37.9%) in Malaysia. Because the PNP site fulfills the criteria for this research (ie, the implementation of a protected area and the presence of legal or other formal mechanisms promoting such an area), we selected it as our study area.

Research Design

This study contains 5 phases consisting of identifying the health literacy issues in this area, confirming the issues, testing the issues, and preventing and analyzing the issues. The 5 phases will be carried out based on the 5 objectives.

Phase 1: Identifying Issues Through a Systematic Review

Overview

In phase 1, we will review the literature to understand the health literacy status among rural communities surrounding protected areas. This phase will involve conducting a systematic review following the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines.

Approach

The systematic review will use a standard search string using the PICO (Population, Intervention, Comparison, and Outcome) structure. For the keyword search, we will use PubMed, Scopus, and Web of Science databases. Later, 2 reviewers will be appointed to appraise all selected studies. The result will compile the highest quality studies relevant to the study objectives.

Eligibility

The selection of results will be based on the following eligibility criteria: (1) full articles written in English and (2) articles published between 2012 and 2022. The exclusion criteria include (1) gray literature and (2) articles outside the scope of our research. The screening process will consider the qualifying requirements established.

Quality Assessment

First, 2 reviewers will conduct a quality assessment using a set of study quality assessments checklist. The checklist consists of eight evaluation criteria: (1) research goals, (2) study design, (3) study outcomes, (4) sample size calculations, (5) analysis of findings, (6) variance estimates for the primary results, (7) adequate reported results, and (8) conclusions. A quality score is one way to incorporate quality into the review process [18]. The reviewers will assign 2 points to articles that meet all

criteria, 1 point if they fulfill some requirements, and 0 points if they do not. Subsequently, the quality score will be calculated by aggregating all elements from the quality assessment tool to provide an overall single score. In case of disagreements, a third reviewer will be appointed.

Data Coding and Analysis

This study employs a thematic synthesis, utilizing a 2-step coding procedure wherein reviewers will code each line of text from the articles separately for its meaning and substance. Before finishing this step, we will analyze every text associated with a particular code to ensure that the interpretation is consistent.

Phase 2: Exploring Stakeholders' Perceptions of Health Literacy Status in Rural Communities Surrounding Protected Areas

Overview

Phase 2 will use focus group discussions (FGDs) and in-depth interviews to achieve objective 2, which is to obtain stakeholders' opinions on health literacy issues among the community in PNP. The results will support the findings for objective 1.

Sample Selection

The selection of the stakeholders will be based on 3 categories, namely, government entities, knowledge-generating institutions, and civil society organizations [19,20]. However, the number of these actors will vary. This method will use purposive sampling to obtain a precise sample size. The expected actors can nominate any other actors with potential contributions to PNP's health literacy issue. This process will be halted when the answers given by the respondents are saturated [21].

Data Coding and Analysis

Data extraction and coding will be done for all Net-Map exercises, with a focus on thematic analysis utilizing information from the interviews. This analysis will mainly involve mapping activities and explaining the impact of protected areas on health literacy. The thematic analysis will follow a 2-step coding process. First, a line-by-line review of the interview data will be conducted to identify the key impacts related to the study objectives. Subsequently, each article will be assigned a code label to cluster all the information into a common theme.

Phase 3: Identifying Health Literacy and Its Associated Factors in Rural Communities Surrounding Protected Areas

Participants and Sampling

This study will focus on the PNP. It covers 2477 square kilometers and was the country's first national park established in Malaysia between 1938 and 1939, originally known as the King George V National Park. Following Malaysia's independence from British rule in 1957, the park was renamed. It is comprised of 3 protected areas in the states of Pahang, Kelantan, and Terengganu to form the central spine of Peninsular Malaysia. The national park has a reputation for being one of the world's oldest tropical rainforests, with an estimated age of 130 million years and a size of 4343 square kilometers.

Local communities in PNP are composed of Malay and Orang Asli (Batek and Semak Beri ethnicities). This location meets the criteria for this study because a protected area has been established and legal and other institutional measures have been established to promote them. The Pahang Department of Wildlife and National Parks (PERHILITAN) manages the PNP. The area is not open to the public except for those who have received prior approval from the authority for research purposes and minimal tourism activity at Kuala Tahan. Currently, the wildlife reserve contains a single research center that serves 2 distinct goals. The national park was originally established at Ulu Tembeling, with the first superintendent's office situated at Kuala Tahan. The southern section of PNP features a river boundary of over 80 kilometers along Sungai Tembeling, the Hulu Tembeling basin's principal river. Indigenous people inhabit the national park, while the Malay community resides near the river. For this study, respondents were drawn from the Malay and indigenous communities from the provinces of Hulu Tembeling and Tembeling Tengah. Table 1 shows the total number of respondents.

Respondents aged 18 years and above may vary in health status, including those with disabilities. A stratified random sampling approach (based on villages) will be employed for both the Hulu Tembeling and Tembeling Tengah provinces. All villages will be identified and visited. The choice of houses in the village will be selected randomly based on the number of houses given by the head of the village (Tok Empat and Tok Batin) and the inclusion criteria among the respondents, such as being able to read, having no cognitive disabilities, and being willing to participate in the survey.

Table 1. The total number of respondents and sample in Pahang National Park (PNP).

Name of village	Race	Province	Head of households (N=2525), n (%)	Sample (N=400), n (%)
Kg Pagi	Malay	Hulu Tembeling	95 (3.8)	15 (3.8)
Kg Kuala Sat	Malay	Hulu Tembeling	142 (5.6)	22 (5.6)
Kg Bantal	Malay	Hulu Tembeling	155 (6.1)	25 (6.1)
Kg Gusai	Malay	Hulu Tembeling	70 (2.8)	11 (2.8)
Kg Bukit Mat Daling	Malay	Hulu Tembeling	141 (5.6)	22 (5.6)
Kg Kuala Tahan	Malay	Tembeling Tengah	657 (26.0)	104 (26.0)
Kg Gol/Lik	Malay	Tembeling Tengah	40 (1.6)	6 (1.6)
Kg Merting/Lubok Payung	Malay	Tembeling Tengah	111 (4.4)	18 (4.4)
Kg Labu/Jong Berlabuh	Malay	Tembeling Tengah	163 (6.5)	26 (6.5)
Kg Pasir Sia/Air Hitam	Malay	Tembeling Tengah	86 (3.4)	14 (3.4)
Kg Selimbar/Chebong	Malay	Tembeling Tengah	58 (2.3)	9 (2.3)
Felda Sg Retang	Malay	Tembeling Tengah	509 (20.2)	81 (20.2)
Kuala Atok	Batek	Tembeling Tengah	35 (1.4)	6 (1.4)
Sungai Tiang	Semoq Beri	Tembeling Tengah	60 (2.4)	10 (2.4)
Sungai Tekal	Semoq Beri	Tembeling Tengah	83 (3.3)	13 (3.3)
Bukit Gam	Batek	Tembeling Tengah	22 (0.9)	3 (0.9)
Sg Keniam	Batek	Tembeling Tengah	35 (1.4)	6 (1.4)
Jeram Aur	Batek	Tembeling Tengah	13 (0.5)	2 (0.5)
Jeram Dedari	Batek	Tembeling Tengah	17 (0.7)	3 (0.7)
Sungai Yong	Batek	Tembeling Tengah	18 (0.7)	3 (0.7)
Sg Tabung/ Teresek	Batek	Tembeling Tengah	15 (0.6)	2 (0.6)

Sample Size

Two approaches will be considered to calculate the optimal sample size (ie, using the odds ratio [OR] and prevalence). The selection will be based on the method producing the higher sample size. For the OR, the sample size will be calculated using the OR of health literacy in Malaysia [22], identified as 3.41 with a 95% CI. We will use the Open Epi Software (version 3.01) to calculate the sample size. With an OR of 3.41, the estimated sample size is 310 as shown in Table 2. Furthermore, Table 3 shows the comparison of sample sizes for exposed and nonexposed groups in Kelsey and Fleiss methods.

In contrast, the second method uses prevalence. In Malaysia, the health literacy prevalence among individuals aged 18 years and above is 35.5% [23]. Using this percentage, the minimum sample size calculated for this study is 323 people for a 95% CI. Since the prevalence sample size is higher than the OR, we decided to use it as our sample size. Considering a dropout probability of approximately 10%, the total sample size needed for this study is about 355 people. However, we will distribute a sample size of 400 people based on the ratio calculated. We estimate that out of 400 adults, approximately 200 households will need to be interviewed based on the assumption that 1 household has 2 adults. To ensure that the provinces within the national park are well represented, the percentage of the selected population is determined to be 24%, 64%, and 12% for Malay in Hulu Tembeling, Tembeling Tengah, and indigenous people, respectively. Using the stratified random sampling techniques, the number of samples allocated for each village is outlined in Table 1.

Table 2. The estimated sample size.

Variables	Values, n
Sample size, n	310
Two-sided significance level (1-alpha)	95
Power (1-beta, % chance of detecting)	80
Ratio of sample size, unexposed/exposed	1
Percent of unexposed with outcome	5
Percent of exposed with outcome	15
Odds ratio	3.4
Risk/prevalence ratio	3
Risk/Prevalence difference	10

Table 3. Comparison of sample sizes for exposed and nonexposed groups in Kelsey and Fleiss methods.

Variables	Kelsey (n=274), n (%)	Fleiss (n=272), n (%)	Fleiss with CC[a] (n=310), n (%)
Sample size, exposed	137 (50)	136 (50)	155 (50)
Sample size, nonexposed	137 (50)	136 (50)	155 (50)

[a]CC: continuity correction.

Inclusion and Exclusion Criteria

Participants in this study are required to be adults aged 18 or above and will be recruited after providing consent. Age verification will be based on their ID cards. Potential respondents may either be healthy or have various physical disabilities and demonstrate a willingness to participate. Additionally, they must be able to communicate in the Malay language. However, people with cognitive impairments will be excluded from the study.

Tools and Instruments

This study will comprise 3 evaluations: health literacy, health, and socioeconomic status. There are 8 parts to the questionnaire, which are outlined in Table 4.

Table 4. Components of the questionnaire.

Component	Description
Part 1: Housing and the environment (head of household only)	Part 1 will capture family structure, household transportation, and water supply.
Part 2: Household income (head of household only)	Part 2 will record the household's annual income from all sources.
Part 3: Sociodemographic characteristics (all household members, including the head of household)	Part 3 will capture sociodemographic information such as date of birth, ethnicity, education, employment status, relationship status, and so on.
Part 4: Health care expenditure and utilization (all household members, including the head of household)	Part 4 questions will capture data on health payments, health care service utilization, traditional and complementary medicine practice, and health care expenditure.
Part 5: Modifiable lifestyle factors (all household members, including the head of household)	Part 5 will ask about tobacco consumption, nutrition, physical activity, and medical conditions.
Part 6: Medical information (all household members, including the head of household)	Part 6 will measure the height, weight, waist circumference, and hip circumference. The calibrated vertical SECA portable 217 stadiometer (SECA GmBH & Co KG) will be used to measure respondents' height, the calibrated SECA 813 digital electronic weighing scale will measure weight, and the SECA 201 ergonomic measuring tape will measure waist (abdominal) and hip circumferences.
Part 7: Quality of life (all household members, including the head of household)	Questions in part 7 will assess the participant's quality of life using standard and generic methods.
Part 8: Health literacy status	Health literacy status will be determined using the HLS-SF-Q12[a] [24]. The perceived difficulty of each health-related task is rated on a 4-point Likert scale (1=*very difficult*, 2=*difficult*, 3=*easy*, and 4=*very easy*), with a possible lowest mean score of 1 and a possible highest mean score of 4. The questions consider the 4 competencies of an individual when dealing with health-relevant information (access/obtain, understand, appraise/judge/evaluate, and apply/use health information) to form a judgment and make health-related decisions for the 3 domains of health care, disease prevention, and health promotion.

[a]HLS-SF-Q12: 12-item Short-Form Health Literacy Questionnaire.

Reliability, Validity, and Trustworthiness

Reliability indicates whether the results can be consistently reproduced or not. In this study, internal consistency is evaluated through the Cronbach α value, with a threshold set at greater than or equal to .70 for satisfactory reliability. At the same time, validity will measure the validity and accuracy of the questionnaire. Face and content validity will be used to measure the validity of the questionnaire. Notably, this study incorporates established questionnaires with preestablished reliability and validity from different sources [22,25].

Data Collection Procedure

A total of 8 interviewers will be required to conduct the survey, working in pairs. For security and dialect reasons, a local representative will be appointed to accompany each team. Before the data collection, the ground staff will introduce the interviewers to the household members to ensure that the head of the household and other members are present and grant permission for the interviewers to enter their personal premises. Once approval is obtained, the interviewer will explain the nature of the study based on the participants' information sheet, which outlines the key details. Subsequently, the information sheet will be provided to the participants for their reference. In addition, the interviewers will reassure the participants that the information provided in the study will remain confidential and their participation is entirely voluntary. The face-to-face interview will begin shortly after the head of the household and other household members have signed the consent form. During the interview, the respondents' height and weight will be measured, contingent on suitability and participant preference. If the head of the household is absent during the visit, the house will be marked on the map, and a second visit will be arranged for the next day. However, the house will be excluded if the head of the household is still not present during the second visit.

Data Analysis Procedure

The data analysis procedure will involve both descriptive and analytical analyses. Initially, a descriptive analysis will focus on the sociodemographic characteristics of the study population. We will examine the distribution of study variables by calculating frequency and percentage, along with reporting mean and SD. Since the outcome of interest is categorical, nonparametric tests will be used. Following the approach outlined in [26], responses categorized as inadequate and problematic will be grouped as inadequate (0), while those categorized as sufficient and excellent will be classified as adequate (1) during the analysis.

For the analytical analysis, we will carry out both bivariate and multivariate analyses to explore the determinants of health literacy among both the study population residing whining the

PNP and the population living outside the PNP. This comparative approach will aim to determine which ecosystem has adequate health literacy. The significance level has been set to $P<.05$. The analytical analysis will be conducted using SPSS software (version 28.0, IBM Corp).

Phase 4: Developing a New Health Literacy Intervention Program for Rural Communities in the Protected Area

Overview

Phase 4 will be conducted via FGD discussion among the stakeholders.

Data Collection Procedure

The data collection process will be based on the opinions of the stakeholders and field experts. We will invite them to the seminar and sharing session to discuss the sustainability of the community near PNP. An invitation letter will be sent to the stakeholders and experts to confirm their willingness to participate in the discussion. They will include representatives from the Ministry of Health, JAKOA, Department of Wildlife and National Parks, heads of villages (Tok Empat and Tok Batin), nongovernmental agencies (NGOs), and academicians who are Taman Negara community health experts. During the seminar and sharing session, they will discuss mitigation measures that are suitable and effective in enhancing the health literacy status of the rural community.

Eligibility

The eligibility criteria for the intervention programs will be based on several factors, including the capacity of these programs, the financial support they received, their geographical location, prior experience in conducting health literacy programs, and willingness to participate. To account for differences in intervention activities, epidemiology, and target populations, we will limit our selection to only interventions that target communities located within the protected areas.

Data Analysis Procedure

During the discussion session, stakeholders will provide information regarding suitable intervention programs to improve health literacy at PNP using Logical Framework Analysis (LFA). The core components of LFA are outlined in Table 5.

Table 5. The core components of Logical Framework Analysis (LFA).

Component	Description
General objectives (goal)	This is the project's overarching goal. The project's benefits are laid forth in the objective goal for the beneficiaries.
Project purpose	The target group's plan of action to effect the desired change is expressed in the purpose. The project purpose frequently refers to modifying the target group's behavior because they use the services or goods the project offers.
Output	The project offers the products, services, and goods to the intended audience. The project is accountable for these outputs.
Activities	The project's processes for delivering the various goods, services, and products are outlined.

Phase 5: Conducting a Cost Structure Analysis of the New Health Literacy Intervention Programs for Rural Communities Surrounding the Protected Area

Overview

Phase 5 is a continuation of Phase 4. We will conduct a cost analysis for every intervention program listed in Phase 4.

Data Collection Procedure

The cost structure will be prepared based on advice from experienced agencies or individuals in the field. A list of intervention activities will be presented as an alternative to the policy makers or any agencies who are interested in improving health literacy among the PNP community.

Economic data on providers' costs will be collected for the financial year 2021 to 2022. The data obtained will contain information on the costs incurred at the intervention and funding agency levels. When valuing economic costs, the opportunity cost of each resource will be considered, encompassing all resources used in the intervention, including those that are donated or subsidized. This approach ensures a uniform method of data collection, enabling reliable cost comparisons among the various interventions.

Data Analysis Procedure

The cost analysis will analyze expenses based on the cost unit, source data, and frequency, with comparisons made across the intervention programs. The cost unit pertains to the expenses associated with each intervention per patient per year. Simultaneously, the sources of data serve as evidence for the interventions, and frequency refers to the number of interventions required annually.

Data Management and Analysis

Data Security

At the end of each day of data collection, the project manager will gather all interviewers and conduct a postmortem session. Any loopholes identified during the process will be addressed immediately to avoid further mistakes and invalidate the collected data. In addition, the project manager will verify if the number of answer booklets corresponds with the number of households surveyed. Upon verification, the answer booklets will be placed in a safe box, while the consent form will be kept in a separate secure box to avoid any information breach. Only the project manager and the principal investigator have access to these secured boxes. Similarly, all recorded videos and voices from FGD and interviews will be safely placed in a Dropbox (Evenflow Inc) for analysis.

Data Entry and Analysis

Data entry from the survey form will be completed within 2 to 4 weeks after completing the groundwork, depending on the number of respondents. Once all data have been entered into SPSS software, we will perform a random cross-checking of the data set to maintain data accuracy. The cross-checking will be set at 20% of the overall questionnaires entered [25]. Data analysis will comprise both descriptive and analytical analyses. Descriptive analysis will be performed on the population's sociodemographic characteristics, BMI measurements, expenditure, utilization of health care goods and services, modifiable lifestyle factors, and reported quality of life. The analytical examination will be conducted to determine the association between sociodemographic characteristics, health status, and socioeconomic status with health literacy status. The results will be analyzed using SPSS software. The data and results will be presented to and validated by field experts and stakeholders of PNP in the form of reports and seminar-sharing sessions.

Ethical Considerations

Ethics approval for this study was granted by the Universiti Sains Islam Malaysia (USIM) Research Ethics Committee (USIM/JKEP/2022-216). Each respondent will sign a written informed consent form before the interview. Academic journals, conferences, and stakeholder seminars will be used to communicate the findings of this research. The protocol received approval from the International Standard Randomized Controlled Trial Number Registry (ISRCTN; 40626062).

Results

The project was funded by USIMl and strategic research partnership grants. Enrollment for the overall project is ongoing. We are conducting a systematic review of health literacy in protected areas and conducting a cross-sectional study based on the survey results to determine the determinants of health literacy in protected areas. Findings from this study will be used to develop a sustainable health intervention module with an effective cost that may be adopted in all protected areas in Malaysia. The first results are expected to be submitted for publication in 2024.

Discussion

Anticipated Findings

The conservation policy of the protected areas has limited opportunities for local communities to harvest natural resources from the ecosystem. Their quality of life has been affected due to inferior education, health, and living conditions compared to communities living in urban areas. This disparity has resulted in challenges for the community in accessing health facilities and infrastructure, thereby limiting their health literacy level. Their remote location and distance from main roads have contributed to this low health literacy. To our knowledge, few studies have been conducted on health literacy and health issues among individuals in protected areas from 4 perspectives: government entities, knowledge institutions, civil agencies, and local communities. Accordingly, this paper proposes a study to investigate the health literacy and health status of communities within and near PNP. In accordance with the recommendations made by the PNP shareholders, this study aims to develop a health intervention program that is efficient and appropriate for community implementation. Health literacy research among people living in protected areas is essential for a deeper understanding of their needs for access to health care, illness prevention, health promotion, and health care. This understanding will guide the development of effective strategies to meet these requirements.

Strengths and Limitations

This study’s strength lies in its mixed methods analysis, employing a triangulation process to converge and validate both qualitative and quantitative data [27]. Moreover, this study will be conducted in multiple phases to discuss the issue comprehensively. This structured approach facilitates incremental progress [28]. Phases 1 and 2 are conceptual phases where the issue is identified and validated through a systematic review by stakeholders in PNP, such as government agencies, knowledge institutions, and civil society organizations. Phase 3 will design and plan the questionnaire and examine the health literacy status and its influencing factors among the community. The stakeholders in the FGD in phase 4 will validate the results of phases 1 to 3. Using these results, the stakeholders will discuss and design an effective health literacy intervention program. Finally, phase 5 will involve the dissemination of the health literacy intervention program to improve the health literacy status in the community. Moreover, a cost analysis will be calculated to analyze the cost of the program.

The study’s limitations became apparent during the FGD session with the stakeholders, as the invited participants did not attend. Consequently, we missed capturing unique macro-level perspectives. Another limitation is that the stakeholders’ views may not be representative of all who live inside or near the protected area in Malaysia or globally. Additionally, the study did not address the distinctions between locals and outsiders. Access to rural areas is difficult logistically, and the potential presence of wildlife, such as tigers, elephants, and bears, further complicates the research process.

Conclusions

In conclusion, this study will determine how different ecosystems, especially in protected areas, impact the health literacy of the local community using a mixed methods approach. The phases of the data collection process, incorporating both qualitative and quantitative methods, aim to comprehensively address the issue of health literacy in the local community. We will use these findings to disseminate a health intervention program, along with a cost structure, to improve health literacy among the protected area's community. The mixed methods study serves as a structured investigative model for evaluating and improving health literacy, health status, and well-being among all protected areas and communities worldwide.

Acknowledgments

This research is funded by an institutional grant from the Universiti Sains Islam Malaysia (USIM; PPI/FPSK/0122/USIM/13722), as well as a strategic research partnership grant USIM/MG/UiTM/FPSK/SEPADAN-K/73622).

We are highly grateful to students of Universiti Teknologi MARA (UiTM) Cawangan Pahang Kampus Raub for their commitment to being part of this project for the data collection, the Jabatan Kemajuan Orang Asli (JAKOA) Jerantut for serving as a mediator between the researchers and the indigenous people, and the communities of the Pahang National Park (PNP).

Data Availability

The data sets generated in this study are available from the corresponding author upon reasonable request.

Authors' Contributions

The conceptualization of the project was led by AA, MHJ, and MIMN. The data collection was led by NAAK, and the development of the questionnaire was a collaborative effort involving NAAK, AA, MHJ, and MIMN. Supervision was provided by AA, MHJ, MIMN, and ZK. NAAK wrote the original draft, which was then reviewed by AA and MIMN.

Conflicts of Interest

None declared.

Abstract

Background: In the United States, autistic people face high rates of co-occurring mental illnesses and premature death due to self-harm, which are indicators of threats to mental well-being. Social inclusion may enhance mental well-being and resilience among autistic people. According to Simplican and colleague's (2015) model of social inclusion for people with intellectual and developmental disabilities, social inclusion is an interaction between community participation and interpersonal relationships. There is limited research on social inclusion that includes the integration of interpersonal relationships and community participation among autistic people or the impact of social inclusion on the well-being of autistic people. Additionally, little evidence exists regarding how autistic people prefer to be included in the community or form interpersonal relationships.

Objective: The long-term objective of this project is to improve social inclusion factors to support the mental well-being of autistic people. This protocol describes a community-based, mixed methods pilot study to develop a definition of meaningful social inclusion for autistic people and to understand the relationship between meaningful social inclusion and mental well-being among autistic adolescents and emerging adults.

Methods: The project uses a community-based, sequential mixed methods design with a formative phase (Phase 1) that informs a survey phase (Phase 2) and concludes with a process evaluation of the community engagement process (Phase 3). During Phase 1, we will recruit 10 community partners (autistic adults and stakeholders) and conduct sharing sessions to cocreate a definition of meaningful social inclusion and a survey of meaningful social inclusion and well-being. During Phase 2, we will recruit 200 participants (100 autistic adolescents and emerging adults and 100 caregivers) to complete the survey. We will examine whether meaningful social inclusion predicts well-being given sociodemographic factors using ordered logistic regression, with well-being categorized as low, medium, and high. During Phase 3, the community partners from Phase 1 will complete a survey on their experiences with the project.

Results: Ethics approval was obtained for this project in March 2023. We have recruited community partners and started the Phase 1 focus groups as of September 2023. Phase 2 and Phase 3 have not yet started. We expect to complete this study by March 2025.

Conclusions: Using a community-based, mixed methods approach, we intended to develop a definition of meaningful social inclusion for autistic people and understand the role meaningful social inclusion plays in the well-being of autistic people.

Introduction

Overview

Mental well-being is a holistic conceptualization of mental health characterized by a lack of symptoms of mental conditions and the presence of positive feelings [1]. Compared to nonautistic people, autistic people often experience poor mental well-being [2], reduced quality of life [3], higher rates of suicidality and premature death due to suicide [4-6], and greater rates of mental health conditions [7-9]. Worldwide, across decades, and across age groups, autistic people have a twofold increase in mental health issues compared to people without autism. For example, rates of mental health issues among the general population in the United States hit an all-time high during the COVID-19 pandemic, with an estimated 40% reporting mental health challenges [10], while rates of co-occurring mental health issues among autistic adolescents and emerging adults during a "typical" time period are as high as 82% [11]. The total size of the autistic population is unknown due to women, gender-diverse people, and people of color being historically underdiagnosed and adult-diagnosed autistic people not being captured in prevalence rates. Even so, current estimates suggest that 1 in 44 children in the United States are diagnosed with autism [12]. The impact of poor mental well-being among autistic people impacts a substantial proportion of the US youth population. The burden of poor mental well-being in the autistic community increases with age [13,14] and shortens life expectancy [5].

A complex interplay of internal and external factors may explain disparities in mental well-being between autistic people and nonautistic people. While endogenous factors such as genetics and neurology play a role, systemic, compounding stressors exogenous to the autistic person can also influence mental well-being. These modifiable, external factors include experiences such as being bullied, masking, and feeling accepted. Autistic people experience higher rates of bullying compared to nonautistic people, and these experiences are linked to a greater risk of mental health issues [15]. Masking (also known as camouflaging) describes the efforts of autistic people to hide autistic traits and avoid negative experiences such as bullying. Similar to bullying, masking is also associated with poorer mental well-being [16-19]. Conversely, when autistic people feel accepted, they report better mental well-being. Higher levels of acceptance by nonautistic people are associated with lower levels of mental distress [20]. Contrary to stereotypes of autistic people, research confirms that interpersonal relationships are important to the autistic well-being [20], and higher levels of community participation are associated with better mental well-being [21,22].

However, current research suggests that autistic people face individual-level social inclusion barriers [20,23] and are less likely to participate in the community [24] or form interpersonal relationships [25] compared to nonautistic people. Additionally, this literature primarily focuses on how autistic people should change to adapt to communities and other people, rather than on how communities and other people could adapt to include autistic people [26]. Because they do not center on the experiences of autistic people, many of these studies focus on independence rather than autonomy and conformity to neurotypical standards as criteria for social inclusion and enforced normalization. Given the historic emphasis on children [7], it is imperative to focus on the mental well-being of autistic adolescents and emerging adults. Social inclusion may hold the key to implementing sweeping changes to improve mental well-being for autistic adolescents and emerging adults [23,27], particularly as identification with social groups is associated with higher levels of mental well-being among autistic people [1]. Social inclusion and mental well-being are research priorities for the autistic community [28], as is shifting the focus from "fixing" the individual to addressing systemic issues external to the autistic person [29].

To the best of our knowledge, no study has integrated both aspects of social inclusion, included the voices of autistic people, and focused on mental well-being. These 2 relationship contexts (interpersonal relationships and community participation) are instrumental in promoting adaptive mental and physical health among autistic people. Interpersonal relationships are important to the well-being of autistic people [20], and higher levels of community participation are associated with better mental well-being [21,22]. This project fills a critical need to develop an understanding of meaningful social inclusion that includes both interpersonal relationships and community participation for autistic people and use this to understand the impact of social inclusion on mental well-being. Without an understanding of how social inclusion factors shape mental well-being, we cannot identify and implement effective and efficient community-level change to improve the well-being and quality of life of autistic people. In the absence of this knowledge, rates of co-occurring mental health conditions, the resulting diminished quality of life, and premature deaths will remain high. Filling this gap with this study is critical, as this information is necessary for policy and planning to improve mental health parity among autistic people.

Conceptual Framework

There is no agreed-upon conceptual framework for social inclusion. However, the ecological model of social inclusion for people with intellectual and developmental disabilities by Simplican and colleagues [30] provides a road map for understanding, measuring, and modifying social inclusion. According to this model, social inclusion is defined as the interaction of interpersonal relationships (family, staff, friends, acquaintances, and partners) and community participation (leisure activities, political and civic activities, employment and education, access to goods and services, and religious and cultural activities).

Study Aims

The long-term objective of this project is to improve social inclusion factors to support the mental well-being of people with autism. Our goal is to address the problem of high rates of poor mental well-being by understanding how social inclusion is associated with this phenomenon. We focus on adolescence and emerging adulthood because this is a key developmental period for autistic people and a challenging time for mental well-being [31,32]. We will meet our goal through two specific

aims: Aim 1: develop a working definition of meaningful social inclusion for autistic people living in the community that is cocreated with the autistic community; and Aim 2: delineate variation in mental well-being by social inclusion (interpersonal relationships and community participation) among autistic adolescents and emerging adults. Our hypothesis is that higher levels of social inclusion will be associated with higher rates of mental well-being.

Methods

All protocols and materials will follow the Academic Autism Spectrum Partnership in Research and Education practice-based guidelines for research coproduced with autistic people [33].

Study Design

Overview

The project uses a community-based, sequential mixed methods design with a primary formative phase that will inform a subsequent secondary survey phase [34] and a tertiary phase that consists of a process evaluation of the community engagement process. This design has been used successfully to capture community member experiences and influence policy changes [35]. In Phase 1, we will conduct sharing sessions with members of the autistic community to cocreate (1) a working definition of meaningful social inclusion and (2) an adaptation of a survey of social inclusion and well-being. In Phase 2, we will deploy the cocreated survey in the autistic community to gather data on their level of social inclusion and mental well-being. In Phase 3, we will evaluate the research processes. Findings from each phase will be integrated using triangulation with the autistic community. We will consider where findings from each part agree (convergence), result in complementary information (complementarity), or disagree (discrepancy).

Phase 1: Formative Research

Sharing sessions will be held virtually through Zoom (Zoom Video Communications), recorded, and transcribed for analysis. Sharing sessions will be facilitated through a series of open-ended questions developed to capture the lived experiences of meaningful social inclusion of autistic community members. Community members participating in the sharing sessions will be provided with informed consent, a 1-page description of the study, the open-ended questions, the draft survey, and the background of the research team. Multiple meetings will be scheduled to (1) develop an understanding of meaningful social inclusion, (2) select and refine survey items, (3) review analysis results, and (4) determine the best ways to disseminate the results that align with the community's agenda. Over the course of the project, the timing, number, and format of the meetings will be negotiated with community partners [36].

Phase 2: Adapted Survey of Social Inclusion and Mental Well-Being

This aspect of the project follows a cross-sectional survey design in which data are captured at a single point in time. Autistic adults living in the community will report on social inclusion and mental well-being using adaptations of existing survey instruments created with community members during the sharing sessions. Data will be gathered through an anonymous web-based questionnaire hosted through the Qualtrics (Silver Lake) platform.

Phase 3: Process Evaluation

Satisfaction with community engagement will be measured by asking community partners at the end of the study to report on their experiences with the community engagement process.

Measures

Overview

Our main variables of interest are meaningful social inclusion and mental well-being. We will measure the identity of autistic people and address potentially confounding variables through sociodemographic variables associated with social inclusion and mental well-being. Whenever possible, short-form versions of instruments will be used to reduce the burden on participants. Items will also be adapted for completion by caregivers reporting on autistic adolescents and emerging adults in their care. Caregivers will be asked if the autistic adolescents and emerging adults in their care also completed the survey to create a subgroup of caregivers providing proxy responses and caregivers providing additional responses.

Identity of Autistic People

The identity of autistic people will be measured using current guidelines for establishing rigor to generalize to autistic people [37], through self-identification, age at diagnosis, diagnosis status (self vs community), and the Ritvo Autism Asperger Diagnostic Scale-14 [38]. This measure will be used for autistic people who will complete the survey. Caregivers will be asked if they care for an autistic adolescent or emerging adult, whether the autistic adolescent or emerging adult was professionally diagnosed, the current age of the person they provide care for, and the age the person was diagnosed.

Social Inclusion

Social inclusion will be assessed using adaptations of the Temple University Community Participation (TUCP) measure [39] for community participation and the Friendship Questionnaire (FQ) for interpersonal relationships [40]. The TUCP contains 26 items that measure independent and self-directed community participation over the last 30 days in the following domains: community activities, employment, education, and volunteering. The TUCP asks (1) for the number of days in the past 30 days that the person engaged in a community activity (0-30); (2) if the activity is important to the person (1=yes or 0=no); and (3) if the activity was done enough, not enough, or too much (−1=not enough, 0=enough, or 1=too much). Although initially created for use with people with complex and chronic mental health conditions, the TUCP has been used to assess community participation among autistic adults [24,41,42].

The FQ contains 35 items that measure multiple aspects of interpersonal relationships, such as having best friends ("I have one or two particular best friends") and the characteristics of friends ("In terms of interests, how similar to your friends do you tend to be?"). The FQ was designed for use with nonautistic and autistic adults [40].

Mental Well-Being

Mental well-being will be captured through the Warwick-Edinburgh Mental Well-being Scale (WEMWBS) [43] and the Depression Anxiety Stress Scales-21 (DASS-21) [44]. The WEMWBS is a 14-item questionnaire measuring positive mental well-being through positive emotions, positive mental health, and psychological functioning. Each item is a positively worded statement (eg, "I've been feeling good about myself") with a 5-point Likert-type scale (1=none of the time to 5=all the time) indicating how often the statement applied to the person over the past 2 weeks. An overall score is calculated by totaling the scores for each item. Higher scores indicate higher levels of mental well-being. The WEMWBS has good content and construct validity, face validity, cross-cultural validity, test-retest reliability (intraclass correlation =.83), and internal consistency, with Cronbach α ranging from 0.89 to 0.93 [43,45]. The WEMWBS has been extensively used to measure mental well-being among autistic adults [1,46]. The DASS-21 contains 3 self-report scales measuring depression, anxiety, and stress. The DASS-21 has been found to function well as a measure of psychological distress among autistic people [47].

Sociodemographic Variables

Sociodemographic variables will include age, gender, race and ethnicity, rurality, income, education, employment status, co-occurring conditions, level of support need, and social functioning using the Social Functioning Questionnaire [48]. Gender, education, race and ethnicity, and co-occurring conditions are items derived from the National Survey on Health and Disability. Gender will include options for gender-diverse people. Employment status is based on items used in the 2021 Behavioral Risk Factor Surveillance System. Participants will be asked to estimate their household income and will be presented with multiple-choice income options. The level of support needed will be determined using items representing assistance needed for activities of daily living and instrumental activities of daily living.

Rurality will be identified using the self-reported residence zip code of the participant's permanent residence and categorized based on Rural-Urban Commuter Area (RUCA) codes. RUCA codes classify US census tracts on a continuum of rural to urban categories using patterns of daily commuting, population density, and measures of urbanization. Whether a participant originated from a rural community will be determined based on residence in a zip code associated with large rural, small rural, or isolated RUCA codes.

Satisfaction With Community Engagement

Satisfaction with community engagement will be measured by asking community partners who participated in the sharing sessions to complete a Community Engagement Questionnaire [36] describing their experiences with the project: (1) What has been your experience with participating in this research study? (2) How satisfied were you with your contribution to this research study? (3) How could your experience be improved? and (4) Is there anything else you would like to add?

Study Participants and Recruitment

Participants will be recruited on the web through groups such as the Autism Foundation of Oklahoma, Autistic Adults of Oklahoma, AutismStillwater's website, AutismOKC's website, tribal organizations, and state department health services caseworkers. Our community partners will leverage their community contacts in each of these groups for the recruitment of participants for the study.

The intended participants for Phase 1 are autistic adults and caregivers of autistic young people. The participants will be older than 18 years and reside in Oklahoma. For Phase 2, the intended participants are (1) autistic adolescents (aged between 10 and 18 years) and emerging adults (aged between 19 and 25 years) residing in Oklahoma, fluent in English, who have a community diagnosis of autism or meet the Ritvo Autism Asperger Diagnostic Scale-14 cutoff for autism and (2) caregivers of autistic adolescents and emerging adults. Phase 3 participants are the same participants from Phase 1. Exclusion criteria include communication impairment and an inability to consent.

For Phase 1 and Phase 3, we will recruit up to 10 autistic community partners to participate in the sharing sessions, and each partner will be paid US $400 for their participation. For Phase 2, we will recruit 100 autistic adolescents and emerging adults living in the community and 100 caregivers to complete the adapted survey. The most recent electronic survey deployed by the Autism Foundation of Oklahoma resulted in 270 respondents. Based on this, we believe 200 respondents is feasible. We will not incentivize the survey. Recent web-based surveys deployed by the research team that were incentivized (ie, had a gift card raffle) resulted in a high number of bots and scammers completing the survey for monetary gain. This, combined with the relatively high number of participants the Autism Foundation of Oklahoma had on their surveys who were not incentivized, led the research team to drop the use of incentives.

Data Analysis

Phase 1: Formative Research and Phase 3: Process Evaluation

The data from the sharing sessions and community engagement questionnaire will be analyzed and interpreted using iterative inductive and deductive thematic analyses. Data will be developed through verbatim transcription of audio recordings, analyzed using Dedoose (SocioCultural Research Consultants), and transformed into concept maps. The transcripts and texts will be reviewed several times and coded based on themes to reduce and display the data and draw conclusions. This process involves (1) familiarizing the research team with the data, (2) coding the data, (3) using the codes to develop initial themes, (4) reviewing the themes as a team, (5) defining the themes, and (6) writing up the results. Inductive codes will be based on emerging codes from the data, and deductive codes will be based on the literature and the open-ended sharing session and process evaluation questions. The credibility of the outcomes will be verified with community members to help ensure we capture the experiences of the community members.

Phase 2: An Adapted Survey of Social Inclusion and Mental Well-Being

We will examine whether meaningful social inclusion predicts well-being given sociodemographic factors using ordered logistic regression, with well-being categorized as low, medium, and high [49]. Models will be adjusted using participant characteristics to hold influences outside of social inclusion constant.

Power Analysis

Qualitative data will be collected until saturation is reached. For quantitative analysis, logistic regression is a nonlinear model, and thus, probability at the mean and 1 SD above the mean is necessary for the power analysis. These values are not available in the literature. We will develop these probabilities through this pilot study for use in a larger study. However, in general, a sample size over 100 with cell counts over 10 is necessary for logistic regression.

Ethical Considerations

Ethics approval for Phase 1 was obtained for this project in March 2023 from the Institutional Review Board of Oklahoma State University (IRB-23-46). Phase 2 and Phase 3 of this protocol will be reviewed and approved, and electronic informed consent or assent, where appropriate, will be attained before beginning any aspect of the study.

Results

The study was funded by Oklahoma Center for the Advancement of Science and Technology in January 2023. Ethics approval was obtained for this project in March 2023. We have developed Phase 1 materials, recruited community partners, developed a draft of the survey, and started the Phase 1 focus groups as of September 2023. Phase 2 and Phase 3 have not started yet. We expect to complete this study by March 2025.

Discussion

Expected Outcomes and Potential Impact

The expected outcomes of this protocol include a definition of meaningful social inclusion for autistic people and an enhanced understanding of the role meaningful social inclusion plays in the well-being of autistic people. The research findings may generate new knowledge on meaningful social inclusion that addresses community-level needs and limited social inclusion among autistic adolescents and emerging adults. This project could advance our understanding of how to improve social inclusion, reduce poor mental well-being among autistic adolescents and emerging adults, and advance our scientific understanding of facilitating social inclusion and integration of autistic people in communities.

Results will be integrated into the Autism Foundation of Oklahoma's training and awareness programs on, for example, employment, education, and criminal justice. The results will also be used to develop new training and awareness programs focused on social inclusion. The proposed study will provide preliminary data for developing interventions for testing (eg, modifying the Autism Foundation of Oklahoma's current training program for employers to hire autistic people) and lay the groundwork for larger studies on enhancing quality of life and social inclusion factors such as interpersonal relationships and community participation for autistic adolescents and emerging adults.

Potential Difficulties and Limitations

We assume that social inclusion is associated with better mental well-being. However, it could be that better mental well-being is associated with higher levels of social inclusion; that is, better mental well-being leads to more social inclusion. This is an issue of endogeneity—when the outcome variable is a predictor and not simply a response (simultaneity bias). We can test for this relationship using the Hausman test for endogeneity, and we also included variables that can be used as statistical instruments should we need to use an instrumental variable analysis to control for endogeneity.

Strength of the Study

Most research on social inclusion and autistic people focuses on exclusion rather than inclusion. This research is typically conducted on autistic children in primary school settings and often excludes the lived experiences of autistic people. This can result in outcomes and recommendations that do not align with the experiences and goals of the autistic community. As such, several strengths of this study lie in our focus on social inclusion rather than exclusion, our centering of the experiences of autistic adolescents and emerging adults, and our use of a community-based mixed methods approach to engage the autistic community. By focusing on the lived experiences of autistic people, we increase the likelihood that the outcomes of this project will have a meaningful impact on the well-being of autistic people.

Acknowledgments

This research project was funded by the Oklahoma Center for the Advancement of Science and Technology (HR23-062) awarded to DJM and MC. The content of this manuscript is solely the responsibility of the authors. Oklahoma Center for the Advancement of Science and Technology does not review or require approval of manuscripts for publication.

Authors' Contributions

DJM and MC designed the study protocol and wrote the manuscript. DN provided content experience. EP and DJM developed the community member engagement materials. DJM, EP, AM, and CL are leading community member engagement and focus

groups. All authors are developing the survey. CL programed the draft survey. All authors provided input for the study protocol, reviewed the manuscript, and will participate in implementing the study protocol.

Conflicts of Interest

None declared.

Abstract

Background: The Bacillus Calmette-Guérin vaccine (BCG) against tuberculosis (TB) shows beneficial nonspecific effects, which are likely related to innate immune training. Until 2016, a single BCG dose was administered to all newborns in Portugal. In July 2016, a clinical guideline established that only children under 6 years belonging to high-risk groups should receive BCG. This might have prevented nonvaccinated children from developing trained immunological responses as effectively as BCG-vaccinated children.

Objective: This study aims to investigate if there is variation in TB-related and all-cause mortality, and severe, moderate, or mild morbidity in children under 5 years of age, and whether such variation might be explained by the BCG vaccination policy change in 2016.

Methods: This population-based historical birth cohort study includes children under 5 years of age born in Portugal between July 1, 2010, and June 30, 2021. Newborns with low birth weight, premature status, or known or suspected HIV infection are excluded. The follow-up period is until the completion of 5 years of age or the end of follow-up (June 30, 2021). The study will use secondary data from the National Health Service user registry, death certificate database, vaccination registry, communicable diseases surveillance system, TB surveillance system, diagnosis-related group information system for hospital admissions and emergency department visits, and primary health care information system. The data will be linked. Primary outcomes include person-time incidence rates of death (all causes and TB), TB diagnosis, and all causes and some specific causes of severe, moderate, or mild morbidity, and the incidence rate ratio of nonvaccinated to BCG-vaccinated children. We will compare the probability of surviving the first and fifth years of life or of not having severe, moderate, or mild morbidity during the follow-up period according to exposure (BCG vaccinated or nonvaccinated, number of doses, and time from birth until the first dose), using the log-rank test for assessing differences in survival rates between exposed and nonexposed children and hazard ratios for quantifying the differences. Moreover, we will perform a proportional hazards regression analysis.

Results: Ethics approval has been obtained. In March 2022, database owners were contacted to present the project and discuss the request for data. A unique identifier will be used. In July 2023, a process of redefinition of the variables per database was initiated. Data were received in October and November 2023. In November 2023, further work was conducted. By April 2024, we expect to start analyzing the full data set.

Conclusions: The results will contribute to the accumulating body of knowledge and might have relevance to guide global BCG vaccination policy. Data linkage can contribute to a swifter mechanism to use available health data to conduct population-based studies and inform policy decision-making.

KEYWORDS

BCG; Bacillus Calmette-Guérin vaccine; policy; Portugal; nonspecific effects; vaccines; heterologous immunity

Introduction

Background

Immunization has led to a significant decrease in mortality in children under 5 years of age. Several studies have demonstrated that the reduction in mortality and morbidity due to vaccination extends beyond the targeted infections. This seems to result from broader nonspecific effects (also termed heterologous immunity) stemming from the synergistic effects of several live vaccines [1-4]. The vaccines demonstrated to have nonspecific effects include the Bacillus Calmette-Guérin vaccine (BCG), polio vaccine, and measles vaccine [5]. Overall, the nonspecific effects of vaccines vary according to age, sex, time to administration, last vaccine administration, previous and concurrent infections and immunizations, interval between vaccines, genetic factors, nutritional state, season, and co-administration of other immunomodulating agents [1].

BCG is a live attenuated vaccine against tuberculosis (TB), which is administered to newborns ideally at birth or before the seventh day of life. Despite its low efficacy for preventing primary infection or reactivation of latent pulmonary infection and TB infection, BCG is effective against childhood tuberculous meningitis and miliary disease [6]. Hence, BCG at birth is recommended in settings with a high incidence of TB, and it is parsimoniously administered in countries with a low incidence and has been removed from routine vaccination schemes in high-income countries with a low TB incidence [7].

BCG was introduced in the 1920s in Sweden, where it quickly became apparent that the all-cause mortality was lower in BCG-vaccinated children than in those not vaccinated [8]. In England and the United States, the same pattern was observed between the late 1940s and early 1960s, where a reduction in mortality from diseases other than TB was estimated in 25% of vaccinated children (95% CI 6%-41%) [1,9]. Later studies showed the same pattern in infant mortality and morbidity [10], as well as in morbidity in the neonatal period [11]. Furthermore, BCG is used as a standard treatment for carcinoma of the bladder and influences the natural history of infectious and neoplastic diseases [1]. More recently, the effect of BCG was tested in viremia after SARS-CoV-2 exposure [12].

Further studies in children from Denmark and Greenland failed to show a decrease in hospitalization due to infectious diseases in vaccinated children [13,14]. On the contrary, a cohort study of children from 19 different countries revealed that BCG-vaccinated children under 5 years of age had a lower risk of suspected acute lower respiratory infection [15]. In Spain, hospitalization rates due to respiratory infection were lower in BCG-vaccinated children, with an attributable fraction of 32% for children under 1 year of age, and a similar finding was noted for sepsis, with an attributable fraction of 53% [16].

A systematic review concluded that BCG has a beneficial effect on mortality in children, with differential effects according to age (earlier administration of the vaccine is associated with greater effects) [5]. Nevertheless, there has been a call for more research on the nonspecific effects of BCG [5,17]. Currently, studies are seeking to further investigate the nonspecific effects of BCG [18] in terms of the effects on allergy and infection [7], severe morbidity, nonaccidental hospital admission, and all-cause consultation in children under 5 years of age [19].

BCG Vaccination in Portugal

In Portugal, BCG began to be routinely administered to all newborn children in 1965. Until 2016, a single BCG dose was administered to all newborns, typically before discharge from the maternity ward (most births in Portugal are hospital-based) or as early as possible thereafter [20].

In June 2016, a clinical guideline established that only children under 6 years of age who belong to high-risk groups (those originating from countries with high TB incidence; having contact with active cases or persons under prophylaxis; having HIV-positive mothers; having parents with a alcohol or drug abuse problem and antecedents of TB; having parents who have been in prison in the last 5 years; living in high-risk TB communities; or traveling to high-incidence countries) should be vaccinated as close to birth as possible [21]. Some of these risks were not considered individually but by proxy, with some parishes (freguesias) thus considered high risk for the criteria defined.

In 2016, 42% of children under 1 year of age had received BCG (compared to 98% in the previous year) [20]. Between 2016 and 2018, the incidence of TB increased by 16% in children under 1 year of age (from 7.0 to 8.1 per 100,000 inhabitants) and 192% in children aged 1 to 5 years (from 2.6 to 7.6 per 100,000 inhabitants) [20].

Between the adoption of the high-risk strategy for BCG vaccination in 2016 and 2018, the infant mortality rate (IMR) remained stable at 3.2‰ to 3.3‰, with important variations between the considered years [20]. In 2019, there was a decrease to 2.8‰. The mortality rate in children under 5 years of age decreased from 3.4‰ in 2016 to 3.0‰ in 2019, but not constantly in this period (eg, during 2018 it was 3.5‰) [20]. No death in children under 5 years of age has been attributable

to TB since the implementation of the high-risk strategy for BCG [20]. Nevertheless, the number of severe cases of TB in children under 5 years of age decreased in 2020 compared to 2018 (4 cases) and 2019 (7 cases), with just 1 case registered in a child without BCG vaccination [22].

Evaluation of the BCG Vaccination Policy

Since the implementation of the high-risk strategy for BCG in 2016, no assessment has been conducted regarding the impact of the BCG policy shift on severe, moderate, or mild morbidity and on mortality in children. It is a common problem that vaccination practices are changed without evaluating the overall health effects of the change and that the nonspecific effects of vaccines are not included in the considerations regarding vaccine policies.

In 2021, the first cohort of children not vaccinated for BCG completed the fifth year of life, and evidence is needed regarding the impact of this strategy, especially given fluctuations in the IMR, a decline in the TB notification rate not accompanied by a decline in the incidence, a higher TB incidence in greater metropolitan areas, and a high median number of days from symptoms to diagnosis [22].

No data have been gathered on overall hospital admissions and morbidity patterns. Similarly, no data have been compiled on the BCG strains used in the country and their differences in terms of efficacy. This evidence will have a bearing on the continuity of the current strategy.

The need for more and better evidence is paramount, especially given that besides deciding on the inclusion of BCG in the country's immunization plan, arguments on the nonspecific effects of vaccines (and not only of BCG) can help overcome vaccine hesitancy. In high-income countries, including Portugal, vaccine hesitancy has been responsible for a decline in coverage rates and for the re-emergence of severe cases of vaccine-preventable diseases such as measles [23,24].

Hypothesis

Given the described effects of BCG on overall mortality, immune and atopic conditions including asthma, and incidence of respiratory tract infections; its nonspecific protection against nonrelated pathogens; and its protective effects that are apparent shortly after immunization and sustained for at least 1 year [2,25], we hypothesize that some of the variations in mortality among children under 5 years of age, in the incidence of TB, and in severe, moderate, and mild morbidity among children under 5 years of age might be partially explained by a reduction in the coverage rate of BCG since 2016. The reduction in the coverage rate of BCG, which resulted from only high-risk children receiving BCG at birth, might have prevented nonvaccinated children from developing trained immunological responses as effectively as BCG-vaccinated children.

Objectives

We aim to investigate the incidence of the specific and nonspecific effects of BCG by comparing the incidences of TB disease and infection; mild, moderate, and severe morbidity; and mortality in the first 5 years of life among children born in Portugal between 2010 and 2021, according to their BCG status.

Methods

Study Design

This population-based historical (retrospective) birth cohort study will compare the incidence of all-cause mortality (including due to TB disease); TB disease; and severe, moderate, and mild morbidity between BCG-vaccinated and nonvaccinated children born between July 1, 2010, and June 30, 2021.

Setting

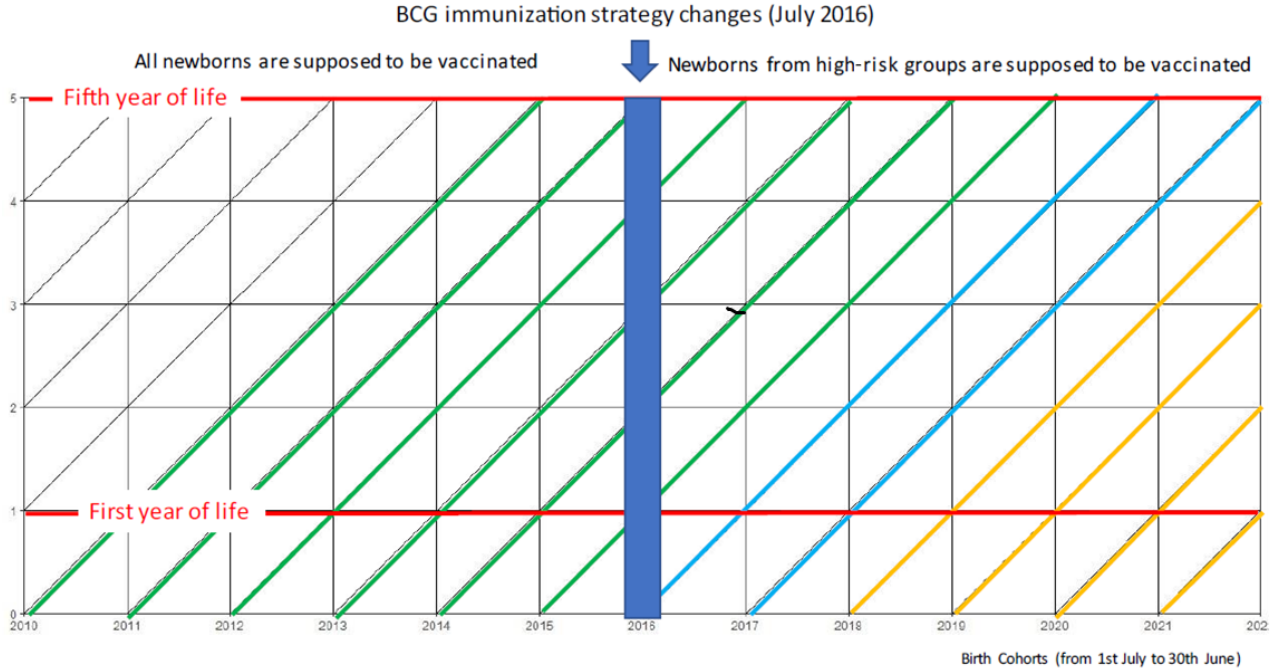
This study will investigate the specific and nonspecific effects of BCG based on the shift in the BCG vaccination policy that occurred in Portugal in July 2016, when a consistently low incidence of TB led to the revision of the National Immunization Plan. Since then, BCG has been administered only to newborns considered to be at higher risk of TB infection, thus creating an opportunity to compare BCG-vaccinated and nonvaccinated children.

The approach adopted by Portuguese public health authorities to define the high risk for TB was based on geographical risk, with, for instance, all children born in some parishes in the metropolitan areas of Lisbon and Porto being offered BCG independent of socioeconomic status, country of origin, or vulnerability. We believe that this type of risk definition has guaranteed enough variability between BCG-vaccinated and nonvaccinated children, thus allowing comparisons of health outcomes between exposed and nonexposed children.

Participants

The study will include children under 5 years of age born and registered in Portugal between July 1, 2010, and June 30, 2021. We have chosen this period because it will allow us to (1) compare the cohorts before and after the change in the BCG immunization strategy (Figure 1); (2) characterize children not vaccinated with BCG and their health outcomes (when universal BCG at birth was recommended); and (3) compare children exposed and not exposed to BCG after the 2016 change in the BCG vaccination strategy.

Figure 1. Lexis graph. BCG: Bacillus Calmette-Guérin vaccine.



Eligibility Criteria

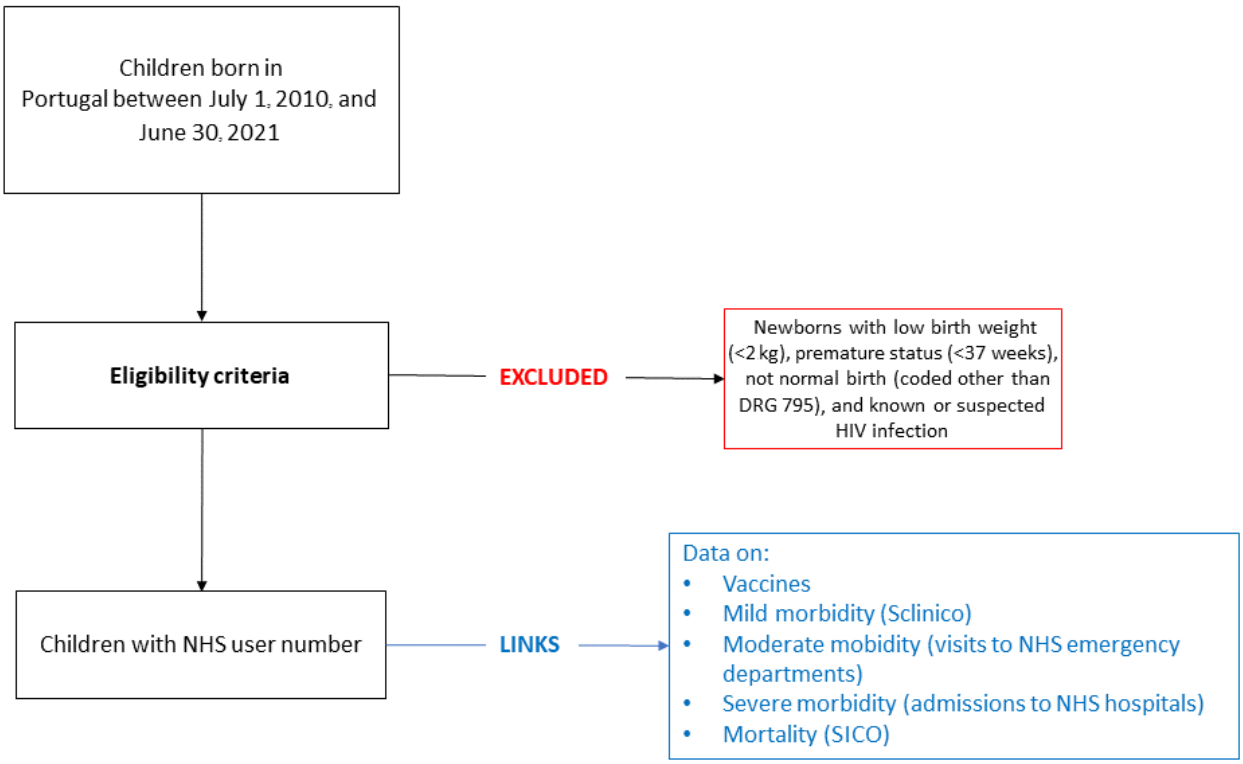
The study will include children born alive in Portugal (births coded as diagnosis-related group [DRG] 795 [normal newborn]).

Exclusion Criteria

The study will exclude newborns who have a weight of <2 kg, are premature (<37 weeks of gestation), or are known or suspected to have HIV infection.

The follow-up period will be until the completion of 5 years of age or the end of follow-up (June 30, 2021) (Figure 2).

Figure 2. Flowchart. DRG: diagnosis-related group; NHS: National Health Service.



Data Sources

The study will be based solely on secondary data. The data sources are the National Health Service (NHS) user registry (RNU), Death Certificate Information System (SICO), vaccination registry, communicable diseases surveillance system (Sistema Nacional de Vigilancia Epidemiologica [SINAVE]), surveillance information system for TB (Svig-TB), DRG information system for hospital admissions and visits to the emergency department (Base de Dados de Morbilidade Hospitalar [BDMH]), and primary health care (PHC) information system (SClínico) of children born between July 1, 2010, and June 30, 2021.

The birth registry database (RNU) contains data on gender, age, PHC center where the child is to be followed up, nationality, and place of residence. The SICO database provides data on the cause and date of death. The vaccination registry includes data on the vaccines administered, date of vaccination, and place of residence. The BDMH database gathers data on hospital admissions and emergency department visits to NHS hospitals, including the date of admission and discharge, diagnosis, type of admission, motive for admission, weight at birth, DRG code, major diagnostic category (MDC) code, complications of pregnancy and delivery, and type and place of delivery. Data from admissions at private hospitals are not included. The SClínico database contains data on socioeconomic status and visits (including motive and diagnosis) to NHS PHC units. Svig-TB is a database for notification and follow-up of TB cases, and SINAVE is the general surveillance information system for communicable diseases, including TB, and regarding TB, it contains data on symptoms at presentation, date of diagnosis, type of treatment, other diseases before TB, risk groups, and outcomes of the infection.

Measurements

Exposure is defined as having received the BCG vaccine during the first year of life and is measured using the vaccination registry. Variables include BCG (yes or no, and number of doses) and time from birth to BCG (in days).

Outcomes

Primary Outcomes

In this study, the primary outcomes for BCG-vaccinated and nonvaccinated infants and children under 5 years of age include the incidence of all-cause death and death due to TB; the incidence of mild, moderate, and severe morbidity; and respective relative risks.

The primary outcomes will be measured as person-time incidence rates of death (all causes and TB); TB diagnosis; and severe, moderate, and mild morbidity in the follow-up period, and the incidence rate ratio of nonvaccinated to BCG-vaccinated children (Table 1). For the outcome of death, data will include death (yes or no), age at the time of death (in days), and cause of death (eg, diseases of the respiratory system and diseases of the skin and subcutaneous tissue). Data on TB diagnosis will include confirmed case (yes or no), presentation of TB, age at diagnosis (in days), duration of treatment, and outcomes of treatment. Severe and moderate morbidity will be measured based on hospitalization and visits to the emergency department of the NHS. Outcomes will be characterized by age at presentation (in days), frequency of admissions or visits to the emergency department, length of stay for hospital admission (in nights), and MDC code for hospitalization and emergency department visits. We will include the outcome of hospital admission (discharged alive or died) in case fatality risk analyses. The outcome of mild morbidity is defined as contact with a medical doctor or nurse at a PHC unit owing to disease or ill health during the follow-up, as well as contact related to a recommended child surveillance scheme or other reasons besides health. It will be characterized through visits to the PHC center owing to disease or ill health (yes or no, and number), age at the visits (in days), and diagnosis (International Classification of Primary Care-2 [ICPC-2]). Mortality and morbidity pertaining to external causes and accidents will not be included in the analysis.

Table 1. Predictable analysis per cohort and outcome.

Analysis[a]	Outcomes
Exposed children in birth cohorts 2010 to 2015 compared to nonexposed children in birth cohorts 2010 to 2015, 2016, 2017, 2018, 2019, 2020, and 2021	Primary outcomes in the first year of life
Exposed children in birth cohorts 2010 to 2015 compared to nonexposed children in birth cohorts 2010 to 2015, 2016, and 2017	Primary outcomes in the first 5 years of life
Exposed children in birth cohorts 2016, 2017, 2018, 2019, 2020, and 2021 compared to nonexposed children in birth cohorts 2016, 2017, 2018, 2019, 2020, and 2021	Primary outcomes in the first year of life
Exposed children in birth cohorts 2016 and 2021 compared to nonexposed children in birth cohorts 2016 and 2017	Primary outcomes in the first 5 years of life
Nonexposed children in birth cohorts 2010 to 2015 compared to nonexposed children in birth cohorts 2016 to 2021	Secondary outcome profile of nonvaccinated children before and after the 2016 BCG[b] vaccination change
Children in birth cohorts 2010 to 2015, 2016, and 2017	Secondary outcomes of the mortality and morbidity profile of children under 5 years of age, and NHS[c] hospital and primary health care utilization profiles
Exposed children in birth cohorts 2010 to 2015 compared to exposed children in birth cohorts 2016, 2017, 2018, 2019, 2020, and 2021	Secondary outcomes of the mortality and morbidity incidence according to BCG strains administered per cohort in the first 5 years of life and first year of life
Exposed children in birth cohorts 2010 to 2015 compared to exposed children in birth cohorts 2016 and 2017	Secondary outcomes of the mortality and morbidity incidence according to BCG strains administered per cohort in the first 5 years of life

[a]Between 2010 and 2015, Bacillus Calmette-Guérin vaccine (BCG) coverage varied between 98.2% and 98.4%. In 2016, BCG coverage was 41.6%.

[b]BCG: Bacillus Calmette-Guérin vaccine.

[c]NHS: National Health Service.

Secondary Outcomes

The secondary outcomes include the mortality and morbidity profiles of children under 5 years of age between 2010 and 2021, including causes of death and morbidity, the profiles of nonvaccinated children, and the NHS hospital and PHC utilization profiles of children under 5 years of age before and after 2016 (Table 1).

Statistical Methods

Through data linkage, we will create a single database that links data from the birth registry, SICO, vaccination registry, SINAVE, Svig-TB, BDMH, and PHC database (SClínico) to reconstruct chronological sequences of morbidity and mortality events from birth until the completion of 5 years of life or the end of follow-up (for the 2018 cohort onwards).

In each of the databases, we will identify the data needed and whether a unique identifier (UI) exists and can be provided with the data set. After having access to the requested data and in case a UI is provided (and common to all databases), we will combine information based on that UI.

In case a UI is not provided, we will link data from several data sets using a range of proxy identifiers (eg, date and place of birth, sex, and place of residence) to identify probable matches.

The type of data linkage method to be used will depend on the type and quality of the linkage variables available in the data sets. However, we anticipate having to use a combination of deterministic and probabilistic methods. Before applying linkage methods, we will clean and standardize the data, thus identifying and removing errors and inconsistencies. Given the expected size of the data sets, we will then select sets of block attributes (eg, sex, date of birth, and initials) and compare record pairs with the same matched attributes within blocks. Subsequently, record pairs will be compared for each linkage variable, and an agreement score will be computed. This score will be used to weigh the probability of a record pair belonging to the same child [26,27].

After obtaining the final database, we will compute person-time incidence rates for primary outcomes in BCG-vaccinated and nonvaccinated children. Using the Kaplan-Meier method, we will compute and compare the probability of surviving the first and fifth years of life or of not having a hospitalization, emergency department visit, or mild morbidity episode during the follow-up period according to exposure. Additionally, we will use a log-rank test for assessing differences in survival rates between exposed and nonexposed children and hazard ratios (and corresponding CIs) for quantifying the differences. To explore the effects of several variables on the survival outcomes, we will use proportional hazards regression analysis. If missing data are below 5%, we will use complete case analysis. Otherwise, the frequency and patterns of missing data will be analyzed, and if appropriate, we will use multiple imputation techniques.

Confounders to be measured and controlled for are sex, health unit, completeness and timeliness of vaccination status and scheme, socioeconomic status, and BCG strain (over the years, administered BCG has been provided by different producers, with different strains).

Ethical Considerations

This study has received ethical approval from the Ethics Committee of Instituto de Higiene e Medicina Tropical (IHMT) – Instituto de Tecnologia Química e Biológica António Xavier (ITQB) NOVA – NOVA School of Law (NSL) – Instituto Gulbenkian de Ciência (IGC) (11.23) [28].

The project protocol was submitted to the Ethics Committee of IHMT – ITQB NOVA (11.23), which issued a conditional authorization in July 2022 [29] that became definitive in December 2023.

Results

This project was approved as an exploratory project by the Portuguese Foundation for Science and Technology in the 2021 competitive call for R&D projects (reference: EXPL/SAU-EPI/0067/2021). It was granted approximately €50,000 (US$ 53,869) and was started in January 2022.

During the first month of the project's implementation, administrative and financial activities were carried out, with a summary of the project sent to members of the Scientific Advisory Board, including the planned activities.

In March 2022, database owners were contacted to present the project and discuss how to officially request the data. A document detailing all the data needed to carry out the study was prepared and sent to the Directorate General of Health. After approval from this body, Serviços Partilhados do Ministério da Saúde (SPMS) and Administração Central do Sistema de Saúde (ACSS) also had to provide authorization to access the data, with the last authorization given in October 2023.

We were informed that a UI would be provided for each database, based on the NHS user number, from the RNU, thus allowing direct linkage of records. However, some of the requested variables had to be reviewed and replaced given the Data Protection Law. In July 2023, a process of redefinition of the variables per database was initiated, with some of the variables requested not being supplied owing to legal restrictions (eg, date of birth had to be replaced by days from birth until the event and information if the child had been born before or after 2016) (Multimedia Appendix 1).

Data were received during October and November 2023. By mid-December, data from SINAVE had not yet been provided. No data were obtained from Svig-TB as we were not granted access. Some of the variables requested from this database were replaced by equivalent or proxy variables from SINAVE (Multimedia Appendix 1).

In November 2023, work was conducted in the databases already provided to restructure the databases, perform quality checks and cleaning, compute exposure variables, transform string variables into numeric variables, and perform coding.

By April 2024, we expect to start analyzing the full data set, which is expected to include around 970,000 children.

Discussion

Principal Findings

If the change in the BCG strategy in 2016 is proven to influence the health outcomes of children in their first year of life and during the first 5 years of life, it would further contribute to evidence that BCG primes the immune system against unrelated pathogens and even other health conditions, strengthening the arguments regarding the nonspecific effects of BCG. Additionally, it would provide evidence of the impact of the high-risk strategy for BCG vaccination and inform future decisions regarding BCG vaccination for children in Portugal and other high-income countries. The results will contribute to the accumulating body of knowledge and might have relevance to guide global BCG vaccination policy.

The use of data linkage can also contribute to a swifter mechanism to use available health data to conduct population-based studies and inform policies. The project will demonstrate the feasibility of conducting large-scale epidemiological register-based vaccine studies in Portugal.

Limitations

The main limitation of this project involves the use of secondary data collected for purposes other than research. The RNU database, which provides the basis for creating a UI, only includes children who have a user number for the NHS. The user number is assigned to each person to identify them when accessing the services of the public health care units of the NHS. People with Portuguese citizenship obtain their user number automatically when they apply for a Citizen's Card. Foreigners with a residence or stay permit in Portugal have to apply for an NHS user number. Most but not all infants are registered shortly after birth.

In August 2016, the Portuguese government created the program "Nascer Utente" (translated to "Born as a User") that allowed for immediate registration in the RNU database, assigning the respective user number. This process is conducted by the hospital (public and private) where the child is born, immediately after birth [30]. We therefore expect a bias toward children born after this date in the RNU database.

The electronic registry of vaccines was started in 2017, and all data before this point had to be back introduced in the database, which could have increased the number of typing errors and other issues. We can again have a bias toward the most recent years in terms of the quality of data.

The number of deaths of children under 5 years of age might be underestimated since very young children tend not to have an NHS user number, especially before August 2016. In this case, we can also expect to have a bias in the age of children who died between July 1, 2010, and June 30, 2021, toward older ones.

The BDMH database only pertains to public hospitals. It does not include data from emergency department visits or hospital admissions in the private sector. The same is true for SClínico, which contains data from PHC centers in the NHS. Children using the private sector are not captured by this database.

Additionally, the case mix (severity) of admissions in public hospitals is usually greater than that in private hospitals, which might introduce a bias toward higher case fatality rates in hospital admissions.

In 2020, 32% of Portuguese people had voluntary health insurance (in 2010, the proportion was less than 20%), and the proportion is dependent on household income, with those in higher income groups showing a higher probability of having voluntary health insurance. As such, we expect a bias toward lower income groups, especially in the last years of the study period [31].

Comparison With Prior Work

This is one of the first studies conducted in Portugal linking several databases. During the COVID-19 pandemic, several data linkage studies were conducted [32,33].

To our knowledge, this is the first population-based study that gathers data on mild, moderate, and severe morbidity and mortality among children under 5 years of age and addresses the nonspecific effects of BCG.

In Portugal, this is the first study to assess the impact of the BCG vaccination policy change on the health of children.

Conclusions

The results will contribute to the accumulating body of knowledge and might have relevance to guide global BCG vaccination policy. The use of data linkage can also contribute to a swifter mechanism to use available health data to conduct population-based studies and inform policy decision-making.

Abstract

Background: Artificial intelligence (AI)–powered digital therapies that detect methamphetamine cravings via consumer devices have the potential to reduce health care disparities by providing remote and accessible care solutions to communities with limited care solutions, such as Native Hawaiian, Filipino, and Pacific Islander communities. However, Native Hawaiian, Filipino, and Pacific Islander communities are understudied with respect to digital therapeutics and AI health sensing despite using technology at the same rates as other racial groups.

Objective: In this study, we aimed to understand the feasibility of continuous remote digital monitoring and ecological momentary assessments in Native Hawaiian, Filipino, and Pacific Islander communities in Hawaii by curating a novel data set of longitudinal Fitbit (Fitbit Inc) biosignals with the corresponding craving and substance use labels. We also aimed to develop personalized AI models that predict methamphetamine craving events in real time using wearable sensor data.

Methods: We will develop personalized AI and machine learning models for methamphetamine use and craving prediction in 40 individuals from Native Hawaiian, Filipino, and Pacific Islander communities by curating a novel data set of real-time Fitbit biosensor readings and the corresponding participant annotations (ie, raw self-reported substance use data) of their methamphetamine use and cravings. In the process of collecting this data set, we will gain insights into cultural and other human factors that can challenge the proper acquisition of precise annotations. With the resulting data set, we will use self-supervised learning AI approaches, which are a new family of machine learning methods that allows a neural network to be trained without labels by being optimized to make predictions about the data. The inputs to the proposed AI models are Fitbit biosensor readings, and the outputs are predictions of methamphetamine use or craving. This paradigm is gaining increased attention in AI for health care.

Results: To date, more than 40 individuals have expressed interest in participating in the study, and we have successfully recruited our first 5 participants with minimal logistical challenges and proper compliance. Several logistical challenges that the research team has encountered so far and the related implications are discussed.

Conclusions: We expect to develop models that significantly outperform traditional supervised methods by finetuning according to the data of a participant. Such methods will enable AI solutions that work with the limited data available from Native Hawaiian, Filipino, and Pacific Islander populations and that are inherently unbiased owing to their personalized nature. Such models can support future AI-powered digital therapeutics for substance abuse.

Introduction

Background

Methamphetamine abuse is highly prevalent in Hawaii, especially among Indigenous Pacific Peoples [1]. Since the 1980s, Hawaii has been considered the methamphetamine capital of the United States. Data from the Pacific Health Analytics Collaborative show that from 2015 to 2018, in total, 1.5% of Hawaiian residents used methamphetamine annually [2]. This was more than twice the national rate of 0.6%. According to the Bureau of Alcohol, Tobacco, Firearms, and Explosives, 71% of all drug cases in Hawaii were related to methamphetamine [3]. There are major methamphetamine-related disparities between Native Hawaiian, Filipino, and Pacific Islander individuals and people of other races in Hawaii, with Native Hawaiian, Filipino, and Pacific Islander individuals exhibiting elevated rates of illicit substance abuse [4]. According to the Centers for Disease Control and Prevention, Native Hawaiian and Pacific Islander high school students exhibited lifetime methamphetamine use of 7.7% versus 3.7% in White students, 2.7% in Black students, 3.1% in Asian students, and 5.7% in Hispanic and Latino students, and these disparities continued into adulthood [5]. Digital interventions powered by artificial intelligence (AI) have the potential to reduce these disparities by aiding clinicians in remotely providing care and monitoring patients between visits, especially among populations living in rural areas in Hawaii. Furthermore, such technology could be useful in relapse prevention for those hoping to maintain abstinence. In Hawaii in 2021, a total of 96% of residents possessed at least 1 piece of hardware with internet capacity, with only 4% lacking access to such equipment, indicating widespread internet access among the population [6].

AI-based detection of substance abuse using biometric signals measured by wearables is an active field of research across several research laboratories globally, as documented in a 2022 review paper by Rumbut et al [7]. Studies in this field tend to collect prediction labels through the remote administration of an ecological momentary assessment (EMA), a methodology in which participants are periodically asked to answer questions about their psychiatric or behavioral state while living as usual [8-10]. Notably, previous AI models suffered from clinically unacceptable performance. The primary reason for this lackluster performance is that prior methods attempted to train models using data from many patients, which is the status quo in deep learning because of the requirement of massive data sets for successful training. In contrast to these prior works, we will develop personalized AI models using a method developed in PW's laboratory, which are capable of learning baseline patterns of human behavior and transferring this knowledge to prediction tasks with very few labeled examples to learn from.

Our research laboratory is particularly qualified to carry out this project as we are already developing computer science methods to support the personalization of AI models for large and mostly unlabeled data streams, with promising preliminary data and publications in preparation supporting this methodology. As a T1 (covering basic discovery) or T2 (initial human trials) project, our proposed study is significant both in terms of equitable substance abuse therapeutics and as a general methodology for clinical and translational research in other domains. There are countless situations in health care where vast amounts of unlabeled data are collected from a single patient. Annotations for the event of interest (eg, substance abuse) are frequently sparsely dispersed. The development of predictive supervised models is infeasible in such circumstances because classical approaches cannot handle the complexity of data, and modern deep learning approaches require vast amounts of data.

Innovation

To support machine learning (ML) development in situations where vast longitudinal data are collected with minimal human-provided annotations, we propose the development of personalized ML models, which are trained solely on an individual's unlabeled data to learn feature representations that are specific to their baseline temporal dynamics. We are creating a novel method and framework that has never been explored in health care, consisting of pretraining neural networks to learn the temporal dynamics of a patient's biosignals. This method will enable deep networks to be trained using relatively small data sets, which would not be possible without the self-supervised approach proposed in this study. This technique is particularly well-suited for massive data sets with few labels.

The application of personalized AI to a diverse population of persons using substances is unique. Native Hawaiian, Filipino, and Pacific Islander communities have been understudied and could benefit from novel treatments to address methamphetamine use. Although we will apply this technological innovation toward the prediction of methamphetamine use, multimodal time-series personalization can be applied to a variety of other biological and health problems where (1) multiple signals are sparsely emitted, (2) the baseline signal patterns are specific to each individual, and (3) it is infeasible to acquire the vast amounts of labels required to train a supervised deep learning model.

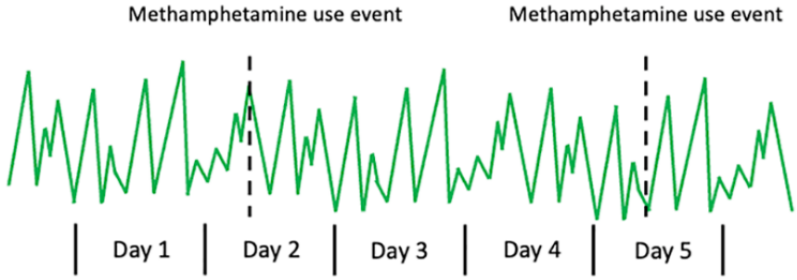
This method has the potential to dramatically advance the field of precision health care by enabling reliable AI predictions from massive but mostly unlabeled data sets, which are trained in a self-supervised manner on data from a single user. This setting of large, unlabeled data sets with sparse supervision appears frequently in the field of digital health care. Notable examples include passive mobile sensing studies for mental health and well-being [11-20], digital therapeutics for children with autism spectrum disorder that record videos of the child [21-37], and passive brain sensors for brain-computer interfaces [38-46]. As such, this study protocol can be considered as one of the first tests of a broader emerging paradigm in precision health.

Methods

Overview

The long-term methodological goal of the proposed work is to develop novel AI methodologies for predicting health events (eg, methamphetamine use and cravings) using biosensors in a personalized manner. This technical innovation will be applied toward the detection of drug use events from wearable device sensors. The inputs to the proposed AI models are Fitbit (Fitbit Inc [47]) biosensor readings, and the outputs are predictions of methamphetamine use or craving (Figure 1). The methods developed can be applied to a variety of biomedical domains.

Figure 1. In many biomedical domains, there exist large data sets with sparse annotations of health events. We propose a "personalized self-supervised learning" method that can support the training of deep neural networks in such scenarios. We will evaluate our method primarily on the prediction of methamphetamine use events using biosignal data from a Fitbit device.



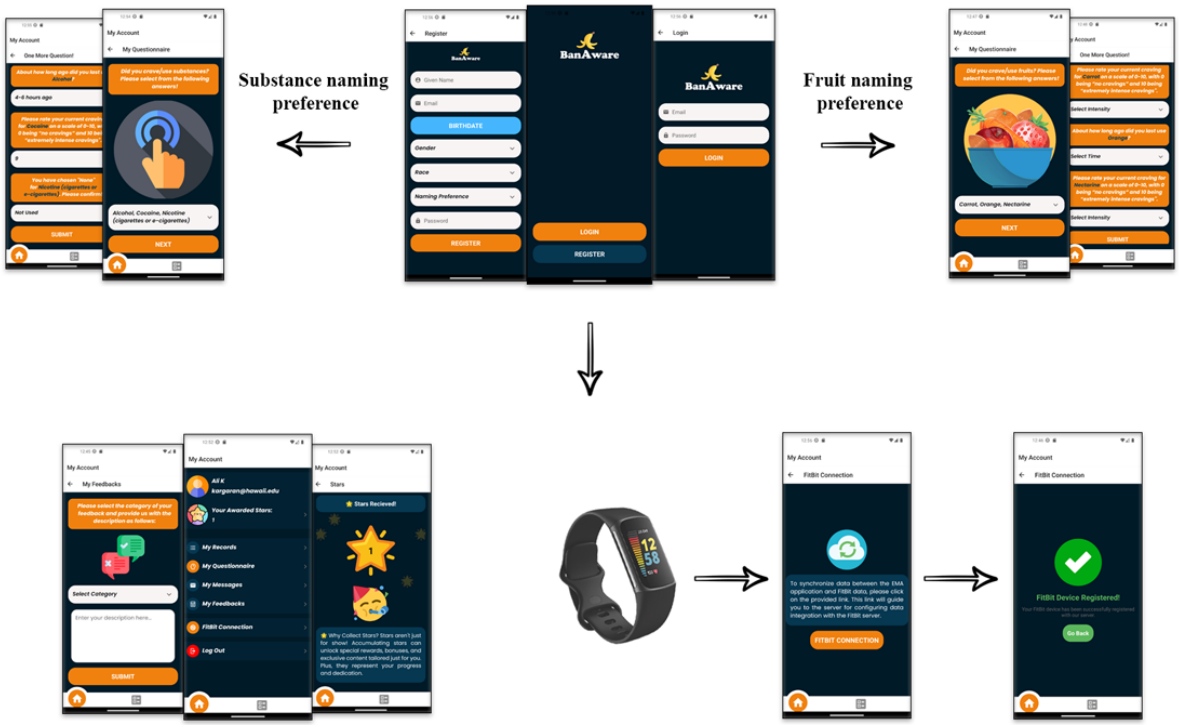
Diagnostic ML models are typically trained and deployed at a population level. In this traditional scenario, a single model is developed to make predictions for all individuals within a population. However, in several health contexts, an event of interest occurs repeatedly for an individual. For example, patients with diabetes have repeated blood glucose spikes, and chronically stressed individuals might have repeated blood pressure spikes. In these cases, ML models can be developed by conducting supervised training on the individual's data only, resulting in a separate personalized model per individual. Although deep learning models have achieved state-of-the-art performance in a variety of health contexts, neural networks require massive data sets that are infeasible to collect for an individual. However, recent advances in self-supervised learning (SSL), or the subfield of ML focusing on pretraining models without any human-provided labels, have made it possible to realize the personalized ML diagnostics paradigm using deep learning by pretraining the weights of a neural network such that it can learn the baseline temporal dynamics without any labels. The pretrained model can then use transfer learning on relatively few labels that are acquired solely from the individual in question. This methodology can work particularly well in scenarios where massive amounts of unlabeled data are collected, such as with continuously worn devices.

Aim 1: To Understand the Feasibility of Remote Digital Monitoring and EMAs in Native Hawaiian, Filipino, and Pacific Islander Communities by Curating Longitudinal Fitbit Biosignals With the Corresponding Substance Use and Craving Labels

Description

We will recruit 40 carefully selected Native Hawaiian, Filipino, and Pacific Islander participants who are either in treatment or have received services from one of our community partners to participate in a 4-week remote Fitbit data collection and concurrent EMA study. EMA studies, which involve periodic digital self-reports about psychiatric and behavioral outcomes *in the wild*, have often been used to understand substance abuse [48], including among persons who use methamphetamine [49]. We expect ≥80% complete data from approximately 25% (10/40) of the participants (refer to the *Recruitment* section for justification). Each participant will wear a study-provided Fitbit Charge 5 watch during all waking hours for at least 15 hours each day. Apart from wearing the device and periodically recording an EMA about their methamphetamine use via a mobile smartphone app (Figure 2), participants will be asked to follow their normal routine throughout the study.

Figure 2. User interface of the ecological monitoring app provided to participants.



Participant Recruitment and Management

We will recruit participants from a combination of sites, including the Hawaii Health and Harm Reduction Center and other sites where the clinical collaborators have connections (ie, Hina Mauka). Potential participants will be eligible for the study if they (1) are aged ≥18 years, (2) self-report consumption of methamphetamine on ≥2 different days per week on average, (3) have no plans to leave Oahu for at least 1 month, and (4) own a smartphone with either a data plan or regular access to a Wi-Fi connection. Potential participants will be excluded if they (1) are homicidal or suicidal, (2) cannot provide informed consent, (3) are not able to complete interviews in English, (4) are expecting incarceration or plan to leave Oahu within the next month, or (5) are unable to provide names and contact information for at least 2 verifiable locator persons for retention purposes.

We will recruit 40 participants in total. A secondary analysis of EMAs for methamphetamine abuse monitoring measured the percentage of participants who reached ≥80% compliance at different frequencies of methamphetamine use, finding that approximately 50% of persons who use methamphetamine 1 to 3 times per month met this 80% compliance bar, and 40% using 1 to 2 days per week met the bar, and 25% using 3 to 4 days per week met the bar [50]. Therefore, we anticipated that approximately 25% (10/40) of the participants will reach ≥80% compliance rate, which is sufficient to demonstrate the feasibility of our AI method, as a separate analysis will be conducted for each participant (ie, 1 model per participant).

Data Collection

We will leverage the existing application programming interface provided by Fitbit to record the user's watch sensor readings and upload the data to the cloud. The Fitbit application programming interface provides access to heart rate (HR), gyroscope and accelerometer readings, breathing rate, blood oxygen saturation (SpO_2) level, and skin temperature sensor readings. These biosensors have previously been used to predict substance abuse and cravings using AI [51-55]. The data will be managed on each participant's smartphone device through an app, implemented for both iOS and Android, which we are actively developing. The study team will install the app on the user's smartphone and configure the Fitbit device during study onboarding.

We will run the study with 8 (20%) of the 40 participants at a time as we have 8 Fitbit Charge 5 devices, resulting in 5 batches of data collection periods. We will record background characteristics, substance use, and treatment history during study intake, and we will record questions pertaining to the tolerability and obtrusiveness of the app during study outtake (Textbox 1). The smartphone app will record EMA responses from the participants throughout the 1-month study period (Textbox 1). At each EMA, we will ask participants to list the approximate times (eg, date, hour, and minute) of their methamphetamine intake in the past 24 hours via a user interface on the smartphone app. Participants will be asked to do the same for cravings. Participants will be prompted to provide EMA responses both when drastic signal changes are detected (ie, event-triggered EMA) and every 24 hours (ie, fixed-interval EMA).

Textbox 1. Study intake and outtake measures and ecological momentary assessment (EMA) questions collected from each participant.

Background characteristics (intake)

- To better describe the sample, participants will be asked about their gender, sexual orientation, age, race or ethnicity, marital status, education, income, employment, housing, and health insurance status.

Substance use and treatment history (intake)

- Questions will be developed to assess current and history of substance use and participation in treatment services.

Tolerability (study conclusion)

- How comfortable was the device?

Obtrusiveness (study conclusion)

- Did the device change your daily routine? Do you have any concerns with continuously Fitbit usage?

Methamphetamine use (EMA)

- Have you used meth since the last time we contacted you?
- Approximately what time did you last use meth?
- How did you use meth the last time you used?

Craving (EMA)

- Please rate your current craving or desire to use methamphetamine at this exact moment on a scale of 0-10, with 0 being “no cravings” and 10 being “extremely intense cravings.”

We will institute procedures to reduce the burden associated with EMA and increase compliance as suggested by Burke et al [56]. To reduce the burden related to time commitment, we are compensating for every signal-contingent response and providing additional compensation when participants respond to >80% of prompts. Participants will be trained extensively on the EMA protocol at baseline, and if they experience any technology-related issues, our research assistants will help troubleshoot these issues remotely. Participants who experience technology-related problems will not have their compensation reduced because of missing prompts.

We will store the curated data from each participant (Figure 2) on a centralized server hosted on Amazon Web Services (AWS; Amazon). Data uploaded from both wearable systems and the smartphone will first run through a preprocessing server hosted on an elastic cloud computing (EC2) instance with data stored on DynamoDB (Amazon). Each table will have columns for the participant ID and timestamp. To ensure privacy and Health Insurance Portability and Accountability Act (HIPAA) compliance, we will encrypt all server-side data and require secret access keys for data access. DynamoDB tables are automatically encrypted on the server side. To add an additional layer of security, we will implement client-side encryption on the mobile app, ensuring encrypted data transmission across an https connection to move data between the devices and AWS. The data will not be accessible without a secret access key. All data will be anonymized.

An anonymized version of participant data will be made available to other computational researchers as a publicly available data set. This data set will be stored on AWS on a HIPAA-compliant server and will be password protected. Researchers will only gain access to this data set by signing a data use agreement. Such data sets exist for activity and emotion recognition from wearable data, but the prediction of methamphetamine use from these measurements will be a challenging task, and other ML practitioners can improve upon our initial AI models with the release of the deidentified data set. This will be the first publicly available data set that includes substance use self-reports alongside wearable sensor readings.

Data Analysis and Interpretation

We will measure the success rate of the remote data collection procedure using the response rate to EMA notifications. We hypothesize that we will observe higher compliance rates with event-triggered EMAs than fixed-interval EMAs. Furthermore, we will document qualitative challenges with the data collection process, tolerability, and unobtrusiveness (Textbox 1). We will conduct an interview with the participants at the study conclusion when the devices are returned. The research team will qualitatively code interview responses to derive recurring themes and design insights.

Potential Pitfalls and Mitigation Strategies

This analysis plan is uniquely robust to incomplete data collection because a separate AI model will be trained and evaluated for each participant. There is no requirement for equivalent data streams between participants nor will the analysis be prevented if the full 28-day data collection period is not achieved. The ML strategy can work with only a few logged methamphetamine use events. We expect approximately 25% (10/40) of the participants to complete the study at a sufficient level of compliance to support personalized ML analysis. This will provide sufficient data to demonstrate the feasibility of personalized ML analysis.

We have budgeted a 4-month buffer period beyond the 5 months required for complete data collection to account for participant delays and no-shows. Because participant data will be uploaded to AWS daily, we will remotely monitor participants through an automated tracking system already developed in our research laboratory and will cease the study if compliance is not logged after 4 days. Another possible issue is Fitbit theft or loss. To minimize this risk, participants will be compensated a minimum of US $135 for study completion and a maximum of US $210, which will be paid when the Fitbit device is returned. In the case of Fitbit device breakage or loss, our laboratory will purchase additional devices with funds separated from Center for Pacific Innovations, Knowledge, and Opportunities, up to a limit of 6 additional devices along the course of the study period.

Aim 2: To Develop Real-Time Personalized AI Models Predicting Methamphetamine Use and Craving With Fitbit Sensor Data

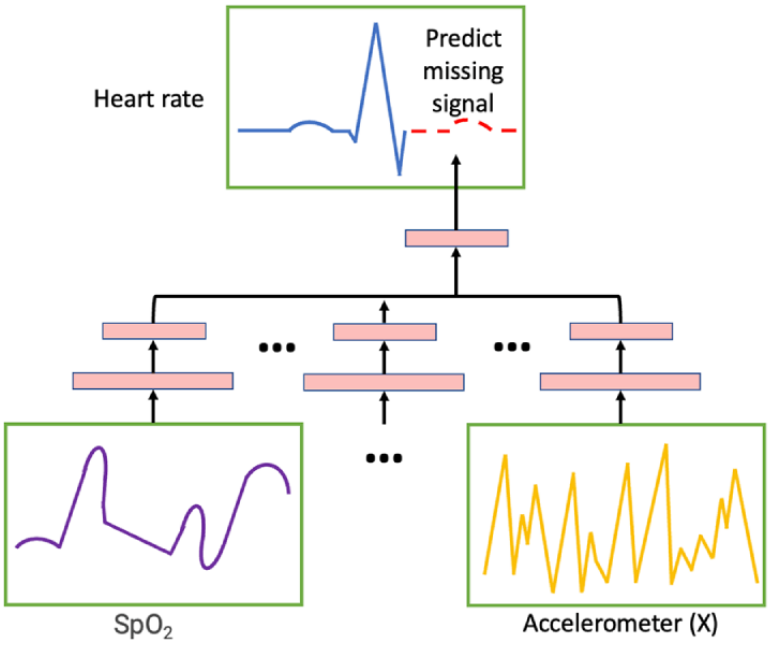
Description

On the basis of extensive support from prior literature, we hypothesize that AI solutions can detect periods of both methamphetamine use and cravings with high sensitivity through the personalization of ML models. Such models will achieve high performance on a single individual through the finetuning of each model using only the data curated from the person of interest for model training. These personalized predictions can trigger the onset of digital therapy. We will develop two AI models per participant: (1) a model that detects methamphetamine use in real time and (2) a model that predicts methamphetamine craving in real time. We hypothesize that model personalization using novel self-supervised pretraining strategies will outperform traditional state-of-the-art AI techniques with <5% of the required label data.

ML Model Training

The inputs to the models will consist of a separate 1D convolutional backbone pretrained for each biometric modality. The convolutional features will be fused upstream into a shared joint dense representation space and finally a dense prediction layer with linear activation for regression prediction (Figure 3). We will implement all models using TensorFlow (Google Brain) [57].

Figure 3. The key methodological computer science innovation of this protocol is the personalization of machine learning models that make predictions from biosignals time-series data without user-provided labels. In this figure, we depict a neural network that is trained to predict a heart rate signal given SpO_2 levels and accelerometer signals from a single participant. SpO_2: blood oxygen saturation.



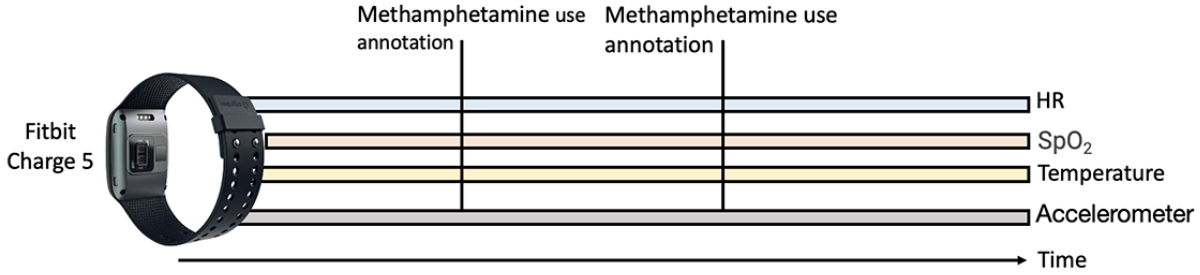
The data augmentation techniques that we apply to the signals will be domain specific, keeping in mind the inherent dynamics of each sensor. For example, for accelerometer data, rotations simulate different sensor placements, and cropping is used to diminish the dependency on event locations [58]. Across several modalities, sensor noise can be simulated through scaling, magnitude warping, and jittering [58]. We will be careful not to apply augmentation strategies that might change the meaning of the underlying signal.

Model Personalization

SSL is usually used to pretrain an entire data set with no explicit labeling by humans to guide the supervision task. We propose to redesign the SSL paradigm toward the task of model personalization. By pretraining a model only on the vast amounts of data curated from a single individual, the weights of the neural network will learn to make predictions using the inherent structure of each participant's biosignals. This is essential because baseline HR, SpO_2, skin temperature, and movement patterns, regardless of stress, will vary drastically across individuals, limiting the performance of general-purpose ML models.

We plan to exploit the multimodal time-series nature of the collected data to perform novel SSL pretraining. We will use ≥1 signal to predict the value of another signal source (Figure 4). The motivation for this approach is that the biometrics of interest recorded by Fitbit are correlated [59-62].

Figure 4. Depiction of the proposed data set, consisting of continuous Fitbit Charge 5 sensor readings and the corresponding methamphetamine use and craving annotations from 20 participants collected over a 4-week period. HR: heart rate; SpO_2: blood oxygen saturation.



Data Analysis and Interpretation

We will train the model on the first 75% of the data (by time) and calculate the balanced accuracy, precision, recall, F_1-score, and area under the receiver operating characteristic curve for the final 25%. This evaluation pattern mimics real-world use, where a model will be calibrated by a user before real-world deployment. It is important to emphasize that we will train and test a separate personalized ML model for each individual (up to 40 separate models).

In a manner similar to our preliminary data, we will evaluate the models by comparing the performance with respect to the number of labeled examples used for supervised finetuning. A plot of this comparison will elucidate the number of methamphetamine annotations required for model calibration to an individual. We will create a separate plot for each study participant as the ML portion of this protocol tests the personalization of ML models rather than a general-purpose one-size-fits-all ML model, which is more typical in ML evaluations.

Feasibility

Self-supervised pretraining has been successfully demonstrated in several contexts in computer science and even health care [59,63,64], although not in the personalized context that we will explore, except for preliminary results that we have recently published [65-68]. Multimodal SSL has demonstrated success in prior literature [69-72], although not in the personalized manner in which we will innovate.

Ethical Considerations

This protocol was approved by the University of Hawaii Institutional Review Board (protocol #2022-01030). In addition, this study has received further scrutiny and approval from the University of Hawaii Data Governance Process (request #230410-3).

Informed consent will be provided by the participants on paper during the intake session of the study.

Participants will provide information about their substance use on a smartphone app that we have created and will install on the phones of each participant. Because Fitbit is owned by Google, participants' Fitbit data will be uploaded directly to Google's cloud servers, which uses the same level of security as other Google products, such as Gmail.

Access to each participant's Fitbit data on Google's cloud servers is implemented through OAuth, which provides clients with secure delegated access to server resources on behalf of a resource owner (ie, the participants of this study). This mechanism is used by companies such as Amazon, Google, Facebook, Microsoft, and X (X Corp, formerly known as Twitter) to permit the users to share information about their accounts with third-party apps or websites. In this case, the "third party" is the study team.

Access to each participant's annotations of substance use and craving from their smartphone app will be immediately uploaded to our secure and encrypted server on AWS, which is HIPAA compliant [73]. The participant's data will be immediately removed from their smartphone after successful uploading to AWS.

All participant data will be analyzed on AWS. A fully anonymized version of the data set will be released to researchers who sign a data use agreement, which will be approved by the University of Hawaii Data Governance Office.

As a precaution, the interface on the app will not be labeled as "substance consumption" and "substance use" but rather as "banana consumption" and "banana use." Furthermore, our data will be stored and labeled as "fruit" rather than "substance use."

The participant's data that will be accessible to the study team will include biometrics data from Fitbit, labels of "banana consumption" and "banana use" with the corresponding timestamps, and a unique participant ID. Digital data will only contain participant IDs rather than identifiable information. A paper copy of the participant's mapping from the participant ID to the name and contact information will be stored on paper and securely locked in a lockbox hidden in PW's desk. The lockbox in PW's desk is secured with a key that only PW has access to, and his desk is in his office, which is secured with another key that only PW has access to. PW's office is located within a suite of offices, which is secured by a third key that only professors in the Information and Computer Sciences Department have access to and which currently only PW has access to.

We will anonymize all the collected data. We will be provided with a Federal Certificate of Confidentiality from the National Institutes of Health, which will protect participants and assure confidentiality and privacy. KTP, a member of the mentorship and community teams, has found that having a Certificate of Confidentiality helps retain participants in lengthy projects.

Compensation Type and Amount

We will provide the participants with US $135 for participation in the study. This amount is commensurate compensation for the requested work (wearing a smartwatch during all waking hours of the day for 4 weeks while continuously annotating their craving events). In addition, this compensation amount is above the market rate of a Fitbit device, helping to mitigate the risk of device theft by study participants.

US $20 will be provided to the participants to cover their transportation expenses for attending 2 in-person meetings on campus.

Furthermore, we will use snowball sampling as a form of recruitment, where participants can choose to refer their acquaintances to the study. Enrolled participants will be encouraged to refer other eligible participants to the study and will receive US $5 each for up to 3 referrals who enroll. The participants will be given 3 recruitment cards to distribute to eligible participants. When a new and eligible enrollee presents the card, the recruiting participant will receive US $5 compensation. If the recruiting participant has already completed the study, they will be contacted via their assigned study phone number (eg, by phone or SMS text messaging) or email to receive the compensation. If this proves unsuccessful, we will reach out to locator contacts or send a letter notifying the participant that they are eligible for the additional compensation.

Finally, we can compensate participants an extra US $40 as an incentive for providing responses on schedule and consistently throughout the study period.

Results

Starting from November 2023, a total of 5 participants visited our laboratory and received Fitbit devices, including 4 (80%) male individuals and 1 (20%) female individual, aged between 22 and 63 years, representing 3 different ethnicities: 3 (60%) are White, 1 (20%) is Mexican, and 1 (20%) is Filipino Hawaiian.

Among the 5 participants, 178 logs have been collected. They completed an average of 8.6 days of EMA activity reporting, with each participant logging their data approximately 4 times per day. In total, the participants reported 40 instances of substance craving and 61 instances of substance use, including methamphetamine, alcohol, cannabis, and nicotine.

Fitbit devices recorded sensor data, including HR, number of steps, SpO_2, HR variability, and breathing rate. HR and number of steps were tracked throughout the day, whereas SpO_2 level, HR variability, and breathing rate were monitored during sleep.

Challenges related to EMA prompt reception were initially experienced by 1 (20%) of the 5 participants, but these were promptly resolved by the research team. In addition, labor-intensive reporting of simultaneous substance use and documenting of constant nicotine use posed difficulties for this participant. Another participant noted increased awareness of substance-related thoughts owing to EMA prompts.

Discussion

Preliminary Findings

To our knowledge, this is the first study to evaluate the feasibility of using a mobile app–based EMA to prospectively capture substance use among the Native Hawaiian, Filipino, and Pacific Islander population. Despite challenges, this study provides evidence to support the feasibility and acceptability of using EMA methods for collecting data on substance use in this population.

Following our research protocol, we successfully recruited 5 participants for our study in the first month of recruitment. Our research protocol, which included 4 scheduled prompts per day, was designed to represent a lower to moderate participant burden [74,75]. Each participant consistently provided an average of 4 logs per day. We received no significant issues or complaints from the participants, and their logging activities have been continuous. This partially aligns with prior studies by Phillips et al [76], Turner et al [50], and Hanson et al [77], who found that it is feasible and acceptable to use EMA to evaluate substances (eg, alcohol and methamphetamine) with people who come from historically marginalized groups.

Meanwhile, 1 (20%) of the 5 participants showed hesitancy regarding privacy concerns when discussing certain types of substances, as reported in the study by Han et al [78] that substance use can still be associated with social stigma. This suggests that building and maintaining a trusting relationship with the participants throughout the study, and even afterward, is crucial.

Despite concerns raised by Adams et al [79] about the potential impact of busy schedules on response rates, no significant problems were encountered in this regard as long as participants initiated their study. However, instances were experienced in which eligible individuals needed to reschedule their meetings because of their demanding work schedules. To accommodate their availability, the research team maintained a flexible schedule to encourage these individuals to visit the laboratory at their convenience. Weekly check-ins were conducted by the research team with the participants to ensure effective participation and promptly address any issues that arose.

Although prior studies, such as those by Cao et al [80] and Rodrigues et al [81], have successfully used Fitbit devices to collect sleep data, one challenge encountered by the research team is the absence of those data (eg, SpO_2 level, HR variability, and breathing rate) that can only be collected while participants are asleep, despite the participants' claims that they wear the Fitbit devices during sleep. To address this issue, the research team recommended that participants activate the sensitive mode for sleep sensitivity in the Fitbit app settings and ensure that they wear the devices tightly or close enough to their wrists. However, this recommendation might negatively affect the

participants' sleep quality, particularly for those who have self-reported sleeping problems.

This research protocol provides compensation to participants for reporting substance use events. However, this approach might lead to an increase in data noise, as observed when 1 (20%) participant provided 7 logs in a single day. The research team will diligently review these data to ensure their effectiveness and minimize potential noise.

None of the participants have reported participation exhaustion owing to the research protocol so far, despite such findings reported by Yang et al [75] and Semborski et al [82] in their studies. This may be attributed to the fact that many participants are still in their first or second weeks of the study. However, the research team observed that contacting participants >2 times per week could induce stress, particularly when technical issues persist without resolution. In response to these observations, the research team has currently limited their contact with each participant to a maximum of 2 times per week to mitigate participant exhaustion. Future studies may benefit from reducing contact frequency and providing clear and efficient instructions whenever such issues arise. Another issue related to participation fatigue or dropout is the extended waiting time for study entry. Despite the research team's efforts to maintain contact with individuals who registered as early as May 2023, some of them may no longer be available or interested after several months of waiting. Future studies should minimize the waiting period to prevent potential disengagement.

One (20%) of the 5 participants expressed concerns about the increased contemplation of substances when responding to EMA prompts. Similarly, Fridberg et al [74] noted a slight increase in self-reported alcohol consequences in their EMA study. One plausible explanation is that certain EMA protocols may induce stress [82], potentially triggering substance use [83]. This study is in its initial stages and cannot provide any conclusions. The research team will closely monitor this participant and conduct weekly check-ins to ensure that there are no adverse effects.

This study has several limitations. Given the small sample size, the preliminary findings do not have enough statistical power to provide any significant findings on participants' substance use and craving patterns or sociocultural factors that might affect those activities. The EMA prompts primarily collect quantitative data related to the scale, timing, or dates of substance use or cravings, excluding information on social and cultural factors that may trigger or influence substance cravings or use. For instance, we could not capture the presence of others during these moments using EMA prompts. Meanwhile, incorporating these questions into EMA prompts as self-reported data could have imposed cognitive demands on the participants, potentially impacting response rates and causing participation fatigue. To address this limitation, we plan to conduct in-depth semistructured interviews to explore the social and cultural factors.

One (20%) of the 5 participants highlighted the challenge of logging multiple substance use instances simultaneously and recommended the implementation of a more user-friendly feature in such situations. Currently, the research team is actively working to enhance this feature. In future studies, it is advisable to consider providing a more intuitive design when requiring participants to submit multiple logs in a more streamlined manner.

Our target population consisted of Native Hawaiian, Filipino, and Pacific Islander individuals; however, none of the team members belonged to this community, despite some team members having lived in Hawaii for >5 years. To address this limitation, the research team will work closely with the local partners, such as Hawaii Health and Harm Reduction Center and Hina Mauka, to ensure that key social and cultural factors are not overlooked.

Another limitation of our study is the exclusion of potentially eligible individuals who do not own a mobile phone or lack internet access. Future research endeavors could enhance inclusivity by considering the provision of mobile phones with a data plan for individuals who lack these resources.

Conclusions

An EMA using smartphone apps offers a broad scope of research perspectives. Its capacity to capture phenomena instantaneously within real-life contexts grants the EMA a promising vantage point for understanding methamphetamine use and cravings among the Native Hawaiian, Filipino, and Pacific Islander population and other racial groups in Hawaii who have experienced methamphetamine-related disparities from the 1980s. Given the dearth of research on this issue within the targeted, historically marginalized group, sharing and presenting a standardized and innovative protocol for conducting EMA studies on methamphetamine use is crucial, which is the primary objective of this study.

We anticipate that this study will yield valuable insights into the feasibility of using EMA methods in this particular population and the sociocultural factors that can affect precise data acquisition. Furthermore, it will enable the development of personalized AI models for predicting methamphetamine-related behaviors within this demographic group. To date, our preliminary findings indicate promising outcomes associated with the use of EMA methods for data collection.

Abstract

Background: A considerable number of minors in the United States are diagnosed with developmental or psychiatric conditions, potentially influenced by underdiagnosis factors such as cost, distance, and clinician availability. Despite the potential of digital phenotyping tools with machine learning (ML) approaches to expedite diagnoses and enhance diagnostic services for pediatric psychiatric conditions, existing methods face limitations because they use a limited set of social features for prediction tasks and focus on a single binary prediction, resulting in uncertain accuracies.

Objective: This study aims to propose the development of a gamified web system for data collection, followed by a fusion of novel crowdsourcing algorithms with ML behavioral feature extraction approaches to simultaneously predict diagnoses of autism spectrum disorder and attention-deficit/hyperactivity disorder in a precise and specific manner.

Methods: The proposed pipeline will consist of (1) gamified web applications to curate videos of social interactions adaptively based on the needs of the diagnostic system, (2) behavioral feature extraction techniques consisting of automated ML methods and novel crowdsourcing algorithms, and (3) the development of ML models that classify several conditions simultaneously and that adaptively request additional information based on uncertainties about the data.

Results: A preliminary version of the web interface has been implemented, and a prior feature selection method has highlighted a core set of behavioral features that can be targeted through the proposed gamified approach.

Conclusions: The prospect for high reward stems from the possibility of creating the first artificial intelligence–powered tool that can identify complex social behaviors well enough to distinguish conditions with nuanced differentiators such as autism spectrum disorder and attention-deficit/hyperactivity disorder.

Introduction

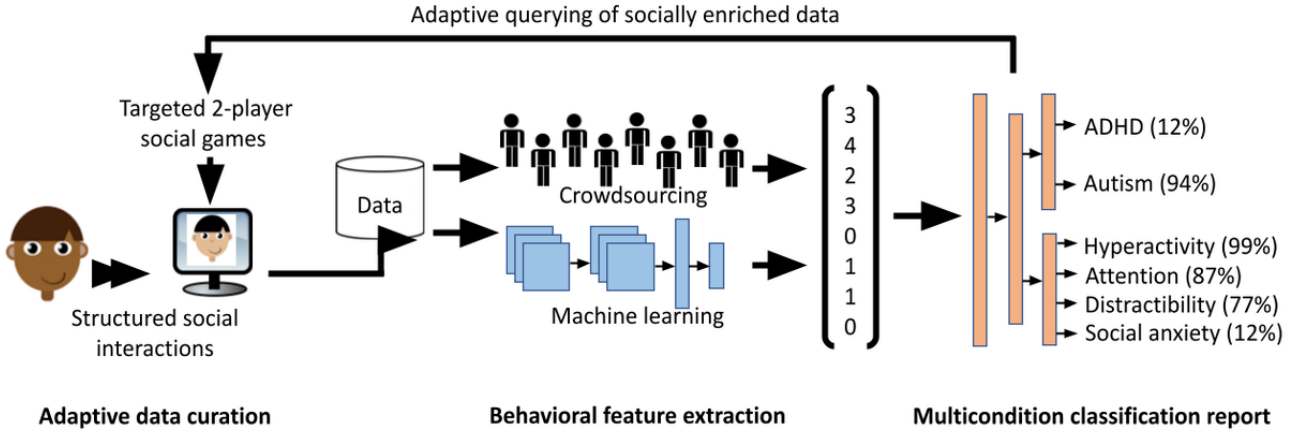
Background

Approximately 17% of minors in the United States aged 3 to 17 years have a diagnosis of ≥1 developmental or psychiatric conditions [1], with the true prevalence likely being higher because of underdiagnosis in rural areas and for minority populations [2]. Unfortunately, timely diagnostic services are inaccessible to a large portion of the United States and global population owing to cost, distance, and clinician availability. Digital phenotyping tools have the potential to shorten the time to diagnosis and bring diagnostic services to more people by enabling accessible evaluations. Although automated machine learning (ML) approaches for the detection of pediatric psychiatric conditions have garnered increased research attention in recent years, existing approaches use a limited set of social features for the prediction task and focus on a single binary prediction.

Many psychiatric conditions affecting adolescents contain overlapping etiologies and phenotypic characteristics. A major difficulty preventing the expansion of computational methods into the simultaneous prediction of multiple related conditions stems from heavy similarities between their phenotypes, creating barriers to achieving specificity and precision. Although some of the key overlapping and distinct features of these conditions are related to behaviors that can be automatically detected with ML methods, such as eye gaze patterns and facial emotion evocation, the majority are too complex for current ML techniques to classify precisely. For example, the degree to which a child enjoys participating in social games and interactions is one of the most salient behavioral features for autism spectrum disorder (ASD) diagnosis [3]. However, building an ML model for behavioral features is infeasible because of outliers and irrelevant, noisy features. These factors contribute to poor data generalization and increase the risk of overfitting. Furthermore, the constraints of existing benchmark data sets, characterized by a limited number of participants, pose challenges for deep learning (DL) models that thrive on substantial, diverse, and representative data to capture complex and nuanced features accurately [4]. By contrast, humans can naturally identify complex and nuanced behaviors by observing their peers. Crowdsourcing, or the use of distributed human workers toward a common goal, has the potential to bridge this gap by enabling rapid feature tagging of complex behaviors on demand. Although crowdsourcing has traditionally been used for public health studies and labeling ML training data, we plan to explore the incorporation of human labels into the feature extraction process. The intuition behind the proposed paradigm is that although nonprofessionals may be unable to directly identify psychiatric diagnoses from videos, many can tag behaviors that are relevant to a diagnosis.

We propose to develop a novel paradigm for accessible and scalable multicondition digital diagnostics of neuropsychiatric conditions by fusing traditional ML with novel human-in-the-loop crowdsourcing approaches. Although this approach (Figure 1) can be applied toward classification between any set of psychiatric conditions, we will focus on attention-deficit/hyperactivity disorder (ADHD) and ASD to maintain feasibility. The approach will comprise (1) developing gamified web applications to curate videos of social interactions adaptively based on needs of the diagnostic system, (2) innovative behavioral feature extraction techniques consisting of automated ML methods and novel crowdsourcing algorithms, and (3) ML models that classify several conditions simultaneously and that adaptively request additional information based on uncertainties about the data. We will collaborate with Dr Dennis Wall, who will provide domain expertise for pediatric developmental delays and methodological guidance for innovative biomedical data science solutions.

Figure 1. Overview of the proposed crowd-powered diagnostic system comprising adaptive gamified data curation, behavioral feature extraction by both crowd workers and computational workflows, and machine learning models for multicondition classification that also output individual symptom estimates and dynamically query participants based on crowd ratings. Each of these 3 major steps is independent yet can be combined to produce a synergistic improvement in remote and accessible diagnostics for pediatric psychiatry. ADHD: attention-deficit/hyperactivity disorder.



The proposed project involves the integration of multiple data modalities for its diagnostic tasks, including from ML and from crowd workers. In our prior work, we have worked with several sources of information such as facial emotion [5,6], body movements [7,8], audio streams [9], and crowd worker ratings [10,11], all of which were used toward the singular goal of digital ASD diagnostics. For this protocol, we hypothesize that the complex and heterogeneous nature of the conditions that

we plan to study requires multimodal data analysis to achieve a clinically acceptable level of performance, and this protocol will involve testing this theory.

Related Work

Psychiatric conditions are widespread globally across demographic groups and geographical boundaries. The prevalence of ADHD is 2.5% in children and 5% in adults [3]. The prevalence of ASD is approximately 1% [3]. Approximately 50% to 70% of individuals diagnosed with ASD also have comorbid ADHD. Access to diagnostics, and therefore care, is limited for populations with low income or large geographic distances from clinicians. Although diagnostic modalities based on biomarkers are promising, they can be inaccessible to underserved populations. By contrast, a large and rapidly expanding portion of the global population has access to digital devices. As psychiatric conditions are fundamentally diagnosed based on behaviors, digital methods to measure behavior have the potential to bring diagnostic services to populations that have been traditionally neglected in health care.

A psychiatrist's diagnostic evaluation process involves identifying ≥1 condition from a large set of possibilities defined by the Diagnostic and Statistical Manual of Mental Disorders, Fifth edition (DSM-5). However, current approaches to digital diagnostics tend to focus on binary predictions. A major bottleneck complicating the pursuit of multiclass psychiatric diagnostics is that behavioral conditions often have overlapping presentations (Table 1), severely complicating the use of purely automated methods.

Table 1. Overlap of a small subset of the core behavioral symptoms of ASD[a] and ADHD[b]. Overlap is determined according to the DSM-5[c] diagnostic criteria [3].

Behavioral symptom	ADHD	ASD
Difficulty with social skills	✓	✓
Concentration issues	✓	
Hyperfixation	✓	✓
Restrictive and repetitive behaviors		✓
High distractibility	✓	
Impulsivity	✓	
Hyperactivity	✓	

[a]ASD: autism spectrum disorder.

[b]ADHD: attention-deficit/hyperactivity disorder.

[c]DSM-5: Diagnostic and Statistical Manual of Mental Disorders, Fifth edition.

In addition, each condition is heterogeneous, and all defining behavioral symptoms do not have to be present to warrant a diagnosis. Psychiatric conditions can either be comorbid (eg, ADHD and ASD) or not (eg, only ADHD or only ASD), creating a diagnosis space that scales combinatorially with each additional condition considered. For feasibility, we will only study 2 conditions to maintain a reasonably sized output space of 4.

The proposed research addresses a critical need in the field of pediatric neuropsychiatric diagnostics, focusing on the challenges posed by the prevalence of developmental and psychiatric conditions among minors in the United States. Current diagnostic practices face limitations in accessibility, particularly concerning cost, distance, and the availability of clinicians [10,12-14]. The *Background* section highlights the potential of digital phenotyping tools to overcome these challenges and expedite the diagnostic process through ML approaches. The field of digital phenotyping is vast and broad. A nonexhaustive list of National Institutes of Health–funded projects for developmental diagnostics includes the work by Guillermo Sapiro (NIH grant number R01MH120093) developing active closed-loop data collection for gaze and motor features for ASD as well as ADHD [15-22], work by James Rehg (NIH grant number R01MH114999) modeling nonverbal communication in atypical and typical development [23,24], work by Robert Schultz (NIH grant number R01MH118327) involving diagnostic computer vision analyses of motor movements displayed in videos of dyadic social interactions involving children with ASD [25], and work by Dennis Wall (NIH grant number R01LM013364) exploring the use of mobile games to acquire computer vision data for DL prediction of individual ASD-related behaviors [26-41].

Previous studies [4,12,42,43] have recognized the potential of ML techniques for detecting pediatric psychiatric conditions. However, a notable limitation of the existing approaches is their reliance on a limited set of social features for prediction tasks, often concentrating on a single binary prediction. For instance, in 2019, Carette et al [12] meticulously analyzed eye-tracking scanpath data using preprocessing procedures such as feature extraction via principal component analysis. The paper delineates comprehensive guidelines for the acquisition of the scanpath image data set. ML models were implemented, including support vector machine, logistic regression, random forest, and artificial neural network with diverse layers. The outcomes underscored the identification of a Childhood Autism Rating Scale score threshold of ≥36 as indicative of severe ASD. Notably, the single-layer artificial neural network model exhibited an improved area under the curve, outperforming support vector machine, which attained 77%. Despite the noteworthy findings, the study conscientiously recognized certain limitations, including a confined participant pool and shorter video scenarios, suggesting avenues for prospective

investigations. This limitation raises concerns about the specificity and precision of these models, particularly when dealing with the overlapping etiologies and phenotypic characteristics inherent in many psychiatric conditions affecting adolescents [44].

The literature [14] underscores the complexity of overlapping psychiatric conditions, such as ADHD and ASD, and the challenges in achieving specificity and precision in their simultaneous prediction. Key behavioral features, such as eye gaze patterns and facial emotion evocation, present opportunities for automated ML methods, but the majority remain too complex for precise classification [10]. For example, a study [45] centered on analyzing eye-tracking image data using a clustering approach with 2 distinct algorithms, K-means and an autoencoder. The findings revealed that 33% of individuals were categorized into cluster 1, indicating the presence of ASD, whereas a higher prevalence of 85% was observed in cluster 2. However, the study lacks clarity on the specific feature extraction technique and parameter settings applied during the clustering process. Therefore, our study introduces a novel paradigm that integrates traditional ML with human-in-the-loop crowdsourcing approaches to address the limitation of feature annotation. The motivation behind this paradigm lies in the belief that although nonprofessionals may struggle to identify psychiatric diagnoses directly, they can effectively tag behaviors relevant to a diagnosis. This shift toward a crowdsourced, human-annotated feature space is a novel approach in the context of pediatric neuropsychiatric diagnostics.

In addition, ML models incorporating both human-annotated and automatically extracted features are hypothesized to outperform models using only 1 type of feature; there is a notable gap in the literature regarding the integration of human-annotated features through crowdsourcing for the specific purpose of enhancing diagnostic accuracy in pediatric psychiatry [4,42,46]. Mauro et al [13] introduced a model to extract sensory features from consumer feedback reviews, considering user preferences and compatibility information. The efficacy of their model was assessed across individuals considered autistic and neurotypical through integration into the recommendation algorithm. However, because the perception of places is inherently subjective, there exists a potential for bias in the feature values derived from explicitly crowdsourced data. Consequently, the authors recommended a comprehensive evaluation of the features through multimodal analysis to enhance the precision and accuracy of the proposed algorithm.

Our proposed research protocol fills a critical gap in the literature by combining automated ML methods with innovative crowdsourcing algorithms, aiming to create a diagnostic system with greater discriminative power than previously achievable in precision psychiatry.

Methods

Overview

In contrast to prior inspirational National Institutes of Health–funded efforts and others like them, we propose an approach to digital phenotyping that expands the possible feature vectors used to classify psychiatric conditions with complex and nuanced social features that only humans can identify using a novel *crowd-powered precision diagnostics* approach. The primary high-risk and high-reward differentiators from prior work are (1) the incorporation of a novel crowdsourcing pipeline into a precision diagnostic system to enable quantification of more complex social features, (2) the adaptive querying of the participant in question within a 2-player game-based system using active learning algorithms that exploit crowdsourced responses, and (3) the differential diagnosis of ASD and ADHD simultaneously. Differentiators (2) and (3) would not be possible without (1). The addition of targeted crowdsourcing into the diagnostic process creates several technical challenges that we will address, including automating the preservation of privacy of participants, efficiently and intelligently quantifying the behavioral feature–tagging ability of crowd workers, and creating algorithms for dynamically assigning workers to new data streams and tasks. Although prior projects have attained successful performances >90% using purely automated DL approaches to differentiate ASD from neurotypical peers [47], our preliminary data show that human-in-the-loop crowdsourced feature tagging of targeted behavioral features results in classification sensitivity, specificity, and accuracy >95%, even when privacy-preserving alternations are made to the video streams [42,48,49]. We hypothesize that incorporating both human observations, which are beyond the current and foreseeable abilities of ML, into the feature extraction process will provide enough social information for automated models to classify each condition using the same video data.

We hypothesize that diagnostic ML models that incorporate both human-annotated features acquired through crowdsourcing (to generate a complex feature space with respect to social human behavior) and automatically extracted features (to provide objectivity when possible) will outperform models that use only automatically extracted features or only human-provided features, as there will likely be nonlinear interactions between features. This complex feature space will allow the classification model to simultaneously distinguish 4 possible outcomes: only ASD, only ADHD, both ASD and ADHD, or neither condition. To support efficient and reliable feature tagging by workers, we will develop novel crowdsourcing algorithms for quantifying the behavioral tagging strengths and weaknesses of each worker. The algorithms will dynamically assign workers to tasks based on their tagging history. We will alter each video to provide privacy protection for the participants while still allowing reliable tagging. To facilitate the acquisition of sufficiently structured data, we will develop a broadly accessible gamified web platform for curating socially enriched video and audio clips in a targeted manner. We will use active learning algorithms to adaptively query for additional data in cases where the presence of a particular symptom is unclear from the current set of ML features and crowdsourced ratings. Each of these innovations (crowdsourcing algorithms, privacy-preserving video alterations, gamified social data capture systems, and active learning algorithms to dynamically query needed data), although useful for the field of precision psychiatry individually, will be combined to create a novel diagnostic system with greater discriminative power than previously possible.

Achieving the precision required to distinguish between ASD, ADHD, both ASD and ADHD, or neither from videos of social interaction using ML at clinically acceptable levels requires a complex social feature space that is not necessarily impossible but highly infeasible with purely automated methods. In contrast, untrained human annotators can identify nuanced social features but are prone to error because of the subjective nature of the task. Combining features extracted by both nonexpert human raters and computational programs can enable precise diagnostics and quantification of behaviors by creating a rich diagnostic feature space. There are several challenges to accomplishing targeted crowdsourcing in a precision health context, which we will address, including privacy preservation, quantifying crowd worker capabilities, and developing algorithms for matchmaking crowd workers with incoming data streams. The rich social feature space provided by crowdsourcing enables improvements to the other aspects of the digital behavioral diagnostics pipeline, including the adaptive assignment of participants to data collection games using active learning crowdsourcing metrics. Although we will focus on ASD and ADHD in particular, the crowd-powered methods we will develop have the potential to benefit diagnostics for any condition primarily evaluated through behavioral observation.

Ethical Considerations

This study has been approved by the University of Hawaii Institutional Review Board (IRB; 2022-00909). We will only collect data from voluntary participants who sign an informed consent (parents) and assent (children) document during the intake session of the study. Participants whose videos will be shared for the 20 crowdsourcing tasks used to filter workers will be contacted by the study team to have a thorough discussion about the planned use of those videos. Workers who are qualified to rate the remaining videos for ≥1 question will be required to complete The Health Insurance Portability and Accountability Act training and The Collaborative Institutional Training Initiative training and will be required to encrypt their laptops using whole disk encryption. These workers will be added to the IRB protocol and will become official members of the study team after thorough training.

Although we will require participants to consent to sharing videos with crowd workers who have undergone thorough training, the clinical translation of this diagnostic system will require a more scalable approach that is sensitive to privacy concerns. We will experiment with privacy-preserving alterations to the curated videos to obfuscate identifiable information from the videos without degrading the feature-tagging performance of workers. Examples include pitch shifting the audio, which will allow workers to understand the content of the speech, and pixelating the video, which will obscure the participant's background and face but would still allow workers to observe body movement patterns. We will measure the extent to which each privacy-preserving mechanism degrades the answers to each question.

We will deidentify the participant data and anonymize any personally identifiable information. All the data will be immediately uploaded to our secure and encrypted server on Amazon Web Services (AWS) [50], which is Health Insurance Portability and Accountability Act–compliant. A fully anonymized version of the data set will be released to researchers only after signing a data use agreement, which will be approved by the University of Hawai'I Data Governance Office.

To ensure that the annotation task is manageable for crowd workers, each 15-minute video will be segmented into five 3-minute clips. During the profiling phase, crowd workers will be compensated US $0.50 per 3-minute video segment rated. Workers who are selected to continue rating videos in the primary portion of the study will be compensated US $0.05 per question answered per video segment, with the opportunity of a bonus of US $0.05 per question if the answer aligns with the clinician ratings for that question. These payment rates are consistent with practices in crowdsourcing research studies in the field of human-computer interaction, and our preliminary studies have shown that the retention rate for this level of compensation is >90% [10,42,49].

Gamified Data Curation

Description

We will develop novel gamified social experiences to curate video data containing diagnostically rich information. Each of these games will impose the structure required to extract salient behavioral features that are comparable across peers. Each game will involve 2 participants interacting on the web application through both the game itself and socially through live video and audio. During gameplay, each participant's camera and microphone will be turned on, and their video and audio will be displayed in a Zoom-style [51] feed to the other participant. The video and audio feeds will be recorded during each session, in addition to keyboard strokes and mouse movements.

Each game will correspond to a subset of targeted behaviors for data capture. The existing literature on "serious games" has documented the usefulness of certain games to capture behaviors related to psychiatric diagnostics, although these games are usually single player. An example is a Go/No-Go game, where the player presses the spacebar in response to a timed "go" prompt in the presence of auditory and visual distractions. This game has been shown to be a reliable estimate of attention, impulsivity, hyperactivity, and executive functioning when recording gaze behavior, response time, and correct reaction rate [52]. We will modify the game so that the "go" prompts are initiated by the social game partner rather than an automated computer, allowing for the capture of socially relevant features. The field of "serious games" for the assessment of psychiatric behaviors is vast, and therefore, we will base all games on previously published literature. However, many behavioral features that we will study will not be tied to a particular game but will rather be observable as a by-product of the social interactions between participants (eg, social anxiety).

One of 7 possible games will be administered each day. A complete list of games and the corresponding behaviors that each game is designed to measure is shown in Table 2.

Table 2. List of previously validated data capture games that have successfully generated data relevant for distinguishing the targeted psychiatric conditions from neurotypical controls.

Game[a]	Targeted behaviors
Go/No-Go [52]	Concentration, impulsivity, hyperactivity, executive functioning, and reaction time
AULA Nesplora [52]	Process speed and motor activity
Plan-It Commander [52]	Planning and organization
Braingame Brian [52]	Working memory, cognition flexibility, and impulsivity
Charades [6]	Emotion evocation and recognition and restrictive and repetitive behaviors
Balloon Popping [53]	Visual motor coordination
Spot The Eyes and Face [53]	Eye contact and face gaze
Free-form conversation[b]	Social anxiety, difficulty with social skills, speech delays, and language narrative

[a]As the games themselves are not central to the innovation of this proposal, details of the gameplay can be found in corresponding references [6,52,53].
[b]Free-form conversation will naturally occur across all games.

The design of the games will be conducted in consultation with a team of practicing clinical psychiatrists at the University of Hawai‘i School of Medicine, including Dr Anthony Guerrero, who is the chair of the Department of Psychiatry and who specializes in digital technologies for pediatric and adolescent psychiatry, as well as Dr Gerald Busch, who is an assistant professor in the Department of Psychiatry and who has experience with digital health solutions for psychiatry.

A minimum of 15 minutes of gameplay will be required each day, although participants may elect to participate for longer. To facilitate consistent data capture across possible computer, microphone, and camera configurations, a pertinent step for enabling comparisons across participants, a calibration program will be developed that will require each participant to align the camera's zoom and their body position before each session. We will extensively test the calibration procedure before the study.

Participant Recruitment and Management

We plan to recruit a total of 400 study participants, comprising 100 individuals formally diagnosed with ADHD, another 100 diagnosed with ASD, a further 100 diagnosed with both ASD and ADHD, and 100 individuals evaluated and confirmed to not have any socially related psychiatric conditions. Our inclusion criteria are as follows: (1) adolescents aged between 14 and 18 (inclusive) years and (2) formally evaluated for ADHD and ASD by a licensed clinician with available documentation. The selection of the final 400 participants that comprise our core data set will be based on the personal information that participants are asked to disclose. Such metadata will be used to ensure a data set that is balanced with respect to race, ethnicity, and gender. The number of participants is based on testing the ability of our system to discriminate between groups of participants. As these groups are balanced, we set the prevalence for binary classification between each condition to 50%. Following a CI of 95%, an estimated theta of 95% [42,48,49], and a width of 15%, the sample size to compute the area under the receiver operating characteristic curve (AUROC) should be 37 [54]. Considering that we have 400 participants, with 100 participants per group, this enables us to follow a common 60:20:20 (train, validation and test ratio respectively) randomized split on the data. That is, we have a sample size (test set) of 40 participants to verify the system's ability to discriminate between the neurotypical participants and the participants who were diagnosed with either ASD, ADHD, or comorbid ASD and ADHD.

Although formal and well-established methods to perform power calculations for ML analyses have yet to be established, most digital diagnostics studies for conditions such as ASD include <100 participants per class in binary classification [47]. We aim to maintain a similar sample size per diagnostic category. The digital social experiences will be delivered to study participants for 15 minutes each day for a 3-week duration, with a single game out of the 7 possible delivered each day. At least 3 distinct 15-minute sessions will be collected per game for each participant, allowing for comparisons across days for analysis of within-peer consistency.

Given the remote delivery of the data collection, a critical challenge will be to ensure that all participants will have a social partner when logging into the study system. The participants will be asked to log in at a particular time each day to be scheduled in advance of the first day of the study. We will host 10 separate time slots and 3 makeup time slots every day of the study, and participants will be automatically matched with a partner during log-in.

Evaluation

We will evaluate the data curation system for (1) compliance of participants with respect to the study procedures during each session and (2) global participation rates. To measure compliance, we will run computer vision face detection algorithms in conjunction with skeletal pose estimation using MediaPipe [55] Python library to ensure that each participant's face, upper torso, and shoulders are fully visible and will calculate the percentage of valid frames across sessions per participant. To measure participation across sessions, we will record the total number of sessions with both participants and the mean session time. In addition to these quantitative analyses, we will run qualitative pilot user studies to understand participants' experiences about the data collection game process, including questions about the entertainment value provided by

the games, the usability of the participant matching and scheduling system, and open-ended feedback.

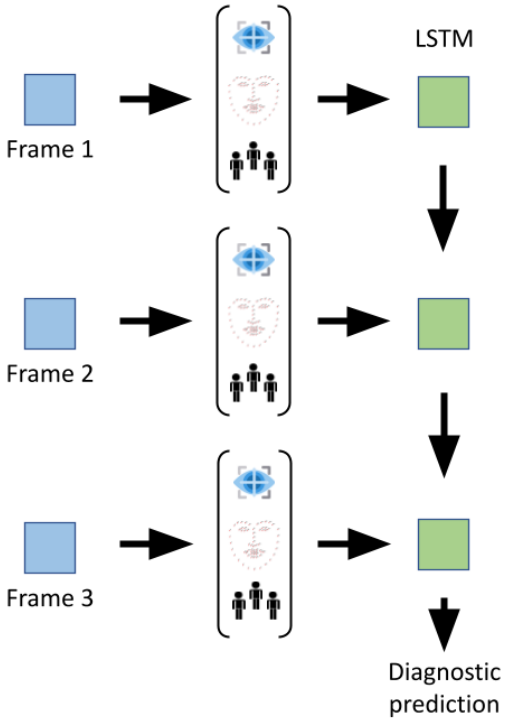
Novel Crowd-Powered and Traditional ML-Based Feature Extraction

Description

We will create 2 pipelines for converting raw video and audio data into interpretable feature vectors that quantify social behavior relevant to ADHD and ASD diagnostics. For behaviors that can be feasibly quantified using computational methods, we will use existing toolkits. For highly complex and nuanced social behaviors that are beyond the scope of current ML tools but that are highly relevant to psychiatric classification, we will use a novel crowdsourcing pipeline to match crowd workers to labeling tasks.

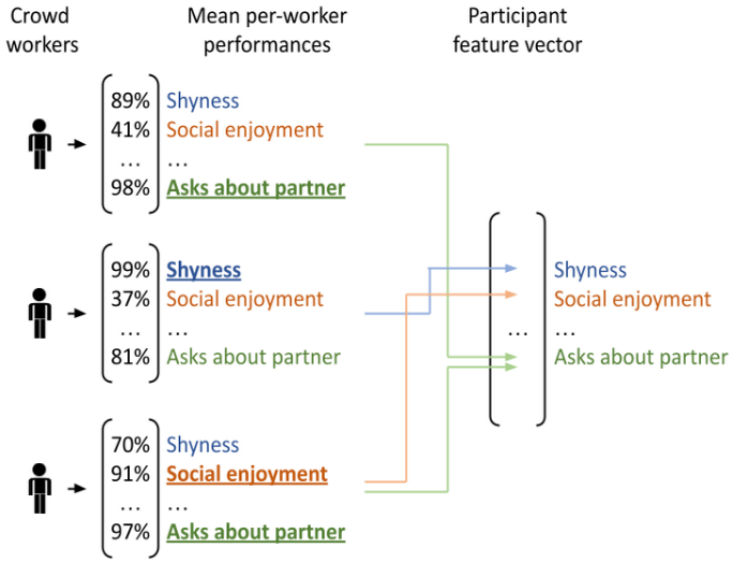
We will perform automatic feature extraction for behaviors potentially related to diagnoses such as the percentage of total conversation time contributed by the participant, eye gaze patterns during the gameplay including the proportion of gaze directed toward the game versus the live video feed of the other participant, vocal prosody and intonation during conversation, natural language processing analysis of the content of the conversation after converting raw audio to text using speech-to-text programs, and breaks in task flow as measured by pauses in game-related keystrokes and mouse movements. The extracted information will be stored for each frame at a sampling rate of 5 frames per second. As depicted in Figure 2, each of these features will be concatenated into a temporal feature vector and used to train a time series DL model such as a long short-term memory recurrent neural network or an attention-based model (eg, transformers). There are existing Python libraries that enable the proposed automatic behavioral feature extraction such as OpenFace [56] and MediaPipe for eye gazing. For facial emotion recognition, we will use Amazon Rekognition [57], an AWS service that provides recognition of disgust, happiness, surprise, anger, confusion, calmness, and sadness in addition to other relevant facial features such as whether the eyes and mouth are open. In the audio domain, pitch will be extracted using the Convolutional Representation for Pitch Estimation library [58], and waveforms will be processed using the librosa library [59].

Figure 2. Feature extraction and quantification of behaviors relevant to neuropsychiatric diagnostics. LSTM: Long Short-Term Memory network.



For complex social features beyond the scope of automated ML-powered computational processing, we will deploy a novel crowdsourcing framework consisting of a crowd worker profiling phase, followed by a study data tagging step. In the first phase, we will post 20 tasks on Amazon Mechanical Turk, each presenting a video acquired through pilot testing of the gamified social data collection platform, followed by a series of multiple-choice questions corresponding to items from the diagnostic criteria for ADHD and ASD, as defined by the DSM-5. Each task will correspond to a separate video, and there will be 4 videos per diagnostic category used to quantify worker abilities. Worker responses will be compared against the Clinical Global Impression gold standard ratings provided by our collaborators in the Department of Psychiatry at the University of Hawai‘i. Crowd workers who align with the ratings of clinical experts on at least 1 behavioral feature, where alignment is defined as <1 categorical ordinal deviation per 2 videos, will be recruited to label the final study data from 400 participants. Recruited workers will only label those features for which their alignment with clinicians was demonstrated during the profiling phase as shown in Figure 3.

Figure 3. Crowd worker assignment to labeling tasks. Each crowd worker will only be asked to label those features for which they agreed with clinicians during a worker profiling step performed before the primary study.



A valuable by-product of this process will be the generation of large behavioral multimedia data sets for ML of complex social features, enabling improved artificial intelligence modeling of human behavior more broadly. With explicit permission from study participants on a per-video basis, we will package and publish the collected data into novel computer vision, audio, and natural language processing data sets for ML. These labeled data sets will be released publicly, providing a stepping stone toward improved automated methods for quantifying complex human behavior.

Evaluation

To assess the effectiveness of the crowdsourcing pipeline, we will compare the performance of crowd workers before and after their recruitment. The preliminary data show that crowd workers who answer similarly to clinicians during filtering continue to perform in a similar manner on new, unseen videos. We will also measure crowdsourcing metrics such as latency to starting a task, interrater reliability, any decline in performance with increased ratings, and the completion rate for all assigned tasks. To evaluate the privacy-preserving mechanisms, we will randomly assign each worker to a single privacy condition per video, only asking them to rate the unaltered videos after the ratings for the privacy condition have been provided. We will measure the mean deviation from clinician answers per privacy condition for each question.

Multicondition Diagnostics With Adaptive Input Querying

Description

We will develop DL models for the multilabel classification of ADHD and ASD, which can emit four possible outcomes: (1) ADHD, (2) ASD, (3) ADHD and ASD, and (4) neither condition. The models will also output the behavioral characteristics that led to the final classification decision by producing the 95% CI of each behavior as derived from both crowd workers and automated computational models. This will involve synthesizing multiple sources of inputs and communicating the result to the end user in a manner that is understandable to the patient or the caregiver. The confidence scores will enable the model to adaptively request more data from the patient and to be specific about which types of data are needed.

To derive an interpretable quantification of each behavioral feature, we will collect clinical categorical ratings of each behavior by licensed psychiatrists at the University of Hawai‘i at Mānoa. We will compensate the psychiatrists for their service and will use the mean of the crowd worker responses as a baseline method for deriving the interpretable quantification of each behavior. Although this method could be sufficient, it is possible that crowd workers have varying levels of rating abilities depending on the qualities of the video and the qualities of the crowd workers themselves. Therefore, we will explore the use of the crowdsourced ratings themselves combined with crowdsourcing metrics derived from worker performance and the computationally generated behavioral features as collective inputs into an ML model for each behavior. Such metrics will include the time spent by each worker providing the annotations for the video, worker rating history for each question, and variability in the worker's answers across videos and within a particular video. It has been previously shown that these crowdsourcing metrics and similar metrics have predictive power in a crowd worker's annotation quality [11]. We will test whether the ML model is a better predictor than the crowdsourced ratings alone. The loss function for the ML model for individual behaviors will optimize with respect to the mean clinician rating per behavior.

To model the multilabel classification problem, we will create separate binary classifiers for ASD and ADHD. Each model will be optimized separately. In comparison with training distinct binary classifiers, a single model trained in a multitask learning setup is able to share parameters between the classification tasks. This helps the model focus on distinguishing features between conditions and has been found to reduce overfitting. We expect that the multitask setting will decrease the number

of false-positive predictions by helping the model recognize features that overlap between conditions.

Using a sigmoid activation function for each independent classifier, the classification system will output a probability score for each diagnostic possibility as well as each of the behaviors defined by the DSM-5, which will be quantified by the system.

Using the output scores of the DL model, an active learning system will be developed that queries for additional data from the user in a targeted manner by suggesting the next game for the participant to play. For each participant, the algorithm will measure the confidence score of each behavioral symptom and produce a list of games for the user to play, sorted by the classifier's mean uncertainty of the behavioral symptoms each game is designed to curate data for. Classifier uncertainty will be measured by the entropy of each classifier's output vector. As neural networks are inherently uncalibrated, we will apply a method published by Kuleshov et al [60] based on isotonic regression to calibrate the probability estimates before measuring uncertainty.

Evaluation

The diagnostic ML model will be evaluated using balanced classification metrics including AUROC, area under the precision-recall curve, balanced accuracy, precision, recall (sensitivity), F_1-score, and specificity. Performance and CIs will be derived through Monte Carlo cross-validation, with each data split consisting of 300 participants in the training set, 50 participants in the validation set, and 50 participants in the test set. All splits will contain a balance with respect to the 5 diagnostic classes, age, gender, race, and ethnicity.

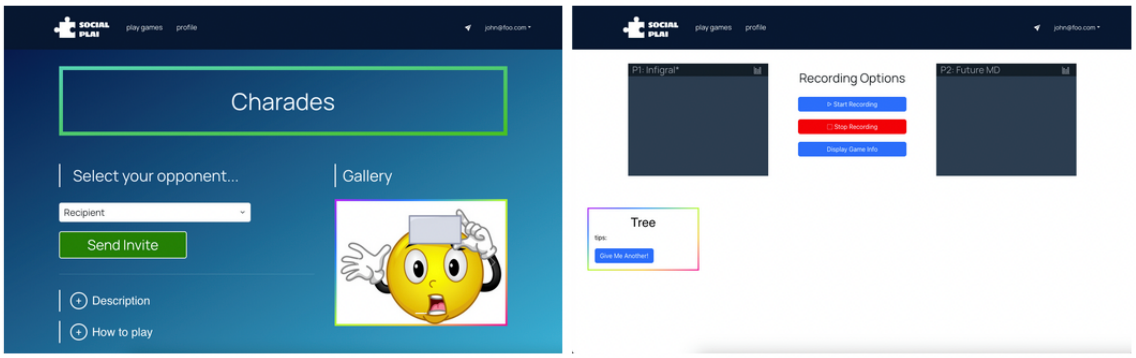
To evaluate the effectiveness of the active learning querying system, we will run post hoc simulations comparing the random selection of new data against targeted requests using active learning. We will train the classification system with 12 sessions of data, hold out the remaining 9 sessions, and plot the performance of each metric against the number of additional samples acquired using both active learning and random selection of data segments.

Results

Gamified Data Curation

A preliminary version of the web interface has been implemented (Figure 4). We are finalizing the features corresponding to video and metadata recording for downstream ML analysis. Over the course of this 5-year study, our objectives are to complete the development of the study's web system by the end of year 1, begin initial recruitment in year 2, and concurrently conduct human-in-the-loop ML analysis while continuing recruitment from years 3 to 5.

Figure 4. Preliminary interface for the study's central web platform. (A) Users who are not a part of the core user study where participant matchmaking occurs can select their game play partner. (B) One of the implemented games, Charades.



Novel Crowd-Powered and Traditional ML-Based Feature Extraction

We have conducted a series of preliminary studies testing the use of crowdsourcing for precision behavioral health, demonstrating that although there is a high degree of variability in crowd workers' innate ability to rate complex social behaviors in unstructured home videos [10], there exists a small fraction of crowd workers on platforms such as Amazon Mechanical Turk who consistently rate in alignment with licensed clinical experts [48,49]. In a study, we demonstrated that a group of 40 crowd workers filtered from an original pool of >1000 workers was able to rate behaviors that, when fed into a classifier trained on clinician records, achieved an AUROC of 0.9904 for one set of features and 0.9872 for another feature set [42]. Our experience of receiving approval from university IRBs and data privacy offices as well as obtaining consent from families to share their videos with crowd workers mitigates any risks related to this novel process.

After applying privacy-preserving modifications to the videos, such as pitch shifting the audio downward and using face detection to box out the child's face, the performance of the model remained >0.95 for both AUROC and area under the precision-recall curve [42]. Although these results show promise for predicting autism in a binary task, they are likely to decline in accuracy when expanding to include ADHD as a diagnosis too. These studies provide strong evidence to support the proposed worker matching procedure, which will enable the more nuanced feature space required for multicondition classification. The prior experience in developing automated

pipelines for managing crowd workers will help streamline the development of the crowd management scripts.

The feasibility of the automatic feature extraction steps comes from the existing packaging of the required functionalities into Python libraries and the high documented performance of these tools. All the ML-powered feature extractors we have used are well documented.

Multicondition Diagnostics With Adaptive Input Querying

In 1 of our preliminary experiments involving 4-way ASD or ADHD classification (only ASD vs only ADHD vs both vs none) using publicly available survey data, a decision tree classifier achieved an F_1-score of 0.75 and Hamming loss of 0.23. The final data set consisted of 270,978 data points and 60 columns, with which we attempted multiple feature selection methods such as recursive feature elimination, decision tree feature importance scores, and logistic regression coefficients to quantify the strength of the relationship between the predictor variables and target variables. Across all 3 methods, the highlighted behavioral features were difficulty in making or keeping friends; difficulty in dressing or bathing; having behavioral problems; having difficulty concentrating, remembering, or making decisions; having anxiety; arguing too much; and sharing ideas or talking about things that really matter. On the basis of these observations, we believe that the games targeting behavioral and motor skills, mentioned in Table 2, can support the research findings and generate relevant data. We will modify the currently implemented games to specifically target these newly identified behavioral features.

The feasibility of DL models relies on the underlying data used to train them. DL has the capacity to learn any discriminative function, provided it has a large enough model and adequate computational power to train a large model. University of Hawai‘i at Mānoa has provided us with a dedicated Nvidia v100 graphics processing unit node and a dedicated Nvidia RTX5000 [61] for computationally intensive research. In addition, the Hawai‘i Data Science Institute has shared computing resources consisting of 346 nodes (8500 cores) with 63.19 terabyte of RAM, 120 graphics processing units, and >1 petabyte of storage. These resources are free to use for University of Hawai‘i laboratories. Collectively, these resources are more than sufficient to train DL models for the proposed data set size.

We have previously trained DL models for making a binary prediction of ASD (Table 3).

Table 3. Preliminary data supporting the use of multimedia data from social games to predict autism spectrum disorder.

Data modality	Prediction performance
Audio	AUROC[a]: 0.815 (0.077 or −0.077)
Facial emotion	Balanced accuracy: 71%
Eye gaze	Recall: 66.2%; precision: 63.5%

[a]AUROC: area under the receiver operating characteristic curve.

Although each of these models used a single data modality (audio, facial emotion expression, or eye gaze), their performances were on par with prior literature [47]. We hypothesize that incorporating additional modalities will not only allow for increased performance within a single class but will also enhance discriminative power across diagnostic categories.

Discussion

Principal Findings

There is a great need for improved, scalable, and accessible diagnostic assessments for neuropsychiatric conditions that require accurate and extensive evaluations. We propose to use a multimodal ML model to study heterogeneous psychiatric conditions through human-in-the-loop computing. Although DL models have been able to successfully classify participants with ASD from their neurotypical peers in prior work, the human-in-the-loop observations can help extract a more nuanced feature subset for the diagnosis of similar yet distinct conditions. We have deployed an initial set of games on the web interface targeting behavioral features, and we have extracted a subset of core behavioral features that aligns with the proposed games and can thus help us to effectively target our digital diagnostic. The crowd worker ratings appear to be of high quality based on our prior studies, aligning with the computationally extracted features and clinician's records, even after the videos are modified. Moreover, the reduced feature subset extracted using preliminary studies from multiclass classification of publicly available survey data has helped us identify the core behavioral features that we intend to target through our gamified approach.

This study aligns with multiple previous works [1,2,5-11,15-41] where the researchers worked with single-modality data to capture the phenotypic behaviors of ASD, ADHD or both. These studies were not only limited by the availability of social features but also by the small size and lack of diversity in the data set [1]. By contrast, our study encompasses several sources of information such as facial emotion, body movements, audio streams, and crowd worker ratings that will improve the predictive capability of the model for comorbid diagnosis and capture the overlapping features. Through this study, we aim to bridge the gap posed by diagnostic and therapeutic challenges in psychiatry using ML techniques. Such noninvasive studies can better use the complex social behaviors to characterize behaviors specific to ASD and ADHD.

The technical aspects of the project are highly feasible, with modest development requirements compared with modern real-time computer gaming systems. The web server will be developed using the Django Python framework [62] and hosted on an Elastic Compute Cloud (EC2) instance [63] on AWS, with extensive existing functionality and documentation existing

for all technologies used. Extensive codes are available on the internet for implementing the video and audio chat features. A full-time developer, an engineering or computer science student, or a postdoctoral researcher can implement the entire system within the span of 4 person-months.

Limitations

Although our initial findings are optimistic, there are some limitations to the study. The primary challenge will be the recruitment and retention of 400 study participants, including the formal clinical validation of the diagnosis for each participant. Although this study can be successfully completed with fewer participants, smaller data sets can affect the model's learning capability, leading to overfitting, noisy outliers, or sample bias. To help manage this recruitment effort, we will hire a full-time clinical research coordinator to recruit and manage the participants. We will work with the clinical collaborators in the Department of Psychiatry to recruit in Hawai i's psychiatric clinics, where our collaborators and their colleagues practice. This will be supplemented with web-based recruitment using targeted advertisements on social media. We have discussed this recruitment plan and desired study size with our collaborators in the Department of Psychiatry, and we hold recurring monthly meetings to strategize about participant recruitment using both our existing access to several clinics in Hawai i and web-based targeted recruitment. In addition, our former mentor and collaborator, Dr Dennis Wall at Stanford University, has access to hundreds of families with adolescent children diagnosed with ASD as well as comorbid ADHD. He is the founder of Cognoa [53,64-69], an artificial intelligence–based digital diagnostic tool for studying early childhood development and pediatric behavior.

There might be technical challenges associated with web applications or user interfaces, which may occur at later stages of the study. The proposed data curation game platform may lack qualities that would garner repeated participant engagement over a 3-week period, such as poor user interface design, poor design of the automated notification system, or poor entertainment quality of the individual games. To mitigate this risk, we will run several iterative design sessions regarding proper implementation of the design process to maximize both user engagement and high-fidelity data collection. We will run several pilot studies to obtain both qualitative and quantitative measures of engagement before running the primary data collection study.

The other potential pitfalls are compliance and tardiness. We will run automated computer vision checks in real time to ensure participant compliance with camera calibration requirements. Another script will send automated text messages and email reminders to late participants, assigning them to makeup sessions. If these mitigation steps fail or if recruitment is unsuccessful and there are <100 participants with valid data per diagnostic category, the study can still be successful with as few as 20 participants per class, as ML studies with approximately 20 participants per diagnostic category have frequently been published in the field [47].

There are also limitations associated with crowdsourcing based on the expertise of the crowd workers or their temporal availability. Although this never occurred during preliminary data collection, a potential pitfall is that some questions may have no workers who consistently rate them in accordance with clinicians. If this occurs, then that question will be removed from any further components of the study (ie, removed as a feature for the diagnostic classifier).

In crowdsourcing, scaling the number of workers does not correlate with the time spent on recruitment. However, to ensure high-quality annotations, we do anticipate spending a considerable amount of time recruiting crowd workers. As mentioned previously, we plan a crowd worker profiling phase based on 20 tasks and data collected through pilot studies with our data-gathering platform. By periodically posing a gold-annotated question and providing a monetary bonus for correctly answering such questions, we incentivize workers to provide high-quality answers. On the basis of our prior studies, we expect that the level of compensation will lead to a worker retention rate of >90%. Furthermore, to account for the loss of workers, we will recruit 3 times more crowd workers than is minimally required for the study. With regard to the number of crowd workers required, we follow the study by Roitero et al [70]. As such, the recommended number of workers will be estimated based on a small amount of data collected during our pilot studies.

When verifying the automatically extracted computational features manually, it is possible that some features will be incorrect. Computational feature extraction approaches are not perfect and are not necessarily robust to unforeseen conditions (eg, dim lighting, obfuscation of certain body parts, and unfamiliar accents). If any feature is consistently unreliable across several participants, then we will remove that feature from the study. There are sufficient features available, so if some do not function as intended, the study can still proceed.

It is possible that the large number of features used to train the DL classification models will be overfitted to the training set, as a data set of 400 samples (of which approximately 300/400, 75% would be in the training set) is relatively small for ML and is unlikely to capture all the intricacies of social behavior that can be expressed with the feature space. If this happens, we will run feature selection and dimensionality reduction algorithms to reduce the number of features used in the model to a minimum viable set and to summarize the feature space in a low-dimensional manner, respectively. The feature selection will enable interrogations into which features are most useful in the differentiation of each condition.

Conclusions

Given the complex nature of neuropsychiatric conditions, ML models can greatly reduce time to diagnosis, for example, by identifying salient information in support of establishing a diagnosis through a low-cost and remote data collection approach. Multimodal data with human-in-the-loop crowdsourcing may improve not only digital diagnostics but also our understanding of the complexity of the conditions. The crowd workers' annotation can also provide data for other computer vision tasks, serving as a promising tool for genetic association, psychological, and kinematic studies.

Acknowledgments

This project is funded by the NIH Director's New Innovator Award (DP2) from the National Institutes of Health (award DP2-EB035858).

Data Availability

The authors intend to create approved subsets of the data that can be shared with other researchers.

Conflicts of Interest

None declared.

Abstract

Background: Liver transplantation (LT) is indicated in patients with severe acute or chronic liver failure for which no other therapy is available. With the increasing number of LTs in recent years, liver centers worldwide must manage their patients according to their clinical situation and the expected waiting time for transplantation. The LT clinic at the Centre hospitalier de l'Université de Montréal (CHUM) is developing a new health care model across the entire continuum of pre-, peri-, and posttransplant care that features patient monitoring by an interdisciplinary team, including an accompanying patient; a digital platform to host a clinical plan; a learning program; and data collection from connected objects.

Objective: This study aims to (1) evaluate the outcomes following the implementation of a patient platform with connected devices and an accompanying patient, (2) identify implementation barriers and facilitators, (3) describe service outcomes in terms of health outcomes and the rates and nature of contact with the accompanying patient, (4) describe patient outcomes, and (5) assess the intervention's cost-effectiveness.

Methods: Six types of participants will be included in the study: (1) patients who received transplants and reached 1 year after transplantation before September 2023 (historical cohort or control group), (2) patients who will receive an LT between December 2023 and November 2024 (prospective cohort/intervention group), (3) relatives of those patients, (4) accompanying patients who have received an LT and are interested in supporting patients who will receive an LT, (5) health care professionals, and (6) decision makers. To describe the study sample and collect data to achieve all the objectives, a series of validated questionnaires,

accompanying patient logbooks, transcripts of interviews and focus groups, and clinical indicators will be collected throughout the study.

Results: In total, 5 (steering, education, clinical-technological, nurse prescription, and accompanying patient) working committees have been established for the study. Recruitment of patients is expected to start in November 2023. All questionnaires and technological platforms have been prepared, and the clinicians, stakeholders, and accompanying patient personnel have been recruited.

Conclusions: The implementation of this model in the trajectory of LT recipients at the CHUM may allow for better monitoring and health of patients undergoing transplantation, ultimately reducing the average length of hospital stay and promoting better use of medical resources. In the event of positive results, this model could be transposed to all transplant units at the CHUM and across Quebec (potentially affecting 888 patients per year) but could also be applied more widely to the monitoring of patients with other chronic diseases. The lessons learned from this project will be shared with decision makers and will serve as a model for other initiatives involving accompanying patients, connected objects, or digital platforms.

Introduction

Background

Liver transplantation (LT) is a surgical procedure to remove a diseased or injured liver that results in liver failure and replaces it with a healthy liver from a donor. LT is indicated in patients with severe acute or chronic liver failure for which no other therapy is available or with hepatocellular carcinoma. Acute liver failure has several causes, including viral (most commonly hepatitis B and C) and drug-induced hepatitis. Chronic liver failure can also have several causes, such as alcoholic liver disease, autoimmune liver disease, and fatty liver disease. LT offers an opportunity to improve not only the health-related quality of life but also the life span of patients living with chronic liver disease and its associated complications.

Liver failure is now the seventh leading cause of death worldwide, with 1.4 million deaths per year. In Europe, >5000 LTs are performed per year, with >140,000 LTs performed over the past 6 years [1] for a European population of 751 million. In the United States, 8906 LTs were performed in 2020 alone, with a total of 24,936 candidates listed for LTs that same year [2]. In Canada, liver failure is the 12th leading cause of death, particularly among the population aged between 25 and 64 years. Cumulative LT activity in Canada has reached 27,488 patients, including 498 transplants from living donors since 1998. In 2020, a total of 565 LTs were reported, with the transplantation rate increasing by 22% over the past 10 years [3]. However, the growing need for LTs also increases the number of candidates on the waiting list, which is greater than the number of viable livers. As a result, the waiting time for transplantations can vary from a few days to >1 year depending on the patient's condition [1].

With the growing number of LTs, liver centers worldwide must manage their patients according to their clinical situation and the expected waiting time for transplants. Moreover, the LT procedure and postoperative period adversely affect the patient's well-being. Therefore, patients should be carefully prepared both physically and mentally to undergo transplantation. Proper management of patients on the waiting list is essential to avoid death or dropout because of deterioration of their condition, as well as to ensure that patients are in the best possible physical, psychological, and social condition before the procedure. These factors are key to the success of the postoperative course [1]. Moreover, the organization of outpatient care is characterized by a certain number of dysfunctions, such as numerous medical consultations with several specialists, which require that patients travel several times to appointments. This is particularly the case with pretransplant assessments, for which patients may need to meet with numerous specialists and undergo several biological, clinical, and imaging tests. These numerous trips put a heavy burden on patients, often resulting in outdated examination results such that patients then have to retake them, unnecessary consultations, and a significant mobilization of caregivers.

However, implementing a model that will meet these requirements is costly and requires the availability of all qualified professionals involved in the LT process. Given the limited human resources in care services, follow-up tools such as mobile apps and web-based platforms may strengthen patient adherence and help empower patients who have undergone transplantation [4]. The mobilization of patients who have undergone transplantation or former patients to provide additional support may also improve patients' motivation and engagement in care [5]. Finally, involving professionals with a mission of health promotion may have an impact on the immediate and long-term health of patients with liver disease. Given this context, the University of Montréal Health Center (*Centre hospitalier de l'Université de Montréal*; CHUM) has decided to implement an innovative health care model to speed up pretransplant assessments, provide interdisciplinary support, and implement social and technological innovations that will enhance patient health.

Aims and Objectives

Drawing on implementation science, this mixed methods pilot study will evaluate the implementation of a new health care model to enhance the clinical condition of patients throughout

their LT experience. In line with the outcome categories proposed for implementation research [6], this study's specific objectives are to (1) quantitatively evaluate the implementation outcomes of a patient platform through connected devices and accompaniment by a former patient (in terms of predefined benchmarks for acceptability, usability, response burden, feasibility [recruitment and retention], and fidelity), (2) identify implementation barriers and facilitators through semistructured interviews with stakeholders, (3) describe service outcomes in terms of health outcomes and the rates and nature of contact with the accompanying patient, (4) describe patient outcomes (based on daily self-reported health data, including symptoms, use of health services beyond the intervention, and patient satisfaction with teleconsultations if received), and (5) assess the cost-effectiveness of the intervention.

Intervention Implementation Strategy

Overview of the Strategy

This study draws on implementation sciences [7] that are intended to foster the adoption or implementation of an intervention. The selected strategies are presented based on the main corresponding implementation phase: preimplementation, implementation, and postimplementation phase. Central to our implementation strategy is our intention to involve patients and stakeholders through various engagement approaches. Our stakeholder engagement strategy is implemented by an interdisciplinary research team that includes not only researchers (MPP, ELR, CB, TP, CV, CR, and MJE), clinicians (CV, AB, GH, and CG), managers (NN and JP), and decision makers (KM and DO) but also patient coresearchers and former patients (FD, LL, and JTL) [8-11]. Our research and intervention development processes are based on a coconstruction methodology that respects the knowledge and responsibility of the stakeholders based on their values, expertise, and perspectives concerning a health condition and its associated care [12,13]. By involving all stakeholders in this project from the outset, we seek not only to detect and address the challenges associated with recruitment, accessibility, acceptability, and the comprehensibility of procedures and instruments [14] but also to enhance the relevance and meaningfulness of our research results [12].

At the CHUM, certain sectors of activity have been prioritized, including the LT clinic, to improve the patient pathway. The LT clinic constitutes a great target for work on a new model of outpatient care as the medical and nonmedical teams are highly motivated; the number of patients is manageable (60 patients undergoing transplants per year); and the clinic offers a platform where it is possible to integrate and coordinate several medical specialties, such as hepatology, nephrology, cardiology, endocrinology, and even psychiatry.

Overview of the Intervention

The proposed intervention is complex; it "comprises multiple interacting components, although additional dimensions of complexity include the difficulty of their implementation and the number of organizational levels they target" [15]. This new health care model is called Transplant'Action Connected in Liver Transplant (TAC) and includes five components implemented before, during, and after LT: (1) clinical team and technical support; (2) a kinesiology-based intervention plan; (3) a nutritional intervention plan; (4) peer support; and (5) the use of a digital platform, including an interface containing the intervention plans with support videos as well as the association of connected objects (COs; ie, a blood pressure monitor, scale, bracelet, and glucometer [if necessary]) to monitor patients' biological variables and physical activity.

Before Transplantation

In the regular care at the CHUM, patients who could potentially benefit from a transplant are assessed by the CHUM's *guichet rapide d'investigation en transplantation du foie* (rapid LT assessment service; GRIT-F), which provides a 1-week pretransplant assessment on an outpatient basis. GRIT-F usually includes a clinical team composed of hepatologists, a pretransplant nurse, and a cardiologist if necessary. Following this assessment, if the results are favorable, the patient is placed on the transplant waiting list. The patient is then monitored exclusively by the hepatologist every 3 months (or more often if the patient presents signs of deterioration). No systematic follow-up by a nurse or other health care professionals (HCPs) is provided during this period.

In the new TAC health care model, the GRIT-F will include additional professionals, such as a kinesiologist, nutritionist, psychologist, cardiologist (if needed), social worker, and accompanying patients. This team assesses not only the patient's clinical situation but also the patient's knowledge and understanding of the disease, living with the disease, the transplant, and drug treatments, as well as their digital literacy. If the patient is placed on the transplant list, the patient benefits from a 1-day individual meeting with the CHUM pretransplant team, consisting of the clinical team (hepatologist, nurse, nutritionist, kinesiologist, and accompanying patient) and the digital health specialist. During this day, an intervention plan is coconstructed with the patient that includes activities to be carried out as well as the fitness and nutritional goals to be achieved. To support them in implementing this intervention plan, the patient receives COs (ie, a blood pressure monitor, scale, bracelet to measure physical activity, and glucometer) as well as access to a digital platform that provides physical exercises and nutritional recommendations. This digital platform tracks the data collected by the COs and provides access to videos. A support plan is also implemented. It includes a follow-up by the transplant nurse every 4 weeks via teleconsultation, by the accompanying patient every month, and by the nutritionist and kinesiologist every month for the first 2 months and upon request thereafter. Technological support is also provided throughout this phase.

During Transplantation

In the regular care provided at the CHUM, the patient is followed by the medical team and the transplant floor nurse and is seen by the pharmacist for medication education. In addition, the services of a physiotherapist and a nutritionist are available on the transplant floor.

In the new TAC health care model, other professionals, such as psychologists, kinesiologists, and nutritionists, will intervene according to the patient's needs. However, the patient who undergoes transplantation continues to benefit from the support

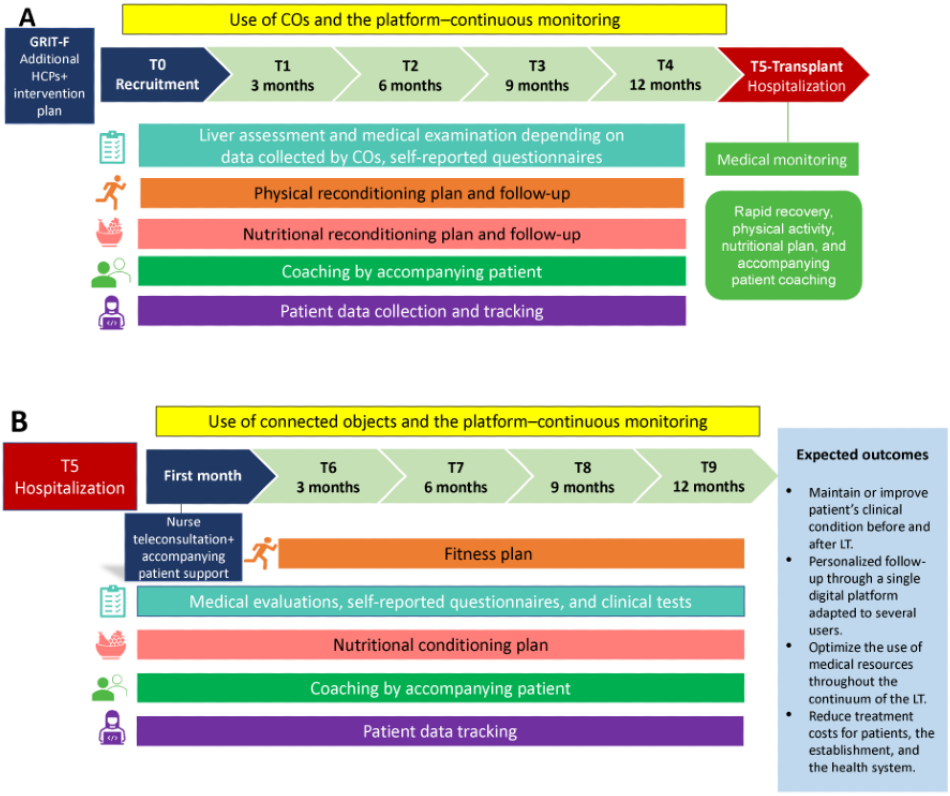
of an accompanying patient. Depending on their clinical condition, the patient can perform kinesiology exercises using a bicycle adapted to the bed. The use of COs during this phase is left to the patient's discretion.

After Transplantation

As part of the regular care at the CHUM, the patient is followed only by the hepatologist and posttransplant follow-up nurse in the months following the transplant.

As part of the new TAC health care model, upon returning home, the patient continues to receive weekly support via videoconference from the nurse and the accompanying patient during the first month and then monthly for 1 year, as well as in-person meetings with the clinical team. The patient resumes the use of COs at any time, and the nutritional plan is adapted as needs emerge. When allowed by the patient's general condition (eg, healing and muscular strength), a new physical exercise plan is proposed in the first 3 to 6 months after transplantation and carried out under the supervision of the kinesiologist and accompanying patient. An overview of the TAC health care model is presented in Figure 1.

Figure 1. Overall view of the intervention indicating key time points for data collection during (A) the pretransplant period and (B) the posttransplant period. CO: connected object; GRIT-F: guichet rapide d'investigation en transplantation du foie (rapid liver transplant assessment service); HCP: health care professional; LT: liver transplant.



Strategies During the Implementation Phase

All the HCPs and accompanying patients will be trained in therapeutic education and motivational interviewing to support the patients throughout their treatment, as well as in the use of the digital platform and COs. The team's role is to provide recommendations on the use of the digital platform, the procedures to follow as part of their intervention plan, the procedures for remote monitoring using the COs, the patient's daily self-assessment, and information on the educational material to be provided to participants through the patient portal.

When patients receive their COs, they will be supported by the digital platform developers and by the CHUM telehealth coordination center. To centralize technical support, the CHUM telehealth coordinator will communicate with the digital platform development team (ML and ECN) to maintain, configure, and update the patient portal for the duration of the project. Regular meetings will be held to discuss the configuration of the digital platform to ensure that it integrates stakeholder recommendations as obtained from engaged HCPs, accompanying patients, and patients. RdP will also be available to provide technical assistance to patients via email throughout the study.

To ensure that the patients' needs are met, the accompanying patients and HCPs will be regularly consulted to obtain their feedback on the proposed procedures for remote monitoring and research material (eg, informed consent documents and all the data collection instruments, including the self-assessment). This will help ensure the relevance, comprehensibility, and comprehensiveness of the results.

To effect cyclical change, MPP is planning 4 prototype tests with engaged HCPs (ie, the clinical team), accompanying patients, and a sample of patients. For each test, the members will receive training on the digital platform; use it for 4 days; and then meet to discuss their experiences, report any problems, and make recommendations. Furthermore, a test is planned of

the patient app portal involving 5 participants to adjust the intervention as required before the project begins with the patients. During that time, all HCPs, accompanying patients, and researchers will be trained on how to use the platform.

Once the platform is ready, patients will be registered to use it. Participants will be guided by a member of the research staff (CV or ME), who will confirm their identity and explain platform functionalities. The remote registration system will send a unique verification code to the user's smartphone with a link to the registration page, where the code will be entered. This is to ensure the security and privacy of patient information.

Strategy During the Postimplementation Phase

Our strategy is to re-examine the implementation phase by analyzing the participants' and stakeholders' views on implementation barriers and facilitators after implementation (based on qualitative interviews).

Methods

Study Design

A single-center pilot study will be conducted following the guidance provided by the CONSORT (Consolidated Standards of Reporting Trials) statement for pilot and feasibility studies [16,17]. It uses a mixed methods embedded design, with quantitative methods to measure the outcome and output and qualitative methods to extend the analysis of the implementation process [18].

Participants

To attain the study objectives, six types of participants will be included in the study: (1) patients who underwent transplantation 2 years before and received regular care (historical cohort or control group); (2) patients who will receive an LT during the next year under the new health care model (prospective cohort/intervention group); (3) relatives of the patients who will receive an LT; (4) accompanying patients who have already received an LT and are interested in supporting patients who will receive an LT; (5) HCPs, including proximity managers; and (6) decision makers.

Eligibility Criteria

Patient Population

All patients selected for an LT at the CHUM who are aged >18 years at the time of registration on the transplant waiting list and are fluent in French or English (written and spoken) will be considered for participation in the study. In addition, patients in the prospective cohort who will receive an LT will have to be able to use COs and remote monitoring platforms. The exclusion criterion for persons in the intervention group is not having a relative who can provide support in their use of the platform and the COs.

Other Population

Persons aged >18 years who are fluent in French or English (written and spoken) and linked to the study will be considered for participation.

Recruitment and Sample

Patient Population (Control Group)

This comprises patients *not exposed* to the new health care model. It consists of a historical cohort focused on the last 50 patients who underwent transplantation and reached 1 year after transplantation before September 2023. They will be identified through the hospital archive department.

Patient and Relative Population (Intervention Group)

This comprises patients (and their relatives) who will receive an LT from December 2023 to November 2024. Knowing that 60 patients receive an LT at the CHUM each year and that it is expected that 80% of these patients will be selected for the research project, we expect that 48 patients will be enrolled. This percentage is an estimate made by the clinical team based on their knowledge of the target population. During the week of the GRIT-F review, the research project will be presented to patients by the accompanying patient and the nurse. On the day that the patient is listed to receive an LT, the research assistant (CV or ME) will meet with the patient to present the project, give the informed consent form, answer their questions, and collect their consent or refusal to participate in the study. Patients who refuse to participate in the study will have the team's support without access to the digital platform and will not have any data collected in addition to what is routinely collected at the clinic.

Accompanying Patients and HCPs

This includes all the persons in these categories involved in patient care.

Decision Makers

This includes all persons involved in facilitating the implementation of the new health care model. It comprises the chairman and chief executive officer, the deputy chairman and chief executive officer, the director of medical affairs or their representative, the director of nursing or their representative, the director of multidisciplinary care or their representative, the director of the Information Technologies and Telecommunications Department or their representative, the director of the Technological Integration and Interoperability Operationalization Centers Department or their representative, the director of the Network Coordination Department or their representative, and the director of research or their representative.

Procedures

Table 1 presents all the study procedures and clinical and output indicators for patient data collection and evaluation to be used in the study. Table 2 details the data collection procedures to be used for accompanying patients, HCPs, and decision makers throughout the study.

Table 1. Clinical and output indicators for patient data collection and evaluation.

Data source and description	Collection time
Clinical examinations	
Hepatic encephalopathy using the Stroop test	Every 3 months (during the medical visit)
Liver Frailty Index	Every 3 months (during the medical visit)
6MWT[a]	During the personal meeting day
Calf circumference	During the personal meeting day
Clavien-Dindo score (eg, presence of infectious complications, presence of wound dehiscence, and revision surgery) [1]	At the end of hospitalization
COs[b]	
Blood pressure	3 times a week
Weight	3 times a week
Capillary glucose (if needed)	3 times a week
Pulse	3 times a week
Number of steps and type of exercise	Continuously (ie, 3 times per day, 7 days per week)
Number of false alerts	Continuously
Number of interventions to solve problems related to COs	Continuously
Replacement of COs because of technological problems	Continuously
Medical records	
Number of medical visits (hepatologist, nephrologist, cardiologist, endocrinologist, psychiatrist, medical specialist in addiction, and dentist; via telephone or in person)	Continuously
Number of nonmedical visits (via telephone or in person)	Continuously
Number of emergency room visits	Continuously
Number of hospitalization days while waiting for the transplant and the reasons for these hospitalizations	Continuously
Number of days between registration on the transplant list and transplant	Continuously
Average length of stay (hospitalization days) for the transplant	At the end of hospitalization
Number of rehospitalizations in the first year after the transplant (average duration, location [eg, intensive care], and reasons for these hospitalizations)	Continuously
Surgical revision	Continuously

[a]6MWT: 6-Minute Walk Test.

[b]CO: connected object.

Table 2. Data collection and procedures for accompanying patients, health care professionals, and decision makers throughout the study.

Data source	Description	Collection time
Accompanying patients		
Documents	• Logbook	Continuously
Questionnaires	• Compassion fatigue risk test [19]	At the beginning and end of the study
Focus group or interview	• Perception of the contribution of the new health care model to follow-up and user experience	At the beginning and end of the study
Health care professionals		
Questionnaires and focus group	• Workplace Ethical Climate Scale [20] • Ability to work with accompanying patients [21] • Contributions of this model of care to improving the patient journey and appropriate use of specialized medical resources+evaluation of technical difficulties and the user-friendliness of the data accessed from medical records	At the beginning and end of the study
Decision makers		
Interview	• Contributions of this model of care and its limits and impact on the service	At the beginning and end of the study

Study Data Collection and Metrics

Platform and Connected Device Implementation Questionnaires

To assess the implementation outcomes (for objective 1), a series of interviews will be conducted 1 and 6 months before the transplant and 6 and 12 months after the transplant. These interviews will include questions on acceptability, response burden, and usability.

To evaluate the effort required to complete the questionnaires and further evaluate acceptability, the perceived response burden measure [22] will be used. It consists of a single question on a 5-point response scale adapted from a survey question from the UK Office for National Statistics.

Usability (the extent to which users can achieve the specific goal of a product) and acceptability (how agreeable, pleasant, or satisfactory the intervention is to the stakeholders [6]) are considered important aspects of implementation outcomes [23]. Both aspects will be assessed using the System Usability Scale questionnaire [24], which consists of 10 items rated on a 5-point Likert scale that are then averaged to produce a total score from 1 to 5. The participants' scores for each question are converted to a new number, added together, and then multiplied by 2.5 to convert the original scores from a scale from 0 to 40 to a scale from 0 to 100. A System Usability Scale score of >68 will indicate that the technology is considered to have an important impact and be useful and easy to use.

Satisfaction with teleconsultations (for objective 4) will be evaluated using the Telemedicine Satisfaction Questionnaire [25], which will be sent to patients after each teleconsultation.

Clinical Questionnaires

To describe the study sample and collect the data needed to achieve the study objectives, a series of validated questionnaires will be completed by all patients. The questionnaires will cover patient characteristics, the assessment of the partnership relationship between patients and professionals (CADICEE) [26], quality of life (SF-6Dv2) [27], the ability to engage in one's own care (PAM) [28], the perception of one's ability to change one's lifestyle habits [29], monitoring of compliance with medication treatments [30], internet-based 24-hour recall (dietary assessment) [31], the Subjective Global Assessment [32], out-of-pocket costs by patients for health care (CoPaQ) [33], and medical visits and consultations. Table 3 presents a summary of the timing and frequency of data collection. The secure internet-based platform REDCap (Research Electronic Data Capture; Vanderbilt University), an application for building and managing web-based surveys and databases, will be used to administer the questionnaires, organize the data collection, and analyze the data.

Table 3. Validated questionnaires for patient data collection and evaluation.

Domain and questionnaire	Dimensions	Number of items	Response scale	Time of measurement
Patient information				
Sociodemographic, medical, and capacity for use of COs[a] questionnaire	• Gender, age group, highest level of education, marital status, native language, ethnicity, and employment status • Medical background, smoking habits, other medical conditions, and chronic diseases (other than chronic liver disease) • Use of COs during a research study in the past	11 items	Varied	T0[b]
Emotional evaluation				
CADICEE questionnaire	• Evaluates the foundations of the partnership relationship between patients and health care professionals • Identifies potential gaps in the partnership	27 items	Varied	T0, T2[c], hospitalization, T7[d], and T9[e]
SF-6Dv2 Health Utility Survey	• Measures of health for QALY[f] calculations • Provides keen insights into patient healing by measuring 6 health domains: physical functioning, role limitations, social functioning, pain, mental health, and vitality	7 items	5-point Likert scale (1=not at all; 5=nearly all the time)	T0, T4[g], T6[h], and T9
Treatment monitoring and lifestyle habits				
PAM-13	• Ascertains the patient's self-reported knowledge, skills, and confidence in the self-management of their health	13 items	4-point Likert scale (1=strongly disagree; 4=strongly agree)	T0, T4, T6, and T9
Monitoring compliance with medication treatments	• Explores the intention or the need for help with current treatment plans	8 items	5-point Likert scale (1=strongly disagree; 5=strongly agree)	T0, T1[i], T2, T4, T6, T7, T8[j], and T9
Financial monitoring				
Out-of-pocket costs of health care for patients (CoPaQ)	• Collects net costs related to the patient's state of health that are not reimbursed by their insurers	33 items	Varied	T0, T1, T2, T4, T6, T7, T8, and T9
Clinical and health condition monitoring				
Online 24-hour recall	• Retrospective method that monitors and assesses an individual's food and drink consumption during the previous day	Electronic interface (images)	Varied	T0, T1, T2, T4, T6, T7, T8, and T9
SGA[k]	• Diagnose malnutrition and identify those who would benefit from nutrition care • History of recent intake, weight change, gastrointestinal symptoms, and a clinical evaluation	Clinical assessment	Varied	T0, T1, T2, T4, T6, T7, T8, and T9
Medical visits and consultations	• Continuous monitoring of medical visits or consultations and the reasons for them	Continuous medical monitoring	Varied	T0, T1, T2, T4, T6, T7, T8, and T9
Hospital care				
Quality of care in hospitalization scale (ESQ-H)	• Self-reported questionnaire with 2 domains measuring patient satisfaction with the quality of medical and nursing care in hospitals • It contains 2 domains: quality of medical information and the relationship with staff and daily routine	18 items	5-point Likert scale (1=poor; 5=excellent)	Hospitalization

[a]CO: connected object.

[b]T0: recruitment.
[c]T2: 6 months after recruitment.
[d]T7: 6 months after transplantation.
[e]T9: 12 months after transplantation.

[g]T4: 12 months after recruitment.
[h]T6: 3 months after transplantation.
[i]T1: 3 months after recruitment.
[j]T8: 9 months after transplantation.
[k]SGA: Subjective Global Assessment.

Clinical Indicators

Clinical indicators will be determined by the physician in charge of the patient or the team's kinesiologist. Among the clinical tests specific to this study, the physician will explore signs of hepatic encephalopathy (ie, deterioration of brain function that occurs in people with severe liver failure) using the Stroop test [34] to assess psychomotor speed and cognitive flexibility by recording the response time to interference between recognizing color fields and writing color names performed at different time points during the study (Table 3). Other clinical tests include the Liver Frailty Index [35], which consists of 3 tests representing 3 major components of the multidimensional construct of frailty in patients with cirrhosis: grip strength, chair stands (muscle weakness), and balance (altered neuromotor coordination). Moreover, the 6-Minute Walk Test (6MWT) [36], which assesses aerobic capacity and endurance, will be performed by the team's kinesiologist during the initial patient assessment (baseline) and every 3 months after the LT. The 6MWT measures the distance covered in 6 minutes (outcome) and will be used to identify changes in performance capacity. In conjunction with the 6MWT, the kinesiologist will also measure calf circumference [37], a representative anthropometric index used to screen for sarcopenia and in patient follow-up to adapt nutritional and exercise plans to meet each patient's needs throughout the posttransplant period. Other clinical indicators will be collected using COs: blood pressure, weight, pulse, number of steps/type of exercise, and capillary glucose (if needed).

In addition, to monitor the platform's reliability, we will look at the number of false alerts, the number of interventions required to solve problems related to COs, and the replacement of COs because of technological problems.

Output indicators will also be collected: number of medical visits (hepatologist, nephrologist, cardiologist, endocrinologist, psychiatrist, medical specialist in addiction, and dentist; via telephone, on the platform, or in person), number of nonmedical visits (via telephone, on the platform, or in person), number of emergency room visits, number of hospitalization days while waiting for the transplant and the reasons for these hospitalizations, number of days between registration on the transplant list and the transplant, number of hospitalization days during the transplant, surgical revisions, and number of hospitalization days after the transplant and the reasons for these hospitalizations.

Accompanying Patient Logbook

All accompanying patients participating in the study will document each of the meetings carried out with the patient in a logbook that will be available to all researchers and medical personnel in the project as well as in the REDCap application. In the logbook, the accompanying patient will provide information about the patient (last name and first name), the context of the meeting (health care facility, date of the meeting, start and end time of the meeting, person who requested the meeting, meeting number, and people present during the meeting), the stage of the patient's trajectory (pre-, peri-, or posttransplant stage), meeting method (in person or remotely and location of the meeting), the themes addressed (general aspects, organizational aspects, consequences on daily and family life, and clinical aspects), the accompanying patient's perceptions of the contribution to the patient and of the relationship with the patient, the difficulties encountered by the accompanying patient, unanswered questions, feedback to the clinical team and planned follow-ups, and any other comments deemed relevant by the accompanying patient. The accompanying patient's logbook can be found in Multimedia Appendix 1.

Coordinator Logbook

The coordinator logbook will capture qualitative and feasibility data that include entries on the following: (1) questions or challenges reported by the participants during consent and baseline educational meetings; (2) details about participant recruitment and fidelity throughout the intervention; (3) the recruitment rate (ie, the proportion of contacted eligible individuals who are included in the study); and (4) the retention rate, defined as the proportion of included participants who are retained over the full follow-up period. Fidelity, or the degree to which the intervention was implemented as intended, will be measured as the proportion of included patients who complete their daily self-assessments over the full follow-up period. The reasons for each of these activities will also be categorized and described based on the detailed information recorded in the coordinator logbook.

Interviews and Focus Groups

All qualitative interviews and focus groups will be conducted individually, preferably in person and, if not, via videoconference or phone. Each interview and focus group will be recorded and follow a semistructured guide with open-ended questions and specific prompts. Although adapted to each stakeholder group, the interview guide includes broad questions on the individual's experience of and thoughts on using the

digital platform follow-up, with prompts on challenges and facilitators [38] as well as open questions to identify information and education needs during the study. The interview guides for each stakeholder group can be found in Multimedia Appendix 2.

With the agreement of patients, accompanying patients, HCPs, managers, and decision makers, all interviews and focus groups will be recorded and transcribed to ensure the reliability of the information collected. The recordings will be transcribed and uploaded into the QDA Miner software (Provalis Research) for further analysis and to identify expected and emerging themes.

Data Analysis

All statistical analyses will be conducted using the R software (R Foundation for Statistical Computing) [39]. For the accompanying patient and coordinator logbooks, descriptive statistics (medians, means, and SDs) will be calculated. Economic analysis will be conducted using the Stata software (StataCorp).

Concerning the various questionnaires, descriptive statistics (medians, means, and SDs), chi-square tests, and 2-tailed *t* tests will be calculated on the populations studied for the sociodemographic characteristics of the patients (eg, age, sex, and characteristics of the care pathway) as well as on all the data obtained at each measurement time (ie, at T0 [assessment to be on the transplant waiting list] and then at 3, 6, 9, and 12 months). Medians, means, and SDs will be calculated for all patients.

For individual nutritional and physical conditioning optimization plans, an analysis will be conducted of the gaps between what was proposed and what was achieved. Statistical analyses will also be used to compare the patient's ability to follow the plan before and after the LT. In addition, multivariate analyses will be conducted based on the intensity of the support provided by the accompanying patients.

For qualitative data, a thematic analysis will be conducted. Coding will be carried out independently by a research agent, students, and the researchers to (1) identify points of convergence and divergence in what is said by the different stakeholders, (2) codify the data using the QDA Miner software to systematize the analysis, (3) build emerging themes, and (4) highlight the convergences and divergences of the intervention.

The quantitative and qualitative data will be compared and analyzed to improve our understanding of the intervention [18]. The barriers and facilitators identified through semistructured interviews with the stakeholders (objective 2) will be used to interpret the findings on patient outcomes, the implementation, and the health services (objectives 1, 3, and 4).

Specific Analysis for Each Objective

Objective 1: To Quantitatively Evaluate the Implementation Outcomes of a Patient Platform With Connected Devices and Accompaniment by a Former Patient

Implementation outcomes will be summarized using descriptive statistics. Acceptability and usability will be evaluated using a linear mixed model for each corresponding outcome. The evaluation of perceived response burden and fidelity will be conducted using a generalized linear mixed model for each corresponding outcome, which is appropriate when the dependent variable is not continuous. For all these calculations, the dependent variable of each model will be the outcome, and the independent variables will be the different time points of data collection (Table 3), 3 sociodemographic variables that are reported to influence patient portal use (gender [man or woman], age [≤50 or ≥50 years], and ethnicity), clinical data from the Stroop test, and the presence or absence of relatives during the transplantation process. The goals of testing each model are to determine whether the outcome's mean score changes significantly over time and whether it differs significantly between the groups represented by the sociodemographic variables over time.

Thus, for acceptability and usability, if at each time point the outcome's mean score is greater than or equal to the predefined success threshold, then the target will be considered met. If it is below the threshold, we will use a unilateral *t* test to test the null hypothesis of threshold attainment as being slightly below this mark does not imply failure given the sample mean's variability. To evaluate threshold attainment during the evaluation of perceived response burden and fidelity, if the observed proportion is under the predefined success threshold, a unilateral *z* test will be conducted as it is appropriate for hypothesis testing with proportions. Finally, an evaluation of feasibility will be conducted by comparing the observed recruitment and retention rates with the predefined success thresholds at the end of the recruitment period and at the 1-year patient follow-up, respectively. If the observed rates are greater than or equal to the success threshold, the target will be considered met. If they are under the success threshold, we will use a unilateral *z* test to test the null hypothesis of threshold attainment.

Objective 2: To Identify Implementation Barriers and Facilitators Based on Semistructured Interviews With Stakeholders

To identify implementation facilitators and barriers and their proposed solutions, 2 analysts will conduct an analysis of the content extracted during the study. The source materials will include semistructured interview and focus group transcripts with the HCPs and the accompanying patients' logbook entries. The analysis will be conducted in three phases [40]: (1) the preparation phase, or the period during which the analysts become familiarized with the data set; (2) the organization phase, when the analysts systematically code the data using the QDA Miner software to identify implementation facilitators and barriers while remaining open to any possible emerging categories; and (3) the reporting phase, which consists of presenting and discussing the identified categories during monthly team meetings with the clinical and research teams to identify discrepancies either in coding or interpretation, ensuring data reliability.

Objective 3: To Describe Service Outcomes in Terms of Health Outcomes and the Rates and Nature of Contact With the Accompanying Patient

A qualitative analysis will be conducted of the patients' health status, including visits to emergency rooms and continuous clinical monitoring as well as the reasons underlying participant contact with the team of HCPs (Table 1). This information will be monitored continuously and extracted from the medical records. Moreover, a content analysis will be conducted to assess the nature of contact with the accompanying patient based on the data collected in the accompanying patient logbooks. In addition, a content analysis will be conducted to assess expectations and experience with the health care model as well as the user experience with the digital platform and COs using data collected during interviews and from discussion groups (Multimedia Appendix 1).

Objective 4: To Describe Patient Outcomes Based on the Daily Self-Reported Health Data, Including Symptoms, Use of Health Services Beyond the Intervention, and Patient Satisfaction With Teleconsultations if Received

Descriptive statistics will be used to report patient outcomes collected from medical records (Table 1), daily health data self-reported through the use of COs, self-reported questionnaires completed throughout the study (Table 3), and patient satisfaction with teleconsultations and tools. For the analysis, each patient constitutes their own reference and comparison. Thus, δ calculations will be conducted, derived by comparing individual questionnaire results with outcomes from the same questionnaires at other time points throughout the study (ie, baseline vs time points before and after transplantation). For continuous outcomes, the mean, SD, minimum, and maximum values will be reported. For ordinal and nominal qualitative outcomes, absolute and relative frequencies (proportions) will be reported. Descriptive statistics will also be presented by gender and age group.

Objective 5: To Assess the Cost-Effectiveness of the Intervention

A cost minimization analysis will be used to meet this objective. The out-of-pocket costs for the patient and the caregiver will be measured using the cost for patient questionnaire, which was developed and validated in Quebec [41,42]. The costs for the health care institution will be measured using the PowerHealth software (PowerHealth Solutions) used at the CHUM, which combines financial data with data in patient clinical files. The costs for the health care system will include the costs borne by the institution, including physician remuneration. To identify these costs, a questionnaire on medical visits and consultations will be sent to the patient every 3 months so that the patient can indicate the number and nature of these events. The *Régie de l'assurance maladie du Québec* pricing manual will then be used to identify these costs.

Ethical Considerations

Approval and Consent

Ethics approval was obtained from the research ethics board at the Centre hospitalier de l'Université de Montréal (CHUM), Quebec, Canada (study ID: 20-5185). The research team and principal investigators at the hospital are responsible for recruitment and monitoring of participants. Any major modifications or protocol deviations are discussed with the other principal investigators during monthly meetings, and any major protocol modifications are reported and submitted to the ethics board for approval. Participants will be approached by the project medical team and then by the research team to inform them about the objectives, benefits, and risks of the research. If the participant is accepted for LT, the research team will meet with the patient and have them sign the consent form.

Safety and Anticipated Risks

There are no direct risks to participants in this study. Data security risks will be addressed through numerous measures, such as copying data to the CHUM Research Centre (CRCHUM) server and protecting them with a user code and password. Moreover, the study questionnaires, semistructured interviews, and accompanying patient logbook sessions may lead to distress related to the transplant procedure or follow-up, the economic details collected, or depression and anxiety explorations. Therefore, these research tasks carry a risk of emotional vulnerability. Individuals who experience psychological distress because of their involvement in the study will be instructed to inform a member of the study staff. Regular psychological assessments or support services will be provided by the team's psychologist throughout the study.

Confidentiality, Data Management, and Cybersecurity

All collected data and personal information will be deidentified (coded) and kept in computer format at the CRCHUM. No identification of individual participants in any images of the manuscripts or supplementary materials will be possible. When the study results are released, participants will not be identifiable. The project's principal investigator (MPP) and coinvestigators will have access to the data and study results. All computer data will be copied to the CRCHUM server and protected by a user code and password. Research data will be retained for 10 years after project closure. The person in charge will be the principal investigator of the study, MPP. To join the scientific community, peer-reviewed scientific publications will be recommended.

Compensation

No financial compensation is offered for participating in this study. However, patients will have access at no cost to all COs and follow-up consultations.

Results

Several study-related activities have already been carried out from July 2022 to October 2023 concerning the intervention implementation, research, and the platform promoter, in addition to funding. Some steps are ongoing.

Implementation Status

To complete the GRIT-F clinical team and strengthen the capacity to monitor patients at the pre-, peri-, and posttransplant stage, a nutritionist, a nurse, a kinesiologist, and a psychologist have been recruited. A total of 5 accompanying patients have

been recruited and, along with the clinical team, trained on their roles and how to work together. A certain number of working committees have also been set up, including the following:

1. A steering committee comprising the physician responsible for the transplant clinic, the nursing comanager, the principal researcher, the 2 research assistants, and 3 accompanying patients. This committee meets every week to oversee the implementation of the project.
2. An education committee was also created in September 2023 to develop the tools needed to carry out the educational assessment, including identification of the patient's LT pathway, and the skills that patients and relatives can develop throughout the LT pathway. This committee also helps identify the resources that can be mobilized to support patients and their relatives and integrate these resources into the life course of the patients on the digital platform. This committee consists of not only the 5 accompanying patients but also all the members of the clinical team, the principal investigator, and representatives of the digital platform, as well as specialists in therapeutic education and health literacy. The committee meets every 15 days.
3. A clinical-technological committee ensures that the development of the platform is aligned with the clinical context and patient experience. This committee comprises the clinical team, accompanying patients, and digital platform representatives. It meets every 2 weeks.
4. A committee on prescriptions and nursing roles has also been set up to develop collective prescriptions to give nurses greater flexibility in their activities.
5. Finally, an accompanying patient community of practice has been formed, bringing together the 5 accompanying patients each week to discuss these practices and react to the research tools intended for them.

Research Status

In total, 2 research assistants and a PhD student have been recruited for ethics monitoring, development of the data collection plan and collection tools, recruitment of participants, and analysis of the data, as well as to ensure adherence to deadlines. This study will be conducted in a tertiary hospital. Written informed consent will be obtained from all participants before any study activities begin. Patient recruitment is expected to start in November 2023. All questionnaires; technological platforms; and clinicians, stakeholders, and accompanying patient personnel have been recruited for this study. The protocol was presented at the Canadian Association for Health Services and Policy Research conference in May 2023. In addition, the researchers will meet monthly to discuss the research plan, including the economic evaluation.

Platform Status

A contract has been signed between a digital platform developer and the CHUM, and 2 members of the company have been specifically designated to the project. Personalized training was offered by the company to all members of the clinical team, the accompanying patients, and the research team.

Funding Status

This study secured funding from the *Institut de la pertinence des actes médicaux* in June 2022.

Discussion

Expected Findings

Through this study, the CHUM LT clinic aims to explore the effects of a new health care model, called TAC, on the patient trajectory in LT. The project will be implemented in three phases: (1) a rapid investigation window model in pretransplant assessment will be developed with the introduction of COs and the mobilization of a kinesiologist, a nutritionist, a pharmacist, 2 nurses, a psychologist, a social worker, a computer technician, and accompanying patients; (2) the model will then be implemented throughout the care pathway, including after transplantation, through the integration of an digital platform that includes not only monitoring via COs but also access to educational material coconstructed with patients; and (3) data from the platform will be integrated into the electronic medical record and the CHUM computerized clinical file. Adjustments will also be made to the digital platform to ensure optimal follow-up with the COs as well as for access to personalized medication and nutritional and physical exercise treatment plans.
