In addition, by predicting depressive symptoms, our study will extend the findings of previous studies since most studies (details in a recent systematic review [43]) in the pervasive health area have developed classification models (eg, to classify depressed and nondepressed individuals) where the complexity of the psychological problem of depression may be lost. For instance, a participant with a PHQ-9 score of 10 has moderate depression [15], and a score of 10 can result from different combinations of the subscores of the 9 symptoms in the PHQ-9. As a result, by classifying participants into a few groups based on the overall score on a scale, it is not possible to precisely determine the depressive symptoms that bother a student. However, it is important to know since each depressive symptom (eg, symptoms in the PHQ-9 [15]) presents a unique phenomenon (eg, anhedonia, sleep disturbance, suicidal ideation) [109]. Therefore, depending on our proposed personalized MTL framework's performance based on real-time data, the proposed app can contribute to early diagnosis of depressive symptoms and precise understanding of a depressed student, which, in turn, may contribute to mitigating depression prevalence.

Our previous pilot studies in Bangladesh on the relation of app usage with depression [35,73] and loneliness [75], classifying depressed and nondepressed students [33] and with and without loneliness [74], showed promising models solely based on resource-insensitive [33] app usage behavioral markers.

Incorporating app usage rhythmic features and also the MTL framework by leveraging the similarities among the symptoms' prediction tasks so that tasks do not hurt one another's performance may help researchers and developers in developing more robust models to predict the symptoms of psychological problems solely through app usage data. In addition, our app's reliance on data retrieved from a smartphone within 1 second [33] may also make it feasible in LMICs since smartphones are more affordable [42] compared to wearables [41] that are usually used to obtain physiological data and extract rhythmic features.

Strengths

The median sample size of previous studies that classified or predicted depression was 58, and none of the studies that developed computational models for prediction tasks had a sample size of over 500, as shown in a recent systematic review [21]. However, we constructed a large data set comprising 2902 students. In addition, the participants of our study are from all 8 divisions of Bangladesh, from both public and private universities and 52 different departments. To the best of our knowledge, this is the largest data set containing data on both app usage and depressive symptoms. Considering these facts, our findings based on the proposed methods may be generalizable, may be robust enough to be impactful in the real world, and may contribute significantly to advancing the knowledge in mobile and pervasive health research areas.

To the best of our knowledge, this will be the first study to explore in depth rhythms based on different app usage behavioral markers, which can create an opportunity to find an alternative source of data to understand the rhythms of daily life without depending on physiological data–based rhythms, which are usually retrieved by costly wearables.

In our recent work based on app usage [33], our developed app had higher performance in predicting depression than the existing systems based on app usage as well. Through feature analysis (for details, please see Ref. [33]), we found that our newly explored behavioral markers (eg, ratio of the hamming distance [33]) were more important than the features used in previous studies. That being said, performance varies depending on the behavioral markers used in a model. Hence, the novel behavioral markers (eg, relative importance of app categories, cousage of apps) we presented in this protocol that were not explored in previous pervasive health research have significance. In addition, to predict depressive symptoms, we will develop a personalized MTL framework. Although an MTL framework has been developed in some previous studies (eg, [65]) to predict a person's mental state, our study will add to this knowledge by showing the performance of a personalized MTL framework.

Limitations

Following previous studies [65,81,82], to analyze rhythms, we have included 2902 participants in this study who had app usage data of at least 2 days and most of whom (n=2849, 98.17%) had app usage data of 7 days. Data of more than 7 days will help us better understand the stability of the rhythms, the rhythm disruption over weeks, and its potential effect on depressive symptoms' appearance. However, we believe our study can work as a primary cursor for future studies to further explore app usage rhythms.

Although our study includes over 2900 students from different divisions of Bangladesh, our proposed app may not be generalizable to every student since behavior varies depending on many factors, such as season, region, [22], and socioeconomic status [23]. We recommend future studies to include participants based on more factors that can impact behavior. Moreover, in our study, although we have included participants from all 8 divisions of Bangladesh, we could not include participants from all 64 districts of the 8 divisions. In addition, including more participants from rural areas could have potential to obtain a more reliable picture of the students' behavior, which, in turn, can be useful to develop a better app.

Conclusion

Predicting depressive symptoms accurately could help in better diagnosis of depression and in taking appropriate steps accordingly. However, existing models regarding symptom prediction are limited by various issues, including low performance (eg, specificity is around or below 60% for most symptoms). Our proposed approach to explore rhythmic features from app usage behavioral markers and the development and validation of the MTL framework through our constructed large-scale data set may provide new insights into rhythms and higher performance in predicting depressive symptoms.

Acknowledgments

This research has been funded by North South University (NSU; ID: NonCTRG-22-26) and the Institute of Advanced Research (IAR; ID: UIU-IAR-01-2022-SE-21) of the United International University (UIU). In addition, the NSU and the IAR (ID: UIU-IAR-01-2022-SE-21) supported publication in *JMIR Research Protocols*. We are grateful to the faculties of universities located in different regions of Bangladesh without whose cordial support, it would not have been possible to conduct this countrywide study. We also thank the participants for their time and willingness to provide data.

Data Availability

Since app usage data are sensitive, making the data publicly available can raise different data privacy and safety concerns (eg, reidentification of the participants [34]). Thus, we do not plan to upload the data to any public data repositories. However, the data can be accessed by sending a reasonable request to the corresponding author.

Conflicts of Interest

Abstract

Background: Ehlers-Danlos syndromes (EDS) are a group of connective tissue disorders caused by fragile lax collagen. Current EDS research lacks racial and ethnic diversity. The lack of diversity may be associated with the complexities of conducting a large international study on an underdiagnosed condition and a lack of EDS health care providers who diagnose and conduct research outside of the United States and Europe. Social media may be the key to recruiting a large diverse EDS sample. However, studies that have used social media to recruit have not been able to recruit diverse samples.

Objective: This study aims to discuss challenges, strategies, outcomes, and lessons learned from using social media to recruit a large sample of females with EDS.

Methods: Recruitment on social media for a cross-sectional survey examining dyspareunia (painful sexual intercourse) in females was examined. Inclusion criteria were (1) older than 18 years of age, (2) assigned female at birth, and (3) diagnosed with EDS. Recruitment took place on Facebook and Twitter (now X), from June 1 to June 25, 2019.

Results: A total of 1178 females with EDS were recruited from Facebook (n=1174) and X (n=4). On Facebook, participants were recruited via support groups. A total of 166 EDS support groups were identified, 104 permitted the principal investigator to join, 90 approved posting, and the survey was posted in 54 groups. Among them, 30 of the support groups posted in were globally focused and not tied to any specific country or region, 21 were for people in the United States, and 3 were for people outside of the United States. Recruitment materials were posted on X with the hashtag #EDS. A total of 1599 people accessed the survey and 1178 people were eligible and consented. The average age of participants was 38.6 (SD 11.7) years. Participants were predominantly White (n=1063, 93%) and non-Hispanic (n=1046, 92%). Participants were recruited from 29 countries, with 900 (79%) from the United States and 124 (11%) from Great Britain.

Conclusions: Our recruitment method was successful at recruiting a large sample. The sample was predominantly White and from North America and Europe. More research needs to be conducted on how to recruit a diverse sample. Areas to investigate may include connecting with more support groups from outside the United States and Europe, researching which platforms are popular in different countries, and translating study materials into different languages. A larger obstacle to recruiting diverse samples may be the lack of health care providers that diagnose EDS outside the United States and Europe, making the pool of potential participants small. There needs to be more health care providers that diagnose and treat EDS in countries that are predominantly made up of people of color as well as research that specifically focuses on these populations.

Introduction

Overview

Ehlers-Danlos syndromes (EDS) are a group of hereditary connective tissue disorders [1]. The overall prevalence and racial and ethnic breakdowns of EDS are unknown [2]. It is estimated that EDS affects between 1 in 5000 [3] and 1 in 3400 [4] and is thought to be underdiagnosed instead of rare [4,5]. Females are diagnosed at a much higher rate than males with 7 females diagnosed for every 3 males [4]. It is unknown if this is due to the difference in presentation between the 2 sexes or how the condition is passed to offspring [6]. The inability to accurately determine the prevalence of EDS makes it difficult for investigators to recruit large diverse samples for studies, limiting the generalizability of results to participants whose demographics match study samples.

Most EDS studies have been comprised of predominately White samples recruited from the United States and Europe. Recruitment has traditionally been done at clinics or hospitals that treat patients with EDS [7], conferences [8-10], local in-person EDS support groups [11], or big data aggregation of national health records [4,12,13]. These recruitment methods limit the diversity of participants. Recruiting via clinics may limit participation to those who are physically and financially able to travel to the clinics; however, access to clinics is improving with the use of telemedicine. Some studies conducted via hospitals or clinics fail to report race or ethnicity demographics in their results [14-18]. Although national health record studies recruit from a large geographic area, to date they have only been completed in small northern European countries with predominantly White populations [4,12,13]. Extracting data from national health records also limits the types of data that can be analyzed to demographics and health care informatics, lacking metrics not included in patients' charts such as symptom burden and personal experiences. Recruiting via EDS conferences includes only participants who are financially able and healthy enough to travel, excluding those who are of low socioeconomic status and the most ill. Furthermore, health care providers who treat and diagnose EDS and EDS researchers are predominantly located in the United States and Europe [19], which likely decreases the number of people diagnosed outside of these regions and, therefore, the number of people who would be eligible to participate in the research. The Ehlers-Danlos Society is an international nonprofit organization that is involved in raising awareness of EDS as well as supporting EDS research through research grants, patient education conferences, and health care provider symposia. The Ehlers-Danlos Society is based in the United Kingdom and the United States and operates in English, which may be a barrier for non-English speaking health care providers and researchers to participate in research and attend symposia. The Ehlers-Danlos Society is based in the United Kingdom and the United States and operates in English, which may be a barrier for health care providers and researchers in non–English-speaking countries for participating in research and attending symposia. However, the Ehlers-Danlos Society is actively trying to connect with or develop a network of EDS providers and researchers in countries where there are few EDS providers such as Japan [20]. Using social media for recruitment may facilitate the recruitment of diverse samples, increasing the generalizability of results to the global EDS population. However, studies conducted since this study in 2019 had similar results with most participants residing in the United States, Canada, the United Kingdom, and Australia [21-23].

Use of Social Media for EDS Study Recruitment

EDS research has started to use social media for recruitment, but no literature has discussed research methods associated with this approach. A benefit of using social media to recruit is that it can reach a global population in a cost-effective manner [24]. Unable to find care for their symptoms and dismissed by health care providers [25,26], people with EDS often turn to support groups on social media to help them find physicians who diagnose and treat EDS, obtain tips about how to manage symptoms, and feel a sense of belonging [26]. The presence of online EDS support groups allows investigators to access groups of people with EDS. Without these support groups, people with EDS would have been difficult to reach due to the relatively low diagnosis rate. Social media lends itself well to recruiting for sensitive topics, such as medical conditions, because it provides a level of anonymity where individuals may be more comfortable disclosing information than if they had provided information in person [24,27].

Purpose

The purpose of this study is to discuss the challenges, strategies, and outcomes of recruiting people with EDS on social media. We will discuss the protocol used to recruit participants for an online survey examining dyspareunia, pain during sexual intercourse, in people with vaginas who have EDS. The methods for this study in particular were chosen because of the successful recruitment of 1178 participants in 4 weeks, which enabled the research team to identify that vulvodynia occurs in half of females with EDS [28]. For this paper, the term EDS will be used to describe people with hypermobile EDS, hypermobility spectrum disorders, as well as other types of EDS. Not all people who have vaginas identify as female and the use of the terms "female" or "women" to describe all people with vaginas is inaccurate. However, for lack of a better term at this time, we will use the term female to describe people in this study.

Methods

Recruitment

We recruited for an open online survey examining dyspareunia in females who had EDS from June 1 to July 7, 2019. The survey, participant screening, and consent were completed on

Qualtrics (Qualtrics). Details of the survey design and findings are reported elsewhere [28]. Inclusion criteria were (1) a self-reported diagnosis of EDS or a hypermobility spectrum disorder previously confirmed by a health care provider, (2) assigned to the female sex at birth and not had genital gender reassignment surgery, (3) 18 years of age or older, and (4) able to read English. The IP addresses were monitored to prevent people from participating more than once.

Ethical Considerations

The study was approved by the University of Illinois Chicago institutional review board (IRB; #2019-0219). Informed consent took place on Qualtrics and involved participants reading a consent form and then selecting whether they agreed and wanted to participate or not. The study data collected were anonymous, and no protected health information or personal identifiers were collected. No compensation was provided for participation.

Social Media Platform Choice

There are 3 basic types of social media platforms—text-based, photo or video-based, and private messaging. The social media quick guide (Table 1) outlines the basic functions and features of the most common social media platforms. Text-based platform posts are centered around text, but images and links can be attached. Image-based platform posts are centered around sharing photos or videos that can include text, but the photo or video is the main part of the post. Private messaging platforms are used to communicate privately between users and cannot be used to post information publicly. Text-based platforms such as Facebook (Meta Platforms) and Twitter (now X; Twitter Inc) facilitate discussion. Facebook works especially well for support groups because of the ability to make groups "private." In private groups, members need to be approved by group administrators to join, group content can only be seen by group members, group content is not searchable via search engines such as Google (Alphabet Inc), and members can be banned for breaking rules. Private groups allow members to discuss sensitive topics with some privacy. X uses hashtags to organize public and private posts. Private posts can only be seen by a user's "friends," people they have identified as knowing. X does not have a group function but instead, information can be searched via hashtags (#). For example, if a user searched for #puppies, all posts that included #puppies in the caption would appear. If a post is private, it would only appear in search results for people who have been identified as friends. Keeping posts private is helpful for discussing sensitive topics but eliminates discussion among members who are not "friends."

Facebook and X were selected for recruitment. Facebook was chosen because of the large number of existing EDS support groups. X was used to explore recruitment on social media via a platform that does not allow group formation. Facebook recruitment protocol and results (Figure 1) outline the recruitment protocol and results used for Facebook.

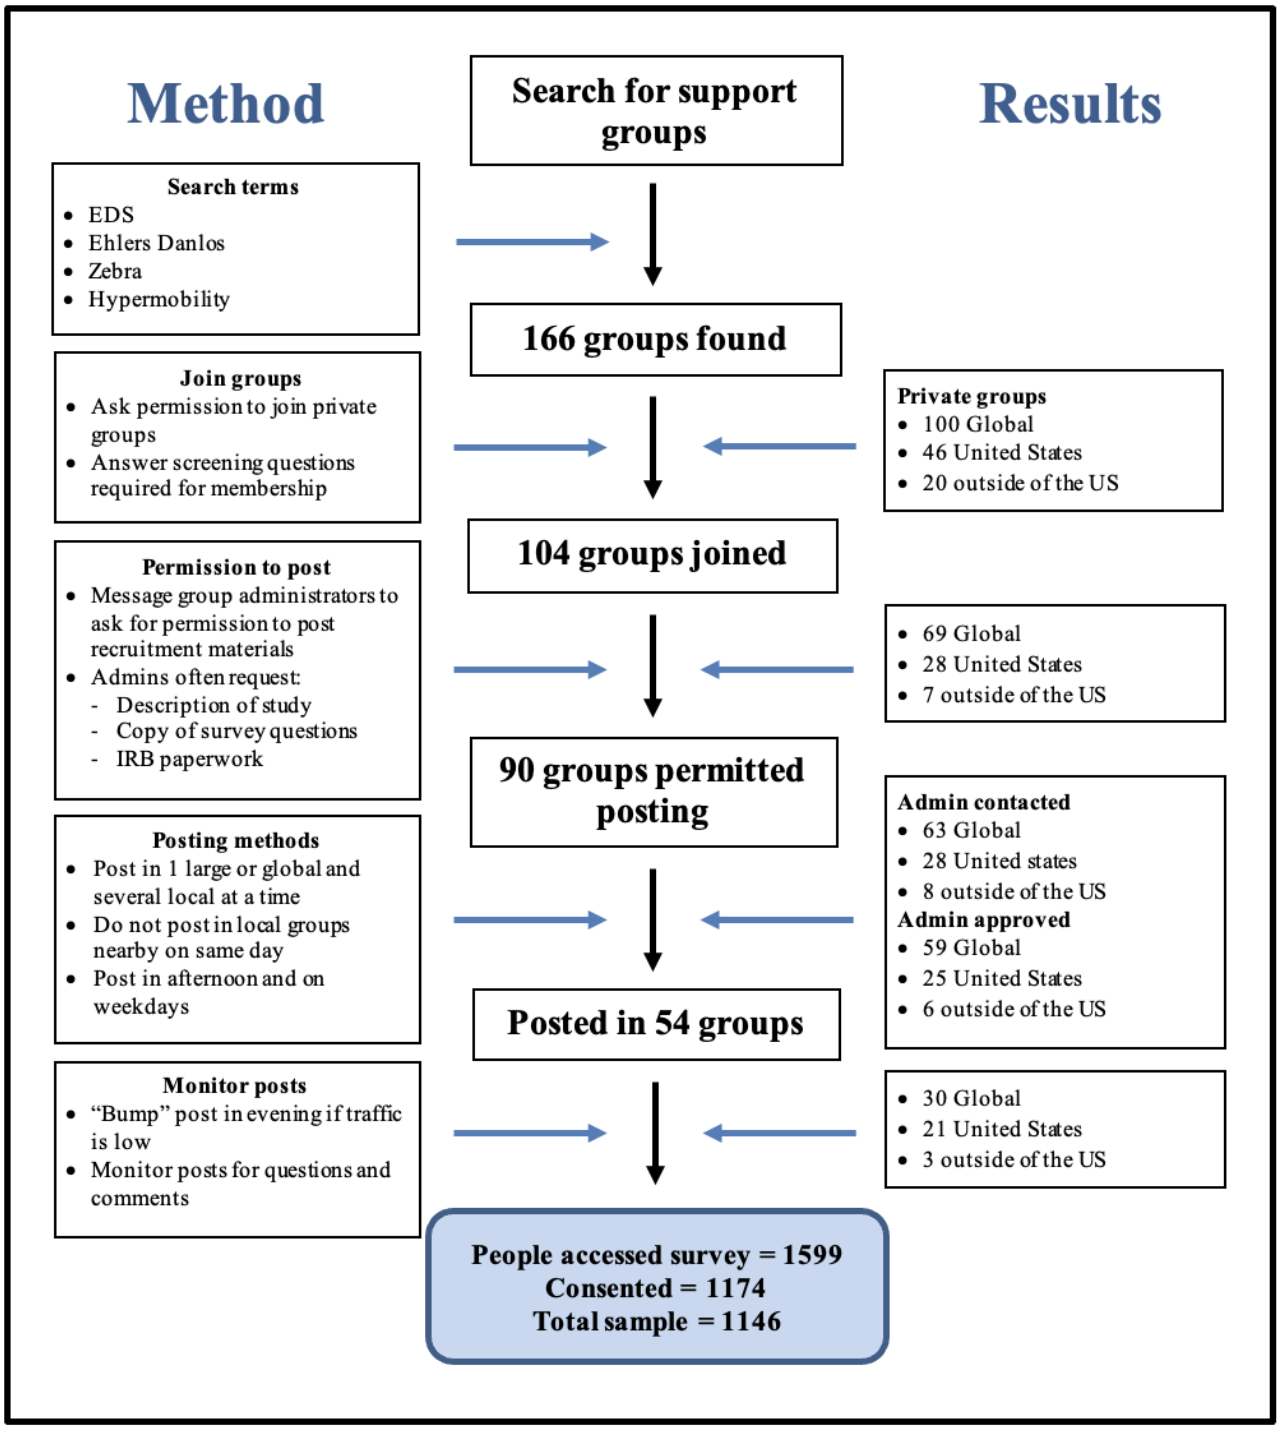
Figure 1. Facebook recruitment protocol and results. EDS: Ehlers-Danlos syndrome; IRB: institutional review board.



Searching for EDS Support Groups in Facebook

Search terms "Ehlers Danlos," "EDS," "Hypermobility," and "Zebra" were used to search for EDS support groups on Facebook. Zebra was used as a search term because it is the mascot for EDS and other rare diseases. Zebra comes from the phrase taught to medical students that if you hear hoof beats think horse and not zebra, as it is more likely to be a horse. When this concept is applied to patients it can cause doctors to miss rare and underdiagnosed diseases such as EDS [29].

Joining EDS Support Groups on Facebook

All support groups the primary investigator (PI) found were private. The PI requested permission to join the private groups. Private Facebook support groups frequently have users answer questions before granting or denying them membership. Groups often require people to have or know someone who has EDS to join. When requesting to join these groups, the PI disclosed that she was a researcher and would like to join the group for the purpose of recruiting for the study. Once the PI joined a group, the administrators of the group were messaged to ask for permission to post the recruitment materials. Messages included information about the PI and the project, and that the

project was approved by an IRB. Although groups did not mandate permission before allowing posting, this approach provided transparency about the PI's motives and helped to build trust between the group and the PI.

Posting Recruitment Material on Facebook

Strategies developed based on previous Facebook use were used to try to reach the most participants possible. Recruitment materials were posted in 3 to 4 groups per day, generally 1 large group of over 1000 members and 3 small groups each with less than 1000 members. Groups in the same geographical area, for example, a Michigan support group and a Great Lakes support group were not posted in on the same day due to the likelihood of membership overlap. Posting recruitment materials in all groups that consented at the same time would limit the visibility of the post to people who were on social media at that time and cause users who are in several groups to see the same post in their feed multiple times and potentially cause them to become annoyed. A feed is like a home page that displays posts from a user's friends and groups of which they are a part. Posts are displayed in chronological order with the newest and most active posts appearing at the top. Active posts are posts that have been commented on or liked. You may comment on your own post to help it move up in a feed; this is called bumping. Posting in different groups over several days will increase the time a post is at the top of a feed for users who are in more than 1 group.

Posting Recruitment Material on X

On X, hashtags related to EDS were searched. Recruitment materials were posted with #EDS by an account specifically made for the study. X posts are limited to 280 characters, requiring a shorter study description than Facebook posts. Prior to posting, the PI interacted with and followed other X accounts related to EDS and pain. X accounts were found by searching for accounts that included search terms in their profile or were included in post hashtags. The same search terms used to search for Facebook support groups were used here. This increased the account's presence and boosted the number of users who would see the posts.

Monitoring Recruitment Posts

All posts on Facebook and X were monitored and any questions or comments were addressed quickly. Responding quickly could keep the post at the top of a user's or group's feed and hopefully address the user's question before they left their social media account and lost interest in participating. Once recruitment goals were met, the PI stopped contacting groups for permission to post and stopped posting recruitment materials.

Statistical Analysis

Recruitment data were analyzed from 3 sources—Facebook search results, Facebook group tracking, and survey response data. Excel (Microsoft Corp) was used to track (1) the name of each group, (2) the size of each group, (3) if permission was given to join the group, (4) who was contacted to ask for permission to post in the group, (5) when the person was contacted, (6) if permission was given to post in the group, and (7) when recruitment materials were posted in the group. Stata Software for Statistics (version 15; StataCorp) was used to analyze descriptive statistics of the search results from the Facebook EDS support groups search. Survey response data were exported from Qualtrics to Excel to be cleaned and then to Stata 15 for analysis. For the original study examining dyspareunia, participants missing key data were not included. For this study, all participants who consented were included. Survey response data were used to analyze participant demographics and their traffic. The traffic of participants was analyzed by calculating the number of participants who accessed the survey during the 6-hour time blocks of 4 AM to 9:59 AM, 10 AM to 3:59 PM, 4 PM to 9:59 PM, and 10 PM to 3:39 AM EST.

Results

Facebook Recruitment

The Facebook recruitment protocol and results (Figure 1) provide the number of groups included in each step of the recruitment process. The EDS support groups search yielded 166 EDS Facebook support groups ranging in size from less than 100 to 33,000. Of the 166 groups found, 104 (63%) gave permission for the PI to join. Common questions asked by group administrators when the PI requested permission to join groups included the following: *Why do you want to join the group?*, *Do you or someone you know have EDS?*, *Do you live in XX city (if the group was focused on a specific geographic area)?*, and *Do you agree to follow the rules of the group?* Group rules often included not taking screenshots of group conversations, not disclosing the identity of members to nonmembers, and no soliciting.

Of the 104 groups that gave permission, 90 (86%) gave permission to post the recruitment materials. Three of the groups that did not permit the PI to join offered to post recruitment materials for the PI. The PI was denied access to post in several groups for cisgendered language in the survey and recruitment materials. These groups preferred the use of specific organs instead of the terms "woman" and "female." Of the 90 groups that gave permission to post, 54 (60%) were posted in before recruitment goals were met. Once the recruitment goals were met posting was stopped by the PI.

When analyzing the data, EDS support groups were divided into 3 categories—global (or no specific geographic location specified); United States for users who resided in the United States (eg, Chicago EDS support group); and outside of the United States for users who resided outside of the United States (eg, Sussex, England EDS support group). The categories of United States and outside of the United States were used because of the high prevalence of US groups and the sparseness of groups from other specific countries. Global groups were separated from the US groups and groups outside of the United States because global groups have different focuses than region-specific groups. Groups specific to a geographic location can be used to help members find local health care providers and members are able to meet in person. Global groups are often focused on broad topics such as comorbid conditions associated with EDS. Global groups were larger in size and more prevalent than the other 2 categories, with 100 global groups found compared to 46 US groups and 20 outside of the US groups. Of the 54 groups in which recruitment materials were posted, 30

(56%) were global groups, 21 (39%) were US groups, and 3 (18%) were outside of the US groups.

User Statistics

There was a total of 110,665 users in the 54 groups posted in; however, this does not take into consideration that users are often members of more than 1 group. The smallest group posted in had 47 members and the largest had 33,170 members. We were unable to calculate a response rate because we were unable to determine how many users saw each post and then accessed the survey. Of the 110,665 people who potentially saw the post, 1599 accessed the survey and 1178 females were eligible, consented, and included in analyses. Of the 1178 consented participants, 1174 were recruited from Facebook and 4 from X. The average age of participants was 38.6 (SD 11.7) years, similar to the average age of participants in big data studies of EDS [4,12,13,30]. Participants were predominantly White (n=1063, 93%), non-Hispanic (n=1046, 92%), and had the most common form of EDS, hypermobile EDS (n=1290,79%) [2]. Participants were recruited from 29 countries with 900 (76%) from the United States and 124 (11%) from Great Britain. The map of the participant's country of residence (Figure 2) shows all the countries from which the participants were recruited. Participant characteristics can be found in the characteristics of the sample (Table 2) [28].

Figure 2. Heat map of countries in which participants reside.

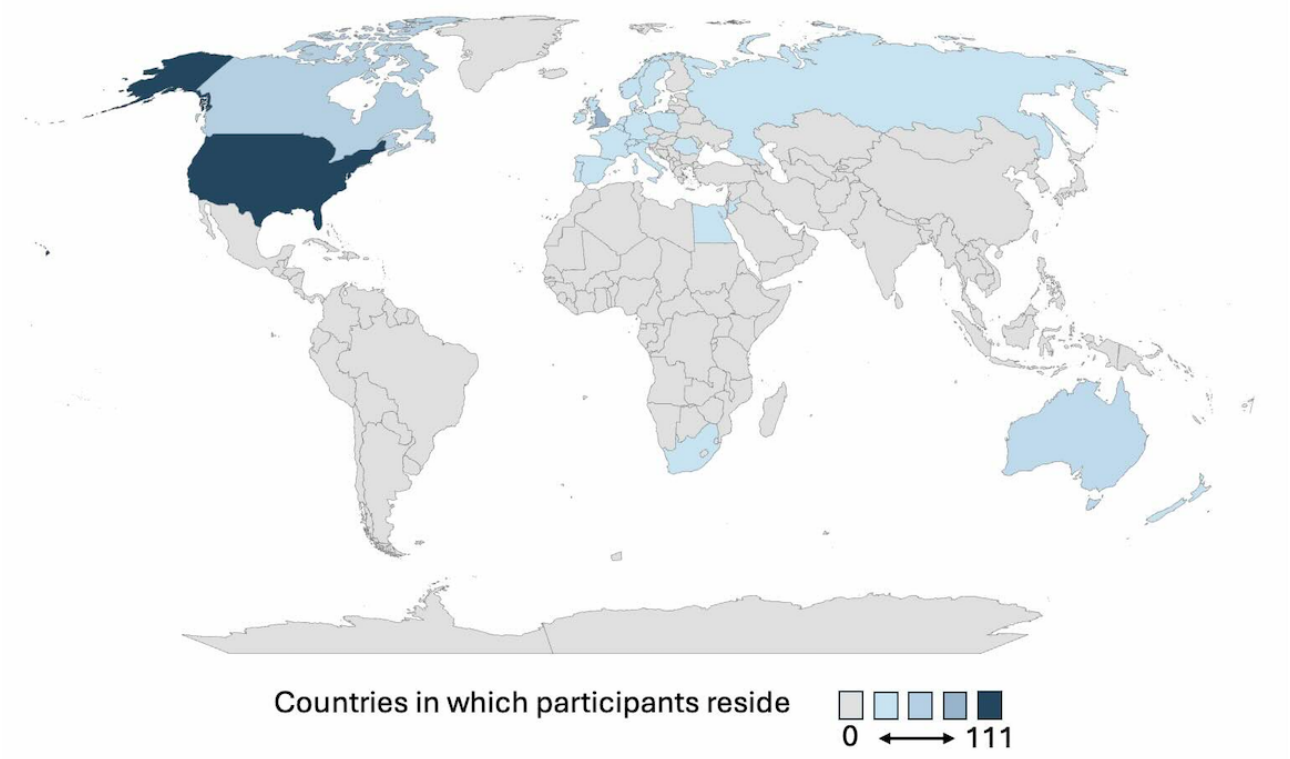


Table 2. Characteristics of the sample (number of females with Ehlers-Danlos syndromes; N=1178) [17].

Demographics	Values
Age (years; n=1141)	
Mean (SD)	38.6 (11.7)
Range	18-76
Sex, n (%)	
Female	1144 (99.8)
Transgender	2 (0.2)
Race[a], n (%)	
White	1063 (92.8)
Black or African American	12 (1.0)
American Indian or Alaskan Native	17 (1.5)
Asian	11 (1.0)
Native Hawaiian or Pacific Islander	3 (0.3)
Other	47 (4.1)
Ethnicity (n=1138), n (%)	
Hispanic or Latino	41 (3.6)
Not Hispanic or Latino	1046 (91.9)
Unknown or not reported	51 (4.5)
Country of residence, n (%)	
Unites States	900 (78.5)
Great Britain	124 (10.8)
Canada	46 (4.0)
Australia	23 (2.0)
Other	66 (5.7)

[a]Participants selected all races they identified with.

Survey Traffic

To examine when participants from different parts of the world accessed the survey and determine optimal posting times for recruiting participants globally, we analyzed what time participants accessed the survey. What time participant accessed the survey was analyzed by time of day and by day of week for the whole sample (N=1178), those residing in North America (n=971), and those residing outside of North America (n=206). The PI posted recruitment materials at different times during the day and night in hopes of recruiting people in different time zones. The North America and non–North America groupings were used for analysis instead of the country of residence due to data sparseness and overlapping time zones of the countries. The busiest time block for recruitment of participants as a whole (n=465, 39%) and among participants in North America (n=411, 42%) was 4 PM to 9:59 PM. Recruitment was busiest from 10 AM to 3:59 PM for participants outside of North America (n=57, 17%). Recruitment of participants outside of North America was more evenly distributed across all time blocks with about 50 participants per time block. The 4 AM to 9:59 AM time block had the least amount of traffic for the whole group (n=130, 11%), participants from North America (n=87, 9%), and participants from outside of North America (n=43, 4%). Monday was the busiest recruitment day for all groups with 301 (25%) participants from the whole sample, 244 (25%) from North America, and 57 (27%) from outside of North America. Saturday through Tuesday were busier than Wednesday through Friday. The day of the week that participants from North America were recruited differed significantly compared to participants from outside of North America (χ^2_6=34.1; P≤.001).

Discussion

Principal Findings

We were able to recruit a large sample in a short amount of time, highlighting the usefulness of using social media, specifically Facebook EDS support groups and X, for recruitment. Our method of recruiting via Facebook can be used to target populations that have access to the internet and use social media. Support groups on social media provide curated groups of people that would otherwise be difficult to find, facilitating recruitment of large groups of participants for rare and underdiagnosed conditions. However, like other EDS studies that recruited via social media, we were not successful at recruiting a diverse sample with our participants being

predominantly from the United States and White. Our results do provide greater detail about the countries participants resided in when they accessed the survey, and their races and ethnicities. Many of the large studies conducted in Northern Europe do not provide demographic details such as race and ethnicity. Providing demographic information is key to assessing the diversity of a sample and evaluate generalizability. Demographic information including race and ethnicity should be included in every study's results. Future directions for research to increase diversity in a sample may include investigators connecting with more support groups from outside of the United States and Europe, use of social media platforms that are popular in other countries, and translating study materials into different languages. More fundamental obstacles potentially include the need for more health care providers that diagnose and treat EDS in countries that are predominantly comprised of people of color, and the need to conduct research that targets these populations.

Challenges That Were Successfully Addressed

Some social media platforms are better than others for recruiting participants. Facebook worked well for recruiting because existing EDS support groups had thousands of members. Posting in these groups allowed the PI to reach many people with EDS with each post. When posting in groups on Facebook, it is easy to see how active a group is based on how frequently people are posting in the group and how many comments and likes the posts receive. Posting in groups on Facebook was chosen over platforms where hashtags (#) are used because these platforms do not have existing groups of people with EDS. On platforms where hashtags are used, the visibility of a post for users is influenced by the number of followers users have. Therefore, for a researcher to reach a lot of people with a post they must create a profile, as well as cultivate a following which can take a fair amount of time. It is also difficult to determine which hashtags are most popular and how people are interacting with hashtags. A better way to share a study on platforms that use hashtags, such as TikTok (ByteDance), is to have existing platform users, with a large group of followers, share the study on their social media page, such as EDS nonprofits.

Our recruitment protocol helped to efficiently keep track of where we were in the recruitment process and within each support group. Documenting the name of each group administrator and when they were contacted allowed the PI to quickly determine what chat conversation was associated with each support group because chats are labeled with users' names and not their affiliated support group. It was also difficult to decide what and when support groups should be posted in. Having the size, where each group was located, and if the group had a specific focus helped determine what groups to post in on a given day. Asking for permission to post recruitment materials in groups was the most labor-intensive aspect of recruitment. On Facebook, messages from users who are not your "friend" are sent to a message request folder that is not easily seen. Typically, when using Facebook Messenger, conversations with "friends" are kept in 1 location and users receive a notification when they receive a new message. This does not happen when a user receives a message from someone who is not a friend. When a message is seen by a recipient in Facebook Messenger, their profile picture appears next to the message. To address the challenge of messages going unseen by group administrators, the PI contacted a different group administrator. Administrators of smaller local groups tended to respond to messages more often and more quickly.

Challenges That Still Need to Be Addressed

Recruiting Participants From Diverse Countries of Residence

Efforts to recruit participants quickly may have led to decisions that decreased the diversity of participants. A total of 21 (45%) of the EDS support groups posted in were US support groups. Anecdotally it seemed easier to recruit from small local EDS support groups because they were more active than global groups, determined by users' engagement such as commenting and liking posts. Support groups that were focused on areas outside of the United States were stricter about allowing people from outside their area to join and post, with 6 (30%) of groups outside of the United States permitting posting compared to 59 (59%) of global groups and 25 (54%) of US groups. Establishing relationships with EDS communities in other countries, to gain permission for research recruitment, may lengthen recruitment. Whether or not establishing these relationships would increase diversity in a sample needs to be assessed. A limitation is that the PI only posted in 3 (50%) of the groups outside of the United States that gave permission before stopping recruiting due to meeting recruitment goals. The decision to post in local US groups over groups based in other countries was based in part on the perception that groups outside of the United States received less traffic. Instead of using groups located outside of the United States, due to perceived low activity, larger more active global groups were targeted. However, it is important to consider that even though a group is global, it may have a large percentage of users from the United States. In the future, global groups and groups outside of the United States should both be a priority for recruiting. It may be beneficial to work with local collaborators, researchers, or advocates who are familiar with the local support groups in their respective countries. Furthermore, social media preferences may differ between countries.

Racial and Ethnic Diversity Within the Sample

Definitions of race and ethnicity vary across the world. This study used the race and ethnicity categories from the US National Institutes of Health with an "other" option added. Identifying racial categories that are used globally and less focused on the United States may make it easier to compare demographics from studies conducted in other countries and may be more inclusive. Our sample was predominately White (n=1063, 93%) The racial and ethnic breakdown of EDS is unknown [2]. In a study looking at EDS diagnoses in hospitalized patients in the United States, 1736 of 2007 (86%) participants were White [30]. However, in the United States, race and ethnicity affect access to care, including receiving an EDS diagnosis and having an inpatient hospital admission, which may cause an overestimation of the percentage of people with EDS who are White. Similarly, there is decreased access to the internet in rural and low-income areas in the United States and abroad. This decreased access disproportionately affects minorities within the United States and people of color abroad,

limiting their participation [31,32]. Big data studies using national health records in predominantly White northern European countries did not report race or ethnicity demographics [4,12,13]. Our high percentage of White participants was likely driven by recruitment from the United States, where structural inequities affect access to care, as well as northern European countries that have predominantly White populations. The lack of access to care and doctors who diagnose EDS outside of North America and Europe [19] likely limits the pool of people from these areas who meet the inclusion criteria of an EDS diagnosis, and therefore, may have impacted the diversity of our study. Similarly, due to the changing terminology for hypermobile EDS and hypermobility spectrum disorders, it is important to include participants with both diagnoses, as a participant's diagnosis may vary based on when or where they were diagnosed, as well as what type of health care provider diagnosed them. There needs to be more health care providers that diagnose and treat EDS in countries that are predominately made up of people of color along with research focused on these specific populations. Research in these groups should be facilitated by members of the EDS community from these groups.

Including LGBTQIA+ Communities

Specific EDS support groups for lesbian, gay, bisexual, transgender, queer or questioning, intersex, asexual, people, as well as those who not listed but identify as part of this community, were targeted for recruitment; however, we were not permitted to post in a few groups because of cisgendered language in our recruitment materials and survey. Facebook EDS support groups preferred the use of gender-neutral language based on the specific organs needed to participate rather than the terms "woman" and "female." To ensure the study is in line with the EDS communities' values and inclusive of nonbinary individuals, researchers should include community representatives in the development of their study.

Limitations

As with other EDS research, our sample was predominately White and from the United States. We were limited by the lack of support groups in countries that were not predominately White. In future research, non-US support groups should receive more focus than US-specific groups. The use of social media platforms likely varies between countries. A wider variety of social media platforms should be explored for use.

The use of social media platforms likely varies between countries. A wider variety of social media platforms should be explored in future research. Additionally, participants were recruited for this survey in 2019, since then there have been many changes in social media including Twitter changing to X and the rise of TikTok. However, the lack of diversity in EDS research persists even as recruitment on social media increases. Identifying recruiting obstacles can help develop methods to overcome them for more diverse and inclusive research.

The survey was conducted without verification of participants' EDS diagnosis and, therefore, may have included people who have not been diagnosed with EDS. For more rigorous and valid results, a participant's EDS diagnosis should be verified; however, this may be difficult via social media. Recruiting via social media may work best for studies that are exploring new areas of research and identifying new phenomena that can then be followed up with more rigorous methods.

During recruitment, an IRB amendment was needed. Until the amendment was approved, recruitment was paused. When recruitment was paused, prospective participants were still able to see recruitment posts, and this caused some confusion. To mitigate confusion, we edited the posts to explain recruitment was temporarily paused. We posted again when recruitment resumed. Commenting on the post that recruitment was live again should have brought the post back up to the top of feeds.

Conclusions

Social media is effective and efficient at recruiting people with EDS for research studies. Text-based platforms that have established EDS support groups such as Facebook are well-suited for recruiting. Specific attention should be paid to recruiting people outside of the United States. Considerations for research on recruitment of participants with EDS include (1) working with local researchers and communities where you wish to recruit from, (2) posting during peak social media traffic time in target areas, and (3) increasing diagnoses and care of patients, which will increase awareness of EDS outside of the United States and Europe. Working with researchers, clinicians, and advocates in areas with support groups outside of the United States may help researchers gain permission to post in groups in these regions and provide guidance on where best to recruit people in their area, as well as ensure survey materials are in line with the EDS community's values. Posting during peak traffic for people outside of North America may help recruit a more global sample. There is still little research on people with EDS outside of the United States and Europe. To engage participants outside of these regions, research materials may need to be translated into other languages. A repository of tools used to evaluate written materials related to EDS in many languages would make it easier for researchers to recruit participants who speak different languages, as well as make results easier to compare across studies. A larger issue may be a lack of EDS providers and researchers in countries outside of the United States and Europe. Research needs to be conducted examining the prevalence of EDS in these areas along with increasing awareness of the condition. Recruiting people with EDS in countries where there are few if any health care providers who diagnose and treat EDS will remain a challenge until awareness of EDS grows and care improves.

Abstract

Background: Chronic abdominal pain is the hallmark symptom of chronic pancreatitis (CP), with 50% to 80% of patients seeking medical attention for pain control. Although several management options are available, outcomes are often disappointing, and opioids remain a mainstay of therapy. Opioid-induced hyperalgesia is a phenomenon resulting in dose escalation, which may occur partly because of the effects of opioids on voltage-gated sodium channels associated with pain. Preclinical observations demonstrate that the combination of an opioid and the antiseizure drug lacosamide diminishes opioid-induced hyperalgesia and improves pain control.

Objective: In this phase 1 trial, we aim to determine the safety, tolerability, and dose-limiting toxicity of adding lacosamide to opioids for the treatment of painful CP and assess the feasibility of performance of a pilot study of adding lacosamide to opioid therapy in patients with CP. As an exploratory aim, we will assess the efficacy of adding lacosamide to opioid therapy in patients with painful CP.

Methods: Using the Bayesian optimal interval design, we will conduct a dose-escalation trial of adding lacosamide to opioid therapy in patients with painful CP enrolled in cohorts of size 3. The initial dose will be 50 mg taken orally twice a day, followed by incremental increases to a maximum dose of 400 mg/day, with lacosamide administered for 7 days at each dose level. Adverse events will be documented according to Common Terminology Criteria for Adverse Events (version 5.0).

Results: As of December 2023, we have currently enrolled 6 participants. The minimum number of participants to be enrolled is 12 with a maximum of 24. We expect to publish the results by March 2025.

Conclusions: This trial will test the feasibility of the study design and provide reassurance regarding the tolerability and safety of opioids in treating painful CP. It is anticipated that lacosamide will prove to be safe and well tolerated, supporting a subsequent phase 2 trial assessing the efficacy of lacosamide+opioid therapy in patients with painful CP, and that lacosamide combined with opiates will lower the opioid dose necessary for pain relief and improve the safety profile of opioid use in treating painful CP.

Introduction

Background

Chronic pancreatitis (CP) is a syndrome characterized by inflammation and progressive architectural destruction of the pancreas. This may result in pancreatic fibrosis with concomitant loss of exocrine and endocrine function, regardless of etiology. The most common symptom of CP is debilitating abdominal pain, which may be constant or flare intermittently. The health care and socioeconomic consequences of CP may be substantial. Notably, painful disease exacerbations often prompt medical evaluation. Patients with constant pain often require daily analgesics for pain relief; further, they may experience disability, subsequent loss of productivity, and frequent need for hospitalization [1].

The treatment of abdominal pain is idiosyncratic and typically based on the skill set of the provider or the resources available at an individual institution. The management of pain in patients with CP has traditionally been based on the assumption that all symptoms have a structural basis. However, in a recent review, it was noted that central sensitization and psychological and social factors are now recognized to potentially contribute to chronic pain, supporting the expansion of therapeutic approaches to include nonstructural behavioral interventions [2]. Although the authors recommended avoidance of chronic opioid use in this patient population, opioids remain a mainstay of therapy at many centers in the United States. However, opioid use may present serious risks, including overdose and opioid use disorder. From 1999 to 2014, >165,000 people died of overdose related to opioid pain medication in the United States [3]. In addition, opioid monotherapy is often insufficient for the management of chronic pain of any etiology. Notably, the single-agent maximum-tolerated dose (MTD) of these drugs may reduce pain by only 25% to 40%, owing to incomplete efficacy, dose-limiting adverse effects, or both. The side effects of opioids, including marked detrimental effects on respiratory, gastrointestinal, and cardiovascular functions, may limit the use of opioid analgesia. In 2016, the Centers for Disease Control and Prevention published a guideline for prescribing opioids for chronic pain, noting that nonpharmacological and nonopioid pharmacological therapies are preferred for chronic pain [4]. If opioids are used, they should be combined with nonpharmacological therapy and nonopioid pharmacological therapy, if possible. Therefore, to minimize side effects, clinicians should prescribe the lowest effective opioid dose. Successful development of an opioid-minimizing strategy would provide clinicians with a new tool to lower the prescribed opioid doses. Studies addressing the efficacy of alternative methods for pain management are necessary. We propose an innovative study and intervention that focuses on the safety and tolerability of a novel combination of narcotic and nonnarcotic approach to pain experienced by patients with CP.

Adjuvant drugs, including antidepressants and anticonvulsants, are often used in combination with opiates for the treatment of pain with modest outcomes. One rather pronounced adverse off-target effect of opioids is an increasing sensitivity to noxious stimuli, even evolving a painful response to previously nonnoxious stimuli (allodynia). This condition is clinically known as opioid-induced hyperalgesia (OIH) [5,6]. The underlying pathophysiology of OIH is complex and may be mediated by central [7-9] or peripheral [10] pathways. An intervention targeted against 1 or more of these mechanisms may potentially limit OIH and lead to improved pain control in patients requiring opioids. On the basis of preclinical published data [11], preliminary studies presented subsequently, and clinical observations [12], we hypothesize that therapeutic targeting of the sodium channel NaV1.7 will improve opioid efficacy for controlling pain in patients with CP. Voltage-gated sodium channels (NaVs) play a key role in the initiation and propagation of action potentials in electrically excitable nociceptive neurons. Specific NaVs in these neurons can be activated by nonclassical opioid receptors [11,13]. This activation and augmentation of NaV-dependent pain sensing appears to counter a few classical opioid effects [14-16]. Therefore, neuronal activation of NaV1.7 could be one of the mechanisms that limit opioid effectiveness [11,13,15,16]. The activation of these channels can be blocked with an existing class of Food and Drug Administration (FDA)–approved antiepileptic seizure drugs that modulate NaVs [11,17-20]. The recent identification of neurobiological mechanisms associated with NaV1.7 and opioid efficacy provide the innovative rationale for this combinatorial opioid adjuvant therapy. The basic drug mechanism is that nonclassical opioid receptors function to increase the NaV1.7 current in nociceptive sensory neurons, leading to drug-induced pain, or OIH. The combination of an opioid and specific antiseizure drugs such as carbamazepine, oxcarbazepine, or lacosamide effectively diminishes the opioid-induced NaV1.7 current [11,13,15]. These preclinical observations in several neuropathic pain-induced injury models lay the foundation for changing the management of chronic pain from empirical symptom control to personalized targeting of specific mechanisms responsible for pain.

Lacosamide is a first-in-class FDA-approved modified amino acid antiepileptic drug that targets NaV1.7. It was approved by the FDA after phase 3 trials as adjunctive and monotherapy in adults with refractory partial epileptic seizures [21]. The mechanism of action of lacosamide is thought to be that it enhances the slow inactivation of NaV1.7 without affecting its fast inactivation [17-20]. Lower concentrations of this drug may also bind to fast-inactivated states in a manner similar to other

antiseizure agents but with slower kinetics of binding and unbinding [20]. Therefore, this means that lacosamide only affects neurons that are depolarized or active for long periods, which is typical of neurons not only at the focus of epilepsy but also central to active pain states. We chose lacosamide as our study drug over other sodium channel inhibitors because it has a favorable side effect profile. Carbamazepine use as an adjunct to opioids is limited by its adverse effects; therefore, the reduced side effect profile of lacosamide may make it a better choice for chronic pain management [22]. In addition, carbamazepine is a well-known inducer of hepatic drug metabolism and therefore may result in a variety of drug interactions that might compromise the efficacy and safety of ongoing therapies. Lacosamide, on the other hand, has minimal interaction with hepatic cytochrome P450 drug-metabolizing enzymes [23]. Lacosamide is a *CYP2C19 substrate* [24]. The drug has a negligible first-pass effect, with a bioavailability of approximately 100%. The maximum lacosamide plasma concentrations occur approximately 1 to 4 hours after oral administration, and the pharmacokinetics of lacosamide are dose proportional. Food intake does not affect its absorption. Notably, *CYP2D6* is responsible for the metabolism of most of the commonly prescribed opiate medications, including codeine, tramadol, hydrocodone, and oxycodone [25]. Furthermore, the *CYP3A4* system regulates the excretion of fentanyl, methadone, and buprenorphine. However, patients receiving methadone will be excluded from participation in Safety, Tolerability, and Dose-Limiting Toxicity of Lacosamide in Patients With Painful Chronic Pancreatitis (STTEPP), as this is a μ-opioid agonist and acts as an antagonist of the N-methyl-D-aspartate (NMDA) receptor [26].

Several studies have evaluated lacosamide as a monotherapy for clinical pain conditions such as fibromyalgia and painful diabetic peripheral neuropathy. Although all studies claimed that lacosamide reduced neuropathic pain and was well tolerated, the outcomes were generally inconclusive and provided only marginal benefits [27-31]. Notably, however, all these studies excluded patients who required opioids for pain control. One clinical case report suggested that chemotherapy-induced painful peripheral neuropathy uncontrolled by opioids alone is accompanied by a dramatic reduction in pain when lacosamide was added to opioid therapy [12]. This provides clinical evidence supporting our rationale for the use of lacosamide in combination with opioids to treat neuron-based symptoms. Therefore, we propose to evaluate lacosamide in conjunction with opioids, which is where evidence consistently shows a benefit. Evidence regarding the effect of lacosamide on NMDA receptor has been shown by its ability to prevent seizures and death in NMDA-induced convulsion test paradigms in mice [32].

Objectives

In this protocol, we will evaluate the safety, tolerability, and dose-limiting toxicity (DLT) of the combination of lacosamide and opioid therapy in patients with CP, as well as the feasibility of the performance of this phase 1 pilot study. The MTD will be determined. Lacosamide, an anticonvulsant that is safe and well tolerated in patients with epileptic seizures, may potentially lower the opioid dose necessary for adequate pain relief in patients with CP. The positive outcomes of this pilot study will then support proceeding with a phase 2 efficacy trial assessing the ability of opioid adjuvants to alleviate abdominal pain in this difficult patient population. In addition, we believe that this combination therapy will serve to significantly enhance the safety profile of opioid use in these patients.

Methods

Study Organization

The Consortium for the Study of Chronic Pancreatitis, Diabetes, and Pancreatic Cancer (CPDPC) has been tasked by the National Institutes of Health (NIH) with the comprehensive clinical, epidemiological, and biological characterization of patients with CP to develop treatments and gain insight into the pathophysiology of CP and its sequelae, including chronic pain, pancreatic exocrine and endocrine insufficiency, and diabetes pancreatic cancer association [33]. All participating clinical centers in the STTEPP trial are CPDPC members and are contributing to a longitudinal cohort study called *Prospective Evaluation of Chronic Pancreatitis for Epidemiologic and Translational Studies* (PROCEED) [34], the first prospective cohort study of pancreatitis in the United States. STTEPP was funded by the National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK; R01DK132709) in April 2022 as a multi-institutional prospective ancillary study within the CPDPC. MD Anderson Cancer Center, University of Texas, will serve as the data coordinating center for STTEPP, and the Institutional Review Board (IRB) at MD Anderson will serve as the single-center IRB for this study. The goal of this clinical research study is to determine whether adding the antiseizure medication lacosamide to opioid pain medications will help in managing chronic, ongoing abdominal pain symptoms caused by CP. The safety of this drug combination will also be studied. This is an investigational study.

Lacosamide

Lacosamide is a Schedule V controlled substance approved by the FDA for the management of seizure disorders. A controlled substance is a drug or other substance that is tightly controlled by the government, because it may be abused or cause addiction. All controlled substances in the United States are classified into 5 schedules. Schedule V drugs, including lacosamide, have the lowest potential for misuse and addiction compared with those in other schedules. Although it has been used off-label to treat pain resulting from nervous system damage, this medication is not FDA approved for the management of abdominal pain. Currently, it is being used to treat abdominal pain for research only. There may or may not be benefits for participants in this study. The participant will be closely followed by a study coordinator and site investigator during participation. Although the actual drug therapy will only last for 7 days, the participant may experience improved control of their abdominal pain symptoms during the study. Future patients may also benefit from what is learned in this study.

Ethical Considerations

This study protocol was approved by the University of Texas MD Anderson Cancer Center Institutional Review Board (IRB

ID 2021-1197). Informed consent was obtained from all participants or their legal guardians. All methods were performed in accordance with relevant guidelines and regulations.

Participation is completely voluntary. Before choosing to participate in this study, participants should discuss any concerns they may have with the study team, including side effects, potential expenses, and time commitment. The participant can read the full list of potential side effects in the *Possible Risks* section of the consent form.

The participant may choose not to take part in this study, and they do not have to participate. They may withdraw from the study at any time. The participant has the right to choose whether to participate in this research study. They may decide to stop participating in the study once they have started. Leaving the study early will not result in any loss of benefits that they already have. Instead of participating in this study, they may choose to continue with their current medications and plan of care.

Study Details

Who Is Eligible to Take Part in the Study?

Patients with ongoing chronic abdominal pain related to CP, even with opioid pain medication treatment, were asked to participate in the study.

How Many Participants Are Expected to Take Part in the Study?

Approximately 24 participants will participate in this multicenter study from approximately 5 institutions. Up to 10 participants will be enrolled at Indiana University.

How Long Will the Participation Be? How Long Will It Take to Complete the Study?

If the patient decides to take part in this study, they will complete a screening visit in person to determine if they qualify for enrollment. This visit will take approximately 30 to 60 minutes. After the screening visit, participation will involve an in-person visit that will last 60 minutes. The participant will be asked to take the study medication (provided at no cost) for the 7 days of participating in the study. The participant will also keep a medication diary to confirm when and how they take the study medications and their pain medications. The final study visit will be an in-person follow-up visit on day 8, lasting approximately 60 minutes. The study team will collect medical history and clinical information, draw blood samples, and ask the patient to complete the visit questionnaires as well as medication diaries of all pain medications they take, including the study medication. The research data will be maintained indefinitely.

What Will Be Done to the Patient If They Agree To Be a Research Subject?

If a patient wants to participate in the study, they will be asked to sign the consent form and Health Insurance Portability and Accountability Act (HIPAA) authorization before starting any study procedures. If they agree to participate in the study, the study team will collect several items on the days of their study visits.

Screening Visit

The screening visit will be completed in person and is expected to last 30 to 60 minutes. The protocol for the screening visit has been described in Textbox 1.

Textbox 1. Protocol for screening visit.

- The participant will be asked about the medicines they have used or are now taking, including all prescriptions and nonprescription medications.
- They will also be asked to provide demographic information (eg, age and ethnicity).
- They will have blood (approximately 7 teaspoons) collected for routine safety tests. These blood tests are important to determine whether they are eligible to participate in the study and to monitor for possible side effects of the study drug. They should fast (ie, eat nothing and drink only water) for at least 8 hours before this blood investigation.
- If the patient can become pregnant, they will undergo a urine pregnancy test. To participate in this study, they must not be pregnant.
- The patient will have an electrocardiogram test performed to measure the electrical function of their heart.
- They will be asked to complete 4 questionnaires related to pain and how it affects their daily life.
- They will be given a medication diary to track the medications they take for pain.
- The study team will review their medical records to confirm eligibility to continue in the study.

Enrollment Visit

The enrollment visit will be completed in person on day 0 and is expected to last for 60 minutes. The protocol for enrollment visit day and the treatment days 1 to 7 is described in Textbox 2.

Textbox 2. Protocol for enrollment visit and treatment days.

Enrollment visit day 0

- The patient will be asked if they have any health problems other than chronic pancreatitis and what medical or surgical procedures they have undergone in the past.
- They will be asked to complete 4 questionnaires related to their pain and how it affects their daily life.
- They will be asked about any health problems they may be experiencing.
- They will be asked what medications they are taking, including all prescription and nonprescription medications.
- Patients' vital signs (eg, heart rate, blood pressure, and temperature), height, and weight will be recorded.
- They will have a physical examination.
- If they can become pregnant, they will have a urine pregnancy test.
- Patients will be given a 7-day supply of the study drug and medication diaries to document all medications taken for pain.

Treatment days 1 to 7

- The lacosamide tablets can be stored at room temperature. Patients will take lacosamide by mouth, 2 times a day, approximately 12 hours apart. They will be asked to try and take the tablets at the same time on each of the 7 days of the study. The tablets may be consumed with or without food. Patients will be asked to swallow the tablets whole with a glass of water or any other liquid of their choice and not chew them.
- Patients will be asked to complete daily medication diaries for all medications taken for pain, including the study drug.

Follow-Up Visit

The first follow-up visit will be completed in person on day 8 and is expected to last for 60 minutes. Subsequently, a follow-up visit will be conducted via telephone on day 21. The protocol for these follow-up visits in described in Textbox 3.

Textbox 3. Protocol for follow-up visits.

Follow-up visit on day 8

- Patients will be asked to complete 4 questionnaires related to pain and how it affects their daily life.
- They will be asked about any health problems they may be experiencing.
- They will be asked what medications they have taken, including all prescriptions and nonprescription medications from the enrollment visit day 0.
- Their vital signs will be recorded.
- They will have a physical examination.
- Blood (approximately 7 teaspoons) will be collected for routine safety investigations. They will need to fast before the blood is collected.
- They will have an electrocardiogram test performed to measure the electrical function of their heart.
- They will return any leftover study drug doses to this visit, in the original bottles.

Follow-up on day 21: phone visit

- Patients will be asked about any health problems they may be experiencing.
- They will be asked what medications they have taken, including all prescriptions and nonprescription medications, from the follow-up visit on day 8.

Risks Associated With the Study

Risks of Receiving the Study Drug

There are risks to participating in any research study. One risk is that the study drug does not relieve the abdominal pain. There is a risk of side effects or feeling bad during this study. Side effects vary from person to person. Everyone participating in this study will be carefully monitored for side effects. It is important that the patients tell the study physician about any side effects that they have during this study, even if they do not think it is related to the study drug. The side effects may range from mild to severe. Study physicians and the company that makes the study drug cannot know all the side effects that may occur, and there may be unknown side effects.

Lacosamide Side Effects

Lacosamide intake can result in common, occasional, or rare but serious side effects.

- *Common* side effects (occurring in >20% of the patients):
  - Dizziness

- *Occasional* side effects (occurring in 3%-20% of the patients):
  - Headache, fatigue, sleepiness, skin wound, nausea, vomiting, diarrhea, bruising, tremors, loss of coordination, difficulty in walking, double vision, blurry vision, eye twitching, and injection site pain

- *Rare but serious* side effects (occurring in fewer than 3% of patients):
  - Irregular or slow heartbeat, fainting, fever, difficulty in forming words or speaking, abnormal brain function (eg, affecting balance and coordination), mental status change (eg, memory loss and impaired thinking), suicidal thoughts or behavior, hallucinations (ie, seeing or hearing things that are absent), liver damage because inflammation, abnormal sensation (eg, pins and needles), walking or balance problems (eg, possible falling), and life-threatening allergic reactions (eg, difficulty breathing, low blood pressure, and organ failure)

- Lacosamide may rarely cause low blood cell counts (red or white blood cells).
  - A low red blood cell count (anemia) may cause difficulty in breathing or fatigue. The patient may require a blood transfusion.
  - A low white blood cell count increases the risk of infection (eg, pneumonia or severe blood infection). Infections may occur anywhere and become life-threatening. Symptoms of infection may include fever, pain, redness, and difficulty in breathing.

In other studies of lacosamide, stopping the drug suddenly did not lead to unpleasant physical symptoms. As a Schedule V controlled substance, lacosamide has a very low potential for abuse. No restrictions on activities need to be followed when taking this drug. However, should the patient have a side effect or feel bad during this study, they should call the study physician. The study physician's telephone number is on the front page of the consent form. They should also call the physician if they have a side effect that makes them visit the hospital during the study.

Other Risks

Collecting blood for investigations may cause pain, bleeding, and bruising. The patient may faint and develop an infection with redness and irritation of the vein at the site of blood collection. Frequent blood collection may cause anemia (low red blood cell count), which may necessitate blood transfusions. Undergoing an electrocardiogram (EKG) may cause discomfort while lying on the examination table, and the tape on the EKG pads may cause skin irritation.

The questionnaires may contain questions that are sensitive in nature. They may refuse to answer any question that may make them feel uncomfortable. If the patient has concerns about completing the questionnaire, they are encouraged to contact their physician or the study chair.

The arm cuff used in measuring blood pressure may feel tight or slightly uncomfortable for a short time, and during the measurement, their hand or arm may experience numbness.

Certificate of Confidentiality

This study is covered by a Certificate of Confidentiality (CoC) from the NIH. With this CoC, the researchers may not disclose or use information that may identify the patient in any federal, state, or local civil; criminal; administrative; legislative; or other action, suit, or proceeding or be used as evidence, for example, if there is a court subpoena, unless the patient has consented for this use. Information protected by this CoC cannot be disclosed to anyone else who is not connected with the research, except if there is a federal, state, or local law that requires disclosure (eg, reporting child abuse or communicable diseases but not for federal, state, or local civil; criminal; administrative; legislative; or other proceedings).

The CoC cannot be used to refuse a request for information, for auditing or program evaluation purposes, from personnel of the United States federal or state government agencies sponsoring the project. A CoC does not prevent the patient from voluntarily releasing information about themselves or their involvement in this research. If the patient wants their research information to be released to an insurer, medical care provider, or any other person not connected to the research, they must provide consent to allow the researchers to release it. The CoC will not be used to prevent disclosure for any purpose you have consented.

Pregnancy-Related Risks

Taking part in this study can result in risks to an unborn or breastfeeding baby, so the patient should not become pregnant, breastfeed a baby, or father a child while in this study. They must use birth control during the study if they are sexually active.

- Male patients should tell the physician right away if their partner becomes pregnant or suspects pregnancy.
- If female patients are pregnant, they will not be enrolled in this study. If they become pregnant or suspect pregnancy, they must tell their physician immediately. Pregnancy will result in exclusion from this study.

Risk of Possible Loss of Confidentiality

Every effort will be made to keep patients' personal information confidential; however, we cannot guarantee absolute confidentiality. No information that could identify the patient will be shared in the publication of this study. Patients' personal information may be shared outside the research study if required by law and with individuals or organizations that oversee the conduct of research studies, and these individuals or organizations may not be held to the same legal privacy standards as physicians and hospitals.

There are some types of sharing the CoC does not apply to. The CoC does not stop reporting required by federal, state, or local laws, such as reporting of child or elder abuse, some communicable diseases, and threats to harm oneself or others. The CoC does not stop a government agency who is funding research from checking records or evaluating programs. The CoC also does not prevent their information from being used

for other research when allowed by federal regulations. The CoC also does not stop sharing of information required by the FDA.

Researchers may release information about the patient when they say that it is okay. For example, the patient may still give them permission to release information to insurers, medical providers, or others not connected to the research.

Costs and Compensation

Will Participants or Their Insurers Be Billed for Any Costs of the Study? If so, Which and What Happens if Insurance Does Not Cover the Costs?

The study will pay for the study drug, blood collection, ECGs, physical examinations, and data collection associated with the research study and for the investigations that are performed for research purposes only.

What Happens if the Patient is Hurt or Became Sick as a Result of the Study?

The researchers have taken steps to minimize the known or expected risks. However, they may still experience problems or side effects, even when the researchers are cautious to avoid them. If the patient believes that they have been harmed, they should notify the researchers listed in Section 6 of the consent form. The team at Indiana University Hospital will provide first aid or emergency care. The cost of this first aid or emergency care may be billed to the patient's insurance company. Additional medical care will be provided if the injury is determined to be caused by the research. If they sign the form, they do not give up their right to seek additional compensation if they are harmed because of being in this study.

Of note, it is important that the patients tell the researchers about any injuries, side effects, or other problems that they experience during this study. They may also need to tell their regular physicians. Furthermore, it is the patient's responsibility to determine the extent of their health care coverage. There are no other monetary compensation programs in place for such injuries. They will not be reimbursed for expenses or compensated financially by MD Anderson or the NIH and NIDDK for this injury. They may also contact the Chair of MD Anderson's IRB at 713-792-6477 with questions about study-related injuries.

Are Patients Paid or Given Anything for Being in the Study?

The patient will be paid US $50 at the completion of enrollment visit day 0 and US $100 at the completion of follow-up visit day 8; both payments will be in the form of gift cards.

Patient Eligibility

Relevant to STTEPP, PROCEED study participants are divided into subcohorts to distinguish the natural history of different disease presentations at the time of admission into the cohort [34]. In STTEPP, we will leverage the resources of the CPDPC by approaching participants already enrolled in PROCEED. This approach will facilitate timely accrual, as these participants have demonstrated an interest in research and willingness to participate in CPDPC studies. Although all participants must meet the criteria for diagnosis of suspected or definite CP as per PROCEED definitions [34], study enrollment will not be limited to participants participating in PROCEED. The STTEPP inclusion and exclusion criteria are listed in Textboxes 4 and 5, respectively.

Textbox 4. Inclusion criteria.

1. Written informed consent and Health Insurance Portability and Accountability Act (HIPAA) authorization for release of personal health information
2. Age ≥18 years at the time of informed consent
3. Suspected (YELLOW 2 or 3) or definite (RED) diagnosis of chronic pancreatitis, as per the Consortium for the Study of Chronic Pancreatitis, Diabetes, and Pancreatic Cancer's *Prospective Evaluation of Chronic Pancreatitis for Epidemiologic and Translational Studies* (PROCEED) study definition with ongoing symptoms of abdominal pain
4. Patients must be maintained on an opioid (except methadone or suboxone) for 4 weeks before enrollment for the treatment of abdominal pain related to pancreatitis, with a daily morphine equivalent dose of 20 mg to 120 mg.
5. Ongoing symptoms of abdominal pain even with opioid use (Visual Analog Score and Brief Pain Inventory average score ≥4, at enrollment)
6. Eastern Cooperative Oncology Group performance status of 0 to 2 (Oken et al [35])
7. Ability to swallow and tolerate oral tablets
8. Females of childbearing potential must have a negative pregnancy test
9. The following laboratory parameters must be met: white blood cell count ≥3.0 K/mm^3, absolute neutrophil count ≥1.5 K/mm^3, hemoglobin ≥9 g/100 ml, platelets ≥75 K/mm^3, creatinine ≤1.5 mg/100 mL, bilirubin ≤1.5 x upper limit of normal (ULN), aspartate transaminase ≤3 ULN, alanine transaminase ≤3 ULN; normal PR interval on baseline 12-lead electrocardiogram.

Textbox 5. Exclusion criteria.

1. Participants with indeterminate chronic pancreatitis (YELLOW 1) as per *Prospective Evaluation of Chronic Pancreatitis for Epidemiologic and Translational Studies* (PROCEED) criteria
2. Treatment with any investigational agent within 30 days before registration or concurrent participation in a clinical trial which involves another investigational agent
3. Rapidly escalating pain that requires parenteral (eg, intravenous or intramuscular) opioid therapy within 30 days of enrollment
4. Known hypersensitivity or allergic reaction to lacosamide, carbamazepine, or oxcarbazepine
5. Pregnant or breastfeeding
6. Diagnosis of epilepsy or a patient who is currently taking antiepileptic drugs
7. Abdominal surgery or pain intervention (eg, endoscopic retrograde cholangiopancreatography with sphincterotomy or stent or stone removal and celiac plexus block) within 90 days of enrollment.
8. Hospitalization for pancreatitis exacerbation or pain management within 90 days of enrollment
9. Patient who currently takes Suboxone or methadone.
10. Other factors which might explain the patient's ongoing symptoms, at the discretion of the enrolling physician.
11. History of autoimmune or traumatic pancreatitis or sentinel attack of acute necrotizing pancreatitis which results in suspected disconnected duct syndrome.
12. Primary pancreatic tumors, pancreatic ductal adenocarcinoma, suspected cystic neoplasm (>1 cm in size or main duct involvement), neuroendocrine tumors, and other uncommon tumors
13. Pancreatic metastasis from other malignancies
14. History of solid organ transplant and HIV or AIDS
15. Known isolated pancreatic exocrine insufficiency (eg, without any eligible inclusion criteria)
16. No medical or psychiatric illnesses or ongoing substance abuse that, in the investigator's opinion, would compromise participant's ability to tolerate study interventions or participate in follow-up.

Objectives and End Point

Our primary objectives are to (1) evaluate the safety, tolerability, and DLT of lacosamide in combination with opioids in patients with CP and (2) assess the feasibility of the performance of a pilot study of adding lacosamide to opioid therapy in patients with CP. As a secondary, exploratory objective, we will assess the efficacy of adding lacosamide to opioid therapy for the treatment of abdominal pain because of CP. The safety end point includes toxicity and DLT of the combination of lacosamide and opioids, defined as grade 3 or 4 toxicities, according to the National Cancer Institute Common Terminology Criteria for Adverse Events v5.0. Tolerability will be assessed by compliance with the intervention. The participants will be evaluated for completing the 7-day trial. The percentage of participants taking 100%, 75%, 50%, and <50% of the study tablets will be recorded. The feasibility end point will include the recruitment rate (ie, the proportion of eligible patients who agree to participate) and the dropout rate, including a qualitative assessment of barriers to retention. The efficacy end point will be assessed using the Visual Analog Score; Brief Pain Inventory, short form, average score; and the Comprehensive Pain Assessment Tool, short form [36] total score. A 50% decrease in pain scores from baseline at study completion will be deemed clinically meaningful. In addition, opioid use will be evaluated, with a decrease of 25% in pain scores from baseline at study completion, identified as clinically significant.

Investigational Plan, Intervention, and Treatment Regimen

We will conduct a dose-escalation trial of lacosamide added to opioid therapy in patients with chronic abdominal pain owing to CP. Participants who meet all the inclusion criteria and none of the exclusion criteria will be included in this dose-finding study. We will use the Bayesian optimal interval (BOIN) [37,38] design to determine the MTD. The BOIN design received a fit-for-purpose designation from the FDA as a drug development tool [39]. The BOIN design is implemented in a simple manner similar to the traditional 3+3 design, but it is more flexible and possesses superior operating characteristics compared to those with more complex model-based designs, such as the continual reassessment method [40]. The target DLT rate for MTD is 0.3, and the maximum sample size is 24. We will enroll and treat patients in cohorts of size 3. The initial dose will be 50 mg taken orally twice a day (100 mg/day), followed by an incremental increase of 100 mg/day in 2 divided doses. The maximum daily dose of lacosamide will be 400 mg/day. The duration of lacosamide administration will be 7 days at each dose level. This target DLT rate and dose-escalation schedule were chosen based on previous trials that had suggested the efficacy and tolerability of comparable doses of lacosamide when used to treat partial seizures and painful diabetic neuropathy. Follow-up laboratory parameters (as obtained at study entry) will be obtained on day 8 (with a 3-day window) after therapy is completed. The trial design is illustrated in Figure 1 and is described as follows:

1. Patients in the first cohort are treated at dose level 1.

2. To assign a dose to the next cohort of patients, dose escalation or de-escalation will be performed according to the rules displayed in Table 1.
3. Repeat step 2 until the maximum sample size of 24 is reached or stop the trial if the number of patients treated at the current dose reaches 15.

In the BOIN design, the number of DLT is the number of patients with at least 1 DLT. When none of the actions (ie, escalation, de-escalation, or elimination) is triggered, the current dose remains unchanged for the next cohort of patients. "N/A" means that a dose cannot be eliminated before treating 3 evaluable patients. After the trial is completed, we will select the MTD based on isotonic regression [38]. This computation is implemented by the "Estimate MTD" tab of the BOIN Design Desktop Program [41]. Notably, each cohort of 3 patients will consist of 3 new patients. Therefore, dose escalation or de-escalation is interpatient (or, more precisely, intercohort), not intrapatient in nature.

Considering the low disease prevalence of CP, including referral bias at academic centers, we chose to avoid the use of eligibility criteria that would narrow the potential recruitment pool. In this phase 1 trial, in which safety, tolerability, and feasibility are the primary outcomes of interest, we propose including all patients with suspected or definitive CP if the above inclusion and exclusion criteria are met. Similarly, although there may be potential variability in patients because of the etiology, duration of CP, or other features of the disease, it is impractical to impose more stringent eligibility criteria during this early phase of the investigation. Doing so would substantially deplete the recruitment pool for this orphan disease and would not be feasible or scientifically justified.

Figure 1. Bayesian optimal interval (BOIN) schema. The BOIN schema is a model-assisted dose-finding design that can be used to determine the maximum-tolerated dose (MTD) of a study drug based on safety or the optimal biological dose (OBD) based on safety and efficacy. DLT: dose-limiting toxicity.

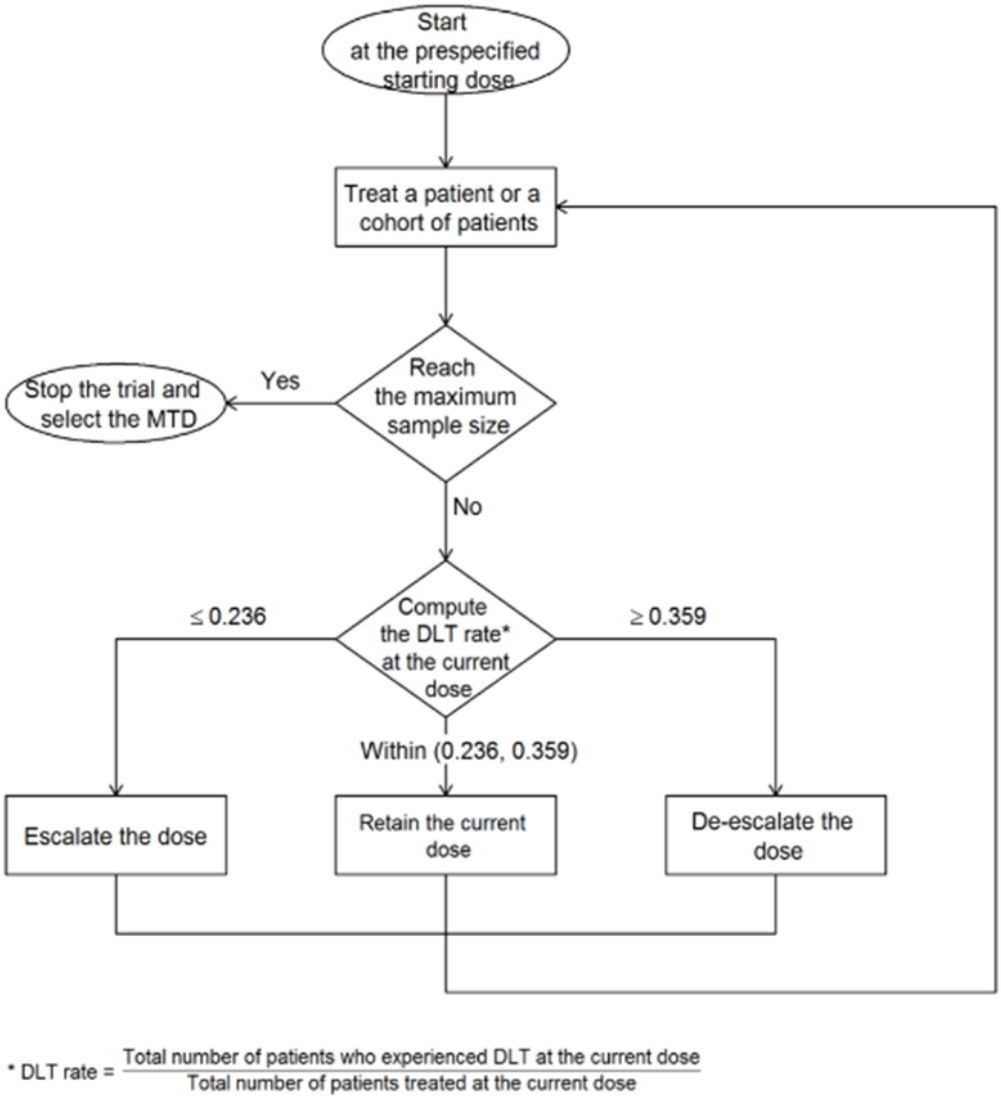

Table 1. Dose-escalation or de-escalation rule for the Bayesian optimal interval design.

Actions	The number of patients treated at the current dose														
	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Escalate if the number of DLT[a] is ≤	0	0	0	0	1	1	1	1	2	2	2	2	3	3	3
De-escalate if the number of DLT is ≥	1	1	2	2	2	3	3	3	4	4	4	5	5	6	6
Eliminate if the number of DLT is ≥	N/A[b]	N/A	3	3	4	4	5	5	5	6	6	7	7	8	8

[a]DLT: dose-limiting toxicity.

[b]N/A: not applicable.

Drug Dispensing and Compliance

In this phase 1 trial, all enrolled participants will receive the active drug lacosamide. There is no placebo group, and there is no blinding to the treatment or dose received. Following the initial drug purchase, the investigational drug service at each participating institution will purchase additional disbursements on an as-needed basis, depending on patient recruitment. Participants will be provided with drug diaries, which will be reviewed for compliance at the end of the study at the final in-person visit. Patients who miss a dose (defined as beyond 2 hours of the patient's typical drug administration time) will not be instructed to take it later on the same day. Patients will be informed not to take missed doses on the subsequent day (ie, the patient should not take more than the prescribed daily dose).

Study Visits

A screening visit for eligibility in person or via telephone will occur at 7 to 30 days prior to enrollment. There will be 2 in-person study visits. During study visit 1 on day 0, baseline study assessments and questionnaires will be completed in person. Drug treatment days will then occur from days 1 to 7. During study visit 2 on day 8 (with a 3-day window), following completion of the 7-day drug treatment period, participants will have a face-to-face clinic visit, where similar assessments and questionnaires will be completed, as per the study calendar (Table 2). Participants will return all unused drugs during this visit for disposal and to monitor compliance.

[a]Medical history and establishment of suspected or definite chronic pancreatitis diagnosis may occur at any time before trial entry.

[b]ECOG: Eastern Cooperative Oncology Group.

[c]EKG: electrocardiogram.

[d]Will include at a minimum: electrolytes, glucose, blood urea nitrogen, creatinine and creatinine clearance, calcium, and hepatic function panel.

[e]Will include detailed use of rescue pain medications and opioids use.

[f]VAS: Visual Analog Score.

[g]BPI: Brief Pain Inventory.

[h]PROMIS: Patient-Reported Outcomes Measurement Information System.

[i]COMPAT: Comprehensive Pain Assessment Tool for Chronic Pancreatitis.

Study Measurements

A site gastroenterologist will review the complete medical history, including medications (particularly opioid use), Eastern Cooperative Oncology Group performance status, physical examination (including vital signs, height, and weight), EKG, and laboratory test results. A site research nurse will collect up to 35 mL of fasting blood using standard protocols. Given the safety or risk protocol of lacosamide and to satisfy inclusion and exclusion criteria, the blood specimens are considered routine safety laboratories and will include electrolytes, glucose, blood urea nitrogen, creatinine, creatinine clearance, calcium, and a hepatic function panel.

The patient, nurse coordinator, and physician case report forms (CRFs) will be completed before study entry. This will be based on a similar CRF currently used in PROCEED. Completion of these forms before enrollment will allow confirmation that the patient is eligible for the study. We will obtain approval from the single-center IRB to share data between protocols with the patients' consent. An additional CRF will be completed by the nurse coordinator in collaboration with the site-specific principal investigator at the follow-up study visit, documenting all side effects noted during the drug treatment phase according to Common Terminology Criteria for Adverse Events (version 5.0).

Safety or Risk Issues

Lacosamide is a Schedule V medication available in tablet, oral solution, and injectable forms. In this study, only the tablet form will be used, and this is available in 50 mg, 100 mg, 150 mg, and 200 mg dosages. For simplicity in drug ordering and distribution, only 50 mg tablets will be used. Lacosamide is FDA approved as monotherapy or adjunctive therapy for partial-onset seizures, with a maximal recommended oral total daily dose of 400 mg, administered in 2 divided doses.

Summary of Known Potential Risks With Study Medication

Side Effects

A complete list of reported side effects from lacosamide trials and postmarketing experience can be found in the medication insert and Amneal Pharmaceuticals website [42]. The common side effects of lacosamide at doses in the range of 200 mg to 400 mg include dizziness (25%), ataxia (6%), fatigue, nausea, diplopia, headache, or tremor (12%-17%). Severe side effects such as cardiac rhythm or conduction abnormalities (first-degree arteriovenous block and atrial fibrillation or flutter, 0.5%) and suicidal ideation or behavior (0.2%) are rare. Case reports have been published regarding episodes of syncope and hypersensitivity reactions.

Prior and Concomitant Medications or Procedures

Relevant information about all concomitant drugs (including prescribed, over-the-counter, or herbal preparations) taken before and during the trial and any dose or dose regimen changes that occur during the trial will be recorded in the source documents and case report form. Owing to the potential drug-to-drug interaction with other CYP3A4 or CYP2C9 inhibitors that may interfere with lacosamide levels, patients taking medications that may interfere with lacosamide metabolism will be monitored carefully. Furthermore, patients taking medications that affect cardiac conduction (eg, sodium channel blockers, β-blockers, and calcium channel blockers), including those that prolong the PR interval, will be carefully observed. We will obtain an EKG before beginning drug therapy and at the end of treatment**.**

The study principal investigators serve as the medical monitors for this trial, overseeing all aspects of the trial, including management of source documentation, adverse event collection, adverse events and protocol deviation reporting, interaction with the Data and Safety Monitoring Board (DSMB), and the creation of corrective and preventive action plans, when necessary. The DSMB will meet to review the study conduct and data relating to safety and efficacy to ensure the continued scientific validity and merit of the study. Following recruitment of the first study participant, summaries will be submitted monthly and reviewed quarterly by the DSMB and will follow the established CPDPC protocols.

Statistical Plan and Analysis

A sample size of 24 was determined and calibrated based on the simulation such that the phase 1 trial has reasonable accuracy (>60% probability) to correctly identify the MTD across a set of practically plausible scenarios. We will use descriptive statistics to summarize the demographic and clinical characteristics of the patients. Safety data will be tabulated by the grade and type of toxicity using descriptive statistics, including mean, SD, and 95% CI. The reduction in pain scores will be summarized by the dose using the mean and 95% CI. As an exploratory analysis, *t* test (2-sided) or Wilcoxon rank-sum test will be used to compare the reduction in pain scores between the doses. The recruitment and dropout rates will be calculated for all patients and by dose and used to determine the feasibility of the treatment. Although the data generated will not have a comparator group (ie, no placebo), these will be helpful in understanding the variability of responses in patients with suspected or definite CP, which in turn will be useful for sample size calculation for a follow-up trial.

Results

As of December 2023, we have currently enrolled 6 participants. The minimum number of participants to be enrolled is 12 with a maximum of 24. We expect to publish the results by March 2025.

Discussion

The management of abdominal pain in patients with CP remains a significant challenge, and innovative approaches to pain management are urgently needed. By potentially limiting OIH, lacosamide may improve pain control in patients requiring opioids. There are no data evaluating the use of lacosamide in patients with CP; this was the impetus of the STTEPP trial. Achieving recruitment goals is a priority. We acknowledge that patients may be unwilling to participate in a dose-finding trial with a low likelihood of long-term therapeutic benefit. Those patients who do note a benefit, however, may choose to be considered for our planned phase 2 trial. The 5 participating centers include experienced researchers, who have led clinical trials in this challenging patient population. In addition, all are members of the CPDPC and participate in PROCEED [38]. This brings substantial synergy to this study because the infrastructure for recruitment and follow-up of study participants is already in place at these institutions. We do not require the study entry to be limited to patients enrolled in PROCEED, to avoid limiting the recruitment pool. However, placing our initial focus on patients participating in PROCEED, particularly those who have demonstrated compliance and return for their follow-up visits, will identify motivated patients who are familiar with the study protocols and the importance of research. The short-term nature of this study should facilitate compliance. Because the safety data of combination therapy with lacosamide and opioids are unknown in patients with CP, this phase 1 trial is necessary. We initially considered the conventional 3+3 design for this study protocol, which suffers several limitations, such as low accuracy in identifying and estimating the MTD and the tendency of underdosing patients. Therefore, we adopted a novel phase 1 trial design (ie, the BOIN design) that allows better statistical learning of the dose-toxicity curve and more reliable identification of the MTD [37].

This study will provide new knowledge regarding the safety, toxicity, and DLT of lacosamide in patients with CP. It is

anticipated that lacosamide will prove to be safe and well tolerated. The results of this pilot study will then support proceeding with a phase 2 trial of assessing the efficacy of lacosamide added to opioid therapy to alleviate abdominal pain caused by CP. We will demonstrate that these pilot trials, in which long-term therapeutic benefits are unlikely, are feasible in this challenging population. This knowledge will facilitate future clinical trials on CP, providing data regarding patient engagement and recruitment that will better inform trial design. Future clinical trials may indicate that a combination of lacosamide and an opioid will achieve better analgesia at lower doses of each drug than either as a single agent.

Acknowledgments

The Safety, Tolerability, and Dose-Limiting Toxicity of Lacosamide in Patients With Painful Chronic Pancreatitis (STTEPP) study is funded by the National Institute of Diabetes and Digestive and Kidney Diseases (1R01DK132709).

In addition, research reported in this publication was further supported by the National Cancer Institute and the National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK) under award numbers related to the Consortium for the Study of Chronic Pancreatitis, Diabetes, and Pancreatic Cancer (CPDPC): U01DK108323 (ELF, JJE, VP), U01DK108328 (YY), U01DK108306 (DY), U01DK108327 (DLC, SYH), U01DK108288 (SSV), U01DK108300 (WP). The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

Data Availability

Deidentified patient data may be shared with investigators from other institutions for ancillary studies upon request. Requests should be made to the study principal investigator.

Authors' Contributions

ELF and FAW wrote the main manuscript and prepared figures and tables. JJE, YY, DY, DLC, SSV, WP, SYH, and VP reviewed and approved this manuscript.

Conflicts of Interest

DY is a consultant for Pfizer, Inc. and gives research support to AbbVie Pharmaceuticals. SSV has received royalty payments for chapters in *UpToDate* on pancreatitis and received travel and honorarium for the *Orlando Health* scientific meeting in December 2023.

Abstract

Background: Opioids are a key component of pain management among patients with metastatic cancer pain. However, the evidence base available to guide opioid-related decision-making in individuals with advanced cancer is limited. Patients with advanced cancer or cancer that is unlikely to be cured frequently experience pain. Opioids are a key component of pain management among patients with metastatic cancer pain. Many individuals with advanced cancer are now living long enough to experience opioid-related harm. Emerging evidence from chronic noncancer pain literature suggests that longer-term opioid therapy may have limited benefits for pain and function, and opioid-related harms are also a major concern. However, whether these benefits and harms of opioids apply to patients with cancer-related pain is unknown.

Objective: This manuscript outlines the protocol for the "Opioid Therapy for Pain in Individuals With Metastatic Cancer: The Benefits, Harms, and Stakeholder Perspectives (BEST) Study." The study aims to better understand opioid decision-making in patients with advanced cancer, along with opioid benefits and harms, through prospective examination of patients' pain experiences and opioid side effects and understanding the decision-making by patients, care partners, and clinicians.

Methods: This is a multicenter, prospective cohort study that aims to enroll 630 patients with advanced cancer, 20 care partners, and 20 clinicians (670 total participants). Patient participants must have an advanced solid cancer diagnosis, defined by the American Cancer Society as cancer that is unlikely to be cured. We will recruit patient participants within 12 weeks after diagnosis so that we can understand opioid benefits, harms, and perspectives on opioid decision-making throughout the course of their advanced cancer (up to 2 years). We will also specifically elicit information regarding long-term opioid use (ie, opioids for ≥90 consecutive days) and exclude patients on long-term opioid therapy before an advanced cancer diagnosis. Lived-experience perspectives related to opioid use in those with advanced cancer will be captured by qualitative interviews with a subset of patients,

clinicians, and care partners. Our data collection will be grounded in a behavioral decision research approach that will allow us to develop future interventions to inform opioid-related decision-making for patients with metastatic cancer.

Results: Data collection began in October 2022 and is anticipated to end by November 2024.

Conclusions: Upon successful execution of our study protocol, we anticipate the development of a comprehensive evidence base on opioid therapy in individuals with advanced cancer guided by the behavioral decision research framework. The information gained from this study will be used to guide interventions to facilitate opioid decisions among patients, clinicians, and care partners. Given the limited evidence base about opioid therapy in people with cancer, we envision this study will have significant real-world implications for cancer-related pain management and opioid-related clinical decision-making.

Introduction

Patients with advanced cancer or cancer that is unlikely to be cured frequently experience pain [1,2]. Although the overall prevalence of pain and pain severity related to cancer appear to be decreasing, 40% of patients with cancer experienced pain during and up to 3 months after cancer treatment [1,3,4]. When stratified by cancer severity, patients with more advanced disease have higher rates of pain: up to 66%, compared to 39% for patients with localized or curative disease [4]. Although patients with any cancer can experience pain, those with breast, lung, head, and neck cancer experience pain most often [5]. Under- and untreated pain in individuals with cancer is associated with a variety of adverse health consequences, including functional limitations (eg, inability to work), suboptimal health behaviors (eg, reduced physical activity), emotional distress, social isolation, high health care use (eg, emergency department and inpatient admissions), and earlier death [6-9].

Opioids are a key component of pain management among patients with metastatic cancer pain [10]. Although rates of opioid prescribing in advanced cancer have not been well described, people with advanced cancer are prescribed long-term opioid therapy (ie, opioid prescription for at least 90 consecutive days) more often than people with limited-stage disease (66% vs 40%) [11]. A recent study using data from the National Survey on Drug Use and Health found that approximately half of cancer survivors with a recent diagnosis (within 12 months of the National Survey on Drug Use and Health survey) were prescribed an opioid during that year (54%) [12]. National guidelines from the American Society of Clinical Oncology [10] and the National Comprehensive Cancer Network [13] support opioids as a cornerstone of pain management for individuals with advanced cancer, suggesting that the benefits of opioid use outweigh the harms for this patient group.

However, many individuals with advanced cancer are now living long enough to experience opioid-related harm. Indeed, some advanced cancers are considered chronic diseases as patients are surviving longer due to improvements in cancer treatments [14]. For example, the median survival of individuals with metastatic breast cancer in a large national cohort of patients with breast cancer in France was 37 months [15], which has increased steadily over the previous decades [16]. Approximately one-third of individuals with metastatic breast cancer [17] or metastatic prostate cancer [18] survive for at least 5 years. This presents a complex clinical context for treating cancer-related pain with opioids, increasing the need to balance opioid-related benefits and harms.

Emerging evidence from the chronic noncancer pain literature suggests longer-term opioid therapy may have limited benefits for pain and function. For example, a recent meta-analysis of randomized controlled trials of opioids versus placebo for chronic (>3 month) “noncancer” pain observed a small improvement in pain of 0.69 (95% CI 0.56-0.82) on a scale of 0-10 that was less than the prespecified minimum clinically important difference of 1 [19]. Other systematic reviews and meta-analyses have yielded similar findings, including a lack of functional improvement with opioid therapy over placebo [20,21]. Analogous data do not yet exist for patients with advanced cancer; given the unique features of cancer pain and the commonly concurrent noncancer pain experienced by patients with cancer, it is important to better understand pain and pain management in persons with advanced cancer.

Opioid-related harms are also a major concern among people prescribed opioids. In one meta-analysis of 26 studies, 23% of participants decided to discontinue opioids due to side effects (eg, nausea and dizziness) [22]. In the general population, long-term opioid therapy is also associated with more serious harms; 21% to 29% develop opioid misuse, and 8% to 12% may progress to an opioid use disorder. Although more rare, opioid overdoses can occur (256 per 100,000 person-years among people recently prescribed opioids vs 36 per 100,000 years among those not prescribed opioids) [23,24]. In studies of noncancer pain, opioid-related harms are consistently related to both ingestion of high-dose opioids (ie, >90 mg morphine equivalents) and coprescription of sedating medications (benzodiazepines and gabapentin) [25-28]. People with cancer are more likely to be represented in the high-dose opioid groups and frequently experience polypharmacy [29,30]. However, whether these benefits and harms of opioids apply to patients with cancer-related pain is unknown.

This manuscript describes the study protocol for “Opioid Therapy for Pain in Individuals With Metastatic Cancer: The Benefits, Harms, and Stakeholder Perspectives (BEST) Study.”

The study aims to better understand opioid decision-making in patients with advanced cancer, along with opioid benefits and harms, through prospective examination of patients' pain experiences and opioid side effects and understanding the decision-making by patients, care partners, and clinicians.

Methods

Study Design

This is a multicenter, prospective cohort study that aims to enroll 630 patients with advanced cancer, 20 care partners, and 20 clinicians (670 total participants). The data collection is underway at 4 clinical sites. Site selection considered geographic diversity (Northeast, mid-Atlantic, West, and Southeast), the balance of urban versus rural patients, sufficient patient volume to reach the enrollment goal, and the ability to recruit based on previous success in cancer studies. Given well-established health disparities in cancer pain and its treatment, we selected sites that demonstrated a track record of successful recruitment of Black and Hispanic patient participants [31]. None of the chosen sites have opioid stewardship committees or programs, which could have the unintended consequence of limiting opioid prescribing [32]. Additionally, we conducted a comprehensive review of state opioid laws in preparation for the study [33], with most states specifying blanket cancer exemption for any opioid limitation, such as dose or limited day supply.

Participants

Patient participants must have an advanced solid cancer diagnosis, defined by the American Cancer Society as cancer that is unlikely to be cured [2]. An advanced cancer diagnosis can include patients who have distant metastases or a recurrence. Patient participants must be their own decision maker as determined by the electronic medical record (EMR) and enroll within 12 weeks of their advanced cancer diagnosis date. The research team will confirm an advanced cancer diagnosis using medical record documentation of pathology results or radiology and oncology documentation. We will recruit patient participants early after diagnosis so that we can understand opioid benefits, harms, and perspectives on opioid decision-making throughout the course of their advanced cancer (up to 2 years). Lived-experience perspectives related to opioid use in those with advanced cancer will be captured by qualitative interviews with a subset of enrolled patients, clinicians, and care partners.

We will specifically elicit information regarding long-term opioid use (ie, opioids for ≥90 consecutive days) and exclude patients on long-term opioid therapy before an advanced cancer diagnosis. Consistent with previous studies, we confirm opioid use in the medical record and will ask patient participants, "Did you take a strong prescription pain medication known as an opioid or narcotic for at least 90 days in a row during the past year? Examples of opioids include oxycodone, hydrocodone, hydromorphone, morphine, fentanyl, buprenorphine, methadone, and combination products such as oxycodone/acetaminophen." This question is consistent with other commonly used research definitions of long-term or chronic opioid therapy [34,35]. Notably, this long-term opioid use definition also excludes individuals who are receiving methadone or buprenorphine/naloxone (suboxone) for the treatment of opioid use disorder, as the potential benefits and harms of opioid therapy in this population are unique and merit separate investigation [36]. This will allow us to understand the benefits, risk factors for harm, and perspectives on opioid decision-making when a patient with newly diagnosed advanced cancer begins an opioid or continues a newly initiated opioid.

From the larger cohort, we will recruit 40 patient participants with advanced cancer—20 who are prescribed opioids at the time of enrollment and 20 who are not. From that sample of 40 patients, we will aim to obtain consent from care partners of at least 20 patients and clinicians of at least 20 patients.

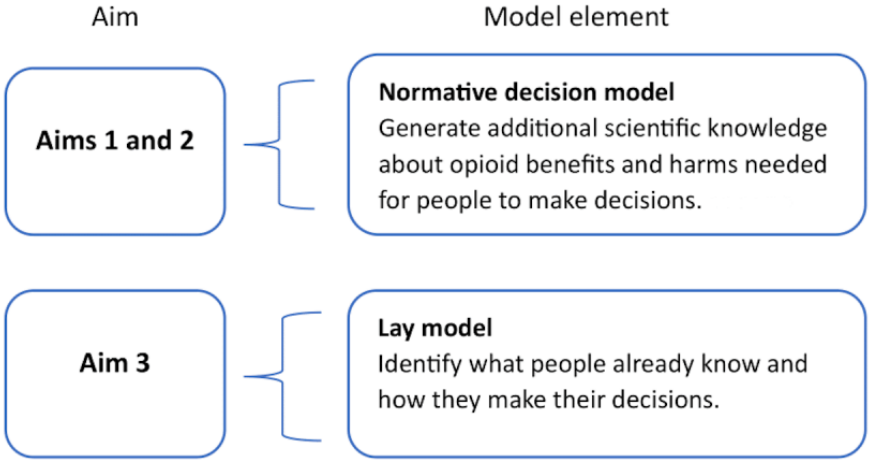
We will exclude individuals younger than 18 years of age, prisoners, pregnant people, and patients currently enrolled in hospice at the time of recruitment from the study. Patient participants do not need to report pain at the time of diagnosis since pain can occur at any point in the cancer trajectory. By including patient participants without pain at the time of diagnosis of metastatic disease, the study has the added benefit of describing the natural history of pain in patients with metastatic cancer for 2 years after diagnosis, filling an existing literature gap [3]. Patients who meet advanced cancer eligibility criteria will be recruited irrespective of their predicted prognosis, due to the inherent challenges of predicting prognosis [37,38].

For qualitative interviews, care partner participants must be a spouse, partner, child, relative, or friend who helps the patient with activities of daily living and health care needs at home, consistent with the National Cancer Institute definition of family caregivers [39]. Clinician participants will be physicians or advanced practice clinicians caring for a patient participant who has opioid prescribing authority and is willing to participate in a qualitative interview.

Theoretical Framework

Our data collection will be grounded in a behavioral decision research (BDR) approach [40] that will allow us to develop future interventions to inform opioid-related decision-making for patients with metastatic cancer. Opioid-related decision-making refers to decisions to initiate opioids or continue opioids over time. The BDR approach consists of 2 components. The first is the characterization of a "normative decision model," which describes the information distilled from existing scientific evidence that experts in the field believe that decision makers (patients, care partners, and clinicians) need to know to be able to make an informed decision. The second is a lay "mental model" of the decision, or what interested parties (ie, patients and care partners) already know and how they currently make their decisions. The normative decision model is a well-established approach for medical decision-making [41], including the development of opioid guidelines [42,43]. Consistent with previous studies, the lay decision model solicits perspectives on what patients, care partners, and clinicians consider foundational knowledge and how they make their decisions [44]. Interventions to support optimal decision-making can bridge the gap between the normative model and the contextual reality of how individuals are currently making those choices. Figure 1 provides the BDR framework-based approach mapped to the study aims.

Figure 1. Study aims mapped to behavioral decision-making model element.



Specific Aims

Using the BDR framework, the objective of this study is to create evidence to guide opioid prescribing in patients with advanced cancer.

The study's aims are as follows:

- Aim 1: To investigate the relationship between opioid therapy and opioid-related benefits.
- Hypothesis 1a: Prescribed opioids will be associated with decreased pain severity and pain interference (coprimary outcomes).
- Aim 2: To investigate risk factors for opioid-related harms.
- Hypothesis 2a: Certain coprescribed medications will be associated with an increased risk of opioid side effects (eg, benzodiazepines and somnolence).
- Hypothesis 2b: Younger age, history of substance use disorder, and history of mood disorders will be associated with a greater risk of opioid misuse and use disorder.
- Aim 3: To understand patient, care partners, and clinician perspectives on opioid-related decision-making.

Study Procedures

Recruitment

Potential patient participants will be identified using EMRs; *International Classification of Diseases, Tenth Revision* diagnosis codes; direct clinician referral; and referral from informational handouts in patient-facing platforms (eg, clinic rooms and chemotherapy teach-back packets). Study sites will develop reports to generate lists of potentially eligible patient participants in accordance with all rules of the HIPAA (Health Insurance Portability and Accountability Act), preparatory to the research exception [45]. The research coordinator will review listed patients' EMRs to verify eligibility following institution-specific procedures for contacting potential patient participants in clinic, over the telephone, or through letters. After receiving permission using one of the methods described above, trained research staff at each site will contact potential patient participants in-clinic or over the telephone to confirm eligibility. Subsequently, research staff will obtain consent, and data will be collected using Research Electronic Data Capture (REDCap; Vanderbilt University), a free and secure web-based application to capture research data [46].

Assessments

Once patients have consented and enrolled in the study, data collection will include patient-reported outcomes (PROs), chart reviews, and interviews. Table 1 provides an overview of the study procedures and time frame.

Table 1. Schedule of research activities.

Study stage	Screening and enrollment	Follow-up			
	Within 12 weeks of the date of diagnosis	Weekly after baseline	Monthly after baseline	Quarterly after baseline	Semiannually after baseline
Prescreening	✓				
Consent, screening, and contact information	✓				
Demographics and medical history	✓				
Baseline and demographics	✓				
Weekly 3-questions pain assessment: pain severity and inference		✓			
Monthly PRO[a] assessment: mood, substance use, symptoms, and opioid misuse (Carey 2-year index)			✓		
Chart reviews: substance use, opioid misuse, and opioid overdose				✓	
Patient calls and chart review: Opioid prescription or dose, benzodiazepine prescription, over or under consumption of opioids					✓
TAPS[b]: substance use and opioid use disorder				✓	
Patient participants, care partners, and clinician interviews				✓	

[a]PRO: patient-reported outcome.

[b]TAPS: Tobacco, Alcohol, Prescription Medication, and Other Substance Use Tool.

Study staff will confirm patient demographics and cancer type from the medical record. Sites will use a chart abstraction tool to gather medication-related data every 6 months. Opioid dose will also be assessed through self-report by reading back the dose and instructions on the opioid bottle and confirmed in the EMR. Patient participants will consent to receiving a phone call from the study staff for pill counts during the latter part of the month of their prescriptions every 3 months.

Patient participants will complete baseline assessments and PROs electronically using REDCap, over the phone, or during clinic visits through a tablet by the study staff. If patient participants are unable to complete PROs, care partners will be permitted to complete the PRO assessments on behalf of the patient participants. We acknowledge that based on systematic reviews in oncology, there may be differences in patient-proxy reports, with proxies having a more negative view of the patient's well-being [47].

The outcome measure for pain will be the Pain, Enjoyment, and General Activity (PEG) scale, a 3-item commonly reliable and validated measure used in oncology populations that asks about pain severity, pain interference in enjoyment of life, and pain interference in general well-being [48-50]. The PEG meets the Initiative on Methods, Measurement, and Pain Assessment in Clinical Trials recommendations and has a 7-day recall period [51]. The PEG will be collected weekly to provide longitudinal impact on pain severity, pain interference, and whether opioids precede any change in pain.

Additional monthly PROs will include information on mood (Functional Assessment of Cancer Therapy-General Well-Being Subscale); comorbidities (Self-Administered Comorbidity Questionnaire); functioning (Carey index); and if prescribed opioids, information on opioid misuse (Patient-Reported Outcomes Measurement Information System), opioid side effects (Patient-Reported Outcomes version of the Common Terminology Criteria for Adverse Events), and substance use (Tobacco, Alcohol, Prescription Medication, and Other Substance Use Tool) [52-56]. These measures were selected because of their favorable psychometrics in the study population, brevity, and similar recall periods. This patient-participant burden is similar to other studies among patients with metastatic cancer [57].

For Aim 3, we will conduct one-on-one interviews with patients, their care partners, and clinicians with the goal of better understanding opioid-related decision-making. These interviews will occur every 3 months for 2 years or until death. The rationale for this frequency is that it strikes a balance between interviewing people often enough for them to remember aspects of opioid decision-making since the last interview but not so often as to ask about opioid-related decisions more frequently than those decisions occur or cause undue participant burden.

Analytic Plan

Aim 1: Data Analysis

This analysis will draw from all patient participants, regardless of whether they are prescribed opioids, so we can compare those who are with those who are not prescribed opioids. We will estimate differences in pain severity and interference between patients treated with opioids versus patients not treated with opioids using linear mixed-effects models, which will allow us to (1) account for repeated measures over time for each patient and (2) adjust for potential confounders. In the linear mixed-effects models, the dependent variables will be based on

the PEG: pain severity (first question is a continuous 0-10 value) and pain interference (mean of 3 PEG items) at each time point. Current opioid prescription, baseline pain severity or interference, and other confounders (ie, factors statistically associated with the exposure and outcome) will be included as fixed effects, while the subject will be included as a random effect.

Power Calculation for Aim 1

Power calculations were performed by simulation to allow a range of parameters to vary in all scenarios. Unlike a randomized trial, in this study we will not have control over the ratio of patients allocated to the 2 comparison groups (eg, there will not be precisely a 1:1 ratio of patients prescribed opioids vs patients not prescribed opioids for comparison). Scenarios were considered where the proportion of patients prescribed opioids was allowed to vary from 30% up to 70%, all assuming a mean baseline PEG of 6 in the patients not prescribed opioids, a reduction in the PEG of 1 point for patients that are prescribed opioids, and a common standard deviation in PEG scores of 2 points [51]. All scenarios considered had at least 90% power to detect a difference of 1 point between groups with a total sample size of 630 patients (allowing for 30%-70% of the population to be prescribe opioids, meaning that with a range of 189 up to 441 patients prescribed opioids during the study period, there is ample power to detect differences between groups). All scenarios had at least 99% power to detect a 2-point difference on the PEG. We acknowledge that up to 40% of patients may drop out during the study due to the morbidity and mortality of patients in palliative care [58]. Data up until the point of attrition will be included in the analysis, and this has also been accounted for in our calculations.

Missing Data for Aim 1

In general, linear mixed-effects models provide unbiased estimates when the data are assumed to be missing at random, meaning that the likelihood of a missing value is not related to the values of the outcome data (in this case, the assumption that missing values for pain are not related to the severity of the patient's pain). The setting of this study will have two basic missingness problems: (1) data that are missing while the patient still lives, either because the survey could not be completed or the patient did not wish to complete the pain instrument; and (2) pain data that are missing because the patient is deceased. The missing at random assumption can never be fully confirmed, so we will perform three sensitivity analyses to see how our results vary under different approaches to handling the missing pain values: (1) multiple imputations; (2) imputing the worst pain value for patients that fail to complete the pain instrument for any reason (including death before the scheduled assessment); and (3) imputing the worst pain value for patients that fail to complete the pain instrument, but omitting patients that have died. It should be noted that in this patient population, death is an expected outcome and not necessarily a negative outcome with respect to end-of-life suffering and pain management.

Aim 2a: Data Analysis

To test our hypothesis that coprescribed medications will be associated with an increased risk of opioid side effects (eg, benzodiazepines and somnolence), we will include only study patient participants who are prescribed opioids. Linear mixed-effects models will be used to assess the relationships between selected risk factors and the corresponding suspected opioid side effects. Each side effect is scored on the respective weekly or monthly assessments. Analyses will be conducted to examine the relationship between coprescribed medications and each of the respective opioid side effects (constipation, nausea, dry mouth, and somnolence) as well as targeted relationships specifically of interest for individual exposures or side effects combinations, including (1) coprescription of other constipating medications and constipation, (2) coprescription of other constipating medications and nausea, (3) coprescription of anticholinergic medications and dry mouth, and (4) coprescription of benzodiazepines with somnolence. We will also examine the association between which opioid is prescribed (ie, morphine vs oxycodone) and each of the same respective opioid side effects (constipation, nausea, dry mouth, and somnolence). The use of linear mixed-effects models will provide estimates of the effect of each risk factor of interest on each of the respective side effects while also allowing the inclusion of longitudinal measurements from patient participants.

Power Calculation for Aim 2a

With an overall sample size of 630, we anticipate approximately 50% (315/630) of the study sample to be prescribed opioids, leaving 315 patient participants available for the analyses pertinent to this hypothesis. We examined a range of scenarios allowing anywhere from 10% to 30% of the eligible participants to have each exposure, performing power analyses to detect a 0.5-point difference in means for each side effect on the 1-5 scale (assuming a SD of 1 point). Power is about 65% if the exposure is rare (10% of patients prescribed opioids) but increases to 87% if the exposure is present in 20% of patients prescribed opioids and 93% if exposure is present in 30% of patients prescribed opioids. Again, we account for up to 40% attrition during the study. Note that patient participants will contribute data until they drop out, and this data will be included in the analysis.

Aim 2: Data Analysis to Test Hypothesis 2b

To test our hypothesis that younger age, history of substance use disorder, and history of mood disorders will be associated with a greater risk of opioid misuse and use disorder, we will perform multivariable Cox regression analyses to assess the respective risk factors of interest. We will use a single prespecified model that includes age, history of substance use disorder, and history of mood disorders using baseline PRO data and chart review.

Power Calculation for Aim 2b

With a total sample size of 630 patients recruited in Aim 1, the power calculation for this subaim assumed a scenario where approximately 50% (315/630) of the patients are prescribed opioids, leaving 315 patients available for this aim. We anticipate opioid misuse will occur in 20% to 30% of patients.

For a rarer event such as opioid use disorder, which is estimated to occur in approximately 10% of the patients, a sample size of 315 patients will be sufficient to support a model with 5 candidate predictor variables.

Missing Data for Aim 2

Unlike Aim 1, missing data should not affect analyses in this aim. The development of opioid-related complications will also be considered an event if it is known to occur and otherwise assumed not to occur during the period patients are under observation.

Aim 3: Data Analysis

The purpose of Aim 3 is to identify what patients, care partners, and clinicians already know and how they make opioid-related decisions to develop the lay model of the BDR. To determine decisional influences, the BDR framework uses the "mental models approach" to elicit these views [59]. To create the BDR framework lay model, we will structure the patient and care partner interviews by focusing on (1) what they already know about opioids, (2) how they make decisions, (3) examining whether this is consistent with or contrary to the normative model of evaluating risks and harms, and (4) how they think decisions around opioid use should ideally be made. The interviews begin with general questions and then become more specific, asking about each topic from the expert model. We will structure the clinician interviews by focusing on (1) their assessment of the patient's pain; (2) approaches to best treating it, including opioids; and (3) their decision-making around opioid prescribing. We will also evaluate whether different patient, care partner, and clinician perspectives are consistent with or contrary to one another.

For the semistructured interviews (40 participants with metastatic cancer from our larger cohort, 20 who are prescribed opioids at the time of enrollment, and 20 who are not), we aim to understand perspectives on deciding to initiate or continue opioid therapy or not. This sample size is based on evidence that suggests thematic saturation is achieved at 8-16 interviews; since we expect up to 40% attrition, this approach will ensure we have at least 20 participants [60]. We will purposively sample [61] to ensure diversity on race, site, and baseline PEG value; we will also recruit some individuals who have a history of a substance use disorder and are therefore at particularly high risk for negative consequences when prescribed opioids.

Similarly, we will recruit patient participants' care partners and clinicians. We will aim for at least 10 people who have care partners who consent to the group prescribed opioids at enrollment and 10 care partners of patient participants who have been prescribed opioids at enrollment. This approach will ensure that we have enough care partners to provide adequate perspective but not severely bias our sample by only allowing the enrollment of individuals who have care partners willing and able to enroll in this study. As described above, we will also purposefully sample 25% of patient participants who do not have care partners so that these perspectives are represented. Interviewing patients and their care partners s and clinicians will allow for triangulation of findings. Additionally, following patients, care partners, and clinicians longitudinally will allow for a detailed understanding of how decision-making changes over the course of metastatic cancer, allow participants to reflect on what they would have liked to know earlier based on what they know now, and provide real-time data on actual decisions (eg, initiation or discontinuation of opioids) on which participants can be asked to comment. Given the challenges inherent in engaging clinicians, we will aim for 15-minute focused interviews.

Trained qualitative researchers will collect and analyze the qualitative data. Interviews will be conducted remotely (through phone or Zoom [Zoom Video Communications], according to the interviewee's preference), and interview recordings will be transcribed verbatim (with details that might identify the interviewee redacted). Coding the data will require a hybrid deductive-inductive approach. A prespecified set of codes will be identified from the normative model. The presence and absence of these codes (eg, the accuracy of knowledge about the relationship between opioids and addiction) will be used to document the consistency between the normative model and stakeholder perspectives. In addition, we will take an inductive analytical approach to identify emergent values and beliefs that are not present in the normative models. Codes will be developed through open coding of the transcripts to determine topics and themes that emerged in the interview transcripts with input on topics or themes that the study team anticipates being relevant, resulting in simultaneously inductive and deductive development of the codebook. A draft codebook including detailed code definitions will be discussed with the study team to ensure that codes reflect both the data as they are emerging as well as relevant topical themes that are important to the team. Codes will be thoroughly checked to determine that definitions are distinct enough to reduce ambiguity in the coding process.

About 25% of the transcripts will be coded by 2 independent, trained qualitative coders to ensure quality and consistency in coding. Coding will then be compared for the purposes of calculating Cohen kappa inter-coder reliability scores [62]. Any coding discrepancies identified during this comparison will be adjudicated by the coders until full agreement on coding is achieved. The finalized coding on these transcripts will be recorded in a single ATLAS.ti file, following which the primary coder will complete the coding of the remaining transcripts according to the codebook and through the adjudication process and discussion by the study team with content and methodologic expertise. This process allows for consistency and quality across transcripts. Once coding is complete and uploaded to ATLAS.ti with quotes associated with codes, we will thematically analyze and determine the relative frequencies of various codes and the most salient themes. The resulting thematic analysis will be discussed with the entire investigator team to use the findings to build lay models of patient, care partner, or clinician decision-making around opioid use for patients with metastatic cancer.

Ethical Considerations

This study has been reviewed and approved by the University of Pittsburgh Institutional Review Board (STUDY20090231), which serves as the institutional review board of record for all research locations. Informed consent is obtained by trained

research staff members at each site. The study was granted a waiver of HIPAA authorization to identify participants who meet study inclusion criteria. The study was granted a waiver to document informed consent for the qualitative interviews conducted in Aim 3. Verbal consent will still be obtained by interviewers before commencing the interview.

Study data will be identifiable while the study is ongoing, as there are many contact points with participants. All study data are segregated by research site, so recruitment team members only have access to the data for participants they have enrolled. The University of Pittsburgh team has access to all study records as the team conducts follow-up assessments. All results that will be published in this study in the future will be done in an aggregate, deidentified manner.

We will reimburse patient participants US $10 for the baseline questionnaire, US $2 per weekly questionnaire, and US $10 per monthly questionnaire (up to US $394 if all questionnaires are completed over the 2 years). Patient participants who complete at least 80% of questionnaires during each year of follow-up will be eligible for an annual bonus payment of US $20. This results in US $434 of total possible compensation for Aims 1 and 2. For Aim 3, patients and care partners will be reimbursed US $30 per interview. Clinicians will not be compensated.

Results

This study was peer-reviewed and funded by the National Institute of Nursing Research in September 2021. Recruitment began in October 2022; we anticipate completing recruitment by November 2024. Follow-up assessments will end by November 2026, at which time we can finalize our data analysis.

Discussion

This paper presents the study protocol for the benefits, harms, and stakeholder perspectives regarding opioid therapy for pain in individuals with metastatic cancers .The study also uses PRO measures, qualitative data collection, and repeated assessments to ascertain how decision-making differs throughout the cancer trajectory, including at the end of life. The protocol is innovative because it addresses the research gap on the benefits and harms of opioids in metastatic cancer in a novel way. This includes our prospective design in patients recently diagnosed with advanced cancer, the collection of data from multiple perspectives (patients, clinicians, and care partners), and the inclusion of a well-known decision-making framework that can facilitate the design of future interventions.

There are several potential challenges or limitations to the research protocol. The first is likely challenges of retention and recruitment that are expected in longitudinal studies, especially in individuals with cancer and serious illnesses. Second, there is a potential for low enrollment or a high rate of missing data due to death, illness, dropout, or participant burden. We have attempted to account for these anticipated issues by having backup recruitment sites and conservative sample size estimates. Third, opioid prescribing is an evolving area of clinical practice and subject to federal and state oversight. It is possible that local and state regulations or institutional policies will change during the study period, resulting in a decrease in opioid prescribing and recruitment issues. Last, prospective investigation of adverse effects such as overdose or opioid-related mortality may be difficult to capture because these events are relatively rare.

At the end of the study, we anticipate the development of a comprehensive evidence base on opioid therapy in individuals with advanced cancer, guided by the BDR framework. The information gained from this study will be used to guide interventions to facilitate opioid decisions among patients, clinicians, and care partners. Given the limited evidence base about opioid therapy in people with cancer, we envision this study will have significant real-world implications for cancer-related pain management and opioid-related clinical decision-making.

Abstract

Background: Pediatric rheumatology is a term that encompasses over 80 conditions affecting different organs and systems. Children and young people with rheumatological chronic conditions are known to have high levels of mental health problems and therefore are at risk of poor health outcomes. Clinical psychologists can help children and young people manage the daily difficulties of living with one of these conditions; however, there are insufficient pediatric psychologists in the United Kingdom. We urgently need to consider other ways of providing early, essential support to improve their current well-being. One way of doing this is to empower parents and caregivers to have more of the answers that their children and young people need to support them further between their hospital appointments.

Objective: The objective of this co-designed proof-of-concept study is to design, develop, and test a chatbot intervention to support parents and caregivers of children and young people with rheumatological conditions.

Methods: This study will explore the needs and views of children and young people with rheumatological conditions, their siblings, parents, and caregivers, as well as health care professionals working in pediatric rheumatology. We will ask approximately 100 participants in focus groups where they think the gaps are in current clinical care and what ideas they have for improving upon them. Creative experience-based co-design workshops will then decide upon top priorities to develop further while informing the appearance, functionality, and practical delivery of a chatbot intervention. Upon completion of a minimum viable product, approximately 100 parents and caregivers will user-test the chatbot intervention in an iterative sprint methodology to determine its worth as a mechanism for support for parents.

Results: A total of 73 children, young people, parents, caregivers, and health care professionals have so far been enrolled in the study, which began in November 2023. The anticipated completion date of the study is April 2026. The data analysis is expected to be completed in January 2026, with the results being published in April 2026.

Conclusions: This study will provide evidence on the accessibility, acceptability, and usability of a chatbot intervention for parents and caregivers of children and young people with rheumatological conditions. If proven useful, it could lead to a future efficacy trial of one of the first chatbot interventions to provide targeted and user-suggested support for parents and caregivers of children with chronic health conditions in health care services. This study is unique in that it will detail the needs and wants of children, young people, siblings, parents, and caregivers to improve the current support given to families living with pediatric rheumatological conditions. It will be conducted across the whole of the United Kingdom for all pediatric rheumatological conditions at all stages of the disease trajectory.

Introduction

Background

Pediatric rheumatological illnesses are chronic inflammatory conditions that affect the musculoskeletal system [1,2]. While some are rare, juvenile idiopathic arthritis (JIA), the most common rheumatological disease of childhood, currently affects 10,000 children and young people in the United Kingdom [3]. JIA occurs as frequently as juvenile diabetes mellitus and 10 times more frequently than acute lymphoblastic leukemia [4]. Children and young people with rheumatological conditions are well known to experience a high psychological burden, with decreased quality of life, increased pain and disease activity, physical disabilities, school absenteeism, suboptimal medication adherence, and transition challenges [1,5]. Up to two-thirds of young people continue with active disease into adulthood [6,7], with visible and invisible symptoms causing marked psychological ramifications. High levels of mental health comorbidity and consequent risk for adverse health outcomes are common in children and young people with rheumatological conditions [1,8]. The British Society of Paediatric and Adolescent Rheumatology (BSPAR) Standards of Care (2010) include the recommendation that a pediatric clinical psychologist should be part of the core multidisciplinary team [9]. However, a 2021 survey of 15 high-volume pediatric rheumatology UK centers highlighted that 7 centers failed to achieve this [10]. In 2019, the British Society of Rheumatology's (BSR) pediatric and adolescent state of play report [11] highlighted poor access to psychology expertise and recommended increased psychology provision. Early identification of children and young people who are struggling is known to improve outcomes, but current systems fall short of providing adequate emotional and mental health support to those with rheumatological conditions [12].

A review examining the impact of living with a child with a long-term health condition revealed that parents perceive that they are not always supported in their quest for information, and their ultimate responsibility for their child's health can be overwhelming [13]. Parents and caregivers described that when information is not available from health care professionals, they are compelled to search for it elsewhere [14] and feel the need to "take charge," becoming advocates for their child through "tenacious information seeking" [15]. Patient and Public Involvement and Engagement (PPIE) activities revealed that available parental support is currently inequitably distributed and accessed. Charity access is inconsistent, with awareness dependent on clinical teams, other parents, or "internet searching." Education support offered at "family weekends" is limited by geography and capacity. Social media closed groups are only available to those who know about them, and due to the unregulated content, parents were skeptical about the levels of support received.

Rheumatologists and nurse specialists in the United Kingdom identified a lack of clinic time as one of the biggest limitations to asking about emotional and mental health support in appointments, followed by the absence of resources when concerns are raised [10]. While clinic time is limited, waiting lists are too long, and an increase in the number of psychologists is awaited, upskilling parents has the potential to improve their child's psychological well-being and prevent the need for later mental health interventions. The James Lind Alliance also supports this in its 10 identified priority areas for mental health in children and young people, specifically: what methods can parents and caregivers use to identify that their child's mental health is deteriorating and what are the most effective early intervention strategies for supporting them to improve mental resilience [16]. In 2023, 5 UK pediatric rheumatology charities were so worried about mental health that they collaborated to develop and deliver a survey to understand the scale of the problem. The results from this work showed that out of 291 parents and caregivers completing the survey, 218 (82%) parents and caregivers reported their child's diagnosis as impacting their own mental health. It also highlighted that 60% of children and young people have needed mental health support since diagnosis (had help, are undergoing help, or are on a waiting list), and in relation to condition specific difficulties, 81% needed help with needle phobia, 80% are reluctant to take their rheumatology medicines, and 78% are struggling with side effects from medications [17].

At the time of this study application, chatbots were being used as a means of providing useful information in a variety of

settings [18]. Chatbots are typically cloud-based programs that require internet-connected devices, and users interact with them in a number of ways, including through text and voice. In particular, chatbots such as Vincent have proven to be useful to enhance mental health [19], iHelper provides guided self-assessment for stress, anxiety, depression, and self-esteem, and Woebot is a text-based conversational agent providing 2-weeks of self-help, proven to significantly reduce depression [20]. Chatbots are beginning to be used in National Health Service (NHS) services, such as "Ask Olli" for parents at Alderhey [21] and "Oriel Assistant" for patients and staff at Moorfields [22], and evidence showed that most internet users would be receptive to using health chatbots [23]. Since the funding for the study was awarded, chatbot interest has progressed rapidly with the launch of commercially available chatbots. Chatbots potential in health care is also growing, with research progressing in this area. For example, ChatGPT and GPT-4 already show promise in translating radiology reports into plain language for families [24]. The exact deliverable for this study, however, is still work in progress and will be decided by the co-design group, taking into account issues such as digital poverty, scalability, advantages and disadvantages of platforms, data security, and outcome measures.

The "Interventions to improve Mental health supPort in families with children And young people with Chronic rheumaTological conditions" (IMPACT) proof-of-concept study aims to design, develop, and test a chatbot intervention for parents and caregivers of children and young people with rheumatic conditions. It is hoped that by empowering parents and caregivers, we will strengthen the support around children and young people, prevent anxieties and uncertainties from escalating, and improve other aspects of pediatric rheumatological care, such as adherence to therapies. This intervention is not to replace human contact but to be an adjunct when human contact is limited, for example, between appointments and while on holiday.

Study Setup

The research team is led by the principal investigator (PL), who is a senior pediatric rheumatology nurse, and the research facilitator (KK), who has a psychology degree and background in pediatric rheumatology research. This study proposal was submitted for a personal postdoctoral National Institute for Health and Social Care Research (NIHR) Advanced Clinical Academic Fellowship (ACAF; NIHR 302864), awarded in 2023 to PL, the first and currently (at the time of writing) only ACAF award given to a nurse in the United Kingdom. The study timeline is from April 2023 to April 2026.

Patient and Public Involvement and Engagement

A strong and engaged UK-wide steering group of children, young people, parents, caregivers, and health professionals is pivotal to the success of this study. The group is composed of 4 children and young people, 4 parents and caregivers, and 3 health care professionals (a clinical psychologist in pediatric rheumatology, a senior pediatric nurse working in rheumatology research, and a clinical informatics expert). The working group currently includes over 30 children and young people, parents and caregivers, health professionals, and key charity stakeholders who have all been involved in the study proposal since idea conception.

PPIE activities began over 2 years ago and helped shape this study. Initially, children, young people, parents, caregivers, and health professionals were asked whether they needed more support in living with a chronic pediatric rheumatological condition. As conversations proved there was a need to increase support to improve psychosocial well-being, discussions moved over time to consider what this may look like. Initially, the intervention was expected to be tailored toward children and young people; however, as conversations continued, parents and caregivers were open about their need for further support for themselves. A digital intervention was suggested that could help to better prepare their child through their "firsts" (first joint injection, first blood test, or first scan), know the right questions to ask in appointments, know how to have conversations with school, know how to encourage medication adherence, know how to talk about distorted body image due to corticosteroid therapy, know how to encourage home exercises, and know how to identify red flags in their child's mental health and where to go for help. During brainstorming activities, the idea of a "chatbot" was presented by a parent and unanimously selected as a potential targeted intervention. Parents and caregivers particularly liked the anonymity of chatbots and their constant availability.

Regular meetings, both web-based and face-to-face, have ensured key decisions have been agreed upon as a group, for example. whether 2 participants from the same family could be included in the focus groups. Key documentation has been reviewed by both the steering and working groups, and they will continue to be involved from the beginning to the end of the study. The methodology used for this study ensures that the study is directed by children, young people, parents, and caregivers, ultimately for children, young people, parents, and caregivers.

Methods

Methodological Underpinnings

This research study uses experience-based co-design (EBCD) methodology to guide the project, underpinned by the Medical Research Council (MRC)-NIHR Complex Intervention Research Framework [25]. EBCD is a form of participatory research that combines user-centered design and learning theory and is delivered through a 6-stage collaborative process (Textbox 1) [26,27]. These stages will be embedded throughout the study, maximizing the potential to use creativity and ideation to generate wide-ranging ideas and maximize opportunities for innovation, as recommended in the recently updated research framework [25].

Textbox 1. The 6 stages of experience-based co-design (EBCD).

Stage:

- Project set-up
- Staff experiences
- Patient and caregiver experience
- Feedback and co-design
- Co-design teams
- Celebration event

A "trigger film" (short film) is integral to the EBCD methodology and highlights "touch points," which elicit shared reflections. For this study, the focus groups and planned exercises during the workshops will be video recorded, then edited to produce the trigger film. This film is useful to understand some of the key decisions made throughout the study and can be a useful aid for dissemination. Using the EBCD methodology is compliant with the NIHR Participant in Research Experience survey, which recommends that "technology provided to participants should be tested for reliability and ease of use and co-designed with the intended users" [28].

Aim

This proof-of-concept study aims to design, develop, and test a chatbot intervention to provide enhanced support compared to current clinical practice that is accessible, acceptable, and usable for parents and caregivers.

Inclusion and Exclusion Criteria

Children and young people aged 8 years or older with a rheumatological condition diagnosed before the age of 17 years and their siblings will be invited to join focus groups. Parents and caregivers of those with rheumatological conditions will also be invited to parent-specific focus groups. Health professionals who care for pediatric and adolescent rheumatological patients will also be invited to join health care–specific focus groups. Those without rheumatological conditions as a child or young person, siblings, or parents of these will not be included. Members of our steering group are also excluded from participating as research participants in the focus groups, although they are welcomed as facilitators.

Designing EBCD Focus Groups

The "core elements" of the revised MRC-NIHR Framework [25] state that it is imperative to understand key uncertainties, consider the context, and engage stakeholders. Therefore, the aim is to understand, from the perspective of children, young people, siblings, parents, caregivers, and health professionals, what support they think would be useful and whether they think this could be delivered within a chatbot intervention. Focus groups will be used to yield rich qualitative data from a range of individuals from across the United Kingdom. A minimum of 8 focus groups are planned, with approximately 6-12 participants in each group. The parent and caregiver groups will outnumber the child or young person, sibling, and health care professional groups as the intervention is ultimately for parents and caregivers. However, we are also interested in asking participants with rheumatic conditions what they would have found helpful for their parents or caregivers to know, asking siblings for their perspectives, and asking health professionals to discuss where they see more support being offered. Groups will be undertaken remotely or face-to-face, depending on the requests of the majority of participants (in line with NIHR PPIE survey findings) [29].

Parents and caregivers, siblings, children, and young people will be recruited using consecutive sampling. Participants will learn about the study through study advertisement flyers in clinical settings or by being given a flyer. Ethical approval has been granted for local pediatric and adolescent rheumatology centers to display and distribute flyers, and in conjunction with pediatric rheumatology charity social media channels and email lists, this should increase the opportunities for inclusivity across all 4 nations of the United Kingdom. A study-specific website has been developed that encourages interested children, young people, or parents and caregivers to contact the study team to find out more, or if they are unable to access technology, their local team can contact the IMPACT research team on their behalf. Language-specific study documentation and interviews will be offered for those for whom English is not their first language. Staff will be recruited by seeing the study flyers and contacting the study team. A sampling matrix will ensure representation from professional groups and centers.

Consent will be sought for audio and visual recording, the former to guide data analysis, while the video recording will form the trigger film. Thematic analysis [30] will be conducted by 2 members of the research team and discussed with the steering group to identify themes critical to shaping chatbot development using NVivo (QSR International). The final themes will help develop the chatbot.

Developing EBCD Workshops

The working group will meet in 2 face-to-face workshops to discuss the themes and help identify the core components of the chatbot intervention. The workshops will use personas and scenarios developed from the focus group discussion to help inform the chatbot development process. Such creative and participatory methods will allow the shared experiences of the members of the working group to shape the intervention development process. The workshop will be video recorded as recommended in the EBCD methodology, with excerpts of the film used later in the trigger film.

Over the last few years, as chatbot technology has developed at an alarming rate, with large language models now leading the way, their popularity has increased [31]. While it is not possible to be specific regarding the content of the chatbot until the focus groups have been completed and analyzed, a content management system will be developed to inform the chatbot development. It is anticipated that the chatbot may include such functions as (1) frequently asked questions, (2) rheumatology-specific information, (3) information about managing "firsts," (4) parental red-flag identification and signposting, and (5) persuasive argument roleplay. Using agile principles, the exact technologies and approaches used may change as the team learns more about the user requirements. Development of the chatbot will occur within existing recommendations such as the National Institute for Health and Care Excellence Evidence Standards Framework for Digital Health Technologies [32], NHS Digital guidance for cloud security [33], and the Department of Health guidelines for "Putting data, digital, and tech at the heart of transforming the NHS" [34].

User Testing the Agile Sprint Methodology

Chatbots can potentially lead to frustration, anger, dissatisfaction, and, at worst, disengagement with the technology if not designed and developed with key stakeholders [35,36]. This is not a new technology; however, using it for this purpose for parents and caregivers of children and young people with rheumatological conditions is new. Therefore, the crucial step before a larger study must be to determine accessibility, acceptability, and usability through user testing.

User testing will occur through an iterative methodology with short product development cycles and the deployment of the prototype to groups of parents and caregivers. This will ensure user feedback directs incremental iterative software development. This process of "agile development" runs in a cycle of design, develop, test, and refine (termed a "sprint"). Every 3-month cycle, we will user-test, analyze, and develop. At least 25 parents and caregivers will be recruited for each cycle, which is anticipated to be up to 4 cycles in total. While the majority of participants will be naïve to each cycle, some may be invited back to 'test' new modifications in the next cycle. Parents and caregivers will be requested to use the chatbot on a number of occasions for a defined frequency of time.

Eligible parents and caregivers will be those of a child or young person who was diagnosed while being aged 17 years or younger with a chronic pediatric rheumatological condition and who agrees to complete the user metrics throughout the testing period. Flyers in local hospitals will again advertise this part of the study to parents and caregivers, who will then contact the study team for further information. If families are identified as those who do not have access to technology, individual conversations will occur to investigate whether a device may be loaned. All parents and caregivers will be sent an information pack and must provide written consent. Of note, the chatbot technology can integrate "Google Translate," and as such, families who do not have English as a first language will be able to participate.

Usability outcome measures and qualitative experiences will be sought in order to understand the acceptability of the chatbot for progression to a future study. Outcome measure selection will be informed by exploring what success would look like for families. These may include such measures as (1) attrition of participants; (2) engagement and duration of conversations; (3) user satisfaction measures, such as the System Usability Scale (SUS) [37,38], the User Experience Questionnaire (UEQ) [37], and the Net Promoter Score (NPS) [39,40]; and (4) semistructured interviews with the final group of "sprint" participants.

Ethical Considerations

The study will be conducted in accordance with the Principles of Good Clinical Practice and the Declaration of Helsinki. Ethical approval from the Health Research Authority has been received for the study (approval received on August 31, 2023, from the Yorkshire & The Humber–Leeds West Research Ethics Committee, IRAS ID: 329476. REC Reference:23/YH/0172). All participants are asked to provide informed written consent or assent (for those aged 16 years or younger, paired with parental or caregiver's consent) before being enrolled in the study. Consent and assent are requested to audio and video record the focus groups and workshops to enable data analysis and the production of the trigger film, while also requesting to use anonymized quotes and pictures of physical creations in dissemination.

Results

The study is ongoing. As of February 28, 2024, we have enrolled 73 children, young people, parents, caregivers, and health professionals in 12 focus groups so far. We have had over 280 children, young people, siblings, parents, and caregivers reach out to be included in focus groups, and therefore an ethics amendment has been sought to increase our recruitment target. This huge interest validates the need for the study, and already interesting ideas are emerging. Preliminary results will be published from the focus groups by the end of 2024 and from the user testing by the beginning of 2026.

Discussion

The rheumatological conditions of childhood affect the whole family. Children and young people have been shown to suffer with their emotional and mental health as they cope with the implications of a chronic health condition. Parents, caregivers, and siblings of the child have also been shown to experience difficulties as they navigate the new normal family lifestyle and the implications of the health condition on their own lives. Parents and caregivers report that for conditions such as JIA, there is a wealth of information available on the internet; however, it is not always clear how robust and trustworthy this information is, while for rarer pediatric rheumatological conditions, there is much less available information, and searching for what little there is can be upsetting and often futile. Providing information and support in the style of a chatbot has many advantages, including physician-ratified and endorsed information, anonymity, being accessible throughout the day and night, and the ability to integrate new novel functions, such

as the ability to practice difficult conversations with the chatbot enacting as their child or young person. Therefore, the aim of this study is to investigate whether a chatbot intervention could provide additional support to families between appointments without the need for human resources.

If the chatbot proves to be a success, then such an intervention may be useful in other diseases and with other populations. If the chatbot shows that parents and caregivers do not find it useful and its function is limited, this is useful learning in the current rapidly advancing technological climate, and further intervention and development may be commissioned. If the intervention is deemed acceptable, then to draw conclusions regarding the effectiveness of the intervention, a further study would be required. Discussions will begin early to scope out options for embedding the chatbot into NHS services in order to enhance the transition from research to service delivery following further assessment. Links to research outputs will be made available on the IMPACT study website [41].

This study has several limitations; primarily, as a proof-of-concept study, it will be difficult to generalize the findings. Coping with a chronic health condition varies on a daily basis depending on disease severity, treatments and their side effects, social support, and daily mood fluctuations. Therefore, the chatbot may prove useful to families for the short duration of this study, but as there is no external control group, analyzing all variables and drawing sound conclusions could be challenging. Also, due to the technological nature of a chatbot intervention, families who do not have easy access to technology may be disadvantaged; however, we are in the process of scoping local technology resources, which can be loaned out if required. We also set a lower age limit (aged 8 years or older) for child participation. This was to be mindful that the questions we are asking children about what else they would have liked support with would be difficult for most children aged 8 years or younger to answer. However, we are aware that in some instances, parents and caregivers feel their younger child may have liked the opportunity to take part.

We believe this study can have significant future applications and implications, such as learning from family perspectives on how we can improve upon current rheumatological clinical care, providing a responsive and tailored intervention to help support families better, and an understanding of how such technology could be embedded into the wider health care system. This is particularly relevant in today's current climate of limited staffing resources and an interest in delivering care differently. This study also offers an insight into how a chatbot could be used for families who live at a distance from their health care site, thus offering advantages over face-to-face support appointments and providing a resource for families, which may in turn lessen the need to contact the local team for support and thus free up valuable resources. The interest in the study so far, at over 280 families who have reached out in just over three months, over double the planned recruitment for the focus groups, is clear evidence that we need to do more to listen to, engage with, and support families further.

Acknowledgments

The authors would like to thank the children, young people, parents, and caregivers who formed the working group and have been pivotal in getting this study started. We would also like to thank all of the pediatric rheumatology charities who have also supported this work from inception to the present day (particularly Children's Chronic Arthritis Association, Versus Arthritis, National Rheumatoid Arthritis Society, Scottish Network for Arthritis in Children, Lupus UK, and Myositis UK) and all of the rheumatological teams across the United Kingdom for their support so far. We would also like to thank Professor Endacott (National Institute for Health and Social Care Research [NIHR] Director of Nursing and Midwifery) for supporting the fellowship application and this study.

PL (ACAF reference number 302864) is funded by Health Education England/NIHR for this research project. The views expressed in this publication are those of the authors and not necessarily those of the NIHR, NHS, or the UK Department of Health and Social Care.

Data Availability

The anonymized data sets analyzed during this study will be available from the corresponding author upon reasonable request.

Authors' Contributions

PL, KK, AK, ALS, RS, GR, and NJS participated in the design, conception, and revision of this study. KK undertook the design and revision. PL substantially contributed to the conception and design of the protocol and its write-up. PL, KK, LRW, AK, ALS, RS, GR, and NJS have approved the submitted version, agreed to be personally accountable for their own contributions, and ensured that any accuracy and integrity issues that may arise in the future will be appropriately investigated and resolved. The IMPACT Steering Group contributed to the design and conception of the study, reviewed the manuscript, and approved the submitted version. The steering group comprises Eire Byrne, Natalia Kasaru, Morgan Pawlett, Cameron Papantoniou, Emily Earle, Nathanael Bourns, Rachel Pulfree-Blythe, Eunice Kasaru, Emma Piepenstock, Gemma Molyneux and Heather Rostron. Further information is available elsewhere [41].

Conflicts of Interest

PL is currently receiving a personal fellowship award from the NIHR fellowship for nonmedical health care professionals (ACAF reference number 302864), and as Patient and Public Involvement and Engagement (PPIE) co-lead for the NIHR Great Ormond Street Hospital for Children NHS Foundation Trust and Biomedical Research Centre (GOSH BRC), she receives some salary support from the NIHR Biomedical Research Centre at GOSH. PL is also a Senior Center Affiliate at The Centre for Adolescent Rheumatology Versus Arthritis at UCL University College London (UCL), University College London Hospital NHS Foundation Trust (UCLH), and GOSH, which is supported by Versus Arthritis (21593). LRW's contribution was underpinned by grants from the Medical Research Council (MRC; MR/R013926/1), Versus Arthritis (22084, 21593), and Great Ormond Street Hospital Children's Charity (VS0518). AK's contribution is supported by a Canada Research Chair in Mental Health and Chronic Disease of Childhood. ALS is supported by an NIHR Clinician Scientist Award (CS-2018-18-ST2-005). This work is supported by the NIHR GOSH Biomedical Research Centre. The views expressed are those of the authors and not necessarily those of the National Health Service (NHS), the NIHR, or the Department of Health.

Abstract

Background: Vocational school students exhibit significant risk behaviors in terms of poor diet, frequent use of nicotine products, inadequate fruit and vegetable intake, low levels of physical activity, and poor mental health. This makes vocational students vulnerable to the development of noncommunicable diseases. Therefore, effective health promotion programs targeting vocational students are required.

Objective: The Danish study “Data-driven and Systems Approach to Health Promotion Among Vocational Students” (Data Health) aims to develop, implement, and evaluate a systems approach to support vocational schools, municipalities, and local communities in implementing locally relevant health promotion actions among and for vocational students. This paper describes the Data Health program and how implementation and preliminary effectiveness will be evaluated.

Methods: The Data Health program offers an iterative 5-step process to develop changes in the systems that shape health behavior and well-being among vocational students. The program will be implemented and evaluated in 8 Danish vocational schools in 4 municipalities. The implementation of the process and actions will be explored using a systems-based evaluation design that assesses contextual differences and the mechanisms through which the program leads to changes in the systems. Preliminary effectiveness at the individual level (students’ self-reported health behavior and well-being) and organizational level (school organizational readiness reported by school staff) will be assessed using a quasi-experimental design, and cross-sectional data will be collected at all 8 schools simultaneously 4 times during the 2-year study period.

Results: This study was launched in 2021, and data collection is expected to be completed in June 2024. The first results are expected to be submitted for publication in January 2024.

Conclusions: We expect that the Data Health study will make significant contributions to complex intervention research by contributing to the paucity of research studies that have used systems approaches in school settings. The study will also provide evidence of successful elements for systems change and effectiveness to determine whether a national scale-up can be recommended.

Introduction

Social Inequalities in Health

Globally, 71% of all deaths are due to noncommunicable diseases (NCDs), and more comprehensive preventive strategies are needed to reduce NCD mortality worldwide [1]. Social gradients exist in NCD risks (tobacco use, physical inactivity, unhealthy diet, and harmful use of alcohol) and NCD-related premature deaths. Populations with higher educational attainment have better health than those in lower socioeconomic groups [2]. Most students attending vocational schools come from low-income families [3,4], and an ordinary vocational degree is defined as "shortened school education." This makes vocational students vulnerable for NCDs, and already as students, they report a high prevalence of tobacco smoking, inadequate fruit and vegetable consumption, physical inactivity, and obesity [5]. For example, in Denmark, 39% of vocational students are overweight (BMI >25 kg/m^2) compared with 14% of high school students, and this prevalence among vocational students is increasing (2014: 30%; 2019: 39%) [6,7]. Despite this, students in vocational education are an often overlooked but important group to target for health promotion to reduce health inequalities [5].

The Complexity of Health Behavior

The application of health promotion can strengthen the capability of individuals to take action and build the capacity of groups, communities, or organizations to act collectively to exert control over the determinants of health [8]. The determinants of health are complex and influenced by underlying dynamic factors at multiple levels (ie, individual, intrapersonal, organizational, environmental, neighborhood, and structural) [9,10]. Evidence suggests that chancing organizational structures and processes and strengthening relationships between organizations are more likely to maintain healthy behavior among individuals than programs that target individual behavior change only [11]. In addition, multicomponent approaches (a combination of structures, processes, and individual behavior changes) for health promotion are more effective than single-component programs [12,13].

A challenge for health promotion is the "voltage drop" that has been identified when effective programs are scaled up across contexts (eg, schools of different sizes), as different contexts lead to different outcomes [14,15]. Vocational students' health behaviors and well-being vary across educational tracks (technical, business, agriculture and food services, social and health services) and regions [7], requiring the use of local data to identify intervention opportunities and priorities. Data-driven programs that use relevant local data to strengthen intervention design are emerging in health promotion research. These programs explicitly consider local conditions as a means of increasing the strength and relevance of the interventions implemented [16,17].

Approaches to Health Promotion in Schools

Schools are important settings that influence health behaviors [18]. In the Danish vocational school reform in 2015, vocational schools were mandated to engage in health promotion to increase students' healthy behavior and well-being and reduce dropout [19]. There is little evidence on how to support vocational schools to implement effective and sustainable health promotion. Vocational schools have struggled to implement and integrate health promotion into their core business [20], so more knowledge is needed about what approaches are feasible, effective, and sustainable in this setting. In Denmark, the smallest administrative unit, the municipalities, are responsible for health promotion among all citizens within their jurisdiction [21]. This places the 92 Danish municipalities as central to vocational school health promotion, but many schools and their students often cross municipal boundaries, making the responsibility for vocational school health promotion unclear and therefore less of a priority in many Danish municipalities [21]. However, previous research shows that municipalities are keen to work with health promotion at vocational schools but often lack a framework for these activities [22].

The World Health Organization's Health Promoting Schools (HPS) principles [23] state that efforts to improve health should go beyond individual behavior change to consider local contexts, organizational and policy changes (eg, from educating individuals to choosing alternative foods to changing the foods available), or a combination of these [14]. In addition, the HPS principles argue that involving the surrounding community and key community leaders will create a more sustainable environment that can support the maintenance of healthy behavior changes among students [24]. Systems thinking has emerged as a method for understanding and changing the drivers of complex health behavior challenges [10,25]. A systems perspective considers a broad approach that engages different groups of participants to contribute to the design, implementation, and evaluation of actions that disrupt current systems and normalize change [10,26]. Identifying and activating modifiable parts of systems (ie, leverage points) is essential to change structures, goals, and beliefs in the systems and thus achieve sustainable health behavior change [27]. Engaging key stakeholders in coordinated efforts [28] has been conducted in recent attempts to apply systems approaches within health promotion (eg, obesity [17,29-31], reducing dietary inequalities [32] and physical inactivity [33], and tobacco control [34]). In combination, HPS approaches and systems thinking provide a set of methods and perspectives that could be effective and sustainable for school health promotion [35].

Objectives

The Data-Driven and Systems Approach to Health Promotion Among Vocational Students (Data Health) study aims to develop, implement, and evaluate a systems approach informed by local data to support vocational schools, municipalities, and local communities in implementing locally relevant health promotion actions among and for vocational students. This protocol describes the Data Health program and how its implementation and preliminary effectiveness will be evaluated at 8 vocational schools across 4 municipalities in Denmark to determine if national scale-up can be recommended.

Methods

The Vocational School Setting

Vocational education in Denmark prepares students for specific occupations and is divided into four main educational tracks: (1) technical (eg, electrician), (2) business (eg, office assistant), (3) agriculture and food service (eg, farmer or chef), and (4) social and health service (eg, health care assistant). Vocational education alternates between school-based training and workplace-based training, with approximately one-third of the time spent in school [36]. Some schools are multisited and have student populations greater than 6000, whereas other schools are located at a single address with a student population of no more than 100. Almost two-thirds of students are men (64.7%), but the gender distribution varied according to educational track; for example, the proportion of men is 89.3% in technical education but only 12.3% in social and health service education [37]. The average age of students is 24 years; some students enroll directly from primary school (aged 15-17 years), whereas others begin later in adult life (39.8% is aged >25 years) [37].

Recruitment

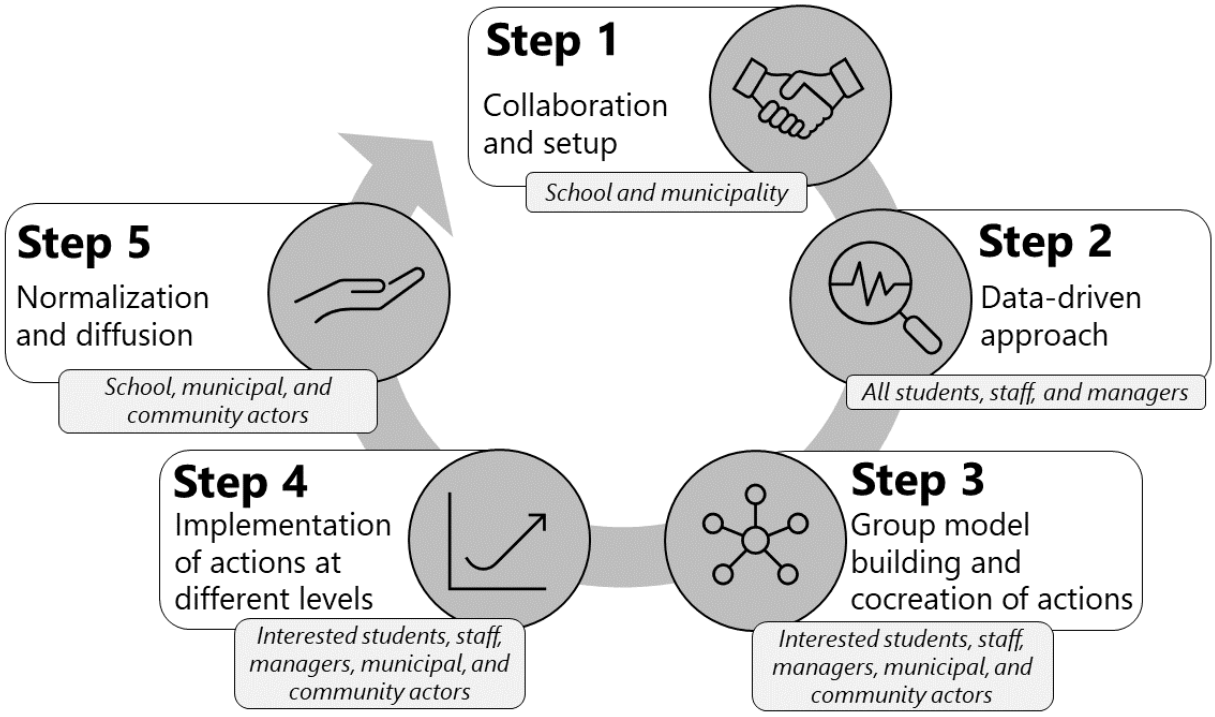
We will use a purposive sampling strategy. A total of 8 vocational schools will be recruited based on the region (Capital Region of Denmark and Region Zealand) and educational track (technical, business, agriculture and food service, and social and health service) to include one vocational school from each educational track in both regions. Simultaneously, the municipalities where the vocational schools are geographically located will be recruited. The enrolled schools and municipalities will be responsible for recruiting community actors with support from the research team, if needed. The role and responsibilities of the actors in the community is described in steps 3 and 4 of the program. In this case, “community actors” refers to individuals, organizations, or companies, both local and national, who can provide resources and social support for the implementation of actions for change.

Content of the Data Health Program

Development

The Data Health program offers an iterative 5-step process (Figure 1) for developing change in the systems to shape vocational students’ health behavior and well-being, combining best practices in health promotion research, including methods from systems science [10,38], data-driven approaches [16,39], and the World Health Organization’s HPS principles [23]. The program was developed by a health promotion research group piloted and formatively evaluated in 1 vocational school and 1 municipality from June 2021 to June 2022. The formative evaluation included observations and interviews and surveys of key participants from both school and municipality. Weekly meetings were held between the evaluator (AS) and the research team to discuss the experiences, barriers, and enablers of implementation. During the formative evaluation, suggestions for program changes were made by exploring the municipality and vocational school environmental contexts and how the program would fit or function within these settings. The research team adjusted and incorporated changes to the program steps throughout the pilot test.

Figure 1. The 5 steps of the Data Health program.



The research team will be responsible for the implementation of steps 1 to 3 of the program but will concurrently build the capacity, motivation, and commitment of the school and municipal program coordinators to be responsible for the implementation of actions and to promote the normalization of the program (steps 4-5).

Step 1: Collaboration and Setup

The Data Health program will begin with the establishment of a formal collaboration agreement between management representatives from the vocational school, the municipality, and the research team. Both the school and the municipality will appoint 1 or 2 staff members as school and municipal program coordinators, respectively. One month of salary will be provided to each school program coordinator (€4000; a currency exchange rate of €1=US $1.09 is applicable) to support program implementation. The roles and responsibilities of the different partners will be clarified and negotiated. Once the collaboration and commitment at the management level has been secured, information about the program will be disseminated by the school management to all staff and students. Dissemination activities include information by email and a kick-off meeting for staff, whereas dissemination for students includes customized posters and flyers distributed in common areas of the school. On the basis of the learnings from the pilot study, we have enhanced the dissemination strategy for the program to boost program visibility at the schools and comprehension among both staff and students.

Step 2: Data-Driven Approach

Local survey data on students' health behaviors and well-being will be collected and analyzed by the research team (see the description of individual outcomes in research question [RQ] 5). To stimulate motivation and interest, the data will be returned to the school and municipality within few weeks in the form of a local health profile. The local health profile covers modifiable health risk factors among vocational students, for example, nicotine use, unhealthy eating habits, physical inactivity, and poor mental health [7]. A simplified version of the health profile will be presented by the research team and the municipal program coordinator at separate meetings for school managers and staff and for students to share and increase their knowledge about health promotion, stimulate discussions and reflections about the results, and promote engagement and motivation for change. On the basis of the data presentations and discussions, the staff and students will be asked to complete a short questionnaire to select the health issue they are most motivated to address. During the pilot, we explored how best to select the specific health issue to be addressed in the remaining steps of the program and who should make this decision. The conclusion was that it is a school management decision, but schools are strongly encouraged to include the perspectives of staff, students, the municipality, and data from the local health profile in the process. To increase the prospect of becoming an iterative model, the local health survey has been designed to match an existing municipal-based health profile system [40] that the school-municipal collaboration can sign up after the research team has withdrawn the program.

Step 3: Group Model Building and Cocreation of Actions

Group Model Building (GMB) is a participatory method from systems science to facilitate a shared understanding of the structures and relationships that shape the system through the creation of causal loop diagrams (CLDs) [38,41]. A CLD helps to build a shared understanding among participants of the cause and effect relationships within a given system and to identify and agree on relevant and important areas for change [41]. In previous community research, this approach has been shown to improve the understanding of the problem, develop consensus

on actions for change among a diverse group of participants, and increase participants' social network [41,42].

GMB is a central part of the Data Health program, as we aim to involve and engage a wide range of participants in developing a CLD and identifying locally adapted actions for change. In this program, the GMB process consists of 3 sessions (GMB1-3), as proposed and applied by an Australian research group at the Institute for Health Transformation, Deakin University [43]. The Data Health research team was trained in the GMB process by this group and then adapted the process and methods to a vocational school setting and vocational students, primarily based on the approaches and results of the pilot test.

In GMB1-2, participants will cocreate a CLD [44] to gain a shared understanding of the perceived causes and drivers of the health issue selected in step 2, for example, poor mental health or physical inactivity. Participants will also identify existing initiatives or programs in the school or community that could have an impact on perceived causes and drivers. GMB1-2 will involve 5 to 10 students, 5 to 10 school staff members, the school and municipal program coordinators, and school management. The school program coordinator will recruit a diverse group of motivated students and staff based on gender, age, and education. The Systems Thinking in Community Knowledge Exchange computer software [45] will be used during this process. At the end of GMB2, participants will identify several community actors who are considered relevant or necessary for the identification and implementation of actions across the school, community, or municipality. These community actors, representing different organizations, sectors and areas of expertise, will then be invited to GMB3 via phone calls. Together with the participants from GMB1-2 and other interested students and staff members, this wider group of participants will identify leverage points in the CLD and prioritize actions to change the system. Within systems thinking, actions can range from minor actions to major actions [27,41]. Minor actions often aim to solve a single issue and can often be implemented quickly with low resource costs (eg, single events), whereas major actions can aim to change paradigms in the way individuals or organizations think and behave and are often more difficult and costly to implement (eg, changes in an organization's goals and beliefs) [27]. The principle in systems thinking is that minor actions can stimulate major actions [27,41].

Participants will identify existing actions or codevelop new actions to change specific elements of the system or the entire system. Actions for further implementation will be selected based on feasibility and expected impact. As a result of GMB3, "action groups" of community actors, staff, and students will be formed, based on motivation, to plan and implement one or more specific actions.

Step 4: Implementation of Actions at Different Levels

In the months following GMB3, the action groups will plan and implement actions for changing the system, assisted by the school and municipal program coordinators. Examples of actions at different levels can be found in the description of program evaluation (implementation of actions [RQ2]). To support the coordinators and action groups, a guide to the development and implementation process has been adapted from previous work [38]. In addition, the Data Health study has reserved funds for each school (€1350) to support the implementation of actions or involvement of community actors to run implementation.

Step 5: Normalization and Diffusion

The school and municipal program coordinators will be responsible for the continuation of the program, and the resources available for this will depend on the priorities of these organizations. The research team will organize meetings between relevant community actors and managers from the school and municipality to encourage the initiated collaborations to remain formalized beyond the program. At these meetings, we will develop a strategy for the continuation of the actions already initiated and a plan for new data collection and development of new local actions. Most municipalities in Denmark have a questionnaire tool [40] for data collection to support the municipalities' work with health behavior and well-being among children and youth. The municipalities will be encouraged to use the tool for future data collection at the program school, as well as at other vocational schools within the municipality.

To increase and maintain momentum for health promotion practices among vocational students, all school and municipal program coordinators and relevant community actors will connect across study sites every 4 months in a community of practice (CoP), initiated by the research team. The CoP is a forum for sharing experiences and learnings on effective strategies for health promotion and collaboration across study sites but will eventually be open to other schools and municipalities interested in implementing the Data Health program.

If all 5 steps are completed as intended, we expect various elements of the Data Health program to be sustained, including the actions implemented, the collaborations initiated, and the organizational practices and motivation to repeat the monitoring to evaluate changes and develop new actions.

Program Evaluation

Research Questions

In total, 5 RQs will comprise the evaluation of the Data Health program:

- RQ1 (process evaluation—steps 2 and 3 of the program): To what extent is the data-driven approach and the GMB process implemented as intended, and what seem to be the most important mechanisms of change and contextual factors?
- RQ2 (implementation of actions—step 4 of the program): What characterizes the planned and initiated actions and what are the unintended consequences related to implementation? Who is involved in the planning and implementation?
- RQ3 (program normalization—step 1 and 5 of the program): What are the opportunities, barriers, and needs for the collaboratives and program to be sustained and normalized?

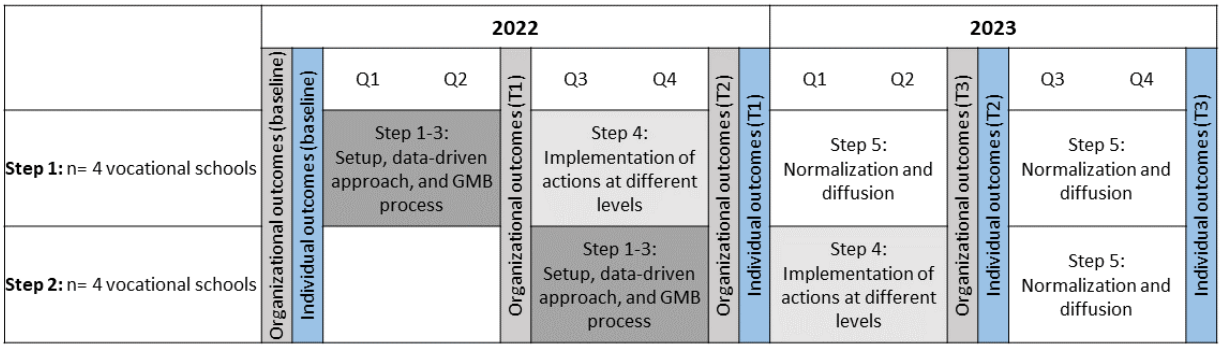
- RQ4 (organizational outcomes): Does the program stimulate organizational changes in schools to work in a more health-promoting direction?
- RQ5 (individual outcomes): Does the program contribute to improvement in health behaviors and well-being among vocational students?

Study Design

To evaluate the implementation of the program, related actions, and systems impact (RQ1-3), we will use a systems-based evaluation design that seeks to understand how the program and the systems adapt to each other [10,46]. Evaluation using a systems perspective needs to adapt as the program unfolds by examining emergent outcomes that result from the interactions of participants [10,46], and it involves examining relationships, interactions, and patterns rather than individual outcomes and static "snapshots" [46,47]. The systems-based evaluation design aims to gain an in-depth understanding of the system as a whole without a "control system." However, it is not possible to include every part of a dynamic system; therefore, it is necessary to define systems boundaries to determine what is considered relevant in terms of what and where to evaluate [46,48]. The starting point for defining the boundaries is the identified primary health issue that each of the 8 program schools has chosen to target. All organizations and interventions relevant to the targeted problem will be considered as part of the system. In terms of system factors, we will focus on modifiable social and physical environmental factors rather than psychological or genetic factors.

We will examine preliminary effectiveness (see descriptions of organizational outcomes [RQ4] and individual outcomes [RQ5]) at the organizational level (ie, school organizational readiness) and at the individual level (ie, students' health behavior and well-being) using a quasi-experimental design with a nonrandomized clustered stepped-wedge strategy. The 8 program schools will be enrolled in 2 steps, matched by educational track (one school from each main track) and geographic location (2 schools from 2 Danish regions). The matched clusters will be assigned to early start (January 2022) or late start (6 months later). This design allows for a sequential roll-out of the program and allows us to control for differences between study sites (vertical control) and secular trends (horizontal control) during the study period [49]. Organizational- and individual-level data will be collected simultaneously at all 8 schools 4 times during the 2-year study period at baseline and at 3 follow-up points (T1, T2, and T3; Figure 2). As systems change takes time to diffuse into individual behavior changes [31], the research team will in due course seek opportunities and funding for longer-term data collection (ie, a 5- and 10-year follow-up).

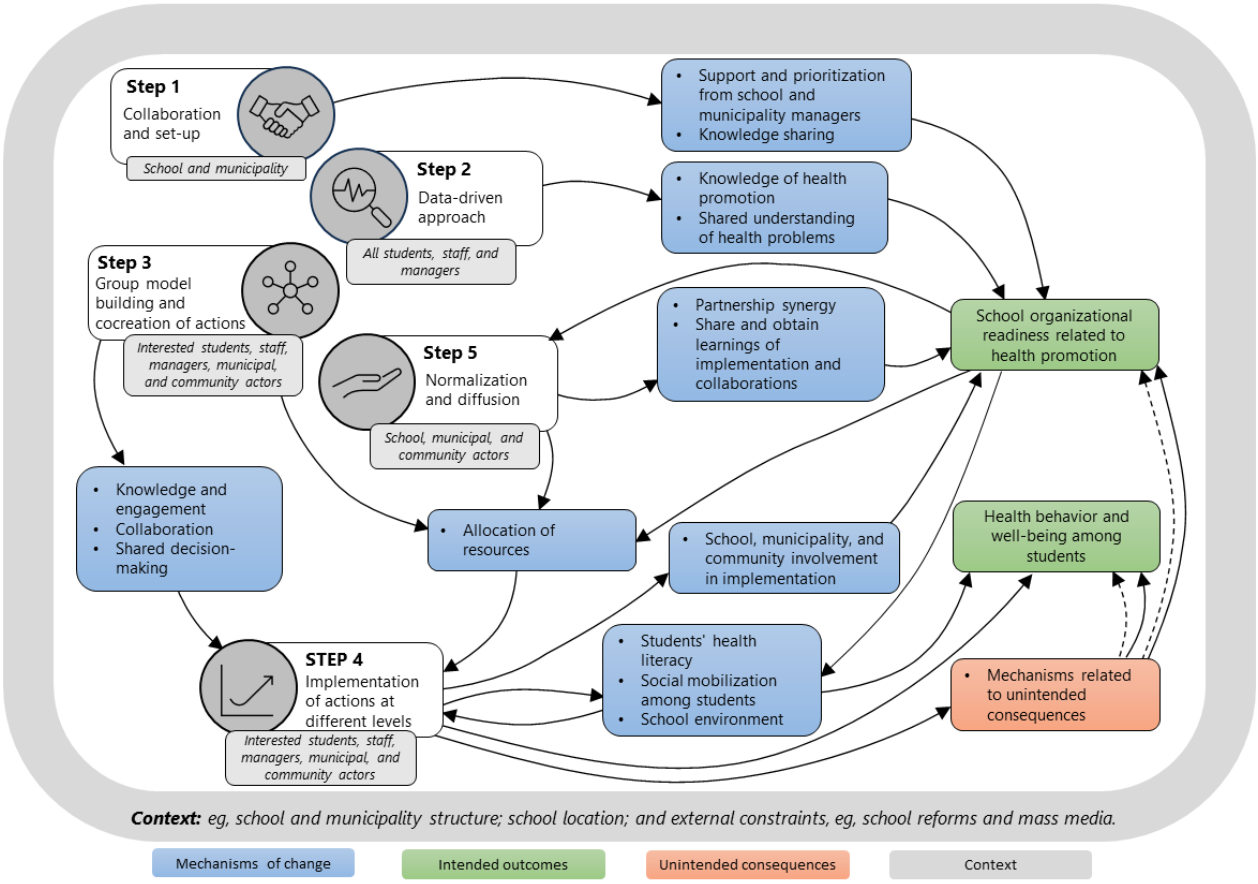
Figure 2. Study design and timeline of the data collection for the effectiveness evaluation. GMB: Group Model Building.



Program Theory

A program theory explains how a program is expected to work and under what conditions [10]. The Data Health program theory (Multimedia Appendix 1) is captured in a series of "if-then" statements and is based on key findings from the pilot test, published literature reporting trial results or theoretical abstractions [8,16,27,50-53], and the research group's experiences and previous research in the field [20,54-57]. Mechanisms of change are the hypothesized causal links between the program components and identified outcomes, triggered within the contexts in which the program is implemented [10]. In total, we hypothesize 6 mechanisms of change as plausible causal links between the data-driven approach and the GMB process and outcomes; these are indicated by mechanisms connected to steps 2 and 3 in Figure 3. To understand the interactions among context, program components, mechanisms, and outcomes; the research group visualized the initial program theory as a systems map, illustrated in Figure 3. The map summarizes our proposed model of how program components are expected to lead to systems change and outcomes. The connecting arrows show how changes in one part of the system are expected to generate changes in other parts of the system. The Data Health program theory and system map will continually be refined and revised as part of the evaluation process.

Figure 3. The Data Health system map.



Process Evaluation (RQ1)

In the process evaluation [58], we will examine whether the data-driven approach and the GMB process (steps 2 and 3 of the program) are being implemented as intended, the associated contextual factors and the mechanisms of change.

Both quantitative and qualitative methods will be used to collect data for the process evaluation (Table 1). Following the Medical Research Council guidelines [58], 5 process evaluation components will be assessed: recruitment, reach, fidelity, dose delivered, and dose received. In addition, we will examine whether the 6 hypothesized mechanisms of change are activated and the extent to which these mechanisms are modified through their interaction with contextual factors. However, we will remain open to other emerging mechanisms.

Table 1. Items, methods, instruments, and frameworks used in evaluation of implementation (research questions 1-3).

Component and items of interest	Methods and data	Applied evaluation instruments and frameworks
Process evaluation—steps 2 and 3 of the program		
Context information		
Examples: • School type • School size • School location • School and municipal structure	• Semistructured interviews with the principal school managers and the municipal program coordinators (after GMB[a]3) • Facts obtained through school and municipality websites	• Medical Research Council guidance [58]
Implementation		
What is delivered: • Recruitment • Reach • Fidelity • Dose • Adaptations	• Registration of participants during meetings and GMB sessions • Exit surveys to all participants (after data presentation meetings, GMB2 and GMB3), semistructured interviews with the school program coordinators (after GMB2) and the principal managers (after GMB3)	• Medical Research Council guidance [58] • COMPACT Stakeholder-driven Community Diffusion Survey [59]
Mechanisms of change		
• Knowledge of health promotion • Shared understanding of health issues • Motivation and engagement • Collaboration • Shared decision-making • Resource allocation • Other emerging mechanisms	• Exit surveys to all participants (after data presentation meetings, GMB2 and GMB3), semistructured interviews with the school program coordinators (after GMB2) and the principal managers (after GMB3)	• Medical Research Council guidance [58] • COMPACT Stakeholder-driven community diffusion survey [59]
Implementation of actions—step 4 of the program		
Actions		
• Number of actions initiated • Primary variable of influence • Action level (beliefs, goals structures, events)	• Semistructured interviews with the school and municipal program coordinators quarterly	• The Systems Thinking in Community Knowledge Exchange computer software [45] • Action Scale Model [27]
Involvement		
• Number of involved participants • Level of involvement in preparation, execution, and implementation of the developed actions	• Semistructured interviews with the school and municipal program coordinators quarterly	• The involvement matrix [53]
Unintended consequences		
• Rippling effects and potential positive and negative unintended consequences of the actions implemented	• The community of practice network will be involved in a process (meetings or workshops) of identifying the rippling effects	• Ripple effect mapping [60]
Program normalization—steps 1 and 5 of the program		
Maintenance of collaboratives		
• Potentials, barriers and needs • Partnership synergy	• Notes from the meetings for program maintenance (6 months after GMB3) • Semistructured interviews with the school manager (after GMB3) and the municipal program coordinator managers (6 months after GMB3)	• Partnership synergy [51]
Program normalization		
• Coherence • Cognitive participation • Collective action • Reflexive monitoring	• Semistructured interviews with the school manager (after GMB3) and the municipal program coordinator managers (6 months after GMB3)	• Normalization process theory framework [61]

[a]GMB: Group Model Building.

Qualitative and quantitative data will be interpreted separately and combined. Quantitative data will be analyzed descriptively, whereas qualitative interviews will be recorded, transcribed, and thematically analyzed in NVivo (Lumivero) [60].

Implementation of Actions (RQ2)

Actions initiated by the school, municipal, or community actors and the consequences of these actions are a direct indicator of systems change. The number of actions initiated and the primary factors in the locally developed CLD that are influenced will be tracked and visually added to the CLD. The Action Scale Model [27] will be used to determine whether the actions address one of four hierarchical levels to change the functioning of the system in the anticipated direction: (1) beliefs (eg, the school creates a local action group as health promotion champions), (2) goals (eg, the school sets new goals for health promotion), (3) structures (eg, school and municipal staff receive training on the complexity of health), and (4) events (eg, a single sport event at schools) [27]. The hierarchical structure suggests that changing beliefs and goals will not only have a greater systemic impact but also be more costly and time consuming than implementing single events [27]. We will also examine which participants (ie, students, school staff and management, municipal staff, and community actors) are involved in the planning and implementation of the actions and how and to what extent they are involved. The involvement levels of the participant groups will be interpreted using the involvement matrix [53].

All actions and involvement will be tracked on a quarterly basis for up to 2 years after GMB3 through semistructured interviews with the school and municipal program coordinators and involved community actors to enable interpretation of the level of system change and engagement across participant groups over time (Table 1).

In addition, an adapted version of "ripple effect mapping" [62] will be used to understand the rippling-initiated actions, effects, and potential positive and negative unintended consequences of the actions implemented. The CoP will be involved in a process to explore and visualize unintended consequences.

Program Normalization (RQ3)

We will explore the opportunities, barriers, and what is needed to integrate the collaboratives and the program into normalized practice (steps 1 and 5 of the program).

The school-municipality collaboration and program normalization will be explored through interviews with school and municipal program coordinators (Table 1). Interview guides inspired by the Partnership Synergy framework [51] will be developed to explore the functioning of the collaborations and the potential for maintenance, and the normalization process theory [61] will be used as a framework for understanding program normalization. In addition, carefully written notes will be taken from the program maintenance meetings, which will be completed as part of step 5 of the program.

Interviews will be recorded and transcribed, and all data will be analyzed thematically in NVivo [60] to understand opportunities, barriers, and needs related to sustaining collaborations and normalizing the program. Finally, we will develop recommendations for the implementation of systems approaches for sustainable health promotion in vocational schools.

Organizational Outcomes (RQ4)

School organizational readiness to address health promotion is selected as a primary organizational outcome. We will apply the "organizational readiness framework" [50] to track change over time. Organizational readiness refers to the extent to which an organization is willing and able to implement change, and the elements in the framework have previously been shown to be related to implementation success [63]. School organizational readiness will be assessed by questionnaires administered to all school staff, supplemented by semistructured interviews with the principal managers at the schools (Table 2).

Table 2. Items, methods, instruments, and frameworks used in evaluation of effectiveness (research questions 4 and 5).

Component and items of interest	Methods and data	Applied evaluation instruments and frameworks
System outcomes		
Organizational readiness		

• Baseline and change in the following:
  • Organizational motivation
  • General capacity
  • Health promotion capacity
	• Questionnaire to staff members (4 times in total)
	• Semistructured interviews with principal managers (after GMB[a]3)
		• Organizational readiness [50]

Individual outcomes		
Health behavior		

• Baseline and changes in the following:
  • Mental health and well-being
  • Physical activity
  • Food intake
  • Nicotine use
  • Alcohol use
	• Questionnaire to all students (4 times in total)	• WHO-5[b] [64] and SGPALS[c] [65]
		• Validated measures from the Danish National Health Survey and the Health Behaviour in School-aged Children study [66]

Health promotion outcomes		

• Baseline and changes in the following:
  • Health literacy
  • Knowledge relevant to the problem of interest
  • Self-empowerment
  • Self-confidence
  • Self-efficacy
  • Behavioral intentions
  • Motivation
  • Social network and interaction
  • Social connectedness
  • Student autonomy
	• Questionnaire to all students (4 times in total)	• HLQ[d] [67]; HLSAC[e] [68] validated measures from the Danish National Health Survey and the Health Behaviour in School-aged Children study [66]

[a]GMB: Group Model Building.

[b]WHO-5: World Health Organization (Five) Well-Being Index.

[c]SGPALS: Saltin-Grimby Physical Activity Level Scale.

[d]HLQ: Health Literacy Questionnaire.

[e]HLSAC: Health Literacy for School-Aged Children.

The questionnaire instrument will adapt and refine existing and tested items [20,69] across 3 dimensions and 10 subdimensions: motivation (relative advantage, compatibility, complexity, and priority), general capacity (culture, climate, and staff capacity), and program-specific capacity (knowledge, skills, and abilities). We will use exploratory and confirmatory factor analyses to initially validate the instrument and assess its internal consistency and convergent validity. The questionnaire will be distributed electronically via email in SurveyXact [70] to all school staff (eg, teachers, counselors, and administrators), and repeated data will be collected 4 times during the study period (Figure 2). Changes in school organizational readiness will be assessed primarily using linear mixed modeling, adjusting for clustering, with school as a random effect and time as a fixed effect.

Interviews with school leaders will contribute to a deeper understanding of how the support and priorities of the school management can stimulate or hinder the school's readiness and willingness to change. The interviews will be recorded, transcribed, and analyzed thematically according to the dimensions and subdimensions of organizational readiness.

To generate a comprehensive understanding of school organizational readiness, a convergent parallel mixed methods design will be used in the analyses [71]. Quantitative and qualitative data will be analyzed independently and then compared, related, and interpreted.

Individual Outcomes (RQ5)

We will explore the indications of effectiveness at the individual level through changes in students' health behaviors and well-being. Items to assess health behavior will primarily consist of validated measures and items used in other national health profile studies in Denmark (Table 2). The research team will preidentify one primary and one secondary outcome indicator item for each targeted health area (ie, dietary behavior, physical activity, alcohol consumption, marijuana and drug use, and well-being). The primary indicator will be an item assessing students' health behavior during school time, and the secondary

indicator will be an item assessing health behavior during leisure time or overall.

Following Bauman and Nutbeam [8], we will assess both health behavior and health promotion outcomes to understand the complexity of health behavior. While health behavior outcomes are expressed in terms of changes in, for example, levels of physical activity or mental well-being, health promotion outcomes are personal, social, and environmental factors that are a means of improving people's ability to change behavior [8]. Therefore, health promotion outcomes are considered intermediate to health behavior (see Table 2 for examples).

The questionnaire data will be collected 4 times (Figure 2). Regardless of the specific health issue each school chooses to address, all students will receive the same questionnaire to identify potential intended and unintended consequences on other health promotion outcomes or behaviors, as suggested in a complex systems sense [46,72]. Electronic questionnaires in SurveyXact [70] will be distributed during school hours by the research team, who will be present in the classrooms so that students can ask questions as they complete the questionnaire. The estimated student population of the 8 program schools is approximately 2000 and, based on previous experience with this procedure [54], we expect that 90% of the students present in class will complete the questionnaire at each of the 4 data collection points. Informed consent will be obtained from all students and can be withdrawn at any time.

Most analyses will be based on cross-sectional data and descriptive in nature, interpreting the mean differences between the intervention and control groups. However, the analyses will also include linear mixed models with time and selected covariates (eg, gender, age, ethnicity, and socioeconomic status) as fixed effects and school as a random effect. It is important to note that the total time of 2 years to assess individual outcomes may be too short to provide conclusive evidence at this level.

Ethical Considerations

The study has been referred to the Capital Region of Denmark's legal center for personal data handling (journal number: P-2021-327). The study will be conducted without approval from the Committees on Health Research Ethics for the Capital Region of Denmark (journal number: 22012766), as this is not required for social health science in Denmark [73]. Participation in research related to the study is voluntary and requires written informed consent from all participants. Consent may be withdrawn at any time. Questionnaire data, key files, audio files, and transcripts of interviews and observations will be stored in a secure folder on the corporate network in accordance with the requirements of the Capital Region of Denmark and European General Data Protection Regulation. Only the principal investigator and those with permission from the principal investigator will have access to data. None of the authors have any financial or competing interests.

Results

This study was launched in 2021, and data collection is expected to be completed in June 2024. The first results will be submitted for publication in January 2024. The results of this research will be disseminated through national and international conferences, peer-reviewed journals, reports, and web-based sources. In addition, key findings will be disseminated through the CoP and other national practice network meetings with stakeholders and policy representatives.

Discussion

Overview

The Data Health study is the first to apply a systems approach to the implementation and evaluation of health promotion programs among vocational school students. The program comprises 5 steps aimed at establishing strong collaborations, building local capacity, identifying leverage points, and generating and implementing collective actions for systems change to improve health and well-being among vocational students. The program will be accompanied by a systems-based evaluation to support the sustainability of program implementation and to determine the scalability of the program. Guided by the Medical Research Council guidance, the evaluation will assess implementation outcomes, contextual differences, and the mechanisms through which the program leads to changes in systems, school organizational readiness, and health behavior and well-being.

Strengths and Limitations

Program Implementation

The steps of the Data Health program are based on systems and health promotion theory, previous health promotion evidence, and formative evaluation at a pilot site. This study has the potential to improve the health behavior and well-being of vocational students and reduce social inequalities in health. The use of systems approaches in communities to address childhood obesity has shown promising results [31,74]. However, adaptation to disadvantaged educational settings may be challenging. One possible challenge is to engage students who are only in school for short periods between workplace-based training. As workplaces are likely to be located across municipalities, it may be difficult to engage students in the GMB process and implementation of actions during workplace training. If possible, we will try to involve the local workplaces in creating collective actions in GMB3 to involve the students, even if they are not physically at the school.

In most health promotion programs, resources often run out before the desired changes in individuals or systems are normalized [75]. The sustainability of actions for system change has been demonstrated in communities, with actions continuing to be implemented years after the reduction in research support [76]. On the basis of locally relevant data and existing capacities and resources, we will test whether the program steps can be successfully sustained. However, sustainable and long-term partnerships between schools, communities, and municipalities can be challenging owing to organizational changes or staff turnover. To address this issue, we will seek to engage and motivate commitment at the management level. In addition, the CoP will serve as an informal capacity building and will expectantly keep the organization as the drivers for systems

change. If the steps in the program prove to be sustainable and effective, the CoP can be used to disseminate knowledge about methods and approaches to other schools and municipalities interested in implementing the Data Health program.

Program Evaluation

This study involves a complex program evaluation. The processes and steps within the Data Health program are systematic but flexible in the sense that the study sites themselves choose the targeted health issue, actions, and process for normalization. The complexity of a systems approach does not allow for a fully randomized controlled trial with a single set of quantitative outcomes [26]. Therefore, we will use a systems-based and quasi-experimental design to test the preliminary effectiveness of the program at an individual and organizational level. We will use mixed methods to account for the complexity and contextual variation. The comprehensive evaluation design of program implementation and outcomes—combining many data sources from different perspectives—will generate new knowledge that can be used in similar or different contexts at the national and international levels.

To our knowledge, few studies have reported on the implementation of systems approaches and sustainment of actions over time [43,77], particularly using GMB as a participatory method. Understanding the use of GMB in a school setting will provide important information for researchers and practitioners regarding enablers and barriers to this approach.

The systems-based evaluation design provides an opportunity to test new system-level evaluation methodologies, such as the Action Scale Model [27], measuring change within complex adaptive systems. There are many uncertainties in studying changes in complex systems, as complex systems are dynamic [26]. Therefore, we recognize that capturing systems change might not be fully comprehensive. To accommodate this, we set systems boundaries to determine what is relevant to capture and will be used to guide the evaluation.

In parallel, we will assess preliminary indications on individual-level outcomes, assessing the effectiveness on students' health behavior and well-being because of systems change. A limitation of this study is that most of the student data will be cross-sectional because of the vocational school structure. The research team will explore the possibility of tracking individuals' educational attainment, employment status, and health registers (compiled by Statistics Denmark [78]) 5 or 10 years postprogram implementation.

This study will test a systems change approach in vocational schools and whether such an approach is suitable for adaptation and scale-up. If this study is shown to be sustainable and effective, the established CoP will support implementation at scale.

Acknowledgments

The authors would like to acknowledge professor Karien Stronks from the Department of Public Health, Academic Medical Centre, University of Amsterdam, for commenting on an earlier draft of this paper and for providing valuable inputs to the study.

Authors' Contributions

CDK, LWR, ALB, and CH conceived the overarching program. AS was responsible for the pilot test and the formative evaluation of the study. CH designed the research design of the study and wrote the main manuscript. RDH, ALB, RFK, AB, and CDK contributed to the research design and writing of the manuscript. LWR, AS, and SA contributed to writing the manuscript. All authors have read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Endovascular thrombectomy (ET), combined with intravenous thrombolysis if possible, is an effective treatment option for patients with stroke who have confirmed anterior large vessel occlusion (aLVO). However, ET is mainly limited to comprehensive stroke centers (CSCs), resulting in a lack of ET capacity in remote, sparsely populated areas. Most stroke networks use the "Drip and Ship" or "Mothership" strategy, resulting in either delayed ET or intravenous thrombolysis, respectively.

Objective: This study protocol introduces the *Leitstellen-Basierte Erkennung von Schlaganfall-Patienten für eine Thrombektomie und daraufhin abgestimmte Optimierung der Rettungskette* (LESTOR) strategy, developed to optimize the preclinical part of the stroke chain of survival to improve the clinical outcome of patients with suspected aLVO stroke. This involves refining the dispatch strategy for identifying patients with acute aLVO stroke using a phone-based aLVO query. This includes dispatching emergency physicians and emergency medical services (EMS) to urban emergency sites, as well as dispatching helicopter EMS to remote areas. If a highly suspected aLVO is identified after a standardized aLVO score evaluation during a structured examination at the emergency scene, prompt transport to a CSC should be prioritized.

Methods: The LESTOR study is a controlled, nonrandomized study implementing the LESTOR strategy, with a stepped-wedge, cluster trial design in 6 districts in southwest Germany. In an interprofessional, iterative approach, an aLVO query or dispatch protocol intended for use by dispatchers, followed by a coordinated aLVO examination score for use by EMS, is being developed, evaluated, and pretested in a simulation study. After the training of all participating health care professionals with the corresponding final aLVO query, the LESTOR strategy is being implemented stepwise. Patients otherwise receive usual stroke care in both the control and intervention groups. The primary outcome is the modified Rankin Scale at 90 days in patients with stroke receiving endovascular treatment. We will use a generalized linear mixed model for data analysis. This study is accompanied by a cost-effectiveness analysis and a qualitative process evaluation.

Results: This paper describes and discusses the protocol for this controlled, nonrandomized LESTOR study. Enrollment was completed in June 2023. Data analysis is ongoing and the first results are expected to be submitted for publication in 2024. The project started in April 2020 and will end in February 2024.

Conclusions: We expect that the intervention will improve the clinical outcome of patients with aLVO stroke, especially outside the catchment areas of CSCs. The results of the accompanying process evaluation and the cost-effectiveness analysis will provide further insights into the implementation process and allow for a better interpretation of the results.

Introduction

Background

Clinical outcomes of patients with acute ischemic stroke due to the occlusion of the proximal large intracranial arteries (large vessel occlusion [LVO]) remain poor when treated with intravenous thrombolysis (IVT) alone [1]. In recent years, the treatment of patients with acute LVO stroke with endovascular thrombectomy (ET), combined with IVT if possible, has been shown to produce tremendous clinical improvement [2].

In contrast to the widespread access to IVT (usually accessible at any type of stroke center—primary stroke centers [PSCs] or comprehensive stroke centers [CSCs]) in German, ET is mainly limited to CSCs due to the need for technological resources and specialized interventional physicians. This leads to a shortage of ET capacities in remote, sparsely populated areas.

Several strategies exist for the management of patients with suspected LVO in geographic areas not primarily served by a CSC, none of which are superior in terms of stroke outcome [3-6]. Currently, most stroke networks use the “Drip and Ship” (DS) or the “Mothership” (MS) strategy. According to the DS strategy, all patients with acute stroke are transferred to the nearest—in nonurban areas, mostly primary—stroke center to receive IVT if appropriate. Only if imaging indicates LVO and the patient is a candidate for thrombectomy would subsequent transfer to a CSC be initiated.

Following the MS strategy, patients with acute stroke are evaluated on scene with a stroke severity score to assess for possible LVO. Patients with a high probability of LVO stroke bypass the PSC and are transferred directly to the CSC, where both IVT and—in case of proven LVO—ET can be performed. Both the DS and MS strategies present advantages and disadvantages. The DS strategy assumes faster administration of IVT, but IVT is delayed due to the time delay in organizing and performing the transfer to the CSC [7]. On the other hand, the direct transfer to a CSC (MS strategy) results in faster initiation of ET but at the expense of delayed or even denied IVT administration due to longer ground transport times.

Since air rescue is the main means of transport for longer distances (>50 km) in the stroke network in southwest Baden-Wuerttemberg (including sparsely populated areas of the Black Forest region), optimizing the transport allocation process could shorten preclinical times in this region and comparable areas. Data from air rescue missions in Germany showed that parallel dispatch of emergency medical services (EMS) and helicopter emergency medical services (HEMS) resulted in equal arrival times of EMS and HEMS at the emergency site, shortest on-scene time, and reduced transport time to the most appropriate hospital [8]. Hence, to optimize prehospital logistics in the event of an LVO stroke, parallel dispatching of EMS and HEMS would require the identification of patients with possible LVO stroke by dispatchers in the emergency control centers (ECCs). Dispatchers already use simple stroke screening algorithms such as the “Face Arm Speech Time” (FAST) scale [9] as the basis for standardized protocol-based stroke detection in medical emergency calls. However, these simple stroke scales (relying on 1 single stroke symptom only) might be insufficient for reliable LVO detection. Lately, many publications have underlined the high value of cortical signs, such as aphasia and neglect, in combination with hemiparesis, to predict the presence of anterior LVO (aLVO), defined as emergent occlusion of the intracranial carotid artery, the tandem intracranial carotid artery, or the middle cerebral artery (M1 or proximal M2 segment) [10-12]. A recent study consistently showed that the reporting lay first responders mentioned aphasia and conjugate eye deviation (as a symptom of neglect syndrome) during emergency calls for patients with aLVO stroke [13]. It may therefore be possible to develop a stroke query specifically designed for the interaction between dispatchers and the reporting lay first responders to detect cortical signs in patients with aLVO stroke in emergency calls (“aLVO query”).

Considering the requirements and disadvantages of the DS and MS strategies, this study’s authors developed the new *Leitstellen-Basierte Erkennung von Schlaganfall-Patienten für eine Thrombektomie und daraufhin abgestimmte Optimierung der Rettungskette* (LESTOR) strategy. The aim is to optimize the dispatching strategy after the identification of patients with acute stroke with a high probability of aLVO stroke at the dispatcher level by using an aLVO query adapted to the dispatchers’ needs. This includes the dispatch of emergency physicians (EPs) in addition to EMS personnel for urban emergency sites and the parallel dispatch of an air ambulance for nonurban emergency sites for longer distances. A highly qualified EP with the most suitable rescue transport equipment arrives at the scene as quickly as possible for a structured assessment of aLVO probability by applying a standardized aLVO score. If a high suspicion of aLVO persists on-site, transport to a CSC can take place as quickly as possible.

With this strategy, this study's authors want to eliminate the disadvantage of the delayed application of IVT in the MS strategy by enabling an early IVT administration comparable to the DS strategy with the help of the fastest possible transport, even to regions far from the CSC, while maintaining the possibility of rapid access to the MS strategy on ET.

Objective

The LESTOR study aims to investigate whether the implementation of an aLVO query at the dispatcher level with subsequent optimization of dispatch (ie, LESTOR strategy) and a structured assessment at the emergency site improves the clinical outcomes of patients with aLVO stroke. We also compare the health-economic metrics of our approach to established allocation strategies.

Intervention

Development and First Evaluation of the aLVO Query for Dispatchers

To identify patients with aLVO during telephone contact with emergency services, we intend to query the combination of hemiparesis with cortical deficits. Cortical signs (such as aphasia, neglect, and gaze deviation) in combination with hemiparesis predict the presence of aLVO with high sensitivity and specificity [10]. The Ambulance Clinical Triage for Acute Stroke Treatment (ACT-FAST) examination steps apply these fundamentals. The combination of right-sided arm paresis and aphasia or left-sided arm paresis with gaze deviation or neglect, respectively, showed high accuracy for aLVO detection in a prospective validation in EMS [14]. An advantage of the ACT-FAST algorithm is that the examination steps are adjusted to the paretic side, resulting in fewer examination steps compared to undirected scores.

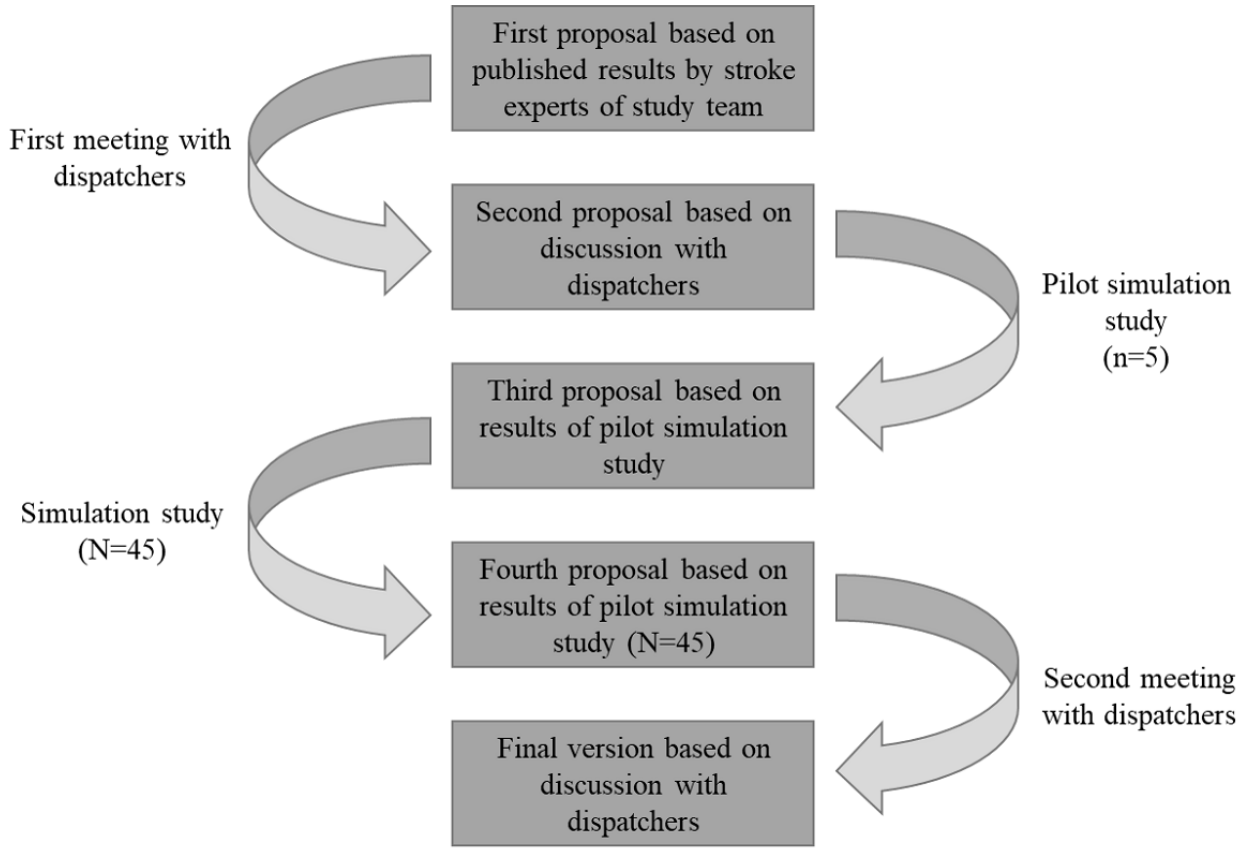
The examination steps for cortical signs and the ACT-FAST algorithm serve as the starting point for the development of the aLVO query for dispatchers. This study's authors focused on adapting the wording of the examination instructions to be comprehensible for the reporting lay first responder during the telephone query and upon collection of the results by the dispatcher on the telephone. The interprofessional development with the dispatchers of the ECCs is decisive since dispatchers are experienced in recognizing serious conditions such as cardiac arrest over the telephone. Given many years of practice in telephone resuscitation, they already have expertise in dealing with complex medical situations and communicating with laypeople who are adapted to these exceptional situations [15].

Through a multistep iteration process, this study's authors constructed an aLVO query for dispatchers aimed at identifying cortical stroke deficits (Figure 1). Stroke experts of this study's team prepared a first proposal based on previously published results [10,16]. Dispatchers (n=6) from the ECC in Freiburg and this study's team adjusted the wording in a consensus meeting about the specific requirements of the emergency call. We then evaluated this second proposal in a simulation study. Simulated patients simulated stroke symptoms with or without aLVO symptoms under controlled conditions. Further, 50 members of the public (potential lay first responders) were confronted with the simulated patients in a randomized block sequence. To ensure blinding, lay first responders simulating the emergency calls were positioned out of sight of dispatchers in another room. The dispatcher conducting the aLVO query with the lay first responder via telephone determined whether the simulated patient presented symptoms suspicious of an aLVO stroke. We recorded these encounters and analyzed this setting with the first participants, which served as a pilot test to check the procedure's comprehensibility and feasibility. Subsequently, this study's team optimized the questions' wording, if necessary. This study's authors then tested this third proposal with the remaining individuals (N=45).

By comparing the dispatcher's decision with the simulated symptoms, this study's team can determine the correct identification. We consider the aLVO query for dispatchers as sufficient if sensitivity and specificity reach at least the values that are achieved with other comparable aLVO screening scores [17] (ie, sensitivity ≥0.75 and specificity ≥0.70). Statistical case number calculations show that assuming this effect, 32 cases would be required to demonstrate significance. We therefore planned conservatively with 45 study participants (considering possible dropouts). If this study's authors do not achieve the abovementioned aims, they will further adapt the aLVO query through more in-depth instructions.

After the simulation study, this study's authors developed the fourth proposal of the aLVO query, which they finally discussed again with dispatchers. The dispatchers and this study's team approved a final version of the aLVO query for dispatchers. By using this complex, multistage procedure, we are striving for the best possible combination of test quality criteria, practical feasibility, and a high level of acceptance during the implementation phase.

Figure 1. Multistage procedure in the development of the aLVO-dispatch protocol. aLVO: anterior large vessel occlusion.



Development of the aLVO-Dispatch Protocol and Integration in the Stroke Detection Protocols in the ECC

We aim at establishing an aLVO-dispatch protocol that queries for eligibility for thrombectomy if the aLVO query is positive. Therefore, the aLVO-dispatch protocol consists of the final aLVO query, which, if aLVO is suspected, is expanded to include a query on the patient's previous state of health and the time window in which the stroke symptoms occurred. The aLVO-dispatch protocol is "LESTOR positive" at the ECC level only, if aLVO is suspected in patients who are not bedridden within the 24-hour window.

All the participating ECCs use electronic dispatch systems with protocol-based dispatching programs. For stroke detection in general, the FAST algorithm is used in all participating ECCs, followed by the immediate dispatch of EMS. We maintain this procedure and implement our aLVO-dispatch protocol directly after completing the first dispatch. Immediately afterward, the dispatcher carries out the aLVO query. If the aLVO-dispatch protocol results in "LESTOR positive," the dispatchers check whether they can optimize the dispatching strategy: within the catchment areas of the CSC, a ground-based EP is dispatched in addition to EMS; outside the catchment area of the CSC, a physician-staffed helicopter is dispatched in parallel. Both protocol-based dispatching programs (FAST and aLVO query) are not mandatory, as the dispatcher can dispatch for unambiguous cases, bypassing the structured dispatching programs to perform faster dispatching.

Development of the aLVO Query for EMS or HEMS

Since EPs and EMS or HEMS need to confirm the aLVO stroke suspicion established by the dispatchers after arrival on the scene, an analogous 2-step procedure is implemented as a secondary survey on scene. In the first step, they apply the FAST scale. If it is positive, they examine cortical symptoms indicative of an aLVO stroke. To enable a comparison between the results of the ECC and EMS or EP or HEMS, as well as to establish a "common" and concerted language at the ECC and EMS or HEMS interface, we closely adapted the examination steps of the aLVO query used in the ECC to the use in EMS or EP or HEMS ("LESTOR Score").

Development of Seminars for Training or Implementation

General Structure of the Seminars

Since the intervention involves neurological examination steps of the patient with stroke that were not previously carried out by the dispatchers or the EMS, EP, or HEMS personnel, this study's authors developed training seminars for all professionals involved in the project. We used didactically carefully designed units for knowledge transfer, including interactive, case-based examples. The didactic training concept builds on principles of the "adult learning theory" (eg, linking to everyday needs and teaching problem-oriented approaches) [18]. Experienced stroke physicians who are part of our study team taught stroke symptoms, recanalizing therapies, and existing referral concepts (DS and MS) with their potential barriers. This study's team then introduced the LESTOR strategy as a new referral concept assessed in this study. aLVO detection, the prerequisite of this

strategy, is visualized with the use of video samples demonstrating simulated patients with hemiparesis and the corresponding cortical symptoms. The stroke experts also taught practical applications of the examination steps and their interpretation, including pitfalls. Due to the COVID-19 pandemic, all the training was held digitally using videoconferencing software. To enable discussions, time slots for discussions were planned at 3 predetermined time points within each seminar.

Adaptions of Seminars for Dispatcher Training

Due to limited practical familiarity with strokes, adjustments for dispatchers included a more detailed description of stroke symptoms, therapies, and referral concepts. Adapted to the dispatchers' workplace situation, we taught the content and application of the aLVO query additionally with a recorded simulated emergency call. To optimize training success, small groups of 4 dispatchers were taught in 4-hour sessions, resulting in 6 to 10 training seminars for each ECC.

Adaptions of Seminars for EMS or HEMS Personnel and EP Training

In the 2-hour seminars for EMS or HEMS personnel and EPs, we introduced the "LESTOR Score" that complements the examination of patients with FAST-positive stroke at the emergency site. To this end, the specifically designed LESTOR app offers additional teaching of the examination steps and algorithm support (see below). Special focus lies on the allocation and prenotification process for patient who are LESTOR positive s.

Supporting Materials

LESTOR App

This study's team has developed a freely available mobile app intended to support the implementation and penetration of the "LESTOR Score" in the EMS or HEMS and for EPs. The main aim of the app is to consolidate knowledge through e-learning modules (eg, instructions, illustrations, and explanatory videos).

Further Materials

Professionals participating in this study can access training and study content digitally to repeat content and train new personnel in the LESTOR approach, including pocket cards and handouts for EPs and EMS or HEMS personnel.

Intervention Implementation

The intervention consists of (1) the implementation of the aLVO-dispatch protocol for suspected stroke at the ECC level, (2) the adjustment of the dispatch in case of a positive aLVO query result, (3) the structured aLVO reassessment on-scene, and (4) the referral strategy of patients with stroke depending on the aLVO probability.

First, after accomplishing stroke dispatch following a positive FAST score, the aLVO-dispatch protocol is started automatically in the ECC, resulting in either "LESTOR negative" (with no further action) or "LESTOR positive" results.

Second, a "LESTOR positive" result of the aLVO-dispatch protocol necessitates a review of the dispatch made: inside the catchment areas of the 2 CSCs, a ground-based EP is dispatched in addition to EMS, whereas outside the catchment area of the 2 CSCs, HEMS is dispatched in parallel.

Third, on the scene, in case of a FAST-positive stroke, EMS, HEMS, or EPs repeat the aLVO query, by applying the aLVO query customized for their situation ("LESTOR Score"), supported by the mobile app or the pocket card.

Finally, the referral strategy of patients with stroke depends on the result of the LESTOR Score on the scene, time window, and preexisting severe impairment due to another disease.

Patients who are "LESTOR positive" without severe impairment due to another disease, and where the duration of symptoms is <24 hours, are transported to the next CSC: via ground-based dispatch when inside the catchment areas of the CSCs, and via air-based dispatch when outside the catchment area of the 2 CSCs. All other patients with stroke are transported to the nearest stroke unit, regardless of whether they are a PSC or CSC.

Methods

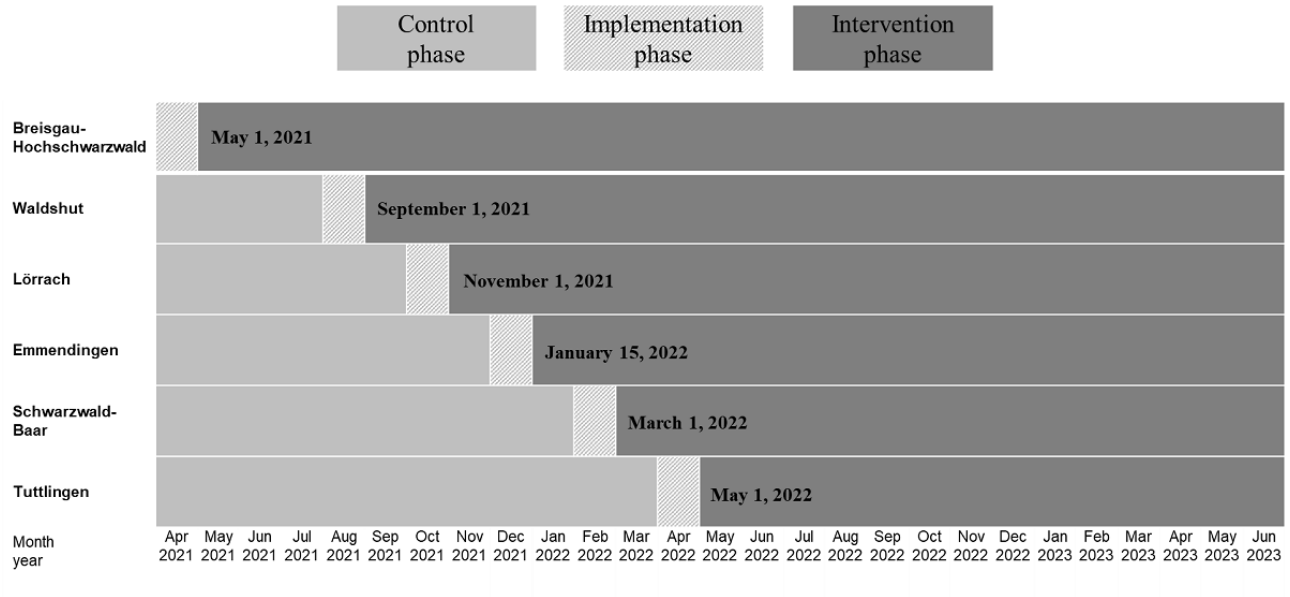
Overview

The LESTOR study comprises various process stages and an accompanying process evaluation. We prospectively registered the trial for the World Health Organization Universal Trial Number and in the German Clinical Trials Register (DRKS00022152) on October 19, 2020.

Study Design

This study's authors performed a controlled, nonrandomized study, introducing the LESTOR strategy with a nonrandomized, stepped wedge, cluster trial design in 6 districts (ie, clusters) in Baden Wuerttemberg in southwest Germany (Figure 2).

Figure 2. Stepped wedge, cluster trial design of the LESTOR study in 6 districts. LESTOR: Leitstellen-Basierte Erkennung von Schlaganfall-Patienten für eine Thrombektomie und daraufhin abgestimmte Optimierung der Rettungskette.



Each cluster includes 1 ECC. Ground emergency medical ambulances are nearly equally distributed across the districts. All 6 districts are supported by 3 air rescue facilities. Further, 6 PSCs and 2 CSCs provide stroke service. The research team sequentially assigns the clusters to the intervention at intervals of 2 to 3 months in an unblinded manner (Figure 2).

This study's team implemented the multicomponent LESTOR approach simultaneously for each cluster's ECC, EMS personnel, EPs, and stroke units. Since HEMS were involved in the intervention from the beginning, this study's authors introduced the LESTOR approach to the 3 air rescue facilities before the implementation of the first cluster.

Each cluster passed through the following phases:

Phase 1 was the control phase (preintervention baseline phase, 3-15 months). During phase 1, ECCs carried out the emergency call and stroke dispatch by local standards: they used the FAST scale for stroke detection, followed by the immediate dispatch of EMS (with additional EP dispatch depending on local conditions). EMS personnel and EPs also used the FAST scale for stroke detection at the scene. The standard allocation for stroke patients was the nearest stroke unit (regardless of whether it is a PSC or CSC). Allocation to CSCs outside their catchment area was based on an individual decision by the EMS or EP to contact the CSC and requires CSC approval. If a helicopter was considered to be the most suitable means of transport on-site, a sequential additional request for the helicopter must be made.

Phase 2 was the implementation phase, when all the professionals involved in acute stroke patient care in a cluster participated in seminars (see above) paralleling the technical implementation of the aLVO query.

Phase 3 was the intervention phase (14-26 months), which follows the intervention's implementation as described above.

Patient Recruitment

In total, 6 districts in Baden Wuerttemberg in southwest Germany participated in the LESTOR study (Breisgau-Hochschwarzwald, Loerrach, Emmendingen, Schwarzwald-Baar, Tuttlingen, and Waldshut) including 6 ECCs; the EMS and EPs of all districts; 3 air rescue facilities; and all the stroke centers of the 6 districts: 2 CSCs (Freiburg im Breisgau and Villingen-Schwenningen) and 6 PSCs—5 of them having a telestroke connection. The maximum distances to CSCs in this study's area were about 120 km by ground and about 80 km by air, while the distances to PSCs were mostly less than 30 km by ground. The distribution of stroke units was specified by the Ministry of Social Affairs in Baden Wuerttemberg, Germany [19].

The 6 districts cover a population of about 1.4 million people living on almost 6000 square kilometers; population density in this area is 233 per square kilometer on average, with the minimum in the district Waldshut (151.4 per square km) and the maximum in the district of Loerrach (283.7 per square km) [20]. According to the Organisation for Economic Co-Operation and Development "Urban-rural classification for NUTS 3 regions" [21], all 6 districts are classified as intermediate regions (rural population between 20% and 50% of the total population). As a regional peculiarity, 5 out of 6 districts have a share of the sparsely populated Black Forest with areas that are difficult to access.

Each district had 1 ECC, operated by the aid organization "Red Cross" and the state administration of each district. EMS was provided in the vast majority by the aid organizations "Deutsches Rotes Kreuz (Red Cross)" and "Malteser," while EPs were organized by the hospitals assuring EP coverage within each district. EMS and EPs were organized at the district level. All 6 districts were supported by 3 air rescue facilities (the German *Deutsche Rettungsflugwacht e. V. Luftrettung*, the Swiss *Rettungsflugwacht Garde Aérienne*, and the Swiss Alpine Air

Ambulance) with 5 helicopters during the day and 4 helicopters at night.

Inclusion and Exclusion Criteria

Inclusion Criteria

Eligible for inclusion were patients aged older than 18 years presenting stroke symptoms that can be treated within 24 hours of the initial symptoms' onset.

Exclusion Criteria

Exclusion criteria were preexisting severe impairment due to another disease (corresponding to level 5 of the modified Rankin Scale [mRS]: "Severe disability; Bedridden, incontinent, requires constant nursing assistance") [22-24], patients in a coma (National Institutes of Health Stroke Scale [25] item of consciousness>2), patients with an unstable clinical status who required emergent life support care, patients hospitalized with acute stroke and suspected aLVO, and patients unlikely to be available for the 90-day follow-up (eg, no fixed home address or visitor from overseas).

Primary and Secondary Outcomes

Primary Outcome

The primary outcome was the mRS score at 90 days in patients with ischemic stroke who received ET. The mRS measures the degree of disability after a stroke with a score ranging from 0 to 6 (0=no deficit; 1=minor deficit without limitations; 2=deficit with limitations; 3=dependence, but independent walking possible; 4=dependence, independent walking no longer possible; 5=being bedridden; and 6=death) [22-24]. The primary outcome was assessed by a structured telephone interview conducted by a central assessor blinded to group allocation.

Secondary Outcomes

Prespecified secondary outcomes were the dichotomization of the mRS (day 90) into scores of 0-2 and 3-6 and the time from emergency call to hospital admission.

Control Variables

Control variables were age, sex, pre-mRS score, and severity of stroke (National Institutes of Health Stroke Scale) [25] at hospital admission.

Data Collection

This study's team asked each participating ECC to share their aLVO-query results with the research team along with time metrics. This study's authors also collected deidentified case data from the 2 ECCs receiving endovascular treatment in a database. A study staff member blinded to group allocation requested the 7-point (0-6) mRS by telephone from patients with stroke receiving endovascular treatment or their guardians 90 days after stroke (unblinded treatment and blinded end point assessment). For the health economic evaluation, this study's authors asked the medical controlling department of the University Medical Centre of Freiburg.

Health Economic Evaluation

This study's team will analyze the costs associated with hospitalization and the intervention for all the patients. Data will be provided by the medical controlling department of the University Medical Centre. This study's authors will also perform a cost-effectiveness analysis, whereby the primary end point (mRS) is related to the total costs.

Power Considerations

A power analysis showed that testing for the statistically significant superiority of the intervention over the control group required far more cases (N=664) than available in the target region during this study's period. This study's authors, therefore, conducted a controlled feasibility study to explore achievable effects and practicability under routine care conditions. This study's team will explore the clinical significance of the intervention effects and refrain from testing for the statistical superiority of the intervention over the control group.

Statistical Analysis

We will use a generalized linear mixed model following the basic model proposed by Hussey and Hughes [26], including the 6 districts as clusters. This study's team will extend the model as proposed by Hemming et al [27] and Li et al [28] to control for the secular trend to avoid potential bias. We will therefore stratify the sample by the 2 stroke centers and add a fixed effect for the secular trend stratified by each of these 2 hospitals, taking into account the control variables. We will assume the same treatment effect in both strata but will exploratively test this assumption by extending the model with an interaction term.

As studies have shown that it is advantageous to examine the full-scale range of mRS—rather than dichotomizing it—this study's authors will account for the ordinal scaling of the mRS [29].

We will conduct exploratory subgroup analyses for cases within and outside of the catchment areas of the 2 CSCs and consider the dichotomous mRS because a favorable clinical outcome is defined as mRS≤2 similar to Goyal et al [2]. In addition, the area under the curve for different mRS cutoff values will be calculated in an exploratory sensitivity analysis.

Missing Values

We will use multiple imputations [30], assuming that the data are missing at random, and perform a full case analysis as a sensitivity analysis for the imputed model.

Process Evaluation

The process evaluation will consist of semistructured, guideline-based individual telephone interviews conducted by trained researchers to assess the implementation process at 2 points in time (in the middle of and at the end of the intervention phase). This study's authors will interview representatives of the ECC, EMS and HEMS personnel, EPs, and first responders. A study nurse will recruit lay first responders of patients receiving ET at the University Hospital of Freiburg to participate in interviews. Key topics for the interviews with medical professionals will be the feasibility of implementation, accessibility, acceptability, appropriateness, fidelity, penetration, and sustainability of the intervention. This study's authors will ask lay first responders about the emergency and personal stress, and the instructions given during the emergency call. Further,

2 independent researchers will use Kuckartz's [31] multistage qualitative content analysis to analyze transcribed data using MAXQDA (VERBI Software GmbH) software.

The results of the first interview round will provide input for a midintervention workshop for all participating medical professionals involved in this study. The workshop aims to discuss the experience and data gained to improve the intervention. The results of the second interview round may help to optimize the intervention for future implementations and projects.

Ethical Considerations

This study's authors did not expect any disadvantages for patients when applying the aLVO query. Even if the aLVO assessment failed and aLVO-positive cases were missed, patients received standard care.

By the local ethics committee, this study's team had established a waiver of consent approach, as a high proportion of patients with stroke with aLVO experienced severe neurological sequelae and had diminished capacity to consent. Moreover, acute psychological distress occurred in approximately 30% of cases during the acute phase, and obtaining consent from relatives, legal guardians, or health care proxies was only possible in a small proportion of cases without causing undue additional psychosocial stress for the representatives [32]. The researchers inform patients using an invitation about a telephone call, which addresses the patient's further neurological course at 90 days after stroke.

For the process evaluation, the interview partners will be informed, in written and verbal form, about this study and must have agreed to the procedure. Project participation will be voluntary and consent can be revoked at any time.

Ethical approval for this study was obtained from the Ethics Committee at the University of Freiburg (416/20; August 10, 2020). The project started in April 2020 and will end in February 2024. All procedures were performed in accordance both with the ethical standards of the institutional or national research committee, and the 1964 Helsinki Declaration and its later amendments or with comparable ethical standards. This study protocol adheres to the recommended SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) checklist.

Results

The development phase of this study was completed and the successful integration of the LESTOR strategy into the daily work was in place before patient enrollment. This study was conducted between April 2020 and February 2024, with final data collected by June 2023 and final analyses and results anticipated by mid-2024.

Discussion

Relevance

More than 7 years after the establishment of ET as the standard therapy for aLVO stroke, the best prehospital care and strategy for patients with aLVO stroke, particularly outside the catchment areas of CSCs, remains unclear.

This study aims to evaluate a new strategy, targeting the essential steps of the prehospital section of the stroke chain of survival. The detection of aLVO stroke in the emergency call enables optimization of the dispatch process in terms of human expertise as well as for means of rescue. Involving the lay first responder in the clinical examination of cortical signs for aLVO detection over the telephone represents a major challenge, which this study's authors aim to address with their multistage, interprofessional development process for the aLVO query in the ECC. Re-establishing the aLVO suspicion by EMS, HEMS, or EPs necessitates the introduction of a structured aLVO examination, which the stroke study team closely adapted to the examination steps of the aLVO query used in the ECC ("LESTOR Score"). The LESTOR strategy might enable a delay-free transport to the CSC and could therefore overcome the disadvantage of the MS strategy and still provide an equally fast initiation to thrombolysis as the DS strategy by maintaining the faster access to ET.

As this new strategy does not require any additional human or material resources, other than training time for all the parties involved, it may be easy to implement in comparable regions. The extensive accompanying process evaluation and the health economic evaluation should help to identify determinants of the implementation and thus optimize the transferability.

Limitations

The project faces several challenges. The pieces of training need to reach many dispatchers, EMS and HEMS personnel, and EPs in all 6 districts. Due to the COVID-19 pandemic, the pieces of training were delivered digitally with videoconferencing software. While this enables more flexibility in terms of participation, it may reduce interactions and learning compared to face-to-face sessions. Despite the extensive development of the query, certain known problems with the detection of a stroke in an emergency call cannot be solved, for instance, the misjudgment of strokes as falls or misclassification of aphasia as confusion or reduced vigilance. Moreover, not all callers may be able to understand and perform the instructions for the aLVO query due to stress during the emergency situation or language barriers. Although this study's team plans the trial in an area with 1.4 million inhabitants, the expected number of patients with aLVO stroke during this study's phase is likely to be too small to assess the statistical superiority of the intervention and could therefore be addressed in future trials.

Conclusion

The LESTOR study aims to optimize prehospital care for patients with aLVO stroke with a focus on reducing inequality in aLVO stroke care within and outside of CSC catchment areas. The proposed LESTOR strategy addresses the earliest possible detection of aLVO symptoms in patients suspected of having a stroke, by using the results of the LESTOR query in the emergency call to guide dispatch decisions. This may enable optimization of the dispatch in terms of human expertise as well as for means of rescue and, in case of aLVO suspicion, create the conditions for a fast and direct transport to the CSC,

including the immediate use of air rescue for longer distances to the CSC. The results of the accompanying process evaluation and the cost-effectiveness analysis will provide further insights into the implementation process and allow for a better interpretation of the results.

Acknowledgments

This study's authors acknowledge support from the Open Access Publication Fund of the University of Freiburg. This research was funded by the Innovation Committee of the Federal Joint Committee (*Gemeinsamer Bundesausschuss*) supported by the Innovation Fund (01VSF19053) and has undergone peer review by the funding body. The funding body had no part in the collection, analysis, and interpretation of study data, nor did it play a role either in the writing or submission of this paper for publication.

Abstract

Background: Telemonitoring of activities of daily living (ADLs) offers significant potential for gaining a deeper insight into the home care needs of older adults experiencing cognitive decline, particularly those living alone. In 2016, our team and a health care institution in Montreal, Quebec, Canada, sought to test this technology to enhance the support provided by home care clinical teams for older adults residing alone and facing cognitive deficits. The Support for Seniors' Autonomy program (SAPA [Soutien à l'autonomie des personnes âgées]) project was initiated within this context, embracing an innovative research approach that combines action research and design science.

Objective: This paper presents the research protocol for the SAPA project, with the aim of facilitating the replication of similar initiatives in the future. The primary objectives of the SAPA project were to (1) codevelop an ADL telemonitoring system aligned with the requirements of key stakeholders, (2) deploy the system in a real clinical environment to identify specific use cases, and (3) identify factors conducive to its sustained use in a real-world setting. Given the context of the SAPA project, the adoption of an action design research (ADR) approach was deemed crucial. ADR is a framework for crafting practical solutions to intricate problems encountered in a specific organizational context.

Methods: This project consisted of 2 cycles of development (alpha and beta) that involved cyclical repetitions of stages 2 and 3 to develop a telemonitoring system for ADLs. Stakeholders, such as health care managers, clinicians, older adults, and their families, were included in each codevelopment cycle. Qualitative and quantitative data were collected throughout this project.

Results: The first iterative cycle, the alpha cycle, took place from early 2016 to mid 2018. The first prototype of an ADL telemonitoring system was deployed in the homes of 4 individuals receiving home care services through a public health institution.

The prototype was used to collect data about care recipients' ADL routines. Clinicians used the data to support their home care intervention plan, and the results are presented here. The prototype was successfully deployed and perceived as useful, although obstacles were encountered. Similarly, a second codevelopment cycle (beta cycle) took place in 3 public health institutions from late 2018 to late 2022. The telemonitoring system was installed in 31 care recipients' homes, and detailed results will be presented in future papers.

Conclusions: To our knowledge, this is the first reported ADR project in ADL telemonitoring research that includes 2 iterative cycles of codevelopment and deployment embedded in the real-world clinical settings of a public health system. We discuss the artifacts, generalization of learning, and dissemination generated by this protocol in the hope of providing a concrete and replicable example of research partnerships in the field of digital health in cognitive aging.

Introduction

Background

In Canada, it is estimated that 2 million people, or 5.4% of the total population, are active users of publicly funded home care services, with more than half of them being aged ≥65 years [1,2]. Home care is considered a priority by the Canadian government and its provincial counterparts [3]. In the province of Quebec, a predominantly French-speaking province in Eastern Canada, the Ministry of Health and Social Services has promoted aging in place since 2003 through a policy known as "Home Support: Always the Option of Choice" ("Chez soi: Le premier choix") [4]. Despite this policy, 40% of older adults in Quebec living with disabilities report unmet home care needs [2], which has been attributed to factors such as the lack of funding, difficulties in recruiting and retaining home care staff, and the increase in care needs in an aging population [5,6]. These challenges, exacerbated by the COVID-19 pandemic, have led to urgent calls in Canada as well as in other countries to better support home care [6,7].

The presence of cognitive deficits is an important risk factor for the loss of functional autonomy [8,9] and is associated with important needs for home care support services [6]. Older adults with cognitive decline, such as those diagnosed with Alzheimer disease, are progressively dependent on others for both instrumental and basic activities of daily living (ADLs), which increases the stress and burden on caregivers (families and relatives) and social and health care services [8,9]. Everyday memory losses and difficulties identifying and recognizing their own limitations affect the ability to recall and report on events, including how they manage their ADLs [10,11]. These individuals may also put themselves at risk by engaging in behaviors that are dangerous to their health and safety, in particular when they live alone (eg, falls, kitchen fires, and medication noncompliance) [12].

Therefore, progressive cognitive decline and its impact on ADLs limit the ability of health and social services to rely on these patients to better understand their home care service needs. This uncertainty can significantly affect intervention plans and resource management [13,14]. On the one hand, this may lead to the costs of some care recipients' needs not being covered by public care services because of a lack of supporting evidence; on the other hand, some services may be offered although they are unnecessary because of clinicians' need to create contingencies to address potential risks [15,16].

In this context, we propose that a key strategy to better understand the needs of older adults with cognitive decline and optimize available human and financial resources lies in the use of digital health technologies, in particular telemonitoring of instrumental and basic ADLs—hereafter referred to as *ADL telemonitoring*.

Telemonitoring of ADLs

ADL telemonitoring is a form of remote monitoring and, as such, a component of telehealth. It is generally used to acquire proxy information about several factors or outcomes relevant to the home care support of older adults, such as functional independence, cognitive state, mobility, risk of falls, and urinary tract infections [13,14,17,18]. The information is based on data collected via several sensors, such as wearables, ambient sensors (eg, motion detectors and contact sensors), radiofrequency identification, and GPS [19]. The resulting profile of the person is based on information collected regarding their behavior in the home over the course of one or several days, such as entering and leaving a room, opening and closing kitchen cupboards, home entrances and exits, and the use of small electrical appliances. Various algorithms can be used to recognize and classify ADLs, including hidden Markov models, linear discriminant analysis, support vector machines, artificial neural networks, and adaptive network fuzzy inference system [20].

ADL telemonitoring can be used in the context of naturalistic scenario-based assessments in which participants are invited to a research laboratory apartment designed to simulate real-life situations. There, participants are usually asked to perform several scripted ADLs, such as cooking a meal, cleaning the apartment, or booking a reservation [21-24].

ADL telemonitoring can also be used in the context of real-life assessments in which participants are asked to continue their daily routine while sensors are installed directly in their homes to collect data on sleeping habits, meal preparation, hygiene,

mobility in the home, periods outside the home, and so on [25,26]. Over time, deviations from previous patterns can be detected and used to assess the ability of an older adult to live independently in the community and detect potential future critical situations [27-30].

Thus, ADL telemonitoring holds great promise to facilitate better understanding of the needs of older adults with cognitive decline, in particular those living alone, in terms of ADL functioning and home care service requirements. Indeed, research in the area of ADL telemonitoring has been expanding over the last 20 years. In a recent umbrella review, Tannou et al [31] identified over 191 experiments in the field and 17 reviews published to date. Despite this dynamism, there is still little available evidence on the effectiveness of ADL telemonitoring and strategies for integrating it successfully into health care systems [31]. Most studies have reported data on prototypes, but very few large-scale deployment studies have been conducted. Therefore, there is a pressing need for more in-depth studies on this subject.

Context and Aim

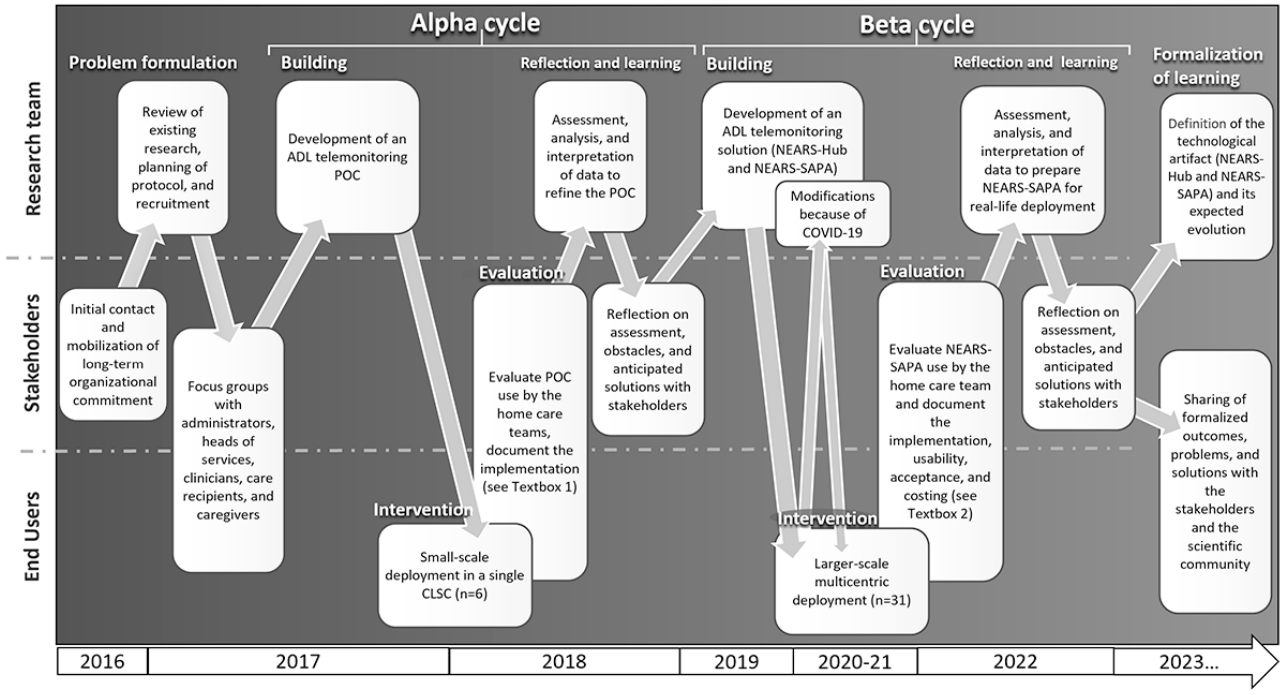
In 2016, the authors were approached by a health institution in the city of Montreal, Quebec, Canada, more specifically by the director of the *Support for Seniors' Autonomy* program (*Soutien à l'Autonomie des Personnes Âgée*s in French; SAPA). SAPA programs aim to support older adults and meet their physical, psychological, and gerontopsychiatric needs both in the community and during hospital stays. The director was searching for innovative ways to support home care clinical teams to better address the needs of older adults with cognitive deficits who live alone. The directorate was also looking for solutions to optimize the use of limited human and financial resources to offer the right service at the right moment. Our team and the top management team decided to engage in a joint research project on ADL telemonitoring, which became the "SAPA Project." The global objectives of the SAPA project were to (1) codevelop an ADL telemonitoring system that addresses the needs of all key stakeholders, (2) deploy the system in a real-world clinical setting and identify the specific use cases, and (3) identify factors that could contribute to ensuring its long-term use in a real-world setting. To foster the project's success, we engaged with all key stakeholders involved in public home care services for older adults with cognitive deficits. We considered that, to ensure the optimal use and adoption of technologies by the health care community, it would be crucial to identify existing solutions or create novel solutions that address the specific needs of all key stakeholders, including the care recipients themselves [32]. To do so, stakeholders had to be involved in every step of the project to align their needs with the technology [33].

Considering the context of the SAPA project, the use of an action design research (ADR) approach was identified as crucial. ADR provides a framework for developing practical solutions to complex problems encountered in a specific organizational setting. It is an iterative process that involves collaborations among researchers, practitioners, and stakeholders in designing [34], deploying, and evaluating interventions that improve the outcomes of a particular problem or issue [35]. This four-stage research process includes (1) problem formulation; (2) building, intervention, and evaluation; (3) reflection and learning; and (4) formalization of learning. ADR proposes the use of multiple cycles of development leading to cyclical repetitions of stages 2 and 3. Carried out in collaboration with the stakeholders (codevelopment process), these cycles allow for the refinement of the technology and related interventions to be implemented subsequently in a real-world setting. The SAPA project underwent 2 iterative technological design cycles entitled "alpha" and "beta." The alpha cycle took place from early 2016 to mid 2018, and the beta cycle took place from late 2018 to late 2022.

A key feature of the SAPA project was its novel methodological approach. In this paper, we present the SAPA research protocol and its various codevelopment and deployment phases for the 2 cycles of ADR. To our knowledge, this represents the first detailed publication of a methodological framework in this field of research. Taking the initiative to share a research design makes it possible to be more transparent about the methodologies used as well as provide an in-depth explanation of the process so that it can be reproduced in the future. It also provides a description of a concrete example of research partnerships in the field of digital health in cognitive aging.

In the following sections, we will present each cycle and stage of the project, which involve multiple research methods as recommended by action research methodologists [36]. Specific methodological details are presented in Multimedia Appendix 1. Figure 1 [35,37] presents an overview of the project's timeline and key elements of each cycle and stage.

Figure 1. Summary of action design research protocol (based on the studies by Sein et al and Schacht et al). ADL: activity of daily living; CLSC: local community services center; NEARS-Hub: Innovative Easy Assistance System–Hub; NEARS-SAPA: Innovative Easy Assistance System–Support for Seniors' Autonomy program; POC: proof of concept.



Note: Stakeholder refers to home care services directorates, administrators, and heads of services. End-users refers to clinicians, care recipient, and caregivers of home care services.

Alpha Cycle

Methods

Background

The SAPA project aimed to provide an in-depth understanding of the potential of ADL telemonitoring in the specific context of the Canadian public health care system, particularly in the province of Quebec. This province has an estimated population of 8.3 million residing in 18 administrative areas referred to as health regions. For a given health region, all public health and social services institutions are networked into integrated health and social services centers (CISSSs [*Centre intégré de santé et de services sociaux*]) or integrated university health and social services centers (CIUSSSs [*Centre intégré universitaire de santé et de services sociaux*]) when located in an area where a university offers an undergraduate medical training program or has an institute in the social services field. These administrative entities are responsible for delivering care and services to the population of an assigned territory via hospitals, residential and long-term care establishments, rehabilitation centers, child and youth protection centers, and local community service centers (CLSC [*Centre local de services communautaires*]). CLSCs offer frontline health and social services, including home care, through dedicated programs.

The alpha cycle of the SAPA project was conducted within the clinical services of the CLSC of one CIUSSS in the city of Montreal referred here as CIUSSS 1.

Problem Formulation

The alpha cycle started with a problem formulation stage aimed at conceptualizing the research problem, securing long-term organizational commitment, and clarifying roles and responsibilities with stakeholders. This stage combined theoretical and experiential knowledge informed by real-life practices [35]. As previously mentioned, the initial problem (ie, the need to support home care clinical teams in meeting the needs of older adults with cognitive difficulties living alone in the community) was brought to the research team by the health institution.

To arrive at a mutual understanding of the problem and prioritize potential technological solutions at the start of the project in late 2016, a descriptive qualitative method was followed [38]. More specifically, individual interviews and focus groups were conducted with key stakeholders (administrators, heads of services, clinicians, older adults, and caregivers; n=23 in total) of 1 specific sector covered by a CLSC of CIUSSS 1 (for more details, see Multimedia Appendix 1, section 1, as well as the study by Couture et al [34]). This sector was chosen by the head administrator as the most appropriate site for project deployment. Participants were questioned about the leverages of and obstacles to the home care of older adults and technology use within this context. At that time, neither the researchers nor the clinical team had a specific technology in mind to address the problem. However, to support the reflection process, several technological solutions were presented to the clinical teams. These included assistive devices and monitoring technologies such as smart home sensors, smart calendars, pill distributors, serious games, and stove safety devices.

One of the main findings was that administrators and clinicians thought that monitoring technologies could help them obtain more objective and reliable information to support their decision-making process to develop an adapted intervention plan with the care recipients [34,39]. More precisely, they

wanted a technology to support their assessment and management of the risks involved in maintaining care recipients at home as long as possible. A second finding was that stakeholders insisted on avoiding the use of cameras or microphones to preserve intimacy and confidentiality [34,39]. They also wanted to avoid wearable technologies as older adults with cognitive deficits would likely forget to wear them. Finally, it was mentioned that an unobtrusive technology requiring little involvement on the part of the older adults would most likely be successfully implemented.

Considering these expectations, ADL telemonitoring seemed to be the most promising technology to fully address the needs expressed by all. At the time of the study, there was no such system available on the market and ready to be deployed in a home care setting. Therefore, we resolved to design a system specifically for this research project based on our previous work [13,24,40-43]. With the stakeholders' approval of the project scope and vision, we secured a long-term organizational commitment as well as funding for the subsequent phases.

Building, Intervention, and Evaluation

Overview

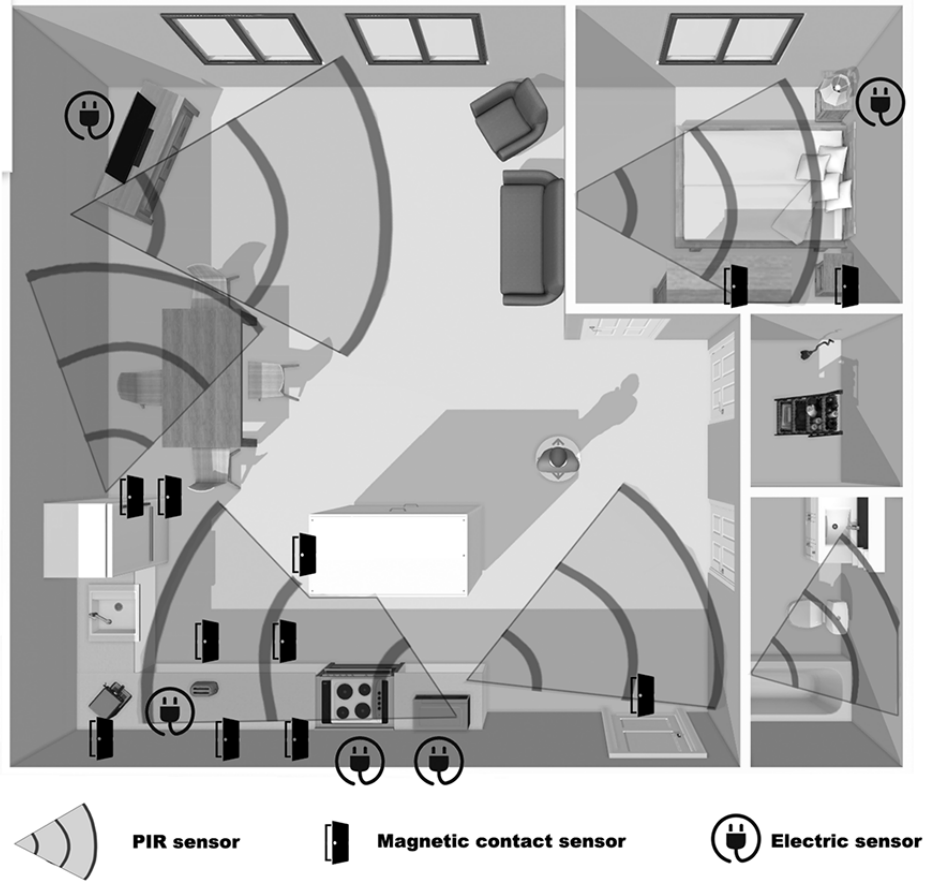
In the second stage of ADR, the initial design of the technological artifact is generated using the problem framing adopted in the first stage [35]. The building, intervention, and evaluation phase, which is an iterative process conducted in the target environment, involves building the technological artifact, intervening in the organization, and evaluating the outcomes. The product of this stage is the design of the artifact.

At this point in the alpha cycle, the overall target and goal of knowledge generation was to design and create an ADL telemonitoring system to support clinicians' decision-making process related to risk management. As is often the case in IT-dominant artifact creation, we opted to develop a proof of concept (POC) that could be quickly developed and tested in the homes of a small sample of older adults receiving home care services (ie, alpha cycle). POC versions are formative and can help validate several anticipated and unanticipated outcomes of technology use and deployment [35]. Early designs serve as lightweight interventions in a limited organizational context.

Building

For the POC, we used a lightweight sensor infrastructure comprising 4 nonintrusive, low-cost, wireless devices similar to the one deployed in the study by Caroux et al [44]. With their consent, sensors were deployed in each participating patient's home: passive infrared sensors, magnetic contact sensors, smart electric switches, and water sensors. Sensors were paired with an Internet of Things device, the VeraPlus Z-Wave Home Controller, which served as the data collection point (ie, a controller). Sensors were positioned in each home so as to capture data on ADLs, including sleeping, cooking, showering, and leaving the home (Figure 2). Multimedia Appendix 1, section 2, provides more details on each sensor's role.

Figure 2. Example of sensor placement in the home. PIR: passive infrared.



Algorithms using an inference system and finite state machine computation models were developed to monitor ADLs such as sleep, periods outside the home, cooking, hygiene, and general activity levels in the home (for more details, see the study by Lussier et al [45]). From these algorithms, it was possible to relay graphical information about the daily habits of the individual to clinicians to support their decision-making process. The information was summarized on a 3-page PDF report sent directly to the clinicians.

Intervention

In the intervention phase, the POC needs to be used firsthand by practitioners from the real-life setting for which it is designed. This participatory process provides opportunities for end users to influence and guide the design.

In early 2017, the POC was presented to clinicians and managers in team meetings in the identified testing sector. Clinicians were invited to identify older home care recipients for whom they thought ADL telemonitoring would be useful. Clinicians who wished to participate filled out a request form about their needs and the care recipient they identified. Complex cases were discussed with the research team to ensure that the needs of the clinician were within the scope of ADL telemonitoring. Recruitment procedures are detailed in Multimedia Appendix 1, section 3.

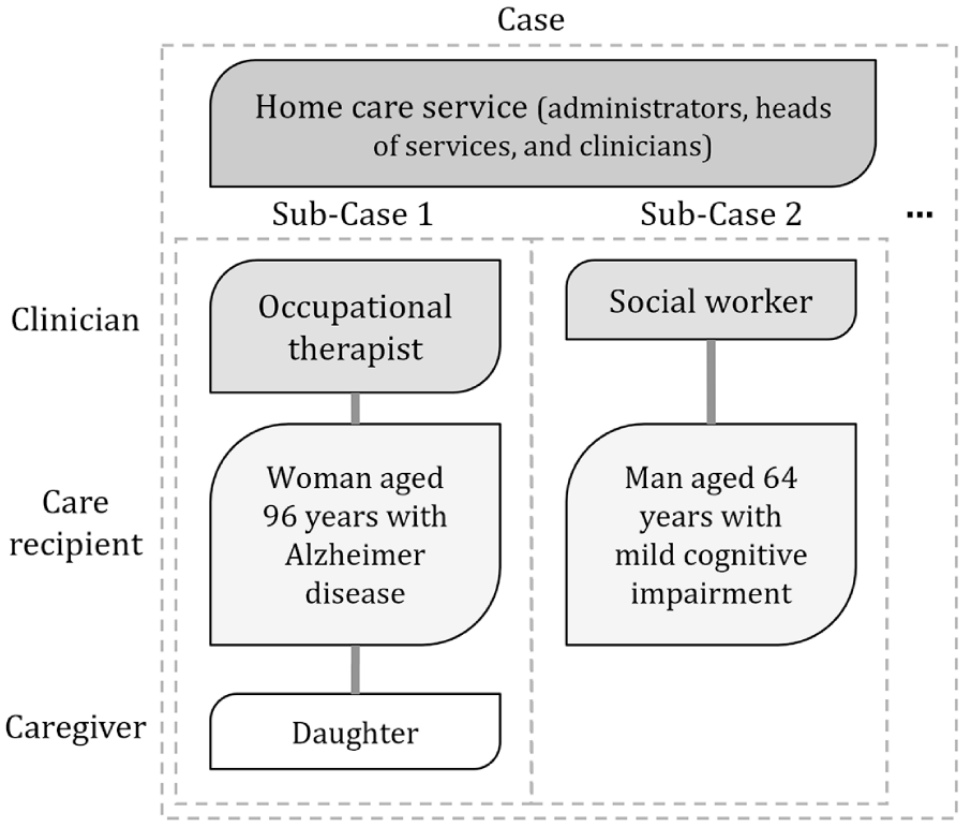
Evaluation

Overview

The general objective of the alpha cycle was to document the feasibility of using ADL telemonitoring in real-life settings and quickly iterate the POC. More specifically, the objectives pursued were to (1) describe the characteristics of the participants and their demands for telemonitoring, (2) describe the use and impact of the POC by the home care teams, and (3) document the facilitators of and barriers to POC use.

To achieve these objectives, a mixed embedded single-case study design was used [46]. Case studies are relevant when the research question requires a comprehensive description of a social phenomenon [46], as is the case here in studying the perspectives of different stakeholders on the feasibility of using technology. The single case was the home care division of CIUSSS 1. The 6 subunits consisted of care recipients (n=6); their clinicians (n=8; 2 were replaced during the project) from home care services; and, when possible, a family caregiver (n=2; Figure 3). These subunits made it possible to shed light on the personalized trajectories of each care recipient as well as the intended and actual use of the system in relation to these trajectories. Multimedia Appendix 1, section 6, provides more details on the subunits and data analysis methods. A mix of quantitative and qualitative data was collected. Textbox 1 provides an overview of the data collection process in the alpha cycle.

Figure 3. Diagram of embedded case study.



Textbox 1. Overview of the alpha cycle data collection, sample, measurements, and variables in the evaluation stage.

Telemonitoring request form filled out by clinicians and with follow-up questions via phone interviews

- Facilitators of and barriers to home care of care recipients
- Demands for telehealth technology

Characteristics of clinicians (n=8) and care recipients (n=6)

- For clinicians: profession
- For care recipients only: age, sex, years of schooling, Mini-Mental State Examination, Montreal Cognitive Assessment, Multiclientele Assessment Tool, Functional Autonomy Measurement System profile, metadata on the home care service received, cognitive evaluation (Rey Auditory Verbal Learning Test; Mini-Geriatric Depression Scale; and Delis-Kaplan Executive Function System Trail Making test, Stroop test, and Tower Test), and Instrumental Activity Profile

Initial individual interviews with care recipients (n=6) and caregivers (n=2)

- Facilitators of and barriers to home care of care recipients
- Anticipated leverages of and obstacles regarding telemonitoring deployment in home care

Total of 3 follow-up focus groups with clinicians after proof of concept installations (n=8)

- Observed facilitators of and barriers to telemonitoring deployment
- Use case, impacts, and general satisfaction regarding deployment

Postdeployment focus groups with administrators (n=2), heads of services (n=5), and clinicians (n=8)

- General facilitators of and barriers to telemonitoring deployment and sustainability
- Impacts of and general satisfaction with telemonitoring

Characteristics of Participants and Demands for ADL Telemonitoring

With the care recipients' consent, their medical history was extracted, including cognitive screening scores as well as needs for home care support, sociodemographic information, and the quantity of home care services required. Metadata were also extracted from the medical records about each service provided by the health network for each care recipient (ie, type of act and its time and duration). Finally, to obtain a more in-depth cognitive profile of each care recipient, a cognitive evaluation, as well as an evaluation of ADL performance, was completed by a research assistant. Multimedia Appendix 1, section 6, provides more details.

Clinicians who identified a care recipient and wished to participate filled out a request form detailing their demands for telemonitoring, the reasons that led them to request remote monitoring for this care recipient, and which ADL they would like to obtain more information about via telemonitoring. Through interviews, they were also asked about facilitators of and barriers to home care for this specific care recipient. After receiving the form, a research assistant called the clinician to provide any further details or clarifications as needed.

Use and Benefits of ADL Telemonitoring

During the follow-up focus groups, clinicians were asked how telemonitoring was used, for which ADL, and how it influenced their decision-making process regarding the recipients' care plan. They were also asked about their satisfaction, whether it was relevant to continue telemonitoring for each care recipient, and why.

Finally, during postdeployment focus groups, administrators, heads of services, and clinicians were asked about their general satisfaction with telemonitoring as well as the benefits it had for clinical practice.

Facilitators of and Barriers to ADL Telemonitoring Deployment

During the initial interviews, care recipients and caregivers were asked whether they foresaw any barriers to and facilitators of the deployment of the ADL telemonitoring system. In addition, to document their perceived needs, they were asked to describe ADLs that were difficult for them to perform, the current help they received, and their unmet care support needs.

In follow-up focus groups, clinicians were asked about the facilitators and obstacles they encountered during deployment.

During postdeployment focus groups, participating clinicians and managers were asked about elements that could promote or hinder deployment of the ADL telemonitoring system in their organization as well as their thoughts regarding the sustainability of this type of system.

Finally, throughout the study, data on several additional factors to be considered were collected: occurrence of adverse events; clinician turnover; reason for care recipient's withdrawal, relocation, or hospitalization; or cause of death.

Ethical Considerations

The alpha cycle was approved by the Centre de recherche de l'Institut universitaire de gériatrie de Montréal research ethics board (CER VN 16-17-22). All participants (ie, care recipients, clinicians, caregivers, and managers) provided informed and

written consent before taking part in the data collection process. Information that could potentially identify participants was securely stored in a locked storage unit or protected by passwords. Whenever possible, data were deidentified through codification. Participants did not receive any monetary compensation.

Results

Overview

The *Reflection and learning* stage of ADR mirror a conventional *Results* section, entailing the analyses and interpretation of the data collected during the evaluation phase. The alpha cycle aimed to develop and deploy the POC in a real-life context as well as quickly reveal anticipated and unanticipated outcomes regarding technology use and deployment. In the following sections, we synthesize the outcomes for each of the 3 objectives. Multimedia Appendix 1, section 5, provides more details on the outcomes.

Characteristics of Participants and Demands for ADL Telemonitoring

The system was deployed in the homes of 4 care recipients with severe cognitive deficits. They all lived alone, and half (2/4, 50%) had family caregivers. Participating clinicians included 3 occupational therapists, 3 nurses, and 2 social workers.

During these interviews, social and health care professionals expressed the need for monitoring data to support their clinical decision-making process. More precisely, they wanted access to technology that could help assess and manage the risks involved in maintaining care recipients at home. In other words, their aim was to gain a better understanding of how care recipients were functioning in their homes. This information would support their intervention plan and help determine which services should be put in place.

Use and Benefits of ADL Telemonitoring

The evaluation stage revealed that the ADL telemonitoring system was used by clinicians to collect additional and reliable data about the home care recipient's ADL routine (for more details, see the study by Lussier et al [15]). In accordance with the demands for ADL telemonitoring, this technology made it possible to gain a better understanding of how care recipients were functioning in their homes, providing an objective measure that complemented other subjective clinical evaluations. More precisely, it was used to confirm or refute hypotheses before developing a comprehensive intervention plan. It was also used to facilitate discussions with the older adults and their families based on consensual information

Overall, clinicians described the monitoring technology as a useful tool for allocating home care services that corresponded to the needs of care recipients and optimizing their autonomy and safety [15].

Facilitators of and Barriers to ADL Telemonitoring Deployment

Overall, the alpha cycle presented several encouraging results regarding the POC's perceived usefulness and reported satisfaction, as well as the feasibility of its deployment in SAPA teams operating in the field [39]. Although the prototype was successfully deployed in 4 care recipients' homes, several obstacles were encountered. In total, 3 main obstacles were identified: the characteristics of some participants, burdensome evaluation protocol, and maturity level of the POC.

First, the technology used for the prototype was suboptimal for some care recipients' profiles. More specifically, a concern was expressed that sensors would exacerbate symptoms of a paranoid personality disorder with invasive thoughts, and consequently, this care recipient was not included in further testing. In addition, the usefulness of the sensors for care recipients presenting important mobility challenges was questioned. For instance, these care recipients performed very few ADLs by themselves and moved around their units in a wheelchair—which decreased monitoring efficiency and accuracy.

Second, the alpha cycle protocol allowed us to better understand the population followed by the CLSC and refine the protocol for evaluating care recipients' characteristics. In fact, our original protocol was too long, formal, and confronting for many care recipients, increasing the risk of a refusal to participate in the study or withdrawal. Thus, it was decided that formal evaluations with care recipients would be reduced as much as possible in subsequent cycles.

Overall, the feedback showed that the prototype was not ready for wider deployment—the installation took too long, data processing was too slow, output analysis was complex and time-consuming, and it was mostly done by hand, among other issues. Finally, despite the lack of real danger, it was decided that water sensors were to be avoided in the future as they were the only type of sensor that generated anxiety in almost all care recipients because of their concerns regarding having wires near water.

Beta Cycle

Methods

Building, Intervention, and Evaluation

Overview

Following the alpha cycle stage and deployment of the POC, CIUSSS 1 was interested in participating in a second cycle of development with a wider deployment. In addition, during the alpha cycle, 2 other institutions from the Greater Montreal area (CIUSSS 2 and CISSS 3) manifested their interest in using the ADL telemonitoring system, and researchers from our team met with managers and clinicians from these institutions. They identified the needs and challenges of home care for older adults with cognitive deficits that were very similar to those encountered by CIUSSS 1. As such, the beta cycle was conducted with CIUSSS 1, CIUSSS 2, and CISSS 3 without repeating the problem formulation stage. Furthermore, a second problem formulation stage was deemed nonrelevant as the alpha cycle results did not indicate a need to refine our understanding of the context.

The general goals of the beta cycle were to further improve the ADL telemonitoring system based on experience gathered during

the POC and deploy this newer version on a wider scale to further document specific use cases and factors that could contribute to ensuring its long-term use in a real-world setting. As the COVID-19 pandemic occurred as deployment for the beta cycle was just starting, many adjustments to the research protocol and monitoring system had to be made. These are summarized in the following sections and detailed in Multimedia Appendix 1, section 6.

Building

Between 2018 and 2019, a blitz of technological developments was undertaken to develop an edge computing based on a distributed architecture that offers more flexibility for integrating new technologies with high performance in data ingestion than the POC developed in the alpha cycle. Details of the system optimization can be found in Multimedia Appendix 1, section 7.

Organized into software modules, the system centralizes data encryption, storage, computation, communication, and system robustness on a single low-power, low-cost computing device. This framework, called the Innovative Easy Assistance System (NEARS)–Hub, integrates nonintrusive sensors in the smart home [47].

Several features were added to build on the alpha cycle learning and address limitations. First, the deployment of sensors was optimized, which not only simplified the installation but also minimized the technicians' presence in the patients' homes. The latter was a particular source of concern for both clinicians and care recipients.

Second, to facilitate rapid data collection, the VeraPlus Z-Wave Home Controller was replaced with a Raspberry Pi 3 linked with a USB Z-Wave controller, offering several options for local data preprocessing and a number of other improvements, such as the automation of collection, maintenance, and data processing; local data storage; and automation of local backups to compensate for service interruptions.

Third, 2 additional types of sensors were integrated into the ecosystem: a heavy-appliance smart electric switch to monitor oven use and pressure mattress sensors that could be added to the bed or couch.

Fourth, a major achievement was compliance with the safety and confidentiality standards required by the Quebec Ministry of Health and Social Services.

Fifth, a web-based user interface supporting advanced data visualization and comparison tools, called NEARS-SAPA, was designed for clinicians, enabling them to monitor (1) 5 significant ADLs (ie, sleep, eating, mobility, activity, and hygiene), (2) relevant object use (eg, fridge, television, and coffee maker), and (3) room occupancy. As a result, the platform provided a broad overview of the ADLs performed by each care recipient as well as some specific information regarding each ADL (eg, the care recipient's sleeping schedule). To compensate for both the inability of research staff to train clinicians because of the pandemic and clinicians' increased workload, the research team simplified reporting, sending a data summary electronically in PDF highlighting the trends and changes in ADLs for each care recipient every 2 months.

Finally, to reduce in-person home visits related to fixing technical problems, a modular and component-based IT infrastructure was built into the NEARS-Hub to solve as many maintenance issues as possible remotely.

Intervention

Strategies based on the alpha cycle were put in place to improve deployment (see Multimedia Appendix 1, section 8, for details). With the involvement of managers from each health institution, it was decided that the project and its opportunities would be presented during regularly scheduled meetings of each targeted profession. Coordinators from different professional teams were asked to promote the project to their colleagues. Although it was not considered an exclusion criterion, clinicians were alerted to poor acceptance and possible adverse outcomes of ADL telemonitoring in individuals with paranoid disorders and extensive mobility challenges.

Evaluation

Overview

For the beta cycle, the objectives were as follows: (1) to describe the characteristics of the participants and their demands for telemonitoring, (2) to describe the use and benefits of the ADL telemonitoring system on a larger scale, (3) to document facilitators of and barriers to its deployment, (4) to evaluate the usability and acceptance of the system, and (5) to estimate the costs related to system deployment and use. To respect COVID-19 sanitary guidelines, interviews and evaluations were conducted through telephone.

Textbox 2 provides an overview of the data collection process used during this cycle. Details can also be found in Multimedia Appendix 1, section 9.

Textbox 2. Overview of the beta cycle data collection, sample, measurements, and variables in the evaluation stage.

Telemonitoring request form filled out by clinicians, with follow-up questions via phone interview

- Facilitators of and barriers to home care of care recipients
- Demands for telehealth technology

Characteristics of clinicians (n=31), care recipients (n=31), and caregivers (n=9)

- For all: demographics
- For care recipients only: Mini-Mental State Examination, Montreal Cognitive Assessment, Multiclientele Assessment Tool, and Functional Autonomy Measurement System profile

Before deployment—individual interviews with clinicians (n=31), care recipients (n=8), and caregivers (n=9)

- Facilitators of and barriers to home care of care recipient
- Anticipated leverages of and obstacles to telemonitoring deployment in home care
- Demands for telehealth technology

During deployment—follow-up individual interviews with clinicians (n=31) every 4 months

- Observed facilitators of and barriers to telemonitoring deployment
- Use case, impacts, and general satisfaction regarding telemonitoring

Questionnaires for clinicians (n=23)

- 10 in-house questions on use
- 7 questions from the System Usability Scale on usability
- 11 questions from the technology acceptance model–2 on acceptance

Questionnaires for care recipients (n=23)

- 3 in-house questions on telemonitoring perceived usefulness
- 8 in-house questions on telemonitoring acceptance

After deployment—focus groups with clinicians (n=8)

- General facilitators of and barriers to telemonitoring deployment and sustainability
- Impacts of and general satisfaction with telemonitoring

After deployment—individual interviews with administrators (n=2)

- General facilitators of and barriers to telemonitoring deployment and sustainability
- Impacts of and general satisfaction with telemonitoring

Estimate of direct, indirect, and intangible costs related to telemonitoring

- Material costs
- Time invested
- Adverse outcomes reported

Characteristics of Participants and Demands for ADL Telemonitoring

For subunit characteristics, we used the same measurements as for the alpha cycle but dropped the cognitive and functional evaluations because of sanitary constraints and adverse reactions reported by clinicians and caregivers from the alpha cycle. For clinicians, age, sex, profession, affiliation, and years of experience in home care services were collected (self-reported). As in the alpha cycle, clinicians who identified a care recipient and wished to participate filled out a request form detailing their demands for ADL telemonitoring. An initial individual interview with the clinician was added before NEARS-SAPA reports were sent to them. This interview was specifically aimed at identifying the demands, facilitators of, and barriers to home care for this specific care recipient.

Use and Impact of ADL Telemonitoring

Qualitative data were similar to those collected in the alpha cycle (Textbox 2), with slight modifications in terms of time points and type of data collection: (1) follow-up focus group interviews with clinicians were replaced with individual

interviews held every 4 months with clinicians following the installation of the sensors and (2) follow-up focus group interviews with administrators and managers were replaced with individual interviews at the end of the cycle.

In addition, after the first follow-up interview, 10 in-house questions specifically related to the ADL telemonitoring system and reported uses were sent to clinicians in the form of a web survey. Finally, 3 in-house questions were administered orally to care recipients regarding their perceptions of the usefulness of the telemonitoring system.

Facilitators of and Barriers to ADL Telemonitoring Deployment

Qualitative data were collected following procedures similar to those in the alpha cycle (Textbox 2), with the same slight modifications as those mentioned previously in terms of time points and type of data collection.

Usability and Acceptance of ADL Telemonitoring

Usability is defined as the effectiveness, efficiency, and satisfaction with which specified users achieve specified goals in particular technological environments [48]. Several measures were added to evaluate the usability of the system. During the initial interview, clinicians were asked whether they foresaw any facilitators of and obstacles to their intended use of the ADL telemonitoring system. During follow-up interviews, they were asked whether there were any barriers to and facilitators of their actual use of the telemonitoring system. A web survey comprising 7 questions from the System Usability Scale [49] was also sent to clinicians. The System Usability Scale is a reliable tool for measuring such usability, and the questions centered on the ADL telemonitoring system and reports. The survey also comprised an 11-question form built from the *perceived usefulness* and *ease of use* sections of the technology acceptance model–2 questionnaire [50]. The technology acceptance model–2 is an information systems theory that maps how users come to accept and use a technology.

To evaluate care recipients' and caregivers' level of acceptance of the presence of the sensors in their homes, they were asked to respond to an oral questionnaire composed of 8 questions developed by the research team.

Cost Estimation of ADL Telemonitoring

We collected metadata on each service provided to care recipients by the CIUSSS and CISSS and recorded them in Intégration CLSC. Intégration CLSC is a provincial ministry database containing personal information and providing data on service requests, users, and interventions concerning services delivered. The database is used to describe frontline services to ensure the quality and efficiency of health and social services. For this study, we examined the monthly count of services received by the care recipients within the time frame of 6 months preceding and 6 months following clinician access to ADL telemonitoring.

Throughout this project, we aimed to document the cost of implementing ADL telemonitoring in the public health care system by totaling direct, indirect, and intangible costs [51,52]. To do so, we documented the material costs (eg, number of devices used, lost material, server maintenance cost, software, licenses, material for fixtures, repairs and maintenance, internet services, and database and server maintenance). We also estimated the time invested by technicians and clinicians over the study period (eg, time for recruitment, needs analyses, installation, training, and technical support). This estimate was validated by the technicians and clinicians during group interviews in the postdeployment phase. The time invested was translated to cost using the common hourly rates for technicians and clinicians. Time dedicated exclusively to research purposes (eg, interviews about the usability of the system) was not included in the deployment costs.

Ethical Considerations

The beta cycle was approved by the Centre de recherche de l'Institut universitaire de gériatrie de Montréal research ethics board, mandated to be the evaluating committee in a multicenter procedure (CER VN 17-18-10). The same protocols and considerations as those in the alpha cycle were followed.

Results

Results corresponds to the *Reflection and learning* stage of ADR. Data collection ended in late 2022. In total, the NEARS-SAPA was installed in 31 care recipients' homes, and 34 clinicians were involved in the beta cycle. Data analyses for the beta cycle are nearing completion, and the results specific to each subobjective will be shared in the future. Three manuscripts currently being written and are expected to be published in 2024-2025.

Discussion

Expected Findings

The aging population and increasing demand for ADL support faced by social and health care services in many countries call for the deployment of innovative solutions to better meet the needs of older adults with cognitive deficits. In close collaboration with 3 public health care institutions in the province of Quebec, we conducted a study designed to arrive at an in-depth understanding of the potential of ADL telemonitoring to support older adults with cognitive decline in the context of a public health care system. More specifically, the objectives of the project were to (1) codevelop an ADL telemonitoring system that addresses the needs of all key stakeholders involved in home care services for older adults with cognitive deficits, including the older adults and their caregivers; (2) deploy ADL telemonitoring in the Quebec public health care system and identify the specific use cases; and (3) identify factors that could contribute to ensuring its long-term use in a real-world setting (ie, participants' characteristics, demands, and use of telemonitoring; facilitators of and obstacles to its deployment; usability and acceptance; and estimated cost of the system). To achieve these objectives, we opted for an innovative research approach with ADR and engaged with all stakeholders involved in home care services throughout 2 iterative cycles of system codevelopment.

The publication of our protocol was part of the completion of the formalization of learning stage, the last ADR stage, comprising the identification of artifacts, generalization of

learning, and dissemination. These 3 components will be addressed in this section.

Identification of Artifacts

In this paper, we report the ADR protocol for the SAPA project and its related artifacts. As a form of ADR result, an artifact encompasses tangible or intangible elements, including objects, documents, processes, or outcomes, shaped by the ADR processes. These artifacts serve as tangible proof of the actions taken and the resulting benefits in the research context. The SAPA project has given rise to IT artifacts such as NEARS-SAPA (a web-based user interface supporting advanced data visualization and comparison tools) and NEARS-Hub (an Internet of Things infrastructure model) [47]. In addition, scientific and clinical artifacts such as the outcomes of the alpha cycle have been published in the form of case studies [15,45]. From data gathered within the beta cycle, our objective is to generate more artifacts, such as presenting comprehensive documentation and analyses of use cases along with factors supporting or limiting the deployment of the ADL telemonitoring system. This endeavor aims to contribute valuable scientific insights into the clinicians' decision-making processes and deployment strategies that will further support the adoption and integration of ADL telemonitoring in real-life home care contexts.

Generalization of Learning

This protocol paper also provides a thorough presentation of the entire project and its intricate phases. It illustrates how ADR principles could apply to the field of ADL telemonitoring, enabling stakeholders to be actively involved in developing technology that is useful, acceptable, and deployable in real-life environments. To our knowledge, a comprehensive ADR protocol spanning 2 cycles of development has not been published so far in the fields of smart environments and ADL telemonitoring. This is surprising as ADR offers a promising framework for developing practical technological solutions to complex problems, such as in health care services [35,37]. In this context, we present the detailed ADR protocol of this project as an outcome or artifact, enabling its replication in similar projects in the future and the generalization of our results.

Furthermore, the SAPA project and ADR protocol are innovative as they include and report the steps involved when ADL telemonitoring is deployed in real life. A recent umbrella review conducted by our team [31] revealed that few real-world deployment studies have been undertaken in the field of smart environments thus far. As an emerging area of research, published studies have primarily focused on the development and conceptualization of technological components, with only a limited number involving small-scale testing in a laboratory context. Consequently, there are limited published data on the deployment strategies required to integrate smart environments into the health care system or community [31], and our project was designed to fill this gap.

To our knowledge, we are the first to have codeveloped and deployed a system in iterative cycles of collaboration with all stakeholders involved in home care support in the context of a public social and health care system. Coconstruction and collaboration are at the heart of ADR principles. Other studies have reported the deployment of similar solutions, but the development or deployment were not carried out using a coconstruction approach in partnership with a health care system and did not consider how stakeholders wish to integrate telemonitoring information into their practice [14,49,53,54]. It has been shown that the codevelopment of technological solutions with all stakeholders and users is an important factor in ensuring that the deployment of sustainable technological solutions proceeds smoothly and leads to their long-term adoption [55]. Our protocol, centered on co-design, use cases, and deployment factors, is parallel to another recently published protocol reporting a clinical trial to document the effectiveness of an ADL telemonitoring platform via a quasi-experimental study [56]. In that study, more than 73 older adults will receive an active and assisted living–based multiservice assistance platform called HomeAssist. The platform includes ADL telemonitoring but also many applications designed for the older adults themselves to help them engage in their daily and social activities. Although the HomeAssist project has not yet been deployed in the home care services context at the time of publication, this type of project is key to advancing the field of ADL telemonitoring, for which very little rigorous experimental data exist thus far [31]. As for ADR procedures, this study illustrates how to realize various cycles of coconstruction and codeployment of a technology in close collaboration with stakeholders.

Although the SAPA project is innovative in terms of its vision and methodology, it operates on a relatively small scale. Therefore, it will be important to conduct larger-scale studies in the future. As a next step, we intend to conduct an evaluative study to determine the benefits of ADL telemonitoring. These benefits could include, for instance, effectiveness in terms of clinician productivity and work, older adults' functional independence, use of other health services, and changes in the living environment, as well as benefits for the institutions in terms of cost-effectiveness [56]. To engage in these types of larger-scale evaluations, we recommend that research teams in the field of ADL telemonitoring rely on recognized models or frameworks of technology implementation and adoption that are well established in the digital health field. For example, the nonadoption, abandonment, scale-up, spread, and sustainability framework by Greenhalgh and Abimbola [55] enables anticipation of the challenges that may arise during the implementation of an eHealth system in a particular environment. As another example, the Clinical Adoption Framework [56] considers the micro-, meso-, and macrodimensions that influence the long-term adoption and sustainability of technological solutions. The use of such frameworks will ensure rigorous development of ADL telemonitoring supported by sophisticated data.

Dissemination

Finally, in terms of dissemination, initial findings from the beta cycle were shared with the participating program managers, heads of services, and clinicians from the CISSS and CIUSSS. Ultimately, the comprehensive results and assessments will be shared with the scientific community, providers of home care services for older adults, managers, and policy makers. There

has been discussion about progressing toward a third cycle of development. The primary objective of such a cycle would be to make NEARS-SAPA fully independent of the research team. Currently, the technology relies on support, supervision, and knowledge transfer from the research team for optimal functionality, posing a significant barrier to broader implementation—including integration into clinical processes—and cost-effectiveness.

Conclusions

This paper reports the protocol for the SAPA project, which used an ADR framework to codevelop and deploy an ADL telemonitoring system in the Canadian public social and health care system. Through 2 ADR iterative cycles, the SAPA project made it possible to consider all stakeholders' needs, expectations, and perceptions in the final telemonitoring strategies proposed as well as the imperatives related to the deployment of such solutions in real test environments. Future studies could follow this protocol and further develop some methodological aspects.

Acknowledgments

This project was made possible through the financial support received from an internal funding program (integrated university health and social services center Centre intégré universitaire de santé et de services sociaux du Centre-Sud-de-l'Île-de-Montréal; alpha cycle), as well as funding from the Canadian Institutes of Health Research and the Natural Sciences and Engineering Research Council of Canada (beta cycle). Part of the technological infrastructure required for both cycles was supported by the Canadian Foundation for Innovation. NB was also supported by a research scholar award from the Fonds de recherche du Québec – Santé. The authors wish to thank Mauricio Chiazzaro, Cédric Démongivert, Yannick Drolet, Renée-Pier Filiou, Paul Guerlin, Catherine Laliberté, Célia Lignon, Maxime Moreau, and Marie-Michelle Ouellet for their valuable contributions to data collection and technological development. The authors also wish to thank their precious collaborators from the health institutions.

Conflicts of Interest

None declared.

Multimedia Appendix 1
Description of specific methodological details for problem formulation, building, intervention, evaluation, and reflection and learning phase for both cycles.

Correction of: https://www.researchprotocols.org/2023/1/e43408

(JMIR Res Protoc 2024;13:e56085) doi:10.2196/56085

In "The Development of a UK Culturally Adapted Version of the Person Attuned Musical Interactions Manual: Protocol for a 2-Phase Mixed Methods Study" (JMIR Res Protoc 2023; 12(1):e43408) the authors made some modifications.

1. The title "The Development of a UK Culturally Adapted Version of the Person Attuned Musical Interactions Manual: Protocol for a 2-Phase Mixed Methods Study" has been revised to:

> *The Development of a UK Culturally Adapted and Modified Version of the Person Attuned Musical Interactions Manual: Protocol for a 2-Phase Mixed Methods Study*

2. *PAMI-United Kingdom* was revised to *PAMI-Modified*, with all subsequent mentions in the paper being changed from *PAMI-UK* to *PAMI-M*.

3. In Table 1, all instances of the word *Dutch* were revised to *Danish*, as the language of the intervention is Danish.

4. Also in Table 1, the phrases in the title and footnote *PAMI-DK* and *PAMI-DK- Person Attuned Musical Interaction Danish Version* have been replaced by *PAMI* and *PAMI-Person Attuned Musical Interactions*, respectively.

5. In the Corresponding Author's address, *Truiumph Road* was corrected to *Triumph Road*.

6. Some sentences were revised to add the words *modified*, *modification* or *modifying* where necessary, as follows:

In the Abstract, in the section Background, "...a team of researchers in the United Kingdom have culturally adapted the tool." has been edited to:

> *...a team of researchers in the United Kingdom have modified and culturally adapted the tool.*

In the Abstract, in the section Objective, "This study aims to investigate the appropriateness of the adapted UK manual for UK care homes and to explore..." has been edited to:

> *This study aims to investigate the appropriateness of the adapted and modified manual for UK care homes and to explore...*

In the Abstract, in the section Conclusions, "This study will be the first to investigate the culturally adapted UK PAMI" has been edited to:

> *This study will be the first to investigate the modified version of PAMI.*

In Background, in the section Person Attuned Musical Interactions Manual, "a UK version of PAMI was developed by a team of researchers at the University of Nottingham" has been edited to:

> *A modified version of PAMI was developed by a team of researchers at the University of Nottingham.*

In Background, in the section Person Attuned Musical Interactions Manual, "The first author's thesis reports the manual development process and the differences between the Danish and UK version of PAMI" has been edited to:

> *The first author's thesis reports the manual development process and the differences between the Danish and Modified version of PAMI.*

In Methods, under the section Training Session, "BW was the researcher who developed the translated PAMI manual as part of her PhD" has been edited to:

> *BW was the researcher who developed the modified PAMI manual as part of her PhD.*

In Methods, under the section Intervention Development, "...the research team liaised with the Danish PAMI team to ensure that any adaptation remained consistent with the PAMI ethos" has been edited to:

> *...the research team liaised with the Danish PAMI team to ensure that any adaptation and modification remained consistent with the PAMI ethos.*

In Discussion, under the section Anticipated Findings, "This study will be the first to investigate the culturally adapted PAMI. Therefore, the data collected in phases 1 and 2 will provide feedback on the appropriateness of the manual for staff..." has been edited to:

> *This study will be the first to investigate the modified PAMI-M. Therefore, the data collected in phases 1 and 2 will provide feedback on the appropriateness of the modified manual for care staff...*

In Discussion, under the section Anticipated Findings, "This study will investigate whether the UK-adapted version of PAMI can benefit residents,..." has been edited to:

> *This study will investigate whether the modified version of PAMI can benefit residents,...*

In Conclusions, the phrase "The study will be the first to investigate the culturally adapted UK PAMI" has been edited to

> *The study will be the first to investigate the modified PAMI.*

In Conclusions, "...and explore participants' experience of using PAMI" has been edited to:

> *...and explore participants' experience of using a modified version of PAMI.*

In the Caption of Figure 2, "PAMI: Person Attuned Musical Interactions" has been edited to:

> *PAMI-M: Person Attuned Musical Interactions-Modified.*

In the caption of Figure 3, the phrase "The manual development process for culturally translating and adapting the Danish Person Attuned Musical Interactions (PAMI) intervention for UK care homes. PAMI-DK: Person Attuned Musical Interactions Danish version; PAMI-UK: Person Attuned Musical Interactions United Kingdom" has been edited to:

> *The manual development process for culturally translating and modifying the Person Attuned Musical Interactions (PAMI) intervention for UK care homes. PAMI: Person Attuned Musical Interactions.*

In the caption of Table 1, "The changes between the Danish and UK Person Attuned Musical Interactions (PAMI)" has been edited to:

> *The changes between the Danish and Modified Person Attuned Musical Interactions (PAMI).*

The correction will appear in the online version of the paper on the JMIR Publications website on January 26, 2024, together with the publication of this correction notice. Because this was made after submission to PubMed, PubMed Central, and other full-text repositories, the corrected article has also been resubmitted to those repositories.

Abstract

Background: Hundreds of nursing professionals graduate each year from Doctor of Nursing Practice (DNP) programs, entrusted with roles as practice scholars and leaders. Graduates are tasked to lead multidisciplinary knowledge implementation projects to improve safety, quality, and key performance metrics. Nevertheless, there is a continued lack of agreement and faculty dissatisfaction with the format, focus, and results of the DNP graduation projects. The use of a wide range of models and methodologies from different sciences for knowledge implementation introduces challenges to DNP students; affects the scientific rigor of the projects; and results in the overuse, superficial use, or misuse of the models. Quality improvement (QI) and program evaluation studies are substantial investments that may lead to waste and even harm if not well conducted. Traditional QI methodologies, commonly used in DNP projects, were found to be uncertain in improving health care outcomes. The complexity of health care systems calls for cross-fertilization between improvement and implementation sciences to improve health care outcomes.

Objective: This study describes the development, implementation, and evaluation of a hybrid model for QI and program evaluation studies to guide scholarship in the DNP program.

Methods: The hybrid model was based on cross-fertilization between improvement and implementation sciences. The model adapted the Getting to Outcome (GTO) and Knowledge to Action (KTA) models as the overarching process models for knowledge implementation. Within each phase of the GTO and KTA models, expected barriers and facilitators for the implementation and adoption of innovation were identified based on the CFIR (Consolidated Framework for Implementation Research). Accordingly, strategies to facilitate the implementation and adoption of innovations were identified based on a refined list of implementation strategies and QI tools. The choice of these models was based on the top 5 criteria for selecting implementation science theories and frameworks. Seven DNP students used the hybrid model to conduct QI projects. Students evaluated their experiences by responding to a Qualtrics survey.

Results: The hybrid model encouraged a comprehensive systematic way of thinking, provided tools essential to implementation success, emphasized the need for adaptability in implementation, maintained rigor in QI, and guided the sustainability of change initiatives. Some of the challenges faced by students included finding reliable and valid measures, attaining and maintaining staff buy-in, and competing organizational priorities.

Conclusions: Cross-fertilization between improvement and implementation sciences provided a roadmap and systematic thinking for successful QI projects in the DNP program. The integration of the CFIR with the GTO or KTA process models, enforced by

the use of evidence-based implementation strategies and QI tools, reflected the complexity of health care systems and emphasized the need for adaptability in implementation.

Introduction

The Doctor of Nursing Practice (DNP) is the entry-to-practice degree for advanced practice registered nurses and focuses on improving health care outcomes, system practices, and health policy through knowledge implementation [1,2]. According to the American Association of Colleges of Nursing, there were 426 DNP programs in the 50 US states and the District of Columbia, in addition to 70 programs in the planning stage, in 2022 [3]. The number of students enrolled in DNP programs increased from 40,834 to 41,021 from 2021 to 2022 [3]. A core requirement for the degree is the design, implementation, and evaluation of a DNP project [4]. The exponential growth in the number of DNP programs is accompanied by a large inconsistency in the format and focus of the DNP projects [5,6]. To provide clarity, the American Association of Colleges of Nursing recommended that projects focus on knowledge implementation by introducing a change to improve health care outcomes and to have a system focus [2]. Despite these recommendations, a study that included 90 DNP program directors revealed the continued lack of agreement with the format and focus of the DNP projects and reported dissatisfaction of 87% of faculty with the DNP projects [7]. To this end, this study aims to describe a model for designing, implementing, evaluating, and sustaining DNP projects.

At a public university in the Southwest of the United States, our School of Nursing requires DNP projects that are quality improvement (QI) or program evaluation focused. Students over the past 10 years used different theories, models, and methodologies to guide the design, implementation, and evaluation of their projects. Although a difference exists between "models" and "frameworks," these terms will be used interchangeably in this paper. The theories, models, and methodologies used by students include (1) evidence-based practice (EBP) models (eg, Iowa Model and Academic Center for Evidence-Based Practice [ACE] Star Model), (2) implementation science models (eg, Promoting Action on Research Implementation in Health Services [PARiHS] Framework, Knowledge to Action [KTA] Framework, and the Consolidated Framework for Implementation Research [CFIR]), (3) program evaluation models (eg, Logic Models and Getting to Outcomes [GTO] Model), (4) improvement models (eg, Donabedian, Kotter, and Lewin Models), (5) QI methodologies (eg, Plan, Do, Study, Act [PDSA] and Six Sigma—Define, Measure, Analyze, Improve, and Control [DMAIC]), and (7) midrange change theories (eg, Rogers' Diffusion of Innovation).

The use of a wide range of theories, models, and methodologies from different sciences for knowledge implementation and uptake and the absence of criteria to guide that selection introduced challenges to our students in all phases of the project; affected the scientific rigor of the projects; and resulted in the overuse, superficial use, and misuse of the models [8]. This was manifested by several poor practices including a mismatch between the intended use of the guiding model and the complexity of the clinical problem at hand; the selection of inappropriate or least appropriate theory or model to guide the intended change; the selection of multiple (more than 3) models and theories without identifying how the relationship between them supports the different phases of the project; superficial use of the theory or model (ie, selective use of phases, dimensions, or criteria, and the elimination of critical components of a model or a theory); inaccurate representation and application of the dimensions; the lack of using a process model to guide the implementation of a change; and most importantly, the lack of integrating the theory or model into all phases of implementing a change (ie, the theory was mentioned in the planning phase but never used in the implementation, evaluation, or sustainability phases).

The lack of understanding of the intended purposes of these sciences and the interchangeable use of terminologies further complicate the situation. Multimedia Appendix 1 [9-17] provides the definitions of these sciences and associated terminologies. Other terms related to knowledge implementation were well-defined by Graham et al [18]. As shown in Multimedia Appendix 1, the goal of these sciences is to improve health by "producing" or "implementing" knowledge to improve the structure, processes, and outcomes of health care systems [9-17]. For example, implementation science, translation 1 science, and translation 3 science focus on the research, with the goal of "producing and generalizing" new knowledge. QI and EBP, on the other hand, focus on improvement and aim at "applying or implementing" the best available knowledge. Program evaluation is a scientific methodology that aims at either producing or implementing knowledge based on the approach used to conduct the evaluation (ie, research vs QI). On the other hand, most of the models used to guide the conduct of implementation science, QI or improvement science, program evaluation, translation 2 science, and EBP share similar theoretical underpinnings (eg, system theories, change theories, and cognitive theories).

The complexity of health care systems calls for a system-thinking approach to QI. System thinking examines the interrelatedness and interdependence among the system's components to understand the system's behavior and design interventions to improve outcomes. A recent systematic review found the effectiveness of continuous QI methodology for

improving health care outcomes to be uncertain. The uncertainty was related to the complexity of health care systems, in addition to poor application of the methodology [19]. In the same vein, a recent systematic review challenged the legitimacy of PDSA-based QI projects in specifying and achieving predefined improvement aims, highlighted the poor and inconsistent application of the methodology, and called for a theoretical rationale to support the conduct of the methodology and interpretation of the results [20]. Similarly, and to better improve the quality of care, Leeman et al [21] and Check et al [22] called for cross-fertilization between improvement (or QI) and implementation sciences. Implementation science extensively studies best implementation strategies for knowledge implementation and uptake, provides process and determinant models for successful implementation, and focuses on the complexity of the system's components in implementation. QI or improvement science provides useful tools to assess the need for the local context, measures outcomes, and adapt available knowledge at the local level.

The availability of many theories and models for knowledge implementation, the challenges faced by our DNP students in model selection and application, the need for a system thinking approach in QI, the shortcomings of continuous QI and PDSA methodologies in improving health outcomes, and the fact that there is no one best theory to guide all types of projects support the need for cross-fertilization and a hybrid approach in theory and model application between QI and implementation sciences. To this end, this paper describes a hybrid approach to QI in DNP projects by integrating GTO and KTA with the CFIR model and complementing that with the refined list of implementation strategies from Powell et al [23]. A hybrid approach between the different sciences is warranted to deepen our understanding of the interrelated, interdependent contextual factors and the complexity of health care systems, processes, and medical conditions.

The study-specific aims are to (1) describe the development, implementation, and evaluation of a hybrid model between improvement and implementation sciences to guide QI and program evaluation studies in the DNP programs and (2) explore the value of the model and challenges faced in all phases of the DNP projects (planning, implementation, evaluation, and sustainability).

Methods

Overview

The methods section describes the hybrid model and its components; the criteria for selecting GTO, KTA, and the CFIR as process and determinant models; the need to adapt existing models; piloting the hybrid model; and the data analysis plan.

Development of the Hybrid Model

Faculty and the DNP curriculum committee at our School of Nursing recognized the necessity for a standardized and rigorous approach to DNP scholarly projects. This awareness sparked discussions within committee meetings regarding the most effective models to guide DNP projects. The first author of this study (AS) led a task force to develop a comprehensive "DNP Project Guide." The guide encompassed various elements such as the purpose of the DNP program; the focus of the DNP projects; settings of the DNP projects; project format; knowledge dissemination approaches; project timeline; interprofessional collaboration; responsibilities and qualifications of the DNP project committee members; DNP project phases; and a cross-map of DNP project courses, project phases, and milestones. Expanding on this groundwork, the first author (AS) led the development of a new model for DNP scholarly projects and solicited input on its different aspects in subsequent faculty meetings.

Description of the Hybrid Model

The challenges faced by our DNP students in model selection and application call for (1) a "process model" to guide all phases of the DNP project, (2) a "determinant model" to focus attention on the complexity of health care systems, and (3) the application of context- and evidence-based implementation strategies to enhance knowledge uptake and sustainability. Drawing from our expertise in implementation science, QI, and program evaluation, along with input from faculty, a decision was made to use GTO as the overarching process model and the CFIR as the determinant model. KTA was also used as another process model due to its wide adoption in implementation science. These models were complemented by the refined list of implementation strategies and other QI tools from Powell et al [23], as described further below. The choice of these models was based on the top 5 criteria for selecting implementation science theories and frameworks [8]. The criteria include empirical support, application to wide settings or populations, explanatory power, description of a change process, and analytical level (ie, individual, organizational, and system).

In terms of empirical support and application to wide settings or population criteria, the CFIR is the most cited determinant model in implementation science [24], KTA is a widely used process model in implementation science [25], and GTO is a widely used program evaluation model [26]. In terms of explanatory power and description of the change process criteria, the selected models focus on the process of implementation and implementation barriers and facilitators during the full scope of innovation or knowledge implementation, that is, before, during, and after implementation. Regarding the analytic-level criterion, the models consider all levels of implementation for successful adoption. Adoption of innovation occurs at the external, organizational, innovation, and individual levels. Considering the full scope of implementation and the multiple levels of adoption should (1) facilitate engaging the right stakeholders in the implementation process, (2) promote the uptake and ownership of the innovation, (3) build key dimensions of organizational capacities to initiate and sustain a change, (4) foster inter- and intraorganizational collaboration, and therefore (5) provide STEEEP (Safe, Timely, Effective, Efficient, Equitable, and Patient-Centered) care.

The hybrid model consisted of "adapted" versions (described below) of GTO or KTA models as the overarching process model for knowledge implementation. Within each phase of the GTO and KTA models, the expected barriers and facilitators for the implementation and adoption of innovation (ie, best

evidence) were identified based on the CFIR—a determinant model. Accordingly, the implementation strategies to facilitate the implementation and adoption of innovation were identified based on the refined list of implementation strategies and QI tools from Powell et al [23]. Multimedia Appendix 2 [18] illustrates the integration of the CFIR constructs and implementation strategies into each phase of the "adapted" GTO and KTA models.

CFIR Model Overview

The CFIR model is a guide to systematically identify and assess barriers and facilitators to a new program and innovation implementation. The model was guided by studies across 13 fields of research and the analysis of 18 theories and models from different disciplines [27]. It includes 39 constructs that can influence implementation success. These are clustered into 5 domains: intervention characteristics, inner setting, outer setting, individuals' characteristics, and implementation process. These constructs can aid or hurt evidence-based program implementation, depending on their manifestation in organizations. Studies using the CFIR have identified the relationships between different constructs and implementation effectiveness [28,29]. Further, GTO studies have explicitly used the CFIR. In a comparison of community-based sites attempting to implement a drug prevention program with and without GTO, GTO sites had significantly higher average ratings than non-GTO sites for 2 constructs from the CFIR process domain: planning and reflecting and evaluating [30]. In addition, GTO sites had higher ratings of program fidelity, despite having worse CFIR ratings on the culture and available resources constructs. These findings suggest that strong planning, evaluation, and reflection—improved with a process model such as GTO—can aid implementation despite a less desirable implementation climate and further support the need for integrating a process model and a determinant model in QI and program evaluation studies.

GTO Model and the Need for Adaptation

The GTO is a 10-phase action-oriented model for planning, implementing, evaluating, and sustaining innovations and programs. The original phases include (1) needs and resources assessment, (2) goals and desired outcomes, (3) best practices, (4) fit, (5) capacities, (6) planning, (7) process evaluation, (8) outcome evaluation, (9) continuous QI, and (10) sustainability [31].

In our hybrid model (Multimedia Appendix 2), the GTO model was adapted in 5 ways to better guide the implementation of DNP projects (Multimedia Appendix 2). First, "fit" and "capacities" phases were combined and expanded to "fitness and absorptive capacities." Unlike "capacity," absorptive capacity reflects the "dynamic capability of the organization pertaining to knowledge creation and utilization that enhances a firm's ability to gain and sustain a competitive advantage" [32]. Absorptive capacity entails 4 multilevels or dimensions of organizational learning and capabilities, which are knowledge acquisition, assimilation, transformation, and exploitation [32]. An organization's absorptive capacity is critical to its innovative capabilities; is a function of the organization's prior related knowledge; and is influenced by all technical, behavioral, and cultural aspects of the organization [32,33]. Accordingly, the "fitness" phase in the GTO model—the match between the innovation and the organization or user or patient population—is embedded into the organizational absorptive capacity. We decided to keep the term "fitness" in the phase name to remind users of the adapted model to examine fitness at multiple levels (ie, organization, end user, and patient population). According to Cox et al [34], organizational capacity revolves around organizational culture and communication, which in turn are linked to 6 capacity dimensions of leadership, strategy, structure or governance, skills, human capital, and accountability. Effective communication and supportive culture are essential to successful implementation and fundamental for the organization to achieve high performance.

Second, an "implementation" phase was added as part of the cyclic phases after the "planning" phase to move the process to "evaluation." This adaptation is congruent with the action-oriented nature of the GTO model. The third adaptation of the GTO model was clarifying that "process evaluation" means "evaluation of the implementation process." The purpose of this change was to eliminate any confusion between "implementation process evaluation" and the evaluation of "process measures." Although there is some overlap between the 2, "evaluating the implementation process" focuses on 6 main measures of implementation fidelity (the degree to which the innovation was implemented as prescribed in the original protocol), penetration, appropriateness, actual adoption, cost, and sustainability of the innovation [35]. On the other hand, a process measure focuses on the workflow and operations performed to achieve the main outcome metrics. The Institute for Healthcare Improvement identified 3 types of metrics in QI: outcome measures, process measures, and balance measures [36]. The outcome metrics are reflected by the goal of the project. Balance measures track the unintended consequences, if any, resulting from implementing a change or innovations. For example, in implementing a clinical practice guideline (CPG) for cancer screening, an outcome measure would be the cancer screening rate, the process measures might be adherence to CPG use and wait time for a patient to obtain a screening appointment, and a balance measure might be the accuracy of the screening results. Similarly, in implementing a provider in triage model in an emergency department, an outcome measure could be the percentage of patients who left without being seen, process measures could be "door to provider time" and nurse and clinician satisfaction with the provider in triage model, and a balance measure could be "left without treatment" and patient satisfaction with emergency department services. In these 2 examples, it is worth noting that "adherence to CPG use" and "nurse satisfaction" (process measures) could also serve as a proxy for "actual adoption" (adherence to CPG use) and "appropriateness" (clinician satisfaction), which are implementation-related measures. On the other hand, not all process measures reflect implementation-related measures. For example, "time to obtain a screening appointment" and "door to provider time" in the examples above are not 2 of the 6 implementation-related measures.

Fourth, we also changed "outcome evaluation" to "evaluation of measures" to reflect the complexity of measures in QI (ie,

process, balance, and outcomes). Fifth, we combined the "continuous improvement" and "sustainability" phases because continuous QI is a sustainability indicator and a central element of sustainable development [37]. Changes and continuous improvements need to be sustained to achieve their values to consumers of care.

KTA Model and the Need for Adaptation

KTA consists of two interdependent, interrelated phases of (1) knowledge creation that is surrounded by (2) an action cycle [18]. Knowledge creation produces guidance and tools to inform practice, while the action cycle is action oriented to select and implement the best available knowledge to improve practice (ie, the focus of QI). Since improvement science involves the "implementation" of the best available knowledge, the use of KTA to guide QI projects is limited to the action cycle. The KTA framework is based on 31 planned action theories about the process of change [25]. Studies using the KTA model have demonstrated the dynamic, nonlinear aspect of knowledge translation and implementation [25]. However, recent scope reviews that used KTA in behavioral change in rehabilitation and educational interventions for the management of sleep disorders supported the complexity of knowledge implementation and recognized the need to (1) complement the KTA model with determinant models to better assess barriers to implementation and influence implementation outcomes and (2) guide the selection of implementation strategies [38,39]. Along the same line, our hybrid model supports the need for a determinant model (ie, the CFIR) to complement a process model (ie, KTA or GTO) and the need for a refined list of context- and evidence-based implementation and QI strategies to improve implementation fidelity, that is, the list of implementation strategies from Powell et al [23].

A great similarity exists between the original phases of KTA and GTO models (Multimedia Appendix 3). Both models address knowledge implementation starting by identifying the opportunity for improvement (problem) through sustainability. Similar to GTO, KTA was adapted in our hybrid model to better guide the implementation of DNP projects as a process model (Multimedia Appendices 1 and 2). The adaptation (Multimedia Appendix 3) includes (1) adding a "Goals and Desired Outcomes" phase, (2) adding a "Planning" phase, (3) changing "monitor Knowledge use" to "Evaluation of implementation" to capture other crucial aspects of the implementation process, (4) changing "Evaluate outcomes" phase to "Evaluation of Measures" to reflect the complexity of measures in QI, and (5) changing "Sustain knowledge use" to "Sustainability" to emphasize the fact that sustainability is not limited to knowledge "use" but includes sustaining all measures (process, outcome, and balance).

Multimedia Appendix 2 presents the GTO and KTA models with the adapted phases and emphasizes the dynamic nature of QI and program evaluation studies, that is, the need to complete some phases concurrently, adapt subsequent phases based on earlier phases and preliminary results, and the need to adapt and revisit earlier phases.

Integrating CFIR, Implementation Strategies, and QI Tools Into the Adapted Process Models

Multimedia Appendix 2 demonstrates the most important constructs to be considered in each phase of implementation in QI and program evaluation studies based on our expertise in improvement and implementation sciences and program evaluation. Researchers can adapt the list of constructs to fit the needs of the study based on the context of implementation [27]. Our selection of the constructs, and consequently implementation strategies and QI tools, in each phase of the implementation process was also guided by research findings related to core context dimensions in implementation science [40]; heterogeneity in implementation outcomes and dimensions of implementation weaknesses [41]; the relationship among organizational culture, capacity, and communication [34]; stages of knowledge use [42,43]; and strategies for aligning QI science and implementation science [21].

Piloting the Hybrid Model

Students enrolled in the DNP program typically choose models to guide their QI projects based on their familiarity with a model, its previous application in similar studies and clinical contexts, or recommendations from their DNP project mentor. Those without prior exposure to the chosen QI guiding model typically grasp its application with the support of their mentor during the phases of designing, implementing, and evaluating their DNP projects. In this study, none of the involved students had prior experience with KTA, GTO, or the CFIR. The first author (AS) of this study served as the primary mentor for 7 DNP students and with support from a comentor guided students through integrating and applying the hybrid model.

The hybrid model was piloted by 7 DNP students: 5 in the post–Bachelor of Nursing–to-DNP track (BSN-DNP) and 2 in the post–Master of Nursing Science–to-DNP track (MSN-DNP). The 2 tracks have the same program objectives, outcomes, and standards for the DNP project. The only difference concerning the project is the time for completion. Students in the BSN-DNP track complete their projects in 3 semesters, while students in the MSN-DNP track complete their projects in 2 semesters.

The hybrid model was described to all students in the first DNP project course. Students in the BSN-DNP track incorporated GTO as the overarching process model, while students in the MSN-DNP track used KTA. All students used the CFIR as the determinant model, Powell et al [23] refined list of implementation strategies, and different QI tools. The latter included tools such as a swim lane workflow analysis, fishbone analysis, Gantt charts for project management, and control charts of trended data for the main outcome variable before, during, and after implementation. Students were familiar with these tools due to prior application in previous courses. Another required tool that guided project implementation was the TIDieR (template for intervention description and replication) checklist [44]. The primary DNP project mentor (AS, the first author of this study) and the comentor (Amanda Bridges) met with the students monthly to help them apply the hybrid model, monitor progress, maintain rigor and sustainability, and help identify and solve implementation barriers early in the process.

GTO offers a range of tools to facilitate its application. The list of tools is available on the model's website. It is important to note that some of these tools were adapted to fit the nature of QI studies, while others were supplemented with more detailed tools in implementation science (eg, TIDieR). For example, students used a Literature Analysis Table that focused on different available interventions or innovations used to improve the primary project outcome. In addition to the conventional analysis of the literature (covering study design, sample, setting, etc), the analysis focused on the features of each innovation, necessary implementation resources, implementation results, factors contributed to implementation sustainability, and lessons learned.

Model Evaluation

The model was evaluated by students using a Qualtrics survey distributed to students via a link at the end of their DNP projects. All students successfully completed their projects in a variety of inpatient and outpatient settings and thus were eligible to participate in evaluating the hybrid model. The survey included two questions soliciting feedback on (1) the value of the hybrid model in project design, implementation, evaluation, and sustainability and (2) the main challenges faced in all phases of the DNP project. Students received 3 reminders to improve the response rate.

Ethical Considerations

The study was approved by the institutional review board of the University of Texas Health Science Center at San Antonio (IRB; protocol 20210487) as a "non-regulated QI educational project." After the IRB approval, the Qualtrics survey was sent to all students who participated in the pilot. The IRB granted a waiver of consent for educational research. An information sheet was presented at the beginning of the survey with details about the value of responding to the survey, anonymity of responses to maximize objectivity, and confidentiality of the data. Voluntary participation was emphasized in the information letter. Compensation was not offered for participation.

Data Analysis

The 4-stage content analysis methodology by Bengtsson [45] was used to categorize narrative data into themes. To maintain, the transparency, quality, and trustworthiness of the analysis, 2 researchers (AS and Ana Vera) performed the analysis separately and met to discuss the findings and reach a consensus. In the decontextualization phase (stage 1), the 2 researchers read the answers provided by students thoroughly to identify meaning units and generate codes. In the recontextualization stage (stage 2), the researchers went back to the original text to ensure they comprehensively captured all ideas and meanings and revisited the unused text for consideration to be included. In the categorization stage (stage 3), the meaning units were condensed to categories or themes without losing the meaning of the content. In the compilation stage (stage 4), quotes were extracted to support the main themes. As the survey responses were anonymous, we refrained from conducting an "informants check," which involves verifying the alignment between respondents' submitted answers and identified themes or meaning units. However, to mitigate this limitation and to improve the confirmability of the findings, the second researcher (Ana Vera) was a colleague with content analysis expertise who was not involved in the study.

Results

All students designed and implemented projects with QI focus, and none of the projects involved program evaluation. All students (N=7) responded to the survey. Multimedia Appendix 4 presents the themes that represent the value of the hybrid model and challenges reported by students in project design, implementation, and evaluation. The themes are presented in descending order of significance, determined by the quantity of student feedback received for each theme. As per students' feedback, the primary strengths of the hybrid model revolved around its capacity to offer a holistic systematic approach to thinking and the necessary tools for effectively communicating project progress and ensuring implementation fidelity. The model helped students in recognizing how various aspects of implementation are interconnected and supported the complex nature of health care systems and knowledge implementation. The model also maintained rigor in QI, presented a roadmap for a successful project, and empowered the institutionalization of innovation for sustainability. Not surprisingly, the model emphasized the need for adaptability in implementation as it reflected the complexity inherent in health care systems.

Despite these benefits, challenges are inevitable in improvement and implementation endeavors. The challenges reported by students include finding reliable and valid measures, establishing and maintaining staff buy-in, timely access to data, and ensuring the project remains an organizational priority given other competing priorities and organizational changes. Other challenges were related to managing the literature review and selecting the right balance measures.

Discussion

Principal Findings

The need for a theoretical basis for knowledge implementation and uptake has been well supported in the literature [40]. Yet, the availability of a mountain of models and theories for knowledge uptake introduces a burden on researchers and practitioners to choose from [46] and results in a "haphazard selection" or a selection that is "driven by convenience or prior exposure" [8]. Selecting the most appropriate model is crucial to provide systemic thinking for project success; enrich the scientific underpinnings of improvement and implementation endeavors; and minimize "the black box of implementation" and challenges in initiating, implementing, evaluating, and sustaining a change [35]. QI and program evaluation projects are substantial investments that may lead to waste and even harm if not well conducted. The complexity of health care calls for a cross-fertilization between improvement and implementation sciences. This paper presented an improvement-implementation hybrid model to guide scholarship in QI and program evaluation studies.

The hybrid model was successfully implemented to guide QI projects in different inpatient and outpatient settings. The hybrid

model provided a roadmap for rigorous and sustainable QI projects and was crucial to implementation success. Faculty who attended the final presentations of DNP projects using the hybrid model praised the systematic methodology for improving health care outcomes and reinforcing the projects' rigor.

Establishing and maintaining staff buy-in was one of the challenges reported by some students during project implementation. Examples of strategies students implemented to overcome this challenge include the use of project champions, securing leadership support, working on a project that is an organizational priority, creating a sense of urgency to the need of the project, communicating milestones and project progress, conducting rigorous training programs with sufficient support resources for innovation use, and engaging users in every step of the project. However, despite these evidence-backed strategies, sustaining staff enthusiasm and support proved challenging due to competing priorities, notably in projects within acute care settings that experienced significant structural changes, such as transitioning to COVID-19–designated units. Additionally, change in unit directors was a factor in delaying some projects and also impacted staff buy-in. The support of unit directors and charge nurses is essential to project success. These leaders usually act as implementation champions and support students in navigating the system.

Most of the other challenges reported by students in project design, implementation, and evaluation were not related to the hybrid model. For example, managing the literature review and selecting the most appropriate balance measures were expected because of the learning curve to attain these skills in graduate studies. In each DNP project, students complete a comprehensive literature search to identify the best available knowledge and innovations that have been implemented in similar settings to improve the main outcome measure. "Having a manageable set of studies to analyze and synthesize," as reported by students, is a function of selecting the best search terminologies and filters or limits. Similarly, the challenges faced by some students in finding instruments for their process measures (eg, "nurse competence in nasogastric tube care") were not model related. Students had to create these measures based on policies and procedures recommended by professional organizations and test the instruments for face validity before using them in their projects. Nurse competence is a prerequisite to the appropriate use of innovation in these projects. Appropriate use, in turn, reflects "actual adoption"—an implementation-related measure. The lack of sufficient valid and reliable measures for the 6 implementation-related outcomes is well reported in the literature [47-49]. Part of this challenge was related to the fact that the selected process measures are specific to the project. These challenges were acknowledged in the limitation section of the DNP projects.

It is worth noting that following the successful outcomes of this trial project, the DNP curriculum committee and faculty opted to formally incorporate the hybrid model into the DNP program. This structured approach aims to ensure consistent and standardized use of the model across all phases of future DNP projects.

Future Considerations

The substantial diversity in the methodological approaches and rigor of DNP projects across various DNP programs presents significant challenges for faculty, students, and health care organizations. In this study, we aimed to deliberately use well-established, empirically tested, and common models; furnish a structured path for systematic QI planning and implementation; and improve the rigor of QI endeavors. Establishing a standardized and rigorous approach is crucial to prevent any waste associated with unsustainable QI projects, minimize the need for deimplementation, and ultimately improve health care outcomes.

For successful implementation, the hybrid model should be integrated into the DNP curriculum. The frameworks, methodologies, and tools used in the hybrid model (Multimedia Appendix 2) may guide DNP education and curriculum revision. Educators in the DNP program can incorporate many strategies and models in their courses to equip students with sufficient knowledge to design and implement rigorous QI projects. These may include, but are not limited to, team science and team development, best practices and models for stockholders' engagement, best practices and models for optimizing organizational absorptive capacities and capabilities, best practices in sustainability and sustainability models, data visualization in QI, and quality metrics (ie, balance, process, and outcome metrics). The integration of improvement and implementation sciences in 1 model may also advance project dissemination using multiple venues (eg, journals that target implementation science and journals that target improvement science).

Widespread adoption of the hybrid model also necessitates dialogue with clinical partners regarding the value of the model. The hybrid model may allow clinicians and change leaders to consider the full scope of implementation, build key dimensions of organizational absorptive capacity in practice, foster inter- and intraorganizational collaboration, and therefore provide a STEEEP care. However, and based on our experience, some clinical partners are accustomed to specific QI approaches (eg, PDSA, continuous QI, and DMAIC) and expect DNP students to demonstrate these approaches in their proposed projects before endorsing project implementation in their settings.

Equally important is the development of a cadre of faculty capable of guiding students in applying improvement and implementation science principles. Schools of nursing should empower faculty with improvement and implementation science competencies, foster an environment conducive to knowledge sharing among faculty members (eg, faculty huddles), and establish a network of faculty engaged in interdisciplinary QI collaborations. This holistic approach aims to bridge the gap between theoretical understanding and the practical application of QI and implementation science, ensuring that QI initiatives are methodologically sound when implemented in health care settings.

By developing the hybrid model, our intention was not to confine the use of other implementation science models. Model selection in QI and implementation science should be supported by a strong rationale that establishes model relevancy to the

study objectives; pragmatic applicability and fitness to the context, clinical problem, and patient population; model creditability through expert consensus and supporting literature; and other important criteria [8]. Justification for model selection is pivotal to ensure a purposeful and methodologically sound approach, thereby strengthening the credibility of QI and implementation science studies.

Limitations

The hybrid model was created to guide DNP students in QI and program evaluation projects. The model was used by 7 students to pilot its feasibility. All students' projects focused on QI, and none of the projects was program evaluation. Although the model provided many benefits and guided the implementation of rigorous projects, the use of the model by a larger number of students is essential to generalize its use as a guide to all DNP projects that focus on QI and to assess its value in program evaluation studies. While we have not formally sought faculty feedback on the newly developed model, all faculty members acknowledge the necessity of a hybrid improvement-implementation approach in DNP projects. The wide use of the hybrid model in the future will require an assessment of faculty experience regarding the model's value in QI for broader applicability. Future studies should incorporate interviews, alongside surveys, to seek faculty and students' input.

Conclusions

Knowledge implementation and uptake are essential yet complex aspects of health sciences to improve health care and systems outcomes. Improvement endeavors require a hybrid model that integrates improvement and implementation sciences. The integration of the CFIR model with the GTO or KTA process models accompanied by the use of evidence-based implementation strategies and QI tools provided a roadmap and systemic thinking for successful QI projects. The hybrid model can be applied to different inpatient and outpatient settings.

Acknowledgments

We thank Dr Amanda Bridges for comentoring some of the Doctor of Nursing Practice projects and all students who participated in the study. We thank Dr Ana Vera for helping in analyzing the data.

Data Availability

The data sets generated and analyzed during this study are not publicly available due to presenting the data as quotes in Multimedia Appendix 4 but are available from the corresponding author on reasonable request.

Abstract

Background: Specific challenges in the health care sector, such as hierarchical structures, shortages of nursing staff, and high turnover of nursing staff, can be addressed by a change process of organizational culture into shared governance. Data from business organizations show that the use of digital voice channels provides employee voice. This approach makes concrete the opportunity for employees to raise their voices by answering surveys and making comments in an anonymous forum, which subsequently positively influences staff turnover and sick leave. Since there is no clear understanding of how a digital voice channel can be used in long-term care to address employee voice, a research gap has been identified.

Objective: The purpose of ADVICE (Understanding Employee Voice Behavior; the acronym for this study) is to understand how the use of a digital voice channel performs in long-term care (residential long-term care and home care facilities). The aim of this study is to understand how the digital voice channel can support staff in making their voices heard and to see what managers need to use the voice channel to change the work environment.

Methods: An embedded multiple-case study will be used to explore the experiences of 2 health care providers who have already implemented a digital voice channel. ADVICE is organized into two main phases: (1) a scoping review and (2) an embedded multiple-case study. For this purpose, focus group interviews with employees, discursive-dialogical interviews with managers, meeting protocols, and data from the digital voice channel will be analyzed. First, all units of analysis from every embedded unit will be separately analyzed and then comprehensively analyzed to obtain a case vignette from every embedded unit (within-analysis). In the second stage, the analyzed data from the embedded units will be compared with each other in a comparative analysis (cross-analysis).

Results: The results will provide insight into how digital voice channels can be used in long-term care to address employee voice. We expect to find how the digital voice channel can empower nurses to speak up and, consequently, create a better work environment. Data collection began in August 2023, and from a current perspective, the first results are expected in summer 2024.

Conclusions: In summary, the results may help to better understand the use of a digital voice channel in the health care sector and its transformative potential for leadership. At the organizational level, research can help to improve the attractiveness of the workplace by understanding how to give employees a voice.

Introduction

Overview

The International Council of Nurses points out that there is a need to reduce the dropout rate in nursing and promote the loyalty of employees to their health care provider [1]. Data from the Austrian Work Climate Index that are related to working conditions in the nursing professions describe that 65% of nurses intend to leave their current position, and 15% have plans to change their profession [2]. Furthermore, according to the NORDCARE report on working conditions in long-term care in Austria [3], the working conditions perceived by nurses have declined in recent years. As justifications, the respondents noted the increase in work demands, staff shortages, and lack of time for caring activities. A low level of autonomy, especially among nurses, is highlighted by the collected data. Nursing assistants and home assistants state that they feel left alone with the responsibility for people in need of care. The NORDCARE report [3] findings are corroborated by data from the Austrian Work Climate Index [2], indicating that 44% of employees lack or have inadequate chances to participate in work activities, which may negatively impact on-job satisfaction.

Background

To promote high-quality, person-centered care in the context of challenges related to nursing turnover as well as the different needs and requirements of different generations, health care providers need to invest in creating a productive work environment [4]. To sustainably change the culture in an organization, the interplay of transformational leadership, shared governance, and action processes is needed [5]. In particular, transformational leadership is presented as a leadership style that is action-oriented and enables development and change through shared governance. Shared governance is seen as a management approach in the sense of enabling all stakeholders and employees to have a voice in decision-making processes [5,6].

Recommendations to implement a change process in organizations using transformational leadership and shared governance are supported by the positive impact of the Pathway to Excellence in Long-Term Care (PTE-LTC) program. This is a special Magnet Recognition Program of the American Nurses Credentialing Center for long-term care. The PTE-LTC program is based on 6 pathway standards: professional development, shared decision-making, leadership, well-being, quality, and safety. The goal is to empower and give frontline staff a voice, promote staff participation in improving outcomes, create a sustained culture, strengthen interprofessional collaboration, and ensure the well-being of employees [7]. Key differences between the Magnet Recognition Program and the PTE-LTC program are that the PTE-LTC program includes a person-centered model of care and unlicensed assistive personnel such as nurse assistants [7]. Research indicates that the focus in health care organizations on a better work environment and higher engagement in shared governance decreases rehospitalization and lowers nurse burnout and job dissatisfaction levels [8-10]. A systematic review shows that certified magnet hospitals, compared with nonmagnet hospitals, have higher job satisfaction levels, less burnout, lower turnover, lower rates of nurse shortages, higher quality of care, and better patient outcomes [11].

The “Relationship-Centered Team Nursing Model for Care Delivery in Nursing Homes” is a nursing care delivery model that attempts to address workforce challenges in long-term care. The model describes 4 assumptions. The first is to skillfully manage a multilevel team with a focus on care coordination and communication; the second is to empower and develop staff and delegate appropriately and responsibly; the third is the requisite preparation of nursing staff to deliver person-centered care; and the fourth is nursing leadership. In conclusion, the model addresses an evidence-based approach, clear communication, and staff empowerment [4]. Clear communication means, according to Siegel et al [4], open, clear, and timely communication between staff, residents, their families, and the involved structures.

The PTE-LTC program and the “Relationship-Centered Team Nursing Model for Care Delivery in Nursing Homes” emphasize the importance of empowering frontline staff so that in practice they can have a participatory voice that aims to influence decisions, communicate ideas, communicate residents’ needs and requirements, and initiate change [4,7]. This participatory element of workplace democracy is known as employee voice. Employee voice refers to all organizational structures, mechanisms, or practices in which employees participate and try to influence their work and the performance of their organization [12,13]. The term employee voice has a long tradition in organizational research and is variously defined in the literature [14]. A summary by Dundon et al [15] describes the concept of employee voice in terms of four characteristics: (1) addressing dissatisfaction, opinions, or suggestions; (2) expressing a collective organizational culture; (3) managing decision-making processes; and (4) demonstrating a cooperative relationship between management and employees in an organization [15]. Elizabeth Wolfe Morrison, a professor of management and organization at the Stern School of Business, New York University, defines employee voice as “informal and discretionary communication of ideas, suggestions, concerns, problems, or opinions about work-related issues, with the intent to bring about improvement or change” [14].

The literature on employee voice addresses promotive and prohibitive factors of voice, such as how supervisors respond to that behavior and the effects that voice has. For example, Holland et al [16] and Kee et al [17] show that mechanisms that address the voice of employees can reduce burnout, promote employee well-being [16], and influence organization development through structures that employees are encouraged to explore and give feedback [17]. However, according to Morrison [14], there is a need to consider how informal employee voice behavior is affected by formal opportunities and channels for voicing, both individually and collectively.

Recent developments in digital and communication technology have opened new opportunities to address employee voice [18-20]. For example, the social and economic scientist and sociologist Ellmer and Reichel [19] describe the possibility of a company mirror or digital voice channel. This digital communications technology enables voice by allowing employees to periodically report their work satisfaction through minisurveys and make anonymous comments in miniforums. Ellmer and Reichel [19] show in their case study that employees are encouraged to speak up and discouraged from an affordance perspective. In this context, the affordance perspective refers to the definitions of Gibson [21] and Norman [22] and means analyzing the possibilities for action that an artifact offers to an actor, as well as the constraints. The possibilities that an artifact can support or hinder a person in achieving a goal. These results indicate that the interplay of material and social aspects, that is, the characteristics of the voice channel and the responses of the management embedded in the respective organizational context, lead to employees perceiving the channel as either promoting or restricting speech. This further leads to whether employees feel encouraged or discouraged to speak up or not speak up [19]. In summary, a digital voice channel can have a positive impact on the identification and attachment of the employees with the company, leading to a reduction in turnover and sick leave, which depends on job satisfaction [16], perception of autonomy, the influence of organizational context [23], and the perception of safety [24] and dependencies [19]. These results indicate that a digital voice channel is not sufficient on its own; it must be seen as a part of an overall approach to shared governance [19].

Based on these findings, due to the increasing challenges related to nursing turnover and the different needs and requirements of different generations, new measures are needed to meet the increasing demand for nurses to ensure high-quality, person-centered care.

To date, the use of a digital voice channel in the health care sector has received little attention. Improvements in the health care structure, IT, organization, and legislation are needed to ensure that health care is error-free, efficient, and effective. The Health & Care Expert Council recommends investing in the promotion of digital health literacy, that is, empowering people to deal competently with the digitalization of health care [25]. Available data indicate that in the health care sector, it can be difficult for employees to have a voice due to hierarchical structures [17,26]. For example, Kee et al [17] research how nursing assistants can develop voice behavior that transcends hierarchical levels. The study results show that by training in personal reflection as well as individual coaching, nursing assistants are able to influence organizational structures and initiate change. As a result, it is necessary to understand the wider context of social processes in an organization to address the voice of employees. For example, to know that psychological safety and commitment-based safety management have an impact on whether nurses are willing to raise concerns and be aware that psychological safety is a social-cognitive variable that varies between individuals within the same work context [27-29]. Research also exists regarding the content and structure of simulation training on speaking up in health care organizations [30,31]. It should be noted that the evidence on simulation training has mainly focused on inpatient and emergency settings, operating theaters, and intensive care units and not on long-term care. Martin et al [32] suggest that relying solely on formal channels may discourage some individuals from speaking up, hence the importance of complementing with informal methods. It is recommended to use a combination of both to encourage a greater variety of voices to be heard. Further studies have examined the implementation of a new role called “guardian” to promote voice in the organization. The research indicates that this role should not only focus on formal acts of voice such as support and advice. Instead, a relationship role between the guardian and colleagues is needed, as well as a well-defined role between the existing channels for voice [33]. As Jones et al [34] and O’Donovan and McAuliffe [35] noted, it is unlikely to find a 1-size-fits-all approach to creating a culture where health care professionals can raise their voice. In summary, it must be mentioned that in the health sector, the term employee voice is not used consistently. The existing literature on the use of voice in health care focuses on the use of voice in the context of patient safety and error reporting. In summary, the current review by Lainidi et al [36] points to the lack of a comprehensive theory of employee well-being and communication in the health care sector, which leads to heterogeneous mechanisms and an unclear understanding of the phenomenon of employee voice in health care. Lainidi et al [36] argue that understanding the concepts of voice and silence from both organizational and employee perspectives is crucial, as is the need for different solutions for different contexts. This means that individual approaches and evaluations are needed to gain a deeper understanding of employee voice, especially in the long-term care sector.

In their systematic review, Mair et al [37] note that the published literature focuses on organizational aspects yet neglects the broader social framework that needs to be considered when introducing new technologies. More recently, Krick et al [38] have recommended more evaluations of digital technologies in a real-life setting. It is not about what is technically possible; rather, it is about how new digital technologies in the daily routine can be designed to consider staff needs and preferences [20,39]. Ong et al [40] address this research gap and analyze the implementation of a digital patient feedback system using normalization process theory (NPT) from May and Finch [41] and May et al [42]. NPT is a middle-range theory that provides a sociological framework to understand social processes. The theory was developed to understand how a practice becomes or does not become routinely embedded in social contexts. A total of 4 key components of the theory are of relevance: coherence,

cognitive participation, collective action, and reflexive monitoring. These 4 components define the process of normalization. Coherence refers to the fact that the practice is an ensemble of beliefs, behaviors, and acts that are defined by a set of ideas about its meaning, uses, utility, and socially defined and organized competencies. The nature of embedding depends on the work that defines and organizes a practice as a cognitive and behavioral ensemble and requires that actors collectively invest meaning in it. Cognitive participation means that normalization depends on the work that defines and organizes the actors involved in a practice. Collective action includes the chain of interactions, that is, a place of mental and material work that deals with organizing and enacting a practice. Reflexive monitoring means the continuous formal and informal evaluation of the patterns of collective action and their outcomes by all participants [41,42]. Collectively, NPT provides an appropriate conceptual framework to understand issues relating to routinization of new technology [37,43]; it will therefore be used in the ADVICE (Understanding Employee Voice Behavior; the acronym for this study) study as the theoretical lens.

This study will fill a gap in knowledge because it aims to understand how staff and managers use a digital voice channel in the social context of health care providers who offer long-term care services, to subsequently understand how employee voice behavior is affected by the digital voice channel, and to explore what opportunities arise for the employees and for the organization through a digital voice channel. The digital voice channel is a browser-based software-as-a-service system that organizations can purchase on a subscription basis. The founders of the digital channel provider aim to empower employees to actively participate in the improvement and decision-making processes in their workplace by giving them the opportunity to (1) periodically report on their job satisfaction through minisurveys and (2) post anonymous comments in a miniforum. On the user interface, a dashboard with a graph shows the progression of a sentiment metric over time, allowing analysis of current and past sentiment levels in the organization. The sentiment metric is based on responses to anonymous minisurveys covering 6 categories: well-being, health, collaboration, potential development, work activity, and organizational culture. The standard pool of questions can be supplemented by various additional pools. Employees can select from a Likert scale ranging from 1 to 7 (1=does not apply at all to 7=completely true). To gather votes, a link to minisurveys (ranging from 3 to 10 questions) is sent to all employees through email at specified intervals (weekly or monthly), depending on the organization's preference. Managers are alerted when new votes or anonymous comments are available. This information, combined with the dashboard, can be used to identify and act on trends and dynamics in the team early on, allowing decisions to be made based on this information.

Aim of This Study

The aims of the study are to investigate the phenomenon of the digital voice channel in a real-life context and to explore opportunities and capture experiences to enable a systematic and professional approach in the future. This means that it is about generating new knowledge to make the new techniques usable and normalized in long-term care. The overall question is as follows: How does the use of a digital voice channel support opportunities to affect employee voice behavior in long-term care?

For the planned scoping review, the following question is relevant: Which opportunities are mentioned in the literature to address employee voice in health care providers?

For the embedded multiple-case study, further questions are relevant:

What are the experiences in long-term care with the use of a digital voice channel? How is the normalization process described in long-term care, and how do they differ?

Methods

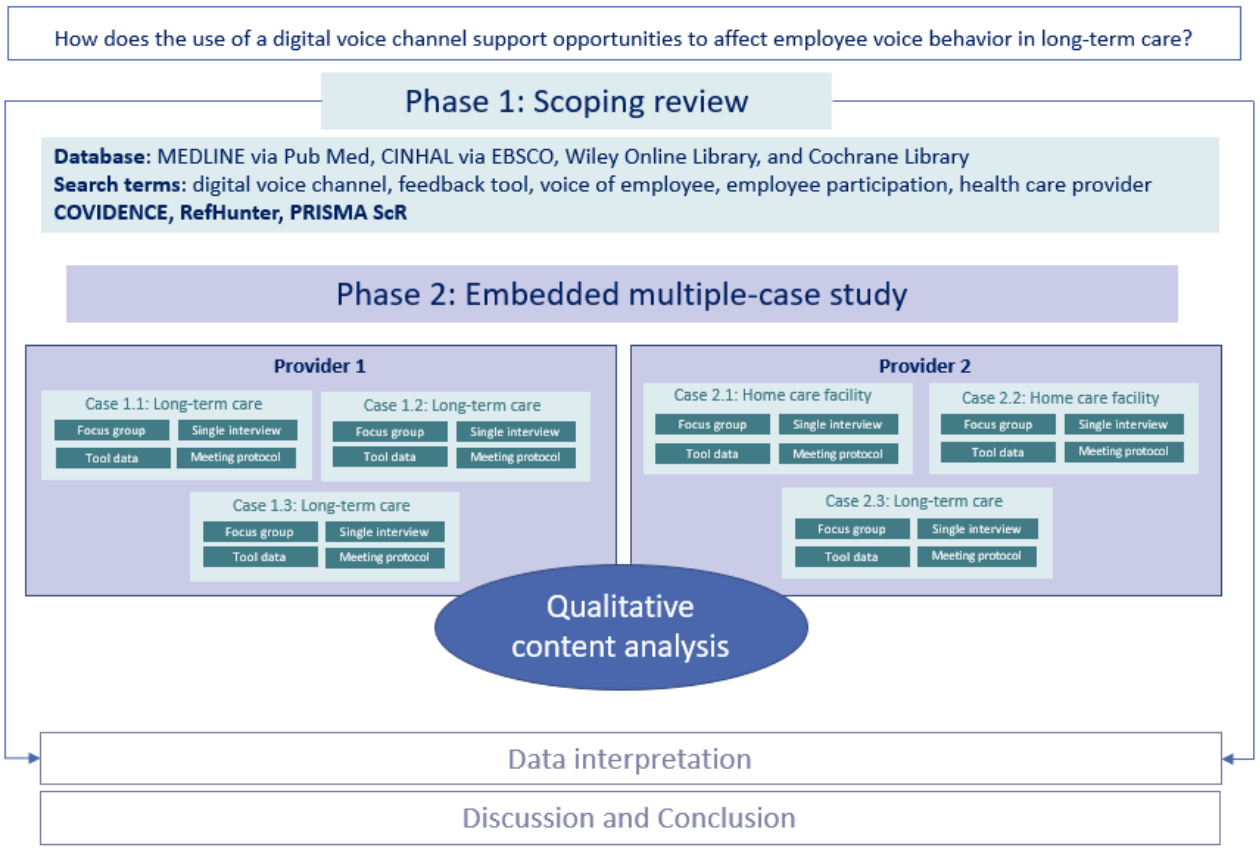
Overview

To answer the research questions, an embedded multiple-case study will be chosen. Case studies can be used to analyze a phenomenon from multiple perspectives in a real-life context [44] to gain a deeper understanding [45]. The case study approach is especially appropriate when there is little understanding of a phenomenon in a certain context [44]. According to Yin [44], case study research is described by 5 components: questions, propositions, cases, data collection, and data analysis. Propositions in ADVICE will result from the scoping review and from NPT. The contexts are 2 health care providers that have already implemented a digital voice channel. These 2 long-term care providers describe the context in which several residential long-term care and home care facilities (cases) operate. Both providers use the same digital voice channel.

To analyze the social processes related to the use of a digital voice channel in health care providers, multiple data sources are necessary to create dense descriptions [44,46]. For this purpose, focus group interviews with employees, discursive-dialogical interviews [47] with managers (plus field notes), meeting protocols, and data from the digital voice channel will be analyzed (units of analysis). The qualitative data and comments in the survey will be analyzed by a deductive-inductive content analysis approach developed by Schreier [48]. Data from the digital voice channel include response rates and frequency of the mentioned topics. These quantitative data are displayed in the digital voice channel and provided by the health care provider. In summary, a phenomenon (digital voice channel) will be analyzed in a real context (2 health care providers) to achieve a deeper understanding of how a digital voice channel becomes a daily routine, that is, normalized [49]. It should be noted that the case definition or units of analysis, as well as other aspects of the research design in a case study, may be revised during data collection [50].

ADVICE is organized into two main phases: (1) the completion of a scoping review and (2) the conduction of an embedded multiple-case study, as shown in Figure 1.

Figure 1. Overview of the research phases of the ADVICE (Understanding Employee Voice Behavior) study.



Phase 1: Scoping Review

The scoping review [51] aims to provide an overview of the literature on employee voice in health care providers and the use of opportunities or interventions such as voice channels, assessments, tools, feedback instruments, feedback training, or meetings to promote having a voice in the organization. To develop the search components, the question is integrated into the PICO (population, interest, and context) schema for qualitative studies [52], as shown in Textbox 1. The scoping review will be conducted using the PRISMA ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) [53].

Textbox 1. PICO schema.

P: population

- Health care provider

I: interest

- Opportunities like digital voice channel

Co: context

- Employee voice

The search process took place in the period ranging from September 2022 to April 2023 in the MEDLINE through PubMed, CINHAL through EBSCO, Embase, Wiley Online Library, and Cochrane Library databases. Furthermore, the reference lists of relevant results will be screened and identified through Google Scholar. The following search terms will be used for the search: digital voice channel, feedback tool, company mirror, feedback, assessment, tool, voice of employee, employee participation, health care provider, long-term care, and home care facilities. Furthermore, the search terms and their synonyms will be linked to search strings using Boolean operators dependent on the databases, as well as MeSH (Medical Subject Headings) terms. After a sensitive search, the research team will consult with each other and adapt the search string. To support the search, the researchers will use the manual for literature search in specialized databases, namely, RefHunter [54]. The inclusion and exclusion criteria shown in Textbox 2 have been derived from the objective and research questions. There will be no restrictions regarding the currency of the literature included.

Textbox 2. Inclusion and exclusion criteria for scoping review.

Inclusion criteria

- Health care provider, residential long-term care, and home care facilities
- Digital voice channel, digital feedback tools, feedback tools, evaluation, assessment, and tools
- Employee voice, employee participation, and team learning
- Qualitative and quantitative studies (all scientific studies)
- English and German

Exclusion criteria

- Other settings similar to business areas
- Summaries and discussions
- Other languages

Covidence is a software for managing and simplifying reviews. The program Covidence supports the review process after the removal of duplicates and enables the screening of the literature by 2 reviewers independently [55]. Specifically, the titles and abstracts will be reviewed against the inclusion and exclusion criteria to identify appropriate studies. In the next step, the full texts of the relevant studies will also be reviewed by 2 reviewers independently. Any disagreements about the eligibility of a study will be resolved by discussion in the research group. For data extraction, a standardized data extraction form will be developed. The form will be tested with the first 3 results and discussed in the research group. The items included in the description of each article will be selected following the Template for Intervention Description and Replication (TIDieR) [56] and Criteria for Reporting and Evaluation of Complex Interventions (CReDECI 2) in health care [57]. Based on the iterative character of the scoping review, all changes will be documented in the protocol [51]. The results of the scoping review will be used to develop propositions and the interview guide used in phase 2 of the ADVICE study.

Phase 2: Embedded Multiple-Case Study

Overview

Based on the results of the scoping review, this research phase aims to go into the field and immerse itself in the day-to-day work of the cases to understand the social processes that involve the promotion of employee voice. A detailed description of the components of Yin's [44] case study research design follows.

Casing

As shown in Figure 1, the ADVICE sample includes 6 different cases that are situated in 2 different contexts (providers 1 and 2). After Sandelowski [50], the cases for a case study are made, not found, through an iterative and theoretical process called casing. The boundary of the cases can be determined by the phenomenon of the use of the digital voice channel and the same scope of long-term care (content boundary). In these cases, the temporal boundary refers to the time of digital voice channel implementation. Starting with the time of implementation in provider 1, (2020) and provider 2 (2021), the end time describes the end of the data collection from the current point of view (2024) [44].

Provider 1 is a health care provider with approximately 1000 employees in different residential long-term care facilities in Austria. A digital voice channel has been used there since 2020. From the current perspective, this health care provider is defined by 3 cases through 3 long-term care facilities.

Provider 2 is a health care provider of several residential long-term care and home care facilities with approximately 5000 employees in Austria. The health care provider has been using a digital voice channel in a pilot phase in a few facilities since 2021. From the recent perspective, this health care provider is defined by 3 cases, namely, 1 residential long-term care and 2 home care facilities. In this case, a long-term residential care facility is an institution where people who need care can live or stay for a period of time under the responsibility of professional health care workers. Home care facilities provide professional care to patients in their own homes. The research team is aware of the different settings (residential long-term care and home care facilities) in the embedded units, which represents a limitation. The use of the different samplings can be argued by the fact that the focus of the analysis is the use of a digital voice channel, as well as employee voice behavior, in long-term care providers. Thus, it is not about the setting of health care providers per se; rather, the commonality is the same setting of long-term care, the same digital voice channel, and therefore, the same organizational culture with different characteristics. Additionally, based on the different settings, additional data, such as individual characteristics of the specific areas and differences, can be generated. The concrete number of employees and number of beds in the embedded units cannot yet be described, as the recruitment phase is only just beginning.

Data Collection

Overview

Based on the recommendation of Yin [44], data collection will take place using multiple sources of evidence. Consequently, data will be collected in the form of focus group interviews, discursive-dialogical interviews [47], meeting protocols, and data from the digital voice channel (anonymous survey data and free comments). During the whole research process, field notes and written memos concerning methodological, personal, and case-related issues will be taken by the first author [58].

These different data are, according to Yin [44], the embedded units of analysis.

Specifically, data from the digital voice channel will be searched concerning the key mechanism of reflexive monitoring drawn from NPT [41,42], for example, how benefits or problems with the digital voice channel are identified or measured.

The Interviews

The interviews will include managers, nurses, and social care professionals in each case. Based on the Austrian Nursing Practice Act, nurses are defined as registered nurses with a diploma and a bachelor's degree (full-time training, 3 years), nursing specialist assistants (full-time training, 2 years), and nursing assistants (full-time training, 1 year). In addition to nurses, social care professionals also work in residential long-term care and home care facilities. There are 3 levels of qualification based on the Social Care Profession Act (home assistant, social care workers, and certified social care workers). Home assistant complete 200 hours of theoretical course and 200 hours of practical training. Social care workers complete a 1200-hour theoretical course and 1200 hours of practical training. Certified social care workers have an 1800-hour theoretical course and 1800 hours of practical training.

It should also be noted that medical care in residential long-term care in Austria varies greatly according to the laws of the individual federal states. In most facilities, it is provided by general practitioners. This means that general practitioners are not employed by the health care provider; they provide medical care by visiting their patients. For example, it is possible for nurses in residential long-term care facilities to have different general practitioners to contact because residents bring their own general practitioners with them. This applies to other health care professionals like physiotherapy, occupational therapy, and speech and language therapy. In summary, this indicates that physicians and health care professionals are not employed in the health care providers and therefore are not using the digital voice channel.

In addition, managers in different positions will be interviewed. The inclusion and exclusion criteria used for the interview participants are summarized in Textbox 3.

The interviews will focus on the following key NPT mechanisms*:* coherence, cognitive participation, and collective action [41]. In the context of ADVICE, coherence means asking about sense-making both as an individual component and as a team component. For example, do the participants see a sense in the use of the digital voice channel or not? Do they see a benefit for themselves and for the team? Cognitive participation includes topics aiming to understand the initiation, promotion, and legitimation of participation. Social norms and formal or informal rules in the team play a role in this key mechanism. For example, are facilitators involved in which role they either have or do not have, and is there a collective commitment in the digital voice channel or not? The collective action mechanism refers to all measures taken to use the digital voice channel. Examples include competencies for workability, such as knowledge work, which is necessary to build trust, and digital competencies [41,59].

Textbox 3. Inclusion and exclusion criteria for interviews.

Inclusion criteria

- Women, men, and diverse
- Nurse (registered nurse, nursing specialist assistant, and nursing assistant)
- Home assistant, social care workers, and certified social care workers
- Manger (nursing director, nursing manager, department manager, deputy manager, head of nursing department, and head of nursing unit or nursing home)
- Employed for at least 6 months in 1 of the 2 health care providers that uses a digital voice channel
- German or English

Exclusion criteria

- Employees who do not work in 1 of the 2 health care providers or who are retired nurses or nursing students
- Employed for less than 6 months in 1 of the 2 health care providers that uses a digital voice channel
- Other languages

During the focus group interviews, nurses will have the opportunity to discuss the use of the digital voice channel. The aim here is to obtain a picture of what nurses need to be able to give a voice and the impact of the voice channel on their voice behavior. Focus group interviews will be conducted with nurses who work in one of the cases of provider 1 or 2 and do not have a management position. Approximately 6 focus groups will be conducted, each with at least 5-6 individuals in each group. Heterogeneity will be considered in the recruitment process. With attention to the professional qualification mix, every professional nursing group will be represented. The focus group interviews will be moderated by the first author with the help of an interview guide based on the results of the scoping review and NPT.

The single interviews will be conducted by the first author in a dialog-discursive interview form based on the interview guide and on the results of the focus group interviews. The reason for choosing dialog-discursive interviews with the help of a semistandardized interview guide is that interviews are

conducted openly on the one hand, while on the other hand, targeted exploratory questions can be asked regarding specific topics. A semistandardized interview guide is intended to be of assistance, whereby the order of the questions, as well as their wording, are flexibly adapted to the interview situation [47]. The semistandardized interview guide will be developed based on the research results of the scoping review and NPT [41,42] using the SPSS principle, according to Helfferich [60]. The number of interviews is based on the fact that at least 1 interview will be conducted at each management level, for approximately 14 interviews in total. It should be mentioned that the data collection will be determined by an iterative approach. Participants will be recruited by the first author through written information as well as through participation in staff meetings to get to know each other directly. Participation will be strictly voluntary. The providers and work councils (employee representation in the health care provider) will provide informed consent before the data collection step.

All interviews will be recorded using a voice recorder. The transcriptions will be performed by the first author, and after the transcriptions, the audio files will be deleted. The transcription of the interviews will follow the content-semantic transcription process word-for-word. Statements in dialect will be, if possible, translated word-for-word into standard German [61]. Before transcription, the interviews will be stripped of any identifiers so that the participants remain anonymous. Table 1 below shows the coding rules used as an example.

Table 1. Exemplary coding rules transcription.

Health care providers and embedded units	Interview	Code
Provider 1		
Case 1.1: long-term care	Focus group interview 1	P1CL1.1F1
Case 1.2: long-term care	Single interview 2	P1CL1.2S2
Provider 2		
Case 2.1: home care facility	Single interview 4	P2CH2.1S4

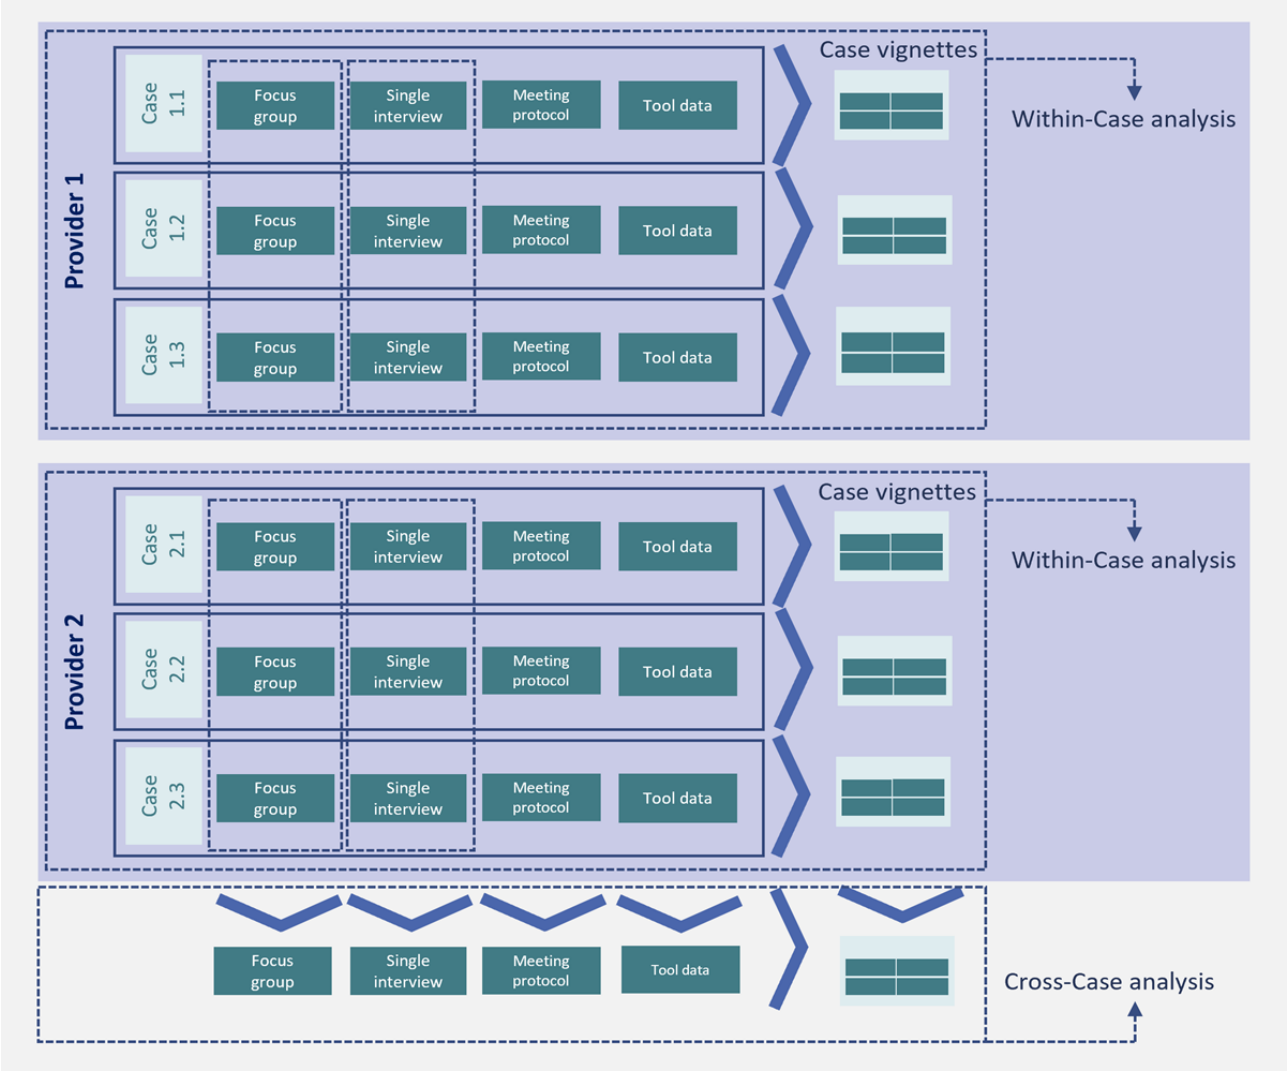
Data From the Digital Voice Channel

Relevant for ADVICE are the response rate, the frequency of topics mentioned, reactions or responses to comments, and, above all, the consistency of the topics mentioned in the interviews. Furthermore, the digital voice channel data ought to corroborate interview statements, for example, indicating infrequent usage of the free comment fields or the absence of any response. It is important to note that this is an iterative process, using different data to get deeper and deeper in understanding the case.

Data Analysis

The principle of data analysis in the case study ADVICE follows the rule of playing with the data and searching for promising patterns, insights, or concepts [44]. Therefore, first, before data analysis, all qualitative and quantitative data will be transferred into MAXQDA Analytics pro software (version 22.2.1; Udo Kuckartz, VERBI software GmbH), where they will be analyzed. Data collection and analysis will be conducted partially in parallel because the case study is an iterative process. The data analysis will be carried out in 2 stages based on the analysis of the individual cases within-case analysis and a subsequent cross-case analysis**,** as shown in Figure 2.

Figure 2. Data analysis.



First, in the *within-case analysis*, the individual cases will be analyzed as independent units, and patterns and peculiarities will be identified. The aim is to obtain an in-depth understanding of the specificities of each case. Therefore, all data from every embedded unit will be comprehensively analyzed. For this step, every unit of analysis (focus group interviews, single interviews, protocols, and data from the digital voice channel) will be repeatedly read and reread by the first author. In this iterative process, first, all focus group interviews will be analyzed in light of these results, and the first author will pursue further data collection within the single interviews. Before the interviews are conducted, the interview guide will be updated based on the results from the focus group interviews. Then, all single interviews from every embedded unit will be interpreted. Afterward, a case description will be written for each case with the results of the interviews (plus data from the digital voice channel). This within-analysis is oriented toward qualitative content analysis with regard to Schreier [48].

Based on the research questions, the first author will derive the categories based on the body of knowledge and then further add to or expand on the inductive codes. To be specific, after the first author has determined the deductive category system based on the theoretical framework, all coding units and context units will be determined in consultation with the research team (ie, sample coding). The category system will then be additionally extended by inductive codes. For example, further categories will be formed that are not represented by the coding guide but are relevant to the understanding of the case. Inductive coding will be performed by the first author and selectively verified with other researchers. In summary, a qualitative content analysis with a theoretical deductive framework will be conducted, that is, a deductive-inductive content analysis [48].

In the subsequent second stage of the cross-case analysis, the analyzed data from the embedded units will be compared with each other in a comparative analysis, and possible distortions caused by individual cases will be identified. The results of the within-analysis will provide content for the case vignettes and serve as a basis for the cross-analysis [44]. In this analysis step, the stacking comparable strategy will be used. This strategy includes case-oriented and variable-oriented cross-case analysis strategies. Each case is analyzed with a standard set of variables (based on the results of the within-analysis). After each case is understood in itself (the results will be the case vignettes), a matrix will be used to analyze each case in depth. From this, patterns and differences will be deduced. The case vignettes will include a case study report title, case description summary

based on the within-case analysis, analyst view, context information, issues, and uniqueness, among others [45,58]. The goal is to understand how the use of the digital voice channel addresses employee voice not only in every embedded single case but also on a meta-level in long-term care. The presentation of the results will follow the format (graphic, matrix, or networks) proposed by Miles et al [58].

Ethical Considerations

All participants will receive overall information about the study and be able to agree to participate and to fill out the informed consent form before the interview. Participation will only take place if the written consent form has been signed by the interviewee. The data will be processed in accordance with the data protection legislation in force, pursuant to the GDPR. The personal data collected (age, sex, professional activity, etc) are processed exclusively in an anonymous form and saved separately from the audio data (such as statements made in interviews).

Ethics approval for the empirical parts of the project was given by the ethics committee of Witten/Herdecke University (S230/2022). The ethics vote was submitted under an expedited procedure in accordance with the rules of procedure of the Ethics Committee of the University of Witten/Herdecke, as it does not raise any difficult ethical or legal issues. Furthermore, no review was requested.

Results

The results will provide insight into how digital voice channels can be used in long-term care to address employee voice. We expect to find how the digital voice channel can empower nurses to speak up and consequently create a better work environment.

The recruitment of the cases from the health care providers took place in consultation with the management and human resources managers. The decision was based, particularly in health care provider 2, on which facilities are already working with the digital voice channel. The recruitment for the focus group interviews and the single interviews began in June 2023.

Data collection began in August 2023, and from a current perspective, the first results are expected in summer 2024.

Discussion

Summary

To retain nurses in a health care organization, it is essential that they have a voice and that their views are heard. Reports from nurses working in the Austrian long-term care sector suggest that working conditions need to be addressed [2,3]. The international PTE-LTC program addresses these challenges. Specifically, this program focuses on empowering nurses, giving them a voice to actively participate in improving outcomes for residents [7]. Employee voice is 1 way of involving employees. It means that employees are able to influence work-related decisions through their feedback [12-15].

The current literature shows that employee voice has a positive impact on reducing burnout, promoting job satisfaction [16], and managing change [11,17]. It is important to note that most of the available data on employee voice in health care focuses on 1 aspect of employee voice, namely speaking up regarding patient safety and managing errors [34-36]. This leads to an unclear understanding of the phenomenon of employee voice in health care [36]. Lainidi et al [36] argue that individual approaches and evaluations are needed to gain a deeper understanding of employee voice, especially in different settings. Recent developments in digital and communication technology have opened new opportunities to address employee voice, for example, as a company mirror or digital voice channel [18-20]. Analyses show that a digital voice channel can have a positive impact on employee identification and commitment to the organization [16]. However, it depends on the organizational culture [16,23,24]. In summary, the research gap is the understanding of employee voice in a specific setting, namely long-term care, and the analysis of the use of a digital voice channel. The NPL [41,42] is used in ADVICE to better understand how the social context influences how the digital voice channel gets used to address employee voice.

We assume that the results will provide insight into how digital voice channels can be used in long-term care to address employee voice. We expect to find how the digital voice channel can empower nurses to speak up and, consequently, create a better work environment. Furthermore, we aim to understand how managers deal with the data from the digital voice channel, whether they use the data, and how they respond to trends and comments in the tool. In summary, the results may help to understand how employee voice behavior is affected by the digital voice channel and to identify what opportunities arise for the employees and for the organization through a digital voice channel.

Strengths and Limitations

We are aware of the different settings, and we try to develop a case understanding of individual cases through our within-case analysis and gain a deeper understanding of employee voice in health care providers by analyzing their similarities and differences. The authors therefore also refer to the NORDCARE report [3], which includes both residential long-term care and mobile care under the term long-term care.

The strength of the method proposed herein lies in the fact that the case study approach addresses the individual experiences of every employee and is oriented to the social processes in the daily routine to understand the use of a new approach to communication (digital voice channel) [44]. These are precisely the aspects that are addressed in the calls for future research on the use of new digital technologies [20,38,39] and employee voice [36]. Potential challenges can be encouraging employees to participate in interviews since these will take up working time, which is very limited due to staff shortages. This challenge can be addressed by attempting to allow the interviews to be completed during duty hours during the recruitment process in consultation with the health care providers. It must be mentioned that the generalizability of case studies is limited based on the high level of specificity and the small number of cases [62]. Furthermore, there is a possibility that, due to the way in which the scope of the data integration of the qualitative and

quantitative data will evolve over the course of the work, the case study will also become a mixed methods case study. This may result from the fact that more attention per individual case and subcase is needed in the data integration process that will occur between the qualitative and quantitative research steps [45]. Both interview bias and selection bias must be considered. Interviewer bias is addressed through constant reflection by the research team. The selection of the health care providers is based on the fact that they are the only ones in Austria who use this digital voice channel. The choice of cases is made by the health care provider themselves. Finally, to avoid conflicts of interest, it must be mentioned that the case selection process is undertaken by the company that provides the digital voice channels. It should be noted that the company is not involved in the research process, and moreover, the name of the company is not explicitly mentioned to avoid conflicts of interest.

Importance of This Study

ADVICE also attempts to address the recommendations of Lainidi et al [36] to consider organizational and employee perspectives to better understand the concepts of voice and silence in a specific context (long-term care). Of course, individual case specifics are considered in the case descriptions, but the main focus is on the digital voice channel used in residential long-term care and home care facilities. At the organizational level, research can help to improve the attractiveness of the workplace by understanding how to give employees a voice.

Acknowledgments

The authors are grateful to Ann Kolanowski, PhD, RN, FAAN (Professor Emerita of Nursing; Professor Emerita of Psychiatry; Penn State Hershey College of Medicine) for her constructive feedback on a draft of this manuscript. This paper is financially supported, thankfully, by the IMC Krems.

Data Availability

Data sharing is not applicable as this is a protocol paper where no data sets were generated or analyzed.

Authors' Contributions

All authors made significant contributions to the research protocol, contributed to editing, and approved the final version of the manuscript. The authors attest that there was no use of generative artificial intelligence technology in the generation of text, figures, or other informational content of this manuscript. DeepL Write (free version; DeepL SE) was only used for spelling and grammar correction.

Conflicts of Interest

None declared.

Abstract

Background: Acceptability and preference research play a crucial role in the design, evaluation, and implementation of any new prevention product in any geographical setting. They also play a critical role in the development of clinical guidelines and policies. A wide range of acceptability studies have been conducted in diverse general and key populations for various new HIV prevention products worldwide. As clinical development strategies are being developed for clinical studies of broadly neutralizing antibodies (bNAbs) as potential HIV prevention products, appropriately tailoring them to address the type of HIV epidemic at hand would be critical for efficient uptake within in-country public health systems and decrease adoption and adherence challenges. Accomplishing this will require comprehensive acceptability and feasibility studies to inform multisectoral efforts that increase access to these products and national policies supportive of access to health care for those in most need. Thus, it is both opportune and important to undertake focused efforts toward informing product development strategies.

Objective: This study aims to understand preferences for product attributes and key behavioral factors influencing adoption and uptake of bNAb prevention products among end-users including female sex workers, men who have sex with men, transgender women, people who inject drugs, and adolescent girls and young women in India and understand the key health system and programmatic perspectives toward the introduction of bNAb prevention products from health service providers and policy makers in India.

Methods: A multisite study will be conducted in Delhi, Mumbai, and Chennai to capture the differences in perspectives among diverse end-users and key informants across the country. The study will use a multimethods design using focus group discussions, in-depth interviews, simulated behavioral experiments, and key informant interviews. A total of 30 focus group discussions, 45 in-depth interviews, 15 simulated behavioral experiments sessions, and 15 key informant interviews will be conducted across 3 sites.

Results: The data collected and analyzed will enable insights on which specific product attributes matter the most to the populations and why some attributes are less preferred; contextual drivers of preferences and choices at individual, interpersonal, social, and structural levels; and relative positioning of bNAb products among other potential HIV prevention products. Insights

from the health service providers and policy makers will provide a critical understanding of the need perception of the potential product in the existing product landscape and what additional efforts and resources are required for potential introduction, delivery, and uptake of the bNAb products in the Indian context.

Conclusions: Insights generated from the abovementioned objectives will represent perspectives of populations of interest across geographies in India, will provide an overview of the acceptability of bNAb products and the feasibility of their introduction in this region, and will inform product development strategies.

Introduction

HIV Prevention Product Landscape

HIV/AIDS has been one of the most devastating epidemics in human history. Since the official recognition of *AIDS* in the early 1980s, a total of 77 million people have been infected globally and approximately half of them have succumbed to the disease. Although effective and affordable antiretroviral (ARV) treatment has transformed HIV from a *death sentence* to a chronic, manageable disease, people with HIV have shorter life expectancy than those without the virus. New infections continue to fuel the epidemic while disproportionately affecting low- and middle-income countries. India has the third largest HIV epidemic in the world, with 2.1 million people currently living with HIV, and the sixth highest incidence with 88,000 new infections per year [1]. In addition, the high variability and ever-changing face of the virus along with the persistent marginalization and stigmatization of populations most at risk remain critical challenges in controlling the spread of HIV infection [2].

Current HIV prevention strategies include a range of behavioral and biomedical interventions, including behavior change campaigns, promotion of consistent use of male and female condoms, use of clean needles and syringes, opioid substitution therapy (eg, buprenorphine), voluntary male medical circumcision, and biomedical tools such as the use of ARV medication as preexposure prophylaxis (PrEP), and the treatment of people living with HIV to reduce viral load to undetectable levels and prevent onward transmission (treatment as prevention). There are several new HIV prevention products in the pipeline that have the potential to reduce the spread of HIV infection, including next-generation ARVs, especially long-acting ARVs [3], intravaginal (dapivirine) ring [4], preventive vaccines, and broadly neutralizing monoclonal antibodies (bNAbs) [5-11]. Multiple studies have highlighted that a single product will not be preferred by all end- users under all circumstances [12,13] because there is a constant evolution in the life journeys, social contexts, and product attributes. Thus, different products may be preferred by end-users at different times. Introduction of a new product does not necessarily mean that the importance or relevance of existing products has been replaced. It is important to identify the unique value of novel interventions and understand end-user perspectives to highlight their value addition to the current prevention landscape. There is a need to create a toolbox and choice sets that will cater to the unique needs of end-users [14]. bNAbs are antibodies that can potentially be used to fight against multiple strains of HIV and are poised to have advantages over other preventive drugs such as the ability to target and act against a broad spectrum of viral strains, longer half-life and hence less frequent dosage, no risk of development of resistance to ARVs used for treatment, and comparatively safe with rare cases of adverse side effects [11,15-19]. More than 200 different bNAbs targeting HIV have been isolated to date, varying significantly in their coverage of global HIV isolates (breadth) as well as the amount required to neutralize the virus (potency). bNAbs have been proven to be safe for humans and can work effectively in preventing HIV infection. The antibody-mediated prevention trial found that an antibody called VRC01 could prevent HIV infection with specific HIV strains when administered every 8 weeks to adults [20]. In addition, combinations of bNAbs engineered with extended half-lives and increased potency are also being developed and tested in trials to ensure lower dosage and lesser frequency that would make the end product accessible and affordable. The World Health Organization (WHO) has also recently published the preferred product characteristics for monoclonal antibodies for HIV prevention [21], and it highlights that based on the needs of various target populations, the antibodies should have longer lasting duration of protection, have minimal side effects, and be delivered as injections, among others. In India, most of the abovementioned prevention options have not yet been rolled out as a part of the national policy, and hence, there is a need to understand the acceptability for bNAbs and their preference vis-à-vis other potential options.

Acceptability and Feasibility Studies for bNAbs

Value of Acceptability and Feasibility Studies

Acceptability and preference research play a crucial role in the design, evaluation, and implementation of any new product in any geographical setting. They also play a critical role in the development of clinical guidelines and policies [22]. A wide range of acceptability studies have been conducted in diverse general and key populations for HIV prevention products including women, adolescent boys and girls, men who have sex with men (MSM), female sex workers (FSWs), people who inject drugs (PWID), and transgender women (TGW) [23-26]. These studies have focused on prevention products such as oral and injectable PrEP, vaginal and rectal microbicides, vaginal

rings, and future HIV vaccines [22,26-29]. The main drivers of prevention product adoption and uptake include product effectiveness, cost, absence of side effects, and multipurpose protection against sexually transmitted diseases and pregnancy [30]. Acceptability studies have shown that emotional and intuitive decision-making for a product choice is also driven by factors such as sexual satisfaction, dimensions of trust, self-efficacy, and sociocultural environments [26,31]. There is evidence for differential preference for prevention products among different populations. For example, in South Africa, FSWs preferred injectable products over oral PrEP and microbicide gel, adolescents preferred a potential HIV vaccine and expressed dislike for a vaginal ring, and MSM preferred rectal microbicides [24,25]. Relative importance of specific product attributes also varied across target populations. For example, the route of PrEP administration was found to be the most important attribute for prospective end-users in Peru, Ukraine, India, and Botswana; FSWs in Kenya; and young women in South Africa [32], whereas the PrEP dispensing site was the most important attribute for participants from Uganda and MSM in South Africa and the second most important attribute for FSWs in Ukraine [32].

There are several standard qualitative methods for assessing the acceptability of an intervention for the target population and setting. Two common methods are focus group discussions (FGDs) and in-depth interviews (IDIs). Moderated FGDs allow for understanding of group dynamics including similarities and differences and allow to probe further on particular topics as they come up in the discussion. This type of interaction generally results in a deeper understanding of the forces in a community that may impede or facilitate the implementation of effective interventions. IDIs are conducted in a one-on-one setting with members of the target communities. They allow for deeper probing to understand more details, have nuanced understanding of sensitive topics, and have an opportunity to monitor changes in tone and body language, which is also an important factor in eliciting key responses.

For the successful development and adoption of any product, it is critical that perspectives from all service providers including health care professionals and community "gatekeepers" are taken into account in the development process [33,34]. Thus, there is a need to gather evidence from diverse populations and multitude of related stakeholders across geographies in India and focus on understanding their perspectives on potential new products such as bNAbs and preferences of different product attributes. These are often conducted through key informant interviews (KIIs).

In India, acceptability and feasibility studies have been conducted for various microbicides and PrEP [35-42]. These studies have been scattered over time and have been restricted to a few geographical locations and key populations. Thus, there is a need to gather evidence from diverse populations and multitude of related stakeholders across geographies in India and also focus on perspectives with respect to the potential new product—bNAbs.

Behavioral Science for Contextualized Understanding of End-User Decision-Making

Apart from the aforementioned methods, there are other qualitative research methods that are necessary to complement some of the emerging insights from the potential end-users. It has often been observed that studies conducted to explore preferences for hypothetical products or willingness to participate in hypothetical trials have shown differences in the stated preferences and intentions versus the eventual decisions and observed behavior of end-users [43-45]. In Kenya, an observational cohort study reported a 90% willingness to participate in future trials; however, during actual trial recruitment, only 30% were willing to actually enroll [44]. In a real-time scenario, end-users may be presented with multiple contextual trade-offs as well as nonconscious factors that may influence their decision-making, and hence, stated versus revealed preferences may be different [45]. It has also been reported that hypothetical choice experiments with end-users provide relatively satisfactory predictive results for positive choices, but they are less effective for predicting negative choices [43]. Thus, to premeditate and elicit the "say-do" gap, one of the useful methods deployed by behavioral scientists is to identify and analyze shortcuts known as heuristics in action, which take off the cognitive load of decision-making and help anticipate and explain potential avenues for gaps between the stated intention and action [46,47].

The cognitive process marking the final behaviors exhibited and decisions made by prospective end-users may be a mix of conscious and nonconscious factors and, hence, cannot always be brought out through in-person discussions alone. Therefore, the application of behavioral science in a simulated context has been found to be extremely beneficial for deciphering the key drivers of decisions and behaviors. In such a situation, the participants in a study do not just have to talk about their past or future decisions but have to actively make a decision in real time in a simulated environment. This provides researchers with a better understanding of the decision pathways of prospective end-users as well as potential aspects of say-do gaps to inform the design and development of products. Toward this, Ethnolab is a behavioral research methodology that often uses a Conundrum game [48] to deploy scenarios based on the preliminary qualitative research findings in a simulated environment and observe user choices in real time. The method has been used in several sociobehavioral and acceptability studies for health programs and interventions, including voluntary male medical circumcision decision-making in Zimbabwe and Zambia [48]; understanding HIV prevention for adolescent girls and young women (AGYW) in South Africa [49]; and estimating the impact of nonconscious drivers of human behavior among pregnant women and mothers of infants as well as with frontline workers on reproductive, maternal, newborn, and child health outcomes in Uttar Pradesh [50].

Population of Interest

As noted previously, India has the third largest HIV epidemic in the world, with 2.1 million people living with HIV, and the sixth highest number of new infections at 88,000 per year [2]. Therefore, ensuring the acceptability and feasibility of any new

potential HIV prevention product in the regional Indian context and needs is critical. The HIV epidemic in India is concentrated among key populations such as FSWs, MSM, PWID, and TGW. The average national prevalences from the government studies range from 1% to 6% (PWID: 6.3%, TGW: 3.1%, MSM: 2.7%, and FSWs: 1.6%) with high interstate variations [51], and access to HIV prevention and treatment services for these populations remain hindered by sociobehavioral and structural barriers including multilayered stigma, discrimination, and marginalization [52,53]. In addition to epidemiological and behavioral diversity across regions and key populations, the rapidly evolving nature of the epidemic as well as changes in risk behaviors owing to the rise in the use of new communication technologies also necessitate systematic and structured inquiry into the health system and end-user contexts and preferences impacting the eventual adoption and uptake of new HIV prevention products such as bNAbs. In addition, although there has been a steady decline in HIV prevalence in India over the last decade, the decline among men has been significantly more rapid than that among women [54]. Similarly, significant gender-based gaps persist in knowledge on HIV prevention among young people (aged 15-24 years); although 75% of the women had heard of HIV (as compared with 89% of men), only 43% of the women in the country knew where to get tested for HIV, and of them, only 14% were ever tested and received results [54]. In addition, the prevalence of intimate partner violence among women of reproductive age (15-49 years) remains high at 22% [54]. Thus, in addition to key populations, it also becomes important to understand the perspectives of AGYW to cover diverse viewpoints and preferences for HIV prevention products, specifically bNAbs.

Study Objectives

The study objectives are as follows:

1. To understand preferences for product attributes and key behavioral factors influencing the adoption and uptake of bNAb prevention products among end-users including FSW, MSM, TGW, PWID, and AGYW populations in India
2. To understand key health system and programmatic perspectives toward the introduction of bNAb prevention products from health service providers and policy makers in India

Methods

Study Population and Sites

The study populations include potential end-user populations such as FSWs, MSM, TGW, PWID, and AGYW and key stakeholders such as health service providers (including frontline health care workers, community-based organization [CBO] or nongovernmental organization [NGO] representatives, and lead community representatives) and policy makers (including national, state, and district level officials or program managers).

The multisite study will be conducted in Delhi, Mumbai, and Chennai regions to ensure coverage of perceptions from North, West, and South India, including differences in perspectives among diverse end-users and stakeholders. These sites also have very high HIV prevalence among the study populations [51].

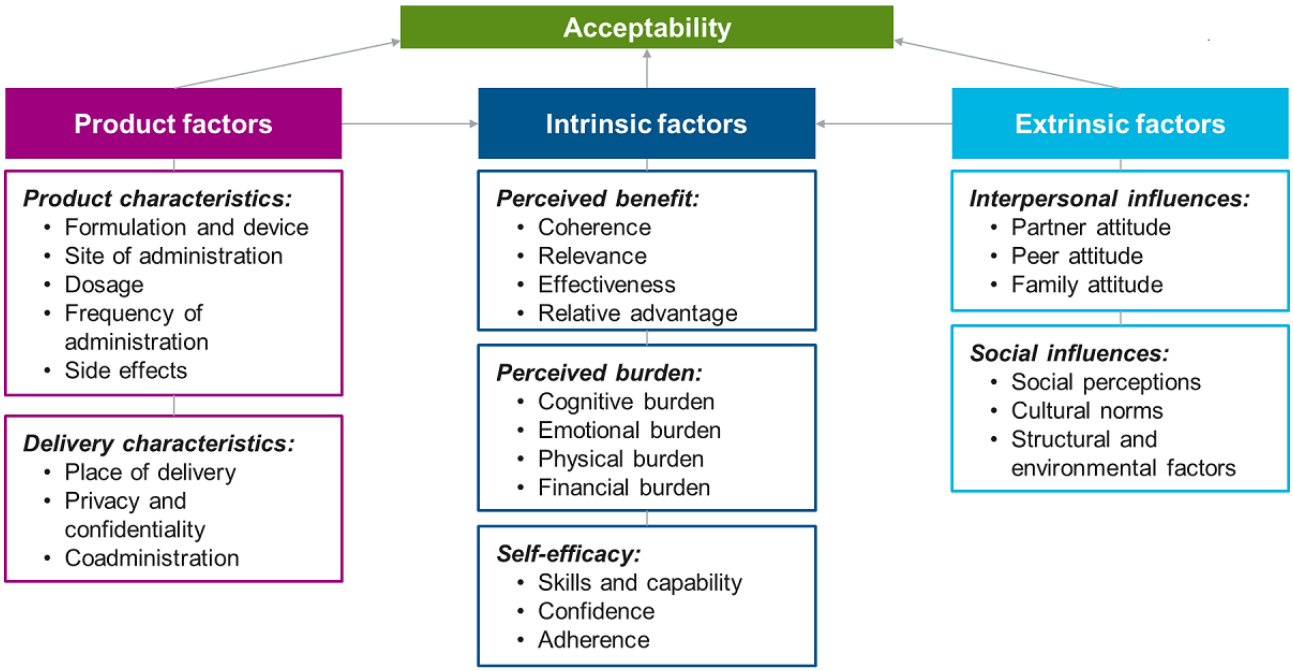
Conceptual Framework

Conceptual Framework for Acceptability

Acceptability may be defined as the extent to which people delivering or receiving a health care intervention consider it to be appropriate based on anticipated or experienced cognitive and emotional responses to the intervention [55]. Several theoretical frameworks are available for understanding acceptability of new HIV prevention products or technologies [41,42,55-57] at the individual and community levels. A recent systematic review proposed a model of acceptability of health interventions, the Theoretical Framework of Acceptability (TFA) [55]. According to TFA, intention to use a health intervention is determined by seven factors: (1) perceived effectiveness, (2) intervention coherence, (3) affective attitudes, (4) burden, (5) ethicality, (6) self-efficacy, and (7) opportunity costs. It was chosen to adapt the TFA to guide exploration of acceptability of bNAbs in this study as it can readily incorporate individual- and community-level influences on attitudes and behavior. The study design was also informed by the conceptual framework developed by Mensch et al [56] to incorporate the various factors operating at individual, interpersonal, community, and structural levels in influencing a person's product-related attitudes and perceptions. In addition to adopting aspects from the social-ecological model, the framework emphasizes the role of actual product-related factors, including product attributes, which also play a role in defining an individual's preferences [56]. Thus, guided by these frameworks, an adapted conceptual framework was used to design this study. In this adaptation, the constructs were embedded within three domains (Figure 1) [55,56]:

1. Product factors: those related to the potential product characteristics (formulation, device, site of administration, dosage, frequency of administration, and side effects) and delivery characteristics (place of delivery, privacy and confidentiality, and coadministration)
2. Intrinsic factors: those related to a person's individual traits and not influenced by external factors. These include a person's those related to a person's individual traits and not influenced by external factors. These include a person's *perceived benefit* of the product (coherence, relevance, effectiveness as well as relative positioning, and advantage of the product among other options), *perceived burden* in using the product (cognitive burden—complexity of dosage and time; emotional burden—fear, anxiety, and discreteness; physical burden—pain, side effects, and impact on sex; and financial burden—cost, travel, and opportunity loss), and *self-efficacy* (skills and capability, confidence, and adherence)
3. Extrinsic factors: those related to external influences including *interpersonal influences* (peer, partner, and family attitude) and *social/structural influences* (social perceptions—stigma and discrimination, cultural norms, and structural or environmental factors).

Figure 1. Conceptual framework for acceptability (adapted from the Theoretical Framework of Acceptability and the conceptual framework for product acceptability).

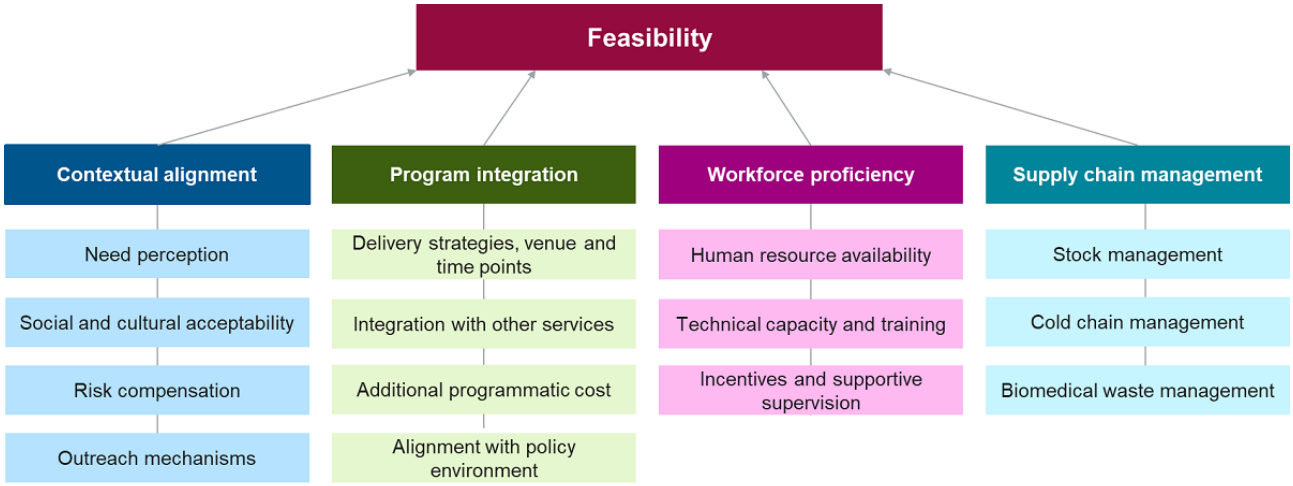


Conceptual Framework for Feasibility

There are multiple factors at the health systems and programmatic levels that service providers such as frontline health care providers, policy makers, and program managers at national, state, and district levels would consider as key issues that are needed for introduction and uptake of bNAbs as HIV prevention products in the future. Thus, complementing the study's conceptual framework for acceptability, which will be used among the end-users, there is a need to have a conceptual framework to assess the feasibility. For this purpose, the framework shown in Figure 2 [58] was adapted from the WHO Framework on Health Systems, which was also used by the WHO for reviewing the impact of new vaccine introduction on immunization and health systems. The broad themes include the following:

1. Contextual alignment: This will enable an understanding of the need perception of the current product, its social and cultural acceptability, the outreach mechanisms that will be needed, and whether there is any risk compensation because of the introduction of this new product.
2. Program integration: This is toward understanding delivery strategies, venues, and time points; possibility of integration with already existing services; additional programmatic costs required; and alignment with the existing policy environment in India.
3. Health care workforce: This will explore the availability of adequate human resources—their distribution and workload, existing technical capacity and additional training needs, and incentives and supportive supervision required to successfully implement the introduction of a potential new product.
4. Integrated supply chain: This will be toward assessing the health systems' readiness in terms of robust stock management, cold chain availability, and biomedical waste management.

Figure 2. Framework for the assessment of feasibility of introduction of potential broadly neutralizing antibody products for HIV prevention (adapted from a study by World Health Organization).



Study Design

Data Collection Methods

Overview

To understand preferences with regard to product attributes and key behavioral factors influencing the adoption and uptake of bNAb prevention products, this study will use a multimethods design [59] to provide a holistic approach based on complementarity and corroboration [60] by including the following qualitative methods:

- FGDs
- IDIs
- Simulated behavioral experiments (SBE)
- KIIs.

Data Collection Through FGDs

FGDs will be conducted among various groups such as FSWs, MSM, PWID, TGW, and AGYW. These discussions aim to understand the preferences and aspirations of prospective end-users regarding characteristics of HIV prevention products. In addition, the research seeks to uncover the key factors influencing their decision-making process including influential individuals and other contextual factors. Furthermore, the aim is to correlate these insights with what motivates or dissuades them from favoring specific HIV prevention options over others. This will be conducted in a small group of 7 to 8 participants. The end-users will also be asked about specific delivery preferences that would guide their adoption of and adherence to novel HIV biomedical prevention tools. FGDs allow the members of the group to collectively brainstorm on the issues, choices, drivers, and solutions, sometimes called a "synergistic group effect" [61]. This also allows for assessing participant behavior in a group setting wherein not only the individual respondent's views are deliberated on, but the voices of the community as a whole are also accounted for.

Data Collection Through IDIs

IDIs will be conducted with additional participants from all the target populations through one-to-one discussions and will cover aspects similar to the FGDs. However, these will provide an opportunity to gather deeper insights as the interviewer can probe more, note the changes in respondent's tone and body language, and also have views that are not influenced by group dynamics or social desirability [62].

Data Collection Through SBEs

SBEs will be conducted in small groups of 5 to 6 end-users to delve deeper into the causative factors of decision-making and potential avenues for intention-action gaps by using interdisciplinary concepts from behavioral economics and decision science. SBEs will use the insights generated from the FGDs and IDIs to construct a range of decision scenarios that end-users could face in deciding their preferences for a potential prevention product. SBEs will then use a game-based research technique (Ethnolab) to understand the context, emotions, and decision levers that influence decision-making based on these scenarios. Ethnolab is designed to minimize the impact of biases in decision-making, such as fear of value judgment, social desirability, and expectation of higher self-control in the future, which make respondents claim behaviors that may not play out in real life, thereby giving rise to "say-do" gaps [48]. Ethnolab would allow participants to not only discuss preferred attributes but also make real-time decisions revealing their preferences through multiple test scenarios. One of the critical objectives is to decipher the patterns of preference exhibited by different respondents across divergent contexts. Therefore, Ethnolab will help to identify the following:

- Past experiences that have led to decision-making criteria, values, norms, or beliefs that influence health behaviors and product preference
- Present goals around health management, relationship management, and life management and how they influence attribute selection
- Factors that could lead to preference reversal.

Data Collection Through KIIs

In addition, to better understand the environmental, market, programmatic, and policy contexts at the national, state, and local levels, along with decision-making factors and pathways informing HIV policy, KIIs will be conducted with policy makers and health service providers to understand their

perspectives on drivers for the adoption and uptake of health innovations. Efforts will also be directed toward seeking their input on implementation and access issues as well as health systems challenges on non–cold chain versus cold chain product requirements and other parameters related to effective delivery and adoption of biomedical interventions to prevent HIV.

Sample Selection

The following sample selection criteria will be followed for the abovementioned methods.

End-Users

The inclusion criteria for the various target groups are:

- Inclusion criteria for MSM, TGW, PWID, and FSWs in the FGDs and IDIs were as follows: Aged at least 18 years, self-identifies as MSM, TGW, PWID, or FSW, and willing to provide informed consent.
- Inclusion criteria for AGYW in the FGD and IDIs were as follows: Aged 18 to 24 years and willing to provide informed consent. According to the Joint United Nations Programme on HIV and AIDS definition, AGYW fall into the age group of 15 to 24 years [63]. However, given the ethical considerations with respect to minor adolescent girls (15-17 y) in the Indian context and keeping in mind their relatively lower exposure to HIV prevention services, it was decided that for the purpose of this study, only adolescent girls aged 18 to 19 years and adult young women aged 20 to 24 years will be included. Efforts will be made during data collection and data analysis to ensure that perspectives from participants aged 18 to 19 years and those aged 20 to 24 years are disaggregated to bring out the unique highlights from these populations.
- For FGDs, diverse typologies and subgroups of MSM (kothis [feminine/primarily receptive role], panthis [masculine and primarily insertive role] , double-deckers or versatile, gay, and bisexual men), FSWs (brothel or bar based, street based, internet or social media based, and home based), TGW (gharana based and nongharana and those in sex work and those who are not), PWID (who use different types of injectable drugs), and AGYW across the age group (adolescents aged 18-19 years and young women aged 20-24 years) will be recruited.
- To explore diverse perspectives, maximum variation purposive sampling [64] will be used to recruit individuals from diverse backgrounds such as engaging in sex work; being from lower and middle class; and being single, living with male or female partners, heterosexually married, and representative of male and female PWID groups.

Key Informants

For KIIs, the inclusion criteria will be as follows:

- Key informants should be aged >18 years, ≥5 years of experience as a community leader or ≥3 years of working experience with population of interest or as a part of the HIV program, and willing to provide informed consent.
- Key informants will include information-rich individuals who have worked with key populations or have some experience of working with AGYW or in the field of HIV. These may include health service providers (physicians, counselors, nurses, CBO or NGO representatives, and community leaders) and policy makers (program managers and district or state or national level officials).

Sample Size

A total of 30 FGDs (2 FGDs per end-user group per site; for 5 end-user groups across 3 sites) and 45 IDIs (3 IDIs per end-user group per site; for 5 end-user groups across 3 sites) will be conducted in Delhi, Mumbai, and Chennai to investigate factors at individual, interpersonal, and sociostructural levels that facilitate or impede the acceptability of bNAbs among susceptible communities in India.

The SBE will mirror the sampling frame and the broad respondent profiles from the FGDs and IDIs. Keeping in mind that Ethnolab elicits the most useful insights in small and intimate settings, the sample would include 6 participants for each end-user group (distinct and different from the participants in the FGD or IDIs) across each site. Thus, the total sample size would be 90. Each instance of Ethnolab will have 6 respondents, and a total of 20 Ethnolab-based SBEs will be conducted across all 3 sites.

In addition, 5 KIIs will be conducted with health care service providers and policy makers in each region, amounting to a total of 15 KIIs. Thus, the total sample size of the qualitative component of the study is expected to be approximately 300 (FGD: 30×8=240, IDI=45, and KII=15).

Implementing Partners

The implementing partners for the study are YR Gaitonde Centre for AIDS Research and Education (YRGCARE), Centre for Sexuality and Health Research and Policy (C-SHaRP), and The Humsafar Trust (HST), who will be responsible for conducting the FGDs, IDIs, and KIIs. The designing of the Ethnolab game–based data collection method will be done by Final Mile and IAVI. Final Mile, in working with other study partners (YRGCARE, C-SHaRP, and HST), will be responsible for the implementation and conduct of the SBE sessions across all study sites.

Data Collection

Overview

Data from FGDs, IDIs, and KIIs will be collected using semistructured interview topic guides. Trained research staff will conduct the FGDs, IDIs, and KIIs. The research staff will receive additional training specific to the content of this study and research ethics. SBEs will be conducted by partner consultants and will also include a round of initial meetings with the other study clinical research center partners to ensure alignment with the findings from the FGDs and IDIs.

Lines of Enquiry for FGDs and IDIs

For the FGDs and IDIs among end-users, the following broad areas will be covered in the lines of inquiry:

1. Preference elicitation questions: Under this process, the group will be asked about individual product attributes and their preference for different features under that attribute. The process will aim to understand which attributes matter most to the populations and the preferences for different

subgroups under that population to gain an overall community-level perspective. Efforts will also be made to understand the reasons for these preferred options. This section would also cover the individual, interpersonal, and social concerns that might drive end-user decision-making.

2. Relative desirability of predetermined product profiles (attribute bundles): As a next step, participants within each focus group will be presented with 4 product profiles comprising 5 to 6 attributes in different combinations (bundles) through a mixture of visual methods and information, education, and communication tools. These are modeled after various HIV prevention products, including the current bNAb product under investigation. Participants will be requested to choose their "most/least preferred" profiles, rank the remaining 2, and explain the reasons behind their choice. In addition to enabling a deeper understanding of preferences and trade-offs, this would also aid in understanding the most critical attributes informing decision-making on product use among prospective end-users.

The topic guide will be translated into native languages (Hindi, Tamil, Telugu, or Marathi), back-translated into English, and then revised in the original language. All discussions will be audio-recorded, transcribed, and translated. They will be deidentified before proceeding for further data analysis. Each FGD and each IDI will span over 60 to 90 minutes.

Data Collection Process for SBE

The SBE sessions will consist of three parts:

1. *Ethnolab Conundrum game*: The Conundrum game will expose participants to multiple scenarios, each ending with a decision conundrum having different possible outcomes. Each scenario will simulate the real-world context of participants by representing a protagonist of the same age, gender, and socioeconomic level in a relevant health-related situation. The scenarios will be constructed using preliminary insights generated from the FGDs and IDIs, with decision points informed by heuristics and behavior science principles. The research is gamified: participants will be asked to respond quickly in real time and choose the option they think will coincide with most respondents in the group and will win points if it does. The game will thus generate responses representative of mental models, emotions, and biases rather than deliberate and rational analysis [48]. Preference reversal will be tested through tweaks in the context simulation and the framing of attributes.
2. *Ideal product profile exercise*: The participants will go through a series of prompts to design the ideal prevention product suited to their needs. This activity will be an adapted version of the product profile ranking exercise used in the first round of qualitative research. It will be designed to give participants an expanded choice set to clearly articulate their trade-offs and allow for tracing certain preference reversal patterns. This will enable an overall high engagement and easy and detailed discussion on product attributes.
3. *Group conversations*: Once the games are over, participants will be split into multiple groups of dyads and triads for group conversations (where scenarios and reactions are still fresh in their minds) regarding the experience, decisions, and preferences in the game [50]. The conversations on the scenarios provide opportunities for improved contextualization of the responses, understanding emotions and other causative factors behind preferences, and tracing decision pathways.

The data generated from the games, along with the ensuing conversations, will help elicit behavioral insights and identify intrinsic drivers and extrinsic factors influencing the preferences and decisions of prospective end-users. The Ethnolab play will last for approximately 60 minutes, and the subsequent group discussions will last for 45 minutes. The overall activity will not exceed 2 hours. The session will involve engaging games to maintain a playful environment, and adequate breaks will also be incorporated to ensure that the time of engagement does not become burdensome for the participants.

Lines of Enquiry for KIIs

Semistructured interview guides will consist of 10 to 12 open-ended questions and scripted probes. The interview guides will be translated into native languages (Hindi, Tamil, or Marathi), back-translated into English, and then revised in the original language. Key informants for each study population will be asked questions for the need perception of a prevention product, preference and importance of product attributes, social and cultural acceptability, risk compensation, health systems readiness, and alignment with the policy environment in India. Each KII will be conducted for approximately 90 minutes.

Data Analysis and Validation

Analysis

The qualitative approach will use triangulation to strengthen and ensure the accuracy of data [65]. According to Denzin and Lincoln [66], triangulation is a process in which several methods are used in the study and might be used in four basic ways: (1) data triangulation, (2) methods triangulation, (3) theory triangulation, and (4) researcher triangulation. In this study, data triangulation, methods triangulation, and researcher triangulation will be used. All transcripts will be redacted (to remove any personally identifying information that might inadvertently have been recorded) and uploaded into NVivo (Lumivero) or Dedoose (University of California). First, a line-by-line review of the transcripts will be performed, and first-level codes will be identified to create a common a priori codebook (based on the adapted conceptual or theoretical framework and topic guides). All codes will be then entered and tagged to associated chunks of text. Texts corresponding to each of the first-level codes will be coded by at least 2 independent analysts and reviewed by senior investigators. Explanatory or theoretical or etic (researcher generated) codes will be arrived at using a constant comparative method [67].

The SBE results will be analyzed using the cognitive and emotional appraisal framework [68] as a base. Appraisal theories are componential theories that view an emotional episode as involving changes in a number of organismic subsystems and

components. The components could include an appraisal, a motivational, a somatic, and a motor component. The framework will be used to generate the codebook and will then feed into the 4 major categories of context, emotions, mental models, and decision levers. This will be done along with the ranking of preferences drawn from the experiential game data. The SBEs will be analyzed to gain an in-depth understanding of (1) preference construction and (2) preference reversal.

Validation

Data source triangulation and researcher triangulation will enhance the reliability and trustworthiness of the findings [69]. Thus, study implementation and data analysis will also incorporate researcher reflexivity and researcher triangulation by maintaining "quicknotes" (a brief summary of every interview or focus group by the interviewers or moderators that will be shared with the analysts and investigators for feedback), writing memos, and engaging in peer debriefing to maintain ongoing awareness of our social location and how it may influence the research process and interpretation. A maximum of 2 interviewers or moderators will be used for every population of interest to ensure that there is minimum bias in the way questions are asked or follow-up probes are used.

Data Security for Storage and Transmission

Names or other personal identifiers will not be collected from the participants. Only the investigators and key research staff at the participating research sites will have access to the transcripts or translated text and digital recordings. As soon as an interview is completed, the audio file will be transferred from the digital recorder to password-protected computers. Subsequently, the file will be deleted from the digital recorder. The transcriptionist and translator will sign a confidentiality pledge stating that they will not reveal any information from the interviews to anyone else. The digital copies of transcripts and translated text will also be stored on password-protected computers.

Only this study's research staff at the participating research site will have access to the audio files, transcripts, and translated text. All digital recordings will be redacted, and any personal identifying information will be removed. Digital recordings will be deleted after 1 year (the 1-year delay is to ensure that there are no gaps in the transcripts). Redacted transcripts will be maintained for 2 years and then destroyed. Informed consent forms will be separately stored and will include signs, initials, or "X" marks rather than names. Unique identification codes will be assigned to all individual records, including digital recordings and transcripts. Hard copies of the data and related documents will be stored in a secure location in locked cabinets in the offices of study and will be accessed only by the research staff.

Ethical Considerations

Institutional Review Board Review and Approvals

The study was presented to the institutional review boards (IRBs) of all 3 implementing partners (HST, C-SHaRP, and YRGCARE), and all comments received were adequately addressed in the protocol. The approved protocol (HST-IRB-50-01/2021; C-SHaRP/0007327/220; YRGCARE-359) will be implemented for data collection and analysis.

Informed Consent Process

Participants for IDIs, KIIs, FGDs, and SBEs will be presented with an information sheet that outlines the scope of the study and a consent form that provides options to sign or put initials or put an "X" mark. This approach has been accepted by the IRB for other previous studies. Given the potentially low literacy levels of some participants, the research assistants will offer to read and explain the information sheet and consent form to the participants. As part of the informed consent process, all potential participants will be informed that their decision to participate or not in interviews or games will not affect the services they currently receive or may receive in the future from their respective community agencies.

Compensation

Participants in the FGDs, IDIs, and SBEs will receive an honorarium of INR 500 (US $6.25) for participating in the study. This amount is based on input from the community advisory boards of the study partners in India. This covers the costs incurred for roundtrip transportation. If the focus group or IDI participants elect to withdraw from the study during data collection, they will still receive compensation. Key informants will receive INR 1500 (US $18.75) (wherever applicable), and this is proposed from previous learning wherein key informants reported loss of wages owing to their participation and suggested that an honorarium should be instituted for KIIs to minimize such experiences. All interviews will be conducted in person, and honorariums will be in cash.

Privacy and Confidentiality Protection of Participants and Do-No-Harm Measures

Overview

Being a qualitative study, with no biological samples collection, there is no medical risk to a research participant of this study. The study also does not pose any financial risk to the participants. However, participants' confidentiality could be compromised through engagement in the study, and participants might feel uncomfortable answering questions about sexual behaviors. Recognizing these possibilities, some mitigation measures that will be adopted are as follows:

1. Unique identity number and no names: No participant names will be collected. Participants will be asked to mark only their initials or put an "X" mark on the consent form. Participants will be identified only by a unique numerical identifier. Individuals will be instructed not to use their surnames but to use a nickname or pseudonym. In addition, all transcripts will be anonymized so that any identifying information that is inadvertently mentioned will be removed from the written transcript.
2. Training for research interviewers or FGD moderators: Interviewers or moderators will be well trained in research ethics and interviewing techniques. They will be trained to be sensitive to the needs of the participants to stop, rest, skip particular questions, or discontinue their involvement

in the study at any time. Interviewers will be clearly instructed that participants are allowed not to answer any question and continue with the interview or to stop the interview at any time. In addition, research interviewers and field research staff will be trained in research ethics and confidentiality and will all be required to sign confidentiality agreements.

3. Explicit information on potential social risks to participants of focus groups: For focus groups, social risks include unwanted disclosure of one's sexual orientation or sexual behaviors and facing possible stigma or discrimination if a member of the larger community discovered the participant's orientation or drug use or sex work status. Furthermore, confidentiality will be maintained by holding interviews and focus groups at discreet locations that many of the participants already frequently visit (eg, local CBO or NGO office). In addition, facilitators and interviewers will be trained in research ethics and there is already a list of transcribers or translators who possess sufficient experience in transcribing research interviews. They are also well versed in the significance of upholding confidentiality and anonymity.
4. Transcription and translation of FGD, IDI, KII, and behavioral experiments: Professional transcribers will be hired for the transcription or translation of audio-recorded interviews (FGDs, IDIs, KIIs, and behavioral experiment discussions). There already exists a list of transcribers or translators with adequate experience in transcribing research interviews and who know about the importance of maintaining confidentiality and anonymity. They (new or experienced) will be oriented about the importance of maintaining the confidentiality of the audio files and transcripts and will be asked to keep all the research information confidential by not discussing or sharing the content of the interviews in any form or format with anyone other than the designated research contact persons. The transcriber or translator will be asked to sign a confidentiality pledge before transcription or translation.

Do-No-Harm Measures

In addition to the mentioned measures, all study staff will be trained in guidelines and policies related to human participant research ethics to ensure no unintended harm to the participants. This will be applicable for all participants, keeping in mind their vulnerabilities, but especially noteworthy for engagement with adolescent populations. The study teams will adhere to the National Youth Policy and also be trained in the guidelines stated by the Rashtriya Kishore Swasthya Karyakram [70].

Plan for Reporting Unanticipated Problems or Study Deviations

The study investigators will report unanticipated problems and study deviations to the local IRB. Such events will also be communicated to International AIDS Vaccine Initiative for further review or escalation, if required. Minor problems and protocol deviations, if any, (which pose no risk to participants or others) will be reported in the annual protocol continuing review.

COVID-19–Related Guidelines

All study data collection–related activities will be conducted by adhering to the state or national guidelines in view of COVID-19.

Possible Benefits to Participants

There are no direct benefits to participants for taking part in this study. However, the participants will be better informed about the various HIV prevention options currently available across the globe and the options under development. The study has the potential to benefit the society and the participant's communities if the data collected are found effective and are adopted in routine service delivery or for further informing bNAb research.

Results

The study is being implemented across 3 sites in India among 5 different populations and key informants. The data collection will be followed by data analysis workshops to enable standardization of analysis across all sites and partners. Extensive analysis based on the analytical frameworks will lead to the expected outcomes of the study.

Discussion

Principal Findings

The study will provide critical insights into factors driving the end-user decision-making with regard to prevention product choices and assess the acceptability of bNAbs in the Indian context. It will also help understand the health system and programmatic factors that would influence product introduction and uptake among target populations in India. The specific anticipated outcomes from the study can be highlighted as follows:

1. *Product preferences*: Insights from the FGDs, IDIs, and SBEs will aid in identifying specific product attributes that matter the most to the end-users and why some attributes have less preference. Within each attribute, it will be possible to identify the options that the respondents feel are more significant to their individual context. Insights will also be generated on end-user preferences that are stable across all contexts and preferences that are dynamic and may vary with changing circumstances. Finally, it will also be possible to outline the acceptability and unique value proposition of bNAb products in the Indian context.
2. *Behavioral factors*: Another outcome of the study will be identification of the most relevant target populations in India for HIV bNAb products and user segmentation of the target population based on key behavioral determinants, including an interplay between user profiles and preferences. The study will also help understand the contextual drivers of preferences and choices at individual, interpersonal, social, and structural levels and aid in delineating the key decision levers and pathways that lead to a preference or reversal of the same. These decision levers could be understood in the form of norms, values, goals, mental models, and emotions and would be critical

to decipher to understand acceptability of a product. In addition, often, the stated preferences are different from the observed choices when they are simulated through real-life situations. Thus, the gamified components will also provide a chance to highlight the say-do gap to inform product development.

3. *Health systems and programmatic readiness*: Insights from the health service providers and policy makers will provide a critical understanding of the needs perception of the potential product in the existing product landscape, understanding of the cultural and social acceptability, and risk compensation. Their views will also provide critical insights into the additional efforts and resources required for potential introduction, delivery, and implementation of bNAb products in the Indian context. This will include program integration perspectives and other structural factors such as workforce availability and supply chain integration. The study will also enable an understanding of the existing policy landscape and alignment of the potential product with the same toward informing the feasibility of introduction.

Insights generated from all the abovementioned outcome domains will represent perspectives of populations of interest across geographies in India and will be collated into management presentations to provide an overview of the acceptability and feasibility of bNAb products in this region toward informing product development strategies.

Limitations of the Study

We anticipate some limitations. First, being a qualitative study, an inherent limitation of the study is that the findings may not be generalizable (in a statistical sense) as purposive sampling, a nonprobability sampling widely used in qualitative research, was used. However, we will try to ensure diversity when recruiting potential participants from various study subgroups, that is, by using maximum variation or diversity sampling, a type of purposive sampling. Such a strategy, along with a detailed description of the settings and participant characteristics, will increase the chances of the transferability of the findings to similar contexts and populations. Second, the study is being implemented by 3 study partners in different settings. Although all interviewers used standardized data collection tools and underwent common trainings, personal differences in interviewing styles may result in varied elicitation of responses from end-users. We will try to reduce this bias by having periodic debriefing sessions with the research team, especially data collectors, which will help the team to reflect on how one's values and beliefs might influence the way we ask questions in the interviews or FGDs or in arriving at inferences when analyzing the data [71].

Conclusions

With the evolution in the HIV prevention research field and the expansion of the prevention toolbox, end-users have a wide spectrum of choices. It is important for product developers to understand the drivers of these choices to clearly articulate the unique value proposition of each product to define their positioning in the choice spectrum. It is also critical to generate timely evidence on target populations, facilitators and barriers of use, relative importance of products, and communication needs to facilitate, plan, and enable policy decisions for the introduction of newer products. Thus, this study will aid in generating insights that will be critical for product developers and policy makers.

Acknowledgments

This study is made possible by the support of the American people through the United States Agency for International Development (USAID) and the US President's Emergency Plan for AIDS Relief (PEPFAR). The contents of this protocol are the sole responsibility of International AIDS Vaccine Initiative and do not necessarily reflect the views of USAID, PEPFAR, or the US Government. The authors acknowledge all end-users, nongovernmental organizations, and community-based organizations who facilitated the data collection process, enabled adequate outreach, and participated in the study.

Data Availability

The data sets generated during the study will be used to analyze the final findings from the study. The analyzed data sets will be available in the main manuscript that will be published highlighting the findings from this study. For data sharing, national policies applicable to Indian research data [72] will be adhered to.

Conflicts of Interest

Some of the authors (JM, SuH, PA, SM, MK) are affiliated with the International AIDS Vaccine Initiative, which is a not-for-profit organization that is involved in the development of broadly neutralizing antibodies. All other authors declare no other conflicts of interest.

Abstract

Background: Lifestyle medicine (LM) is the use of therapeutic lifestyle changes (including a whole-food, plant-predominant eating pattern; regular physical activity; restorative sleep; stress management; avoidance of risky substances; and positive social connection) to prevent and treat chronic illness. Despite growing evidence, LM is still not widely implemented in health care settings. Potential challenges to LM implementation include lack of clinician training, staffing concerns, and misalignment of LM services with fee-for-service reimbursement, but the full range of factors facilitating or obstructing its implementation and long-term success are not yet understood. To learn important lessons for success and failure, it is crucial to understand the experiences of different LM programs.

Objective: This study aims to describe in depth the protocol used to identify barriers and facilitators impacting the implementation of LM in health systems.

Methods: The study team comprises team members at the American College of Lifestyle Medicine (ACLM), including staff and researchers with expertise in public health, LM, and qualitative research. We recruited health systems that were members of the ACLM Health Systems Council. From among 15 self-nominating health systems, we selected 7 to represent a diversity of geographic location, type, size, expertise, funding, patients, and LM services. Partway through the study, we recruited 1 additional contrasting health system to serve as a negative case. For each case, we conducted in-depth interviews, document reviews, site visits (limited due to the COVID-19 pandemic), and study team debriefs. Interviews lasted 45-90 minutes and followed a semistructured interview guide, loosely based on the Consolidated Framework for Implementation Research (CFIR) model. We are constructing detailed case narrative reports for each health system that are subsequently used in cross-case analyses to develop a contextually rich and detailed understanding of various predetermined and emergent topics. Cross-case analyses will draw on a variety of methodologies, including in-depth case familiarization, inductive or deductive coding, and thematic analysis, to identify cross-cutting themes.

Results: The study team has completed data collection for all 8 participating health systems, including 68 interviews and 1 site visit. We are currently drafting descriptive case narratives, which will be disseminated to participating health systems for member checking and shared broadly as applied vignettes. We are also conducting cross-case analyses to identify critical facilitators and barriers, explore clinician training strategies to facilitate LM implementation, and develop an explanatory model connecting practitioner adoption of LM and experiences of burnout.

Conclusions: This protocol paper offers real-world insights into research methods and practices to identify barriers and facilitators to the implementation of LM in health systems. Findings can advise LM implementation across various health system contexts. Methodological limitations and lessons learned can guide the execution of other studies with similar methodologies.

Introduction

Cardiovascular disease, diabetes, and other chronic illnesses (including mood disorders) continue to be the leading causes of morbidity and mortality in the United States [1,2]. An estimated US $4.1 trillion is spent annually on health care for individuals with chronic physical and mental health conditions [2]. Poor health behaviors, such as a less healthy diet, physical inactivity, and substance use, exacerbate these conditions and cost the United States an estimated US $1.3 trillion per year [3]. An estimated 75%-90% of chronic illnesses could be prevented by lifestyle modification [4].

Lifestyle medicine (LM) is a "medical specialty that uses therapeutic lifestyle interventions as a primary modality" to prevent, treat, and reverse chronic conditions [5]. This "evidence-based, whole-person, prescriptive lifestyle change" is built around 6 pillars: a whole-food, plant-predominant eating pattern; regular physical activity; restorative sleep; stress management; avoidance of risky substances; and positive social connection [5]. These innovative and comprehensive approaches, especially those related to diet, have been shown to promote healthy weight, decrease the risk of type 2 diabetes, reduce cardiovascular risk factors, and improve quality of life [6-15]. Experts estimate US $116 billion could be saved annually through modest changes in health behavior and care delivery that result in improved treatment rates, increased physical activity, reduced smoking, and reduced obesity [16].

Interest in LM is growing, as evidenced by the rising membership of the American College of Lifestyle Medicine (ACLM), which increased by approximately 300% between 2018 and 2021 [17]. In 2017, the American Medical Association House of Delegates emphasized the importance of LM treatment by passing a resolution supporting providers to prescribe healthy lifestyle behaviors [18]. Despite these advances, adoption in clinical practice is slow [12,13,19-21], and additional research is needed to better understand the barriers and facilitators to implement this approach in health care settings [20].

The Consolidated Framework for Implementation Research (CFIR) is commonly referenced in the implementation science field to characterize factors that can influence the successful implementation of health services [22]. It includes 5 domains: intervention, inner setting, outer setting, individuals involved, and the implementation process. About 13% of the estimated 625 health systems across the United States are members of the ACLM Health Systems Council and are at varying stages of LM implementation [23,24]. Commonly, the inner setting of LM takes place within primary care and the general internal medicine environment, as well as medical specialties such as diabetes and oncology. Implementation processes and strategies can often extend across disciplines, such as the case with the modification of electronic medical records to prompt behavioral screening and referrals. Systematic implementation of LM faces various challenges, including inadequate leadership support and clinician training in the inner setting and patient preferences and reimbursement complexities in the outer setting [19,20,22,25]. A 2019 survey of ACLM members assessed respondents' current practice of LM, including reimbursement, quality measures, and patient outcomes [26]. In reviewing findings (published elsewhere), ACLM leadership and consultants determined that greater critical richness and additional details could be achieved through a qualitative examination of a subset of US health care systems with LM programs.

ACLM's mission calls for additional high-quality research, education, and advocacy to continue building evidence that LM should be more comprehensively implemented by US health care systems [27]. However, the current literature lacks documentation of the most effective implementation strategies to support LM practice. To address this gap, we are conducting a multi–health system case study to understand the factors that led to the development, growth, and maintenance of successful LM programs within health systems. Specific aims of *Lifestyle Medicine Integration in Health Systems: A Case Study Project* include: (1) examining in-depth 8 LM programs and constructing a detailed case narrative report for each system; (2) identifying factors influencing the initiation and growth of LM practices; and (3) describing common facilitators and barriers across health systems to the continued implementation of LM.

This paper outlines the study protocol, including case selection, data analysis, and dissemination of research findings. It will aid in interpreting study findings and advise the research execution of other studies that incorporate similar methodologies across various settings.

Methods

Overview

In response to a gap in the rich understanding of barriers and facilitators to implementing LM in health systems, the research team selected a qualitative research approach investigating multiple health systems as individual case studies. This multiple case study approach incorporates insights from multiple instances of the phenomenon of interest [28,29].

This paper describes the 8 steps used to conduct this research, as outlined in Table 1. At the time of this writing, steps 1-5 have been completed and steps 6-8 are in progress.

Table 1. Protocol steps for the Lifestyle Medicine Integration in Health Systems study.

Step	Activity	Status[a]

6	Iterative preparation of case study narratives	In progress
7	Preparation of cross-case reports	In progress
8	Dissemination of findings	In progress

[a]As of February 1, 2024.

Step 1: Formation of Study Team (Completed)

The study team comprises team members at ACLM staff and researchers with expertise in public health, LM (including behavior change), and qualitative research. As the national medical professional organization representing physicians and other health professionals practicing LM, ACLM is uniquely positioned to form and coordinate this study team. In addition to representing individual practitioners, ACLM also coordinates a network of health systems, the Health Systems Council (HSC). This group comprises integrated health systems around the United States committed to growing their LM service offerings and sharing their experiences and learnings with other council members [24]. In July 2021, the study team initiated regular (weekly or biweekly) meetings to discuss research aims and methods. The study team has continued to meet throughout the duration of the project.

Step 2: Selection of Methods (Completed)

Through discussion at regular meetings and review of qualitative literature, the study team identified the methods that would be used for this project. We selected a qualitative case study approach, embracing constructivist epistemology (the belief that there is no one truth and that findings are created by the interaction between the patients or informants and the observer or data collector) [30]. Case studies are a qualitative methodology that facilitates the exploration of a specific topic through the development of complex narratives, promoting rich insights from multiple sources within single and multiple cases [28,31,32]. Although findings are heavily influenced by contextual factors, the cross-case reports (described later) provide insights that can be transferred to other settings. This need for transferability suggests a multiple case (rather than single-case) design would be appropriate for the identified research questions [32].

We selected case studies to allow for contextual diversity and triangulation, or the gathering of evidence from multiple data sources, to yield convergent findings [28,33]. To facilitate triangulation, the study methodologies included data collection from multiple stakeholders and source types (in-depth interviews, document review, survey responses, and direct observation). Further, document review allows for the gathering of evidence by interviewers ahead of interviews and reduces the burden on informants [32]. We selected in-depth interviews instead of focus groups to allow for triangulation from different perspectives (both individual experiences and professional roles) and reduce social desirability bias and fear of disclosure among informants [34]. Finally, direct observation (in the form of in-person site visits) yields insights that interviewees may have accidentally omitted due to their own familiarity with their particular context.

Step 3: Recruitment and Training of Study Team (Completed)

The study team is coled by the principal investigator (MCK) and a senior investigator with expertise in qualitative research and case study methods (JG). Additional expert advisors representing ACLM (TAH and KLS) and academic institutions (MLA, SMS, ND, and MMR) offer critical insights and guidance to protocol development and implementation. All data collection was completed by researchers who are external to ACLM, apart from 2 students who were previously involved as members of ACLM. ACLM staff advise on study design or implementation, participate in team meetings, and are part of the iterative review process, but do not conduct data collection.

There were 8 data collectors, who primarily comprised graduate-level students trained in the fields of public health and medicine. Data collectors were hired as research assistants and recruited through study team networks. All data collectors completed data collection training designed and delivered by the academic consultant. The training included general principles of qualitative research, qualitative interviewing techniques, and a review of the study protocol.

Step 4: Case Study Nomination and Selection (Completed)

Multiple case studies are recommended to contain 4-10 cases to achieve sufficient variability while providing a manageable amount of transferrable insights [28]. Stake [28] identifies 3 criteria that should be present when selecting cases: (1) the case must be relevant to the quintain (or phenomenon of interest, which is LM implementation); (2) the cases must provide contextual diversity; and (3) the cases must allow researchers to observe and explore complexities and contexts.

We followed a purposive sampling approach that leveraged the preexisting ACLM HSC network, which is uniquely positioned

to access health systems with LM programs. From March 21-April 1, 2022, recruitment emails were disseminated through ACLM HSC email communications. During the recruitment period, 15 health systems were self-nominated by an employee representative from each interested health system. The self-nomination form captured data on the health system's geographic location, patient demographics, payer types, LM practitioners, programs available, and the estimated reach of the LM program.

Table 2 includes selected self-reported data for the participating health systems and describes geographic location by census-based US regions to preserve health system anonymity [35]. Data reported through the nomination form were not corroborated and should be interpreted conservatively. One health system (site code H) did not complete the nomination form and was recruited through a different mechanism, described below.

Table 2. Summary of self-reported characteristics of participating health systems.

Site code	Region	Level of focus[a]	Reach[b]
A	South	Subspecialty	Small
B	West	Specialty	Large
C	Midwest	Subspecialty	Medium
D	West	Specialty	Medium
E	South	Specialty	Medium
F	Midwest	Subspecialty	Small
G	West	Specialty	Large
H	South	—[c]	—

[a]"Specialty" indicates lifestyle medicine is a stand-alone area of treatment programming; "subspecialty" indicates lifestyle medicine is an adjunct approach embedded in other treatment specialties.

[b]Reported estimated number of patients receiving care at the time of nomination, where "large" is >5000, "medium" is 1000-5000, and "small" is <1000.

[c]Not available.

Study team members reviewed all self-nomination forms and came to a consensus through discussion about which cases to include to achieve contextual diversity, including variability in program size, age, geographic location, payer model, and population served. We selected 4 instrumental cases that were generally representative of the "typical" nominees seen but varied in the aforementioned characteristics [28]. We also selected 2 intrinsic cases that offered a unique context due to their stage (either very early or relatively mature in development), size, and extent of LM practice integration [28]. Selected cases were invited to confirm participation through a health system representative authority.

Partway through case recruitment and data collection, the study team determined that a contrasting case was needed to demonstrate the experiences of a health system that had initiated and then aborted an LM program. The study team agreed that this perspective would yield unique insights about implementation barriers to LM. This iterative approach is an accepted multiple case study procedure, through which redesign can emerge partway through case selection [32]. Original recruitment strategies did not satisfy this need, and the study team used an additional recruitment strategy that built upon individual communications rather than wide-reaching HSC communications channels. One case (site code H) was recruited using this approach and varied slightly in the data collection methods described below.

Step 5: Iterative Data Collection (Completed)

Overview

Each participating health system was assigned a single data collector as a site lead, whose responsibilities included coordinating data collection and drafting the case narrative. The site lead managed a team of 1-2 other data collectors, who conducted individual interviews with different members of the health system's LM team. Overall, 4 types of data were collected: in-depth interviews, site visits, existing documents, and study team notes.

In-Depth Interviews

The study team conducted at least 6-8 in-depth interviews with individuals identified in each participating health system. Health system liaisons were asked to identify employees who were integral to the implementation of the LM programming. They were provided a list of potential types of roles sought for interviews and asked to prioritize individuals who served as health system leaders or administrators (including billing professionals) and physicians. Other health care professionals delivering LM were also requested and included nurse practitioners, registered dietitians, behavioral health specialists, health coaches, exercise physiologists, physical therapists, kinesiologists, and mental health professionals. Only in the instance of the contrasting case were former employees also invited to participate in interviews.

Interviews lasted 45-90 minutes and were conducted through video call (typically), telephone (rarely), or in-person (rarely). When using video call, interviewees had the option of

participating with their camera on (typically) or off (rarely). Interviews were open-ended and exploratory and followed a semistructured interview guide designed to achieve the study aims and allow for adaptability based on the interviewee or health system context. The interview guide was iteratively designed by study team members and loosely structured on the CFIR model [22]. Minor updates to the interview guide were made as emergent topics were identified.

In alignment with the CFIR, interviewees were asked about the inner (structural characteristics, culture, and available resources) and outer (patient population, billing, or payer practices) settings of their health system in addition to individual factors (their specific role and the roles of others) [22]. They were also asked to describe their understanding of the intervention (LM), how it differs from other types of medicine within their setting, and how it was adapted for their specific setting. The interview also included questions about barriers, facilitators, and processes related to program launch and growth. Interviewers were trained to probe topics particularly relevant to the interviewee or health system context. If warranted, the interviewer requested a follow-up interview with an interviewee. These follow-up interviews were intended to answer specific questions, provide missing details, or explore a topic not previously discussed. The most recent version of the interview guide at the time of publication is available in Multimedia Appendix 1.

The 2 study team members assigned to each participating health system were responsible for participating in each associated interview, either as a primary interviewer or as an interview reviewer, which involves reviewing the transcript. Interviews were recorded using the video meeting software (Zoom; Zoom Video Communications [36]) or a recording device (or sometimes both for redundancy) and stored in a secure location on the cloud. Recordings were transcribed using the Microsoft One Drive (Microsoft Corporation) transcription and then manually reviewed and edited for accuracy by study team members. Additionally, interviewers documented emerging themes or other contextual factors following each interview.

Document Review

Interviews were supplemented by the review of available health system documentation. The study team collected and reviewed publicly available annual reports, websites, program promotional materials, strategic plans, and relevant community health needs assessments. Interviewees were asked about additional materials they thought were relevant to the interview themes, and such materials (which may include organizational charts, internal planning documents, and patient education materials) were also reviewed. The study team maintained a database of all reviewed documents to aid in identifying additional documents for review. Interviewers referenced documents if and as needed when reflecting on and taking notes about past interviews, preparing for upcoming interviews, and sharing updates during study team discussions. For example, if an interviewee mentions an LM program that is referenced by multiple names, the interviewer can reference the health system website and patient recruitment materials to confirm the official name of the program. Additionally, documents are referenced during the preparation of the case study narratives and cross-case analysis to corroborate findings, fill in missing details, and provide illustrative examples. For example, if a health system reported promoting referrals by sending email communications to physicians, the language from the communication may be included in the case study narrative as an example of that recruitment strategy.

Site Visits

An in-person site visit occurred for 1 site and included unstructured observations of the settings and conversations with health system employees, which mirrored themes included in the in-depth interview guide. Photos from the site visit (including patient waiting areas, exam rooms, dining and exercise facilities, offices, and other available areas) are referenced in the qualitative data analysis. Otherwise, site visits were not conducted. This decision was made due to the restrictions of the COVID-19 pandemic.

Weekly Study Team Discussions and Iterative Review (Currently in Progress)

Following the principle of emergent design [37], the study team meets 2-4 times per month to debrief from interviews and discuss emerging themes. During team meetings, data collectors report on themes from recent interviews, and the study team discusses how findings enhance the understanding of health system LM implementation and identifies areas to probe further in future interviews. This is also when the study team discusses similarities and differences among health systems and determines the need for potential changes to the study protocol, case selection, interview guide, case narrative outline, and cross-case analysis. Additionally, study team members report on current events and publications that are relevant to research aims. Meeting recordings and minutes are available for study team members to reference during data analysis.

Step 6: Preparation of Case Study Narratives (Currently in Progress)

In collective case study analysis, it is prudent to conduct individual analysis initially (described below) and follow with cross-case analysis (described in step 7) [38]. Through an iterative and collaborative process, the study team developed a case report format that is followed for the preparation of each case narrative to facilitate intercase comparison. This requires that case narratives open with a presentation of objective data, including name, location, size, payer model, etc. The following sections align with the overall study aims and include potential barriers and facilitators to initiation and sustainment. After completing 2 of the case study narratives, the study team decided to add 2 additional sections focused on clinician training and provider burnout to capture emergent themes. All case reports will follow the same report template (the original 2 case study narratives were revised to align with the updated structure) but vary in length and subtopics covered specific to each health system. The case narrative template is included in Multimedia Appendix 2.

The site's lead data collector is primarily responsible for writing the case study narrative. Other study team members review and comment on case narrative drafts until a consensus is reached. As appropriate and necessary, study team members may conduct

additional follow-up interviews or share versions of the case narratives with interviewees (with individual identifiers removed) to facilitate member checking. Additionally, 1 team member is responsible for reviewing all reports for consistency in form, content, and style.

Step 7: Cross-Case Analysis (Currently in Progress)

Following the completion of case study narratives, the study team completes cross-case analyses focused on topics of interest. Specific analysis topics are not yet final but will likely include billing, care delivery models, clinician training, leadership support, buy-in, intervention content, workplace culture, and burnout. Each cross-case analysis will yield a manuscript to be submitted for peer-reviewed publication. Because the cross-case analyses are not yet complete, the following methods offer a high-level overview of the procedures planned for each analysis report.

Some cross-case analyses will follow the multiple case study methodology reported by Stake [28], which includes the following steps: (1) plan the cross-case analysis and identify themes relevant to research questions; (2) become familiar with individual cases; (3) assess case utility for each cross-case theme; and (4) sort and merge findings relevant to themes. In the Stake [28] approach, a series of interactive worksheets are completed to identify emergent themes, guide analysts through their review of case narratives, and plan and execute a cross-case report. This case study analysis methodology was selected as it preserves contextual information to a large degree. Other cross-case analyses may leverage a coding approach, which uses search queries to identify relevant segments of transcripts or documents and then applies an inductive coding schema to the resulting data.

Step 8: Dissemination of Findings (Currently in Progress)

The study team plans to disseminate a series of manuscripts. This paper offers an overview of the methods conducted and planned for data collection, analysis, and reporting. We also plan to disseminate shortened, deidentified versions of the case study narratives to serve as vignettes for consideration by other practitioners. Additional papers will provide insights for each of the cross-case analyses by comparing and contrasting specific findings for each case study site and highlighting common practices seen in instrumental cases and unusual situations seen in intrinsic cases [28]. These can advise on the implementation and integration of LM programs into health systems that can be applied in other settings to initiate or scale current LM offerings.

Additionally, we plan to share deidentified case narratives with the respective participating health systems. This serves the dual purpose of (1) facilitating member checking and (2) offering the benefit of an external perspective to participating health systems.

Ethical Considerations

The University of New England's institutional review board (IRB) reviewed the study protocol and determined it was exempt from IRB review and oversight (project number 1221-21). Before the interview, all participating individuals completed a written informed consent, which included an overview of the study purpose, a request for participation, a description of privacy protection efforts, and a review of potential risks and benefits. Participants were not compensated for their time.

Results

At the time of this writing (February 1, 2024), the study team has completed all the interviews at 8 health systems. The team interviewed 63 individuals, 5 of whom participated in a follow-up interview, resulting in 68 total interviews. Every site included an interview with at least 1 administrator and physician. Across all sites, interviews were conducted with 25 health system leaders or administrators; 16 physicians; 7 registered dietitians; 6 behavioral health specialists or health coaches; 4 nurse practitioners; 2 exercise physiologists, physical therapists, or kinesiologists; 2 mental health professionals; and 1 individual with an unclassified role.

The study team has completed initial drafts of all 8 case study narratives and is abridging and deidentifying them for member checking and broader dissemination. Cross-case analysis is underway to identify critical facilitators and barriers, explore clinician training strategies to facilitate LM implementation and develop an explanatory model connecting practitioner adoption of LM and experiences of burnout. Additional analyses may investigate how billing strategies, care delivery models, leadership support or buy-in, and intervention content can impact LM implementation in health systems.

Discussion

Overview

This research is the first multiple case study examining facilitators and barriers to LM implementation in health system settings. It will address a gap in the literature by providing insight into the barriers and facilitators to adopting LM practice in health systems. Below is a discussion of limitations, strengths, and opportunities for further research.

Limitations

ACLM serves as the primary funder for this work, potentially introducing a pro-LM bias. To reduce the influence of this bias, the study team was intentionally designed to be diverse and include experts who are external to ACLM and thus not biased in the same way that ACLM affiliates are. Additionally, all methodological and analysis decisions are made during study team meetings, which include multiple perspectives, including 1 senior advisor, in addition to ACLM.

In some cases, the study team was challenged to identify interviewees who comprehensively represented the breadth of LM activities in a single health system. This is partly due to the size and complexity of participating health systems. Individual interviewees were identified by 1 or 2 liaisons at each health system and sometimes did not include groups or types of individuals who would have offered valuable insights. For example, 1 site provided names of individuals who were involved in implementing one specific LM program but were

not familiar with the LM residency program that was offered by a different unit of the health system. This resulted in in-depth data about the specific LM program but fewer insights into the LM residency offerings. Additionally, some health systems were unable to allow nonexempt employees to participate in in-depth interviews because the study was not compensating interviewees for their participation. This resulted in an overrepresentation of leadership and an underrepresentation of front-line workers and intervention delivery personnel. To address these challenges, the study team circled back to health system liaisons to request interviews with additional individuals whose perspectives were not initially included, although the requests were not always met. Data collection methods did not directly include patients or community members, resulting in a gap in these perspectives. Interviewees were asked to speak about the experiences of these individuals, but future research should also investigate these perspectives, specifically.

Finally, site visits and in-person interviews were limited due to restrictions associated with the COVID-19 pandemic. We were only able to conduct 1 site visit, which was conducted in person. To adapt, we revised our methods to prioritize internet-based interviews. Through this process, we learned that internet-based interviews facilitated easier scheduling and access to individuals and often yielded high-quality interviews that were thought to be comparable to in-person interviews. Considering the added logistical benefits, the study team determined the internet-based interview approach to be preferable to in-person site visits. No interviews were conducted in person.

Strengths

This multiple case study methodology and our iterative team-based approach are strengths of this research. By preserving the context of each case, researchers can gain a rich understanding of the many factors impacting the phenomenon of interest [28,31]. Although the selection of ACLM HSC members allows for insights into the experiences of early adopters, the findings may not be translatable to relatively more nascent programs. Throughout the early stages of case selection, our team reviewed health system components to ensure variability in program maturation. We intentionally selected health systems with more recently established LM programs and also sought out and recruited a contrasting case that had initiated and then greatly reduced LM programming. However, the study would have been further strengthened by the inclusion of additional negative cases. The heterogeneity of participating health systems will contribute to the transportability of the study findings. Future research should investigate if and how barriers and facilitators are different among health systems that are not currently aligned with LM.

A strength of this study is that the cases and analyses take place at the health system level, allowing a more comprehensive perspective that incorporates all CFIR domains [22]. Health systems are complex systems of hospitals, clinics, and individuals connected through joint ownership or management [38]. Within these systems are varying cultures (“individuals involved” domain), policies, and processes (“inner setting” domain), which can impact practices (“process domain”). Examination at the health system organization level offers insights into the macrolevel factors (“inner” and “outer setting” domains) that impact LM implementation. Gaining permission to work with such large and complex organizations can be challenging, however, and in some instances, investigation was delayed and even prohibited due to the inability or unwillingness of health system leadership to provide permission for participation. Some health system leaders expressed confidentiality concerns, noting that patient perspectives of the organization and their practices were a critical consideration.

Conclusions

This protocol paper offers real-world examples of research methodologies used to gather data on a series of health systems. Additionally, the study findings will yield practical insights into strategies to effectively implement LM in health systems. Health system leaders and administrators can draw on these findings to establish and grow their own LM programs and integrate LM practices into existing services. Expanded access to LM treatment may result in improved morbidity and mortality outcomes related to chronic diseases [1,6,12].

Acknowledgments

The authors would like to thank the participating health systems and staff for their support of this project, as well as American College of Lifestyle Medicine employees, including Kaitlyn Pauly, who advised on this work.

Data Availability

The data presented in this study cannot be shared due to privacy concerns and the inability to adequately secure the identity of the participants.

Authors' Contributions

MCK and JG are co–principal investigators. MLA, JG, MCK, and SMS contributed to the methodology. MLA was involved in writing and preparing the original draft of the manuscript. MLA, ND, JG, TAH, MCK, MMR, KLS, SMS, and BW contributed to the writing, reviewing, and editing of the manuscript. MCK and SMS were responsible for project administration. MCK was responsible for funding acquisition. All authors have read and agreed to the published version of the manuscript.

Conflicts of Interest

MCK, TAH, and KLS are employed by the American College of Lifestyle Medicine. The other coauthors receive consulting payments from the American College of Lifestyle Medicine.

Abstract

Background: Diabetic eye screening (DES) represents a significant opportunity for the application of machine learning (ML) technologies, which may improve clinical and service outcomes. However, successful integration of ML into DES requires careful product development, evaluation, and implementation. Target product profiles (TPPs) summarize the requirements necessary for successful implementation so these can guide product development and evaluation.

Objective: This study aims to produce a TPP for an ML-automated retinal imaging analysis software (ML-ARIAS) system for use in DES in England.

Methods: This work will consist of 3 phases. Phase 1 will establish the characteristics to be addressed in the TPP. A list of candidate characteristics will be generated from the following sources: an overview of systematic reviews of diagnostic test TPPs; a systematic review of digital health TPPs; and the National Institute for Health and Care Excellence's Evidence Standards Framework for Digital Health Technologies. The list of characteristics will be refined and validated by a study advisory group (SAG) made up of representatives from key stakeholders in DES. This includes people with diabetes; health care professionals; health care managers and leaders; and regulators and policy makers. In phase 2, specifications for these characteristics will be drafted following a series of semistructured interviews with participants from these stakeholder groups. Data collected from these interviews will be analyzed using the shortlist of characteristics as a framework, after which specifications will be drafted to create a draft TPP. Following approval by the SAG, in phase 3, the draft will enter an internet-based Delphi consensus study with participants sought from the groups previously identified, as well as ML-ARIAS developers, to ensure feasibility. Participants will be invited to score characteristic and specification pairs on a scale from "definitely exclude" to "definitely include," and suggest edits. The document will be iterated between rounds based on participants' feedback. Feedback on the draft document will be sought from a group of ML-ARIAS developers before its final contents are agreed upon in an in-person consensus meeting. At this meeting, representatives from the stakeholder groups previously identified (minus ML-ARIAS developers, to avoid bias) will be presented with the Delphi results and feedback of the user group and asked to agree on the final contents by vote.

Results: Phase 1 was completed in November 2023. Phase 2 is underway and expected to finish in March 2024. Phase 3 is expected to be complete in July 2024.

Conclusions: The multistakeholder development of a TPP for an ML-ARIAS for use in DES in England will help developers produce tools that serve the needs of patients, health care providers, and their staff. The TPP development process will also provide methods and a template to produce similar documents in other disease areas.

Introduction

Diabetic Eye Screening and Its Delivery in the United Kingdom

Diabetic eye screening (DES) aims to prevent vision loss from diabetic retinopathy (DR), a sight-threatening microvascular complication of diabetes [1]. In the United Kingdom, people with diabetes aged 12 years or older undergo yearly fundus photography with images interpreted by human graders to detect and assess the severity of DR. This allows detection of DR in its early asymptomatic stages, facilitating early referral to hospital eye services where treatment is more effective [2,3]. DES is associated with improved clinical [4] and economic [5] outcomes and a reduction in blindness from DR since its introduction in 2003 [6]. However, DES is both labor and resource intensive [7], and costs are expected to increase with a projected rise in diabetes prevalence [8]. In the United Kingdom, grading is undertaken by experienced professionals in a quality-assured and controlled multilevel system [9] with a high sensitivity for sight-threatening diseases [10]. However, grading represents a significant cost despite the fact that the majority of people with diabetes have no evidence of DR or only mild disease [11] and are at low risk of visual loss in the near term [12].

Automated Retinal Imaging Analysis Software

DES grading is considered a promising use case for automation, and indeed, DES in Scotland has used automated retinal imaging analysis software (ARIAS) since 2012 [13,14]. This software uses "symbolic" artificial intelligence (AI) with grading "rules" programmed by humans [15] and is used in a primary grader role. The Scottish "autograder" has demonstrated a sensitivity of 90.5% (95% CI 89.3%-91.6%) and specificity of 67.4% (95% CI 66%-68.8%) for referable disease or ungradable images [13], with 50% of images it graded in 2018 requiring no further human review [16]. It is, however, unable to process the optic disc–centered images acquired in screening protocols elsewhere in the United Kingdom and has not been adopted outside Scotland [17].

Subsequent advances in AI, most notably in machine learning (ML), where AI "learns" patterns from data it is presented as opposed to being programmed by humans, have given rise to a newer generation of machine learning–automated retinal imaging analysis software (ML-ARIAS). These have demonstrated better performance than symbolic tools on

routinely collected UK screening images, including disc-centered photos. Heydon et al [18] found ML-ARIAS was able to achieve sensitivity and specificity of 95.7% (95% CI 94.8%-96.5%) and 54% (95% CI 53.4%-54.5%), respectively, for referable disease or ungradable images in a large sample taken from routine screening in 3 UK programs. A health technology assessment has also estimated that ML-ARIAS in a triage or primary grader role could be cost-effective and cost-saving compared to purely manual grading [17]. Consequently, there have been calls for ML-ARIAS's adoption into DES in the United Kingdom [19].

Bridging the Implementation Gap

In response to these calls, the UK National Screening Committee (NSC), an independent scientific advisory group that advises UK governments on screening programs, commissioned a review to ascertain whether ARIAS should be more widely adopted in 2021 [19]. While the review found evidence suggesting ML-ARIAS to be safe, accurate, and cost-effective, it also highlighted evidence gaps that prevented a recommendation for their use. The review highlighted that the acceptability of ML-ARIAS with patients and health care professionals was unknown, as was their real-world performance post implementation, recognizing that this may be affected by a range of clinical and technical factors. While research to address these evidence gaps is currently ongoing [20], the review's conclusions reflect an awareness in the wider field of health care AI that evidence of good diagnostic accuracy cannot predict the impact tools will have post deployment. This awareness contributes toward a growing "implementation gap" [21,22] or "chasm" [23] in health care AI, with increasing numbers of tools failing to be adopted into clinical use following promising research. This situation has a number of negative consequences, such as significant opportunity cost, with tools' development requiring significant public [24] or private investment [25], as well as a failure for patients, health care professionals, or systems to realize the benefits tools may offer for a lack of appropriate evidence generation.

A similar situation has existed in the pharmaceutical and medical device industries for decades. Despite significant investment in research and development, few biomarkers, drugs, or devices are ever adopted into routine clinical care, often failing to achieve regulatory approval or demonstrate sufficient clinical or economic benefits to health care providers [26,27]. To combat this situation, pharmaceutical companies began to outline the characteristics necessary for a successful product in the earliest stages of development, summarizing these in "target product profiles" (TPPs). These documents often incorporate considerations essential to successful clinical use but not covered in traditional research, such as interaction with existing care pathways and resource constraints. TPPs are used to guide research development as part of a broader "quality by design" approach that has been encouraged by regulatory agencies [28,29] and widely adopted in industry with notable successes [30,31]. TPPs have since been used by governments [32], health care providers [33], and nonprofit organizations [34] for drugs [35,36] and medical devices [37], particularly in the context of infectious diseases [38,39] and the developing world [40,41].

Aim

This study aims to produce a TPP for an ML-ARIAS for use in English DES (E-DES), enabling the development of ML tools that match the needs of people with diabetes, health care professionals, regulators, and providers. This work will focus on the English context, as variations in the commissioning and organization of DES between UK nations may affect the stakeholders needed as well as the TPP's final contents. However, we hope this work will be valuable for screening programs in other nations in the United Kingdom and beyond.

Objectives

The objectives of this study are to (1) identify which characteristics should be addressed in a TPP for an ML-ARIAS (this will be achieved through an overview of systematic reviews of TPPs, a systematic review of digital health TPPs, and by extracting standard's from the National Institute of Health and Care Excellence's (NICE) Evidence Standards Framework for Digital Health Technologies (ESF); (2) draft specifications for an ML-ARIAS TPP through semistructured interviews with members of key stakeholder groups; and (3) validate the contents of a TPP for an ML-ARIAS through a modified Delphi consensus study.

Methods

Ethical Considerations

Ethical approval for this study has been granted by the University of Birmingham Institutional Research Board (ERN_2023-0620). The study will be undertaken in accordance with the Helsinki Declaration of 1975, as revised in 2000. Informed consent will be sought from participants. The interviews and consensus meeting will be recorded and transcribed, with participants given the opportunity to opt out with deletion of their responses up to a week after their interview or meeting date, after which their responses will be anonymized and therefore no longer attributable to them. Recordings of the interview and consensus meeting will be deleted following transcription, with the anonymized transcripts stored on secure institutional research servers for up to 10 years. Delphi participants will be informed that their responses are anonymized and therefore cannot be deleted following submission. Contact details they provide in order to be able to participate in the consensus meeting will be stored on secure servers until the end of the study, after which they will be deleted.

People with diabetes participating in the study advisory group (SAG) and consensus meeting will have their travel costs reimbursed as well as their time reviewing documents or attending meetings at £25 (US $31.57) per hour in line with National Institute for Health and Care Research (NIHR) guidance [42,43].

Identifying Key Stakeholder Groups

The successful use of ML-ARIAS in E-DES will require the approval, collaboration, and consent of a diverse range of stakeholder groups. To ensure our TPP is both comprehensive

and authoritative it is therefore important to incorporate the knowledge and opinions of all these groups in its development.

A recent qualitative systematic review on stakeholder perspectives of clinical AI implementation identified the following key stakeholder groups influencing implementation: patients, carers, and the public; health care professionals; health care managers and leaders; regulators and policy makers; and developers [44]. Mapped to our use case and context, these broad stakeholder groups can be further divided as follows: people with diabetes, carers, and the public; E-DES technicians and graders, as well as ophthalmologists (health care professionals); managers of E-DES services provided by either the NHS or independent providers (health care managers and leaders); the Medicines and Healthcare Products Regulatory Agency (MHRA), NICE, the Care Quality Commission (CQC), and NSC (regulators and policy makers); and ML-ARIAS developers. Our study will aim to encompass the opinions of all these groups as outlined below.

Study Delivery and Oversight

Study Management Group

A study management group (SMG) led by the chief investigator AKD will be responsible for the design and delivery of the study.

Recruitment

SMG members will be recruited from the host institution to facilitate ease of communication and regular meetings.

Sampling

The SMG will include experts in the relevant clinical, scientific, and methodological domains, project management support, and a person with diabetes.

Study Advisory Group

The SMG will be supported by a SAG, which will bring additional breadth of expertise from a range of key stakeholder groups. The SAG will provide critical feedback and advice throughout the project in quarterly project review meetings and at specific junctures outlined in the protocol and ad hoc.

Recruitment

SAG recruitment strategies will be tailored to individual stakeholder groups. People with diabetes will be recruited through diabetes charities. Clinical and methodological experts with previous experience developing TPPs will be identified through their publications in the field. Representatives of relevant regulatory and policy bodies will be recruited through their organizations (NSC, MHRA, NICE, and CQC).

Sampling

The SAG will aim to recruit at least 2 representatives from each of the broad stakeholder groups previously identified, with the exception of ML-ARIAS developers, omitted to avoid bias arising from conflict of interest. Experts in TPP development and health economics will also be invited to the SAG to add a greater breadth of expertise.

User Group

A TPP user group (UG) consisting of ML-ARIAS developers will be assembled to provide feedback on the TPP as outlined below to ensure feasibility is factored into the development process.

Sampling

The UG will consist of only ML-ARIAS developers.

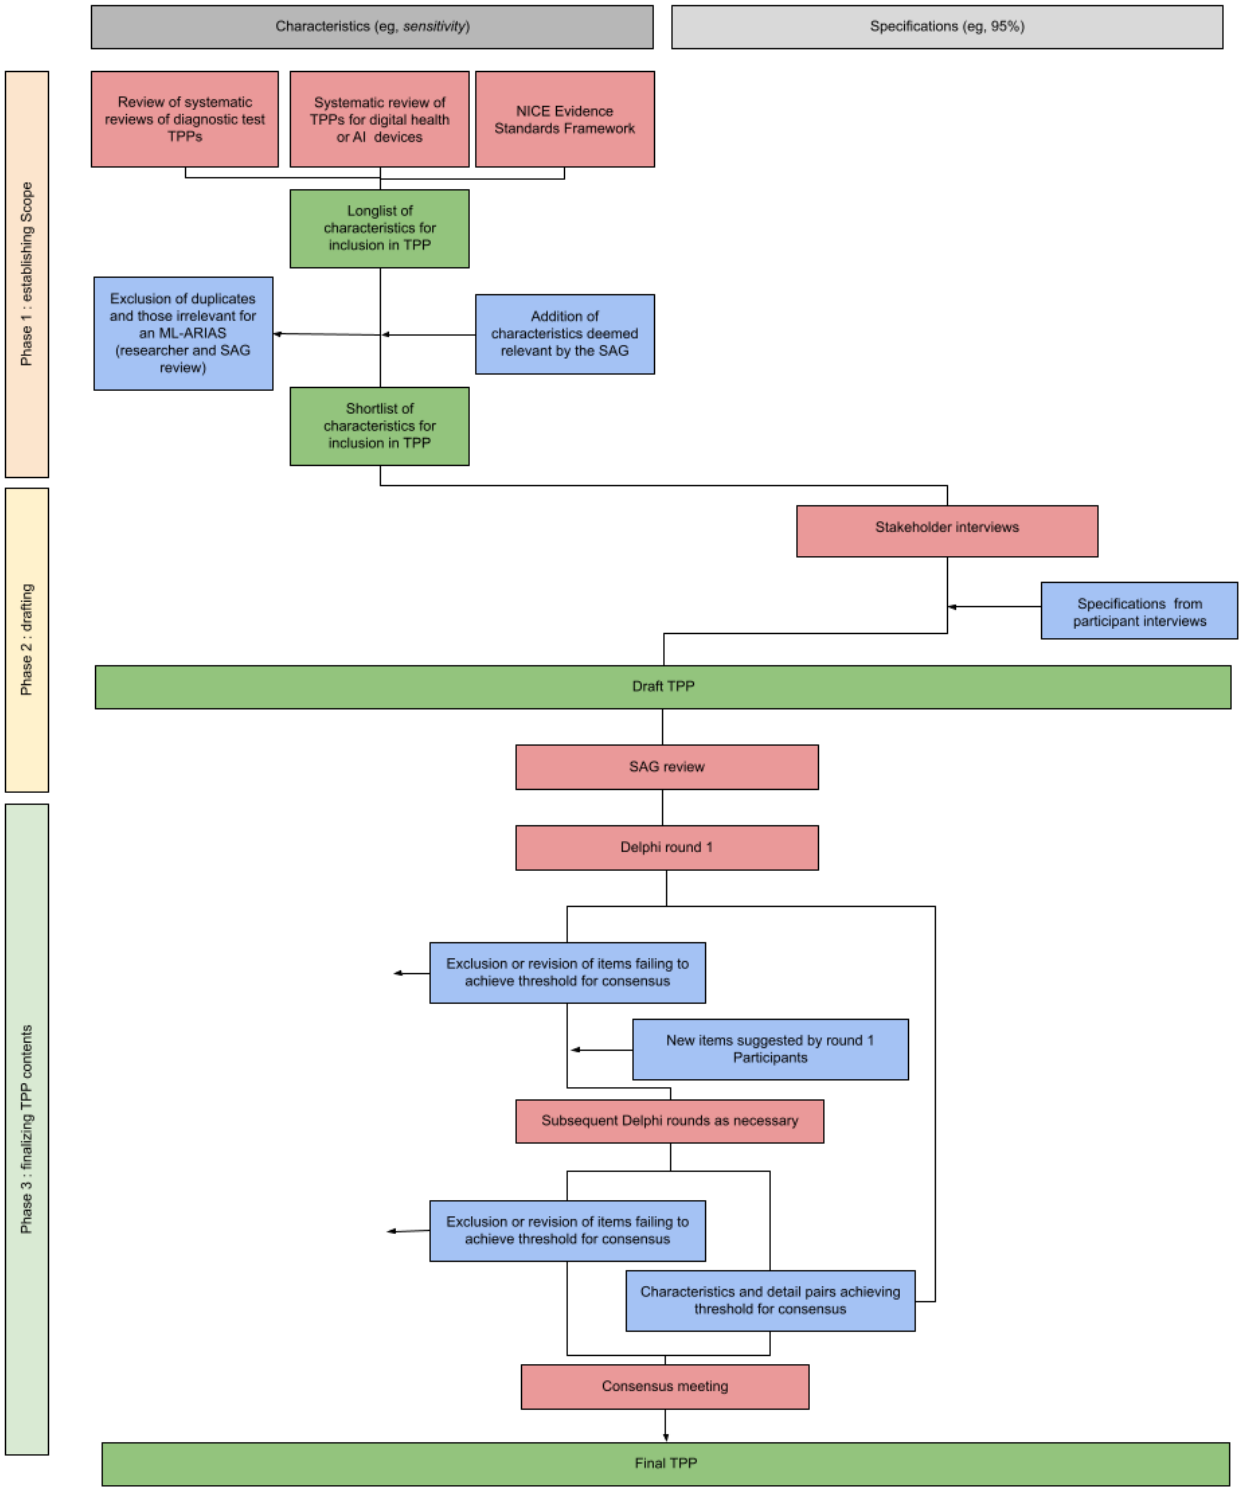
Recruitment

Developers with ML-ARIAS approved by British, European, Australian, or US medical device regulators will be invited to participate, along with those with technologies included in the UK NSC's 2021 review.

Phase 1: Literature Reviews to Establish the Scope of an ML-ARIAS TPP

See Figure 1 for an overview of the ML-ARIAS TPP development process.

Figure 1. Diagram of the machine learning–automated retinal imaging analysis software (ML-ARIAS) target product profile (TPP) development process. AI: artificial intelligence; NICE: National Institute for Health and Care Excellence; SAG: study advisory group.



Rationale

This phase will seek to establish what characteristics a TPP for an ML-ARIAS should address in order to be both relevant and comprehensive. A long list of potential characteristics for inclusion in an ML-ARIAS TPP will be generated through 2 reviews. These will be built on the work of Cocco et al [45], who published a list of all characteristics previously reported in diagnostic test TPPs in a 2020 systematic review.

Overview of Systematic Reviews of Target Product Profiles for Diagnostic Tests

This will seek to identify all systematic reviews of diagnostic test TPPs with the aim of extracting the characteristics reported in each review or the TPPs they capture. Based on a scoping search, we anticipate this review will include the systematic review by Cocco et al [45] and any new resources published since.

Systematic Review of TPPs for Digital Health Tools

As Cocco et al's [45] review did not include any TPPs for digital health tools, our long list of potential characteristics may therefore omit characteristics unique to these tests. The purpose of this review is to identify all TPPs published for digital health tools (including AI) and extract the characteristics they report. This will include TPPs for therapeutic as well as diagnostic devices.

Multimedia Appendix 1 includes MEDLINE search strategies for both reviews, developed in consultation with an information specialist and using validated search filters where possible [45-47]. Strategies for other bibliographic databases will be adapted from these, as will a web search strategy using a systematic method previously reported [48]. The 2 reviewers (TM and JH) will perform a title and abstract screening, then a full-text review to assess eligibility. Disagreements will be arbitrated by the senior investigator (AKD).

Generating AI-Specific Characteristics from NICE's Evidence Standards Framework for Digital Health Technologies

Rationale

As scoping searches for digital health TPPs have returned very few TPPs for AI and specifically ML tools, relying on the above reviews alone to determine the scope of our TPP may risk omitting characteristics unique to these devices and essential for their successful deployment. To generate AI-specific characteristics, we will therefore adapt standards from NICE's ESF for digital health technologies, a gold standard tool designed to evaluate digital health technologies for UK commissioning decisions. This was revised in 2022 to encompass AI devices, with the new AI standards being generated through a multistakeholder Delphi consensus process [49,50]. The 2 reviewers (TM and JH) will review the ESF, extracting relevant standards, with disagreements resolved by discussion or arbitration by the senior investigator (AKD). The extracted standards will be adapted into characteristics and added to the long list from the earlier reviews.

Shortlisting Characteristics for Inclusion in a Draft TPP

The list of candidate characteristics will be reviewed by the SMG to remove any irrelevant to the use case or proposed technology and consolidate the remainder, removing any duplicates. Disagreements between SMG members will be resolved through discussion and arbitration by the senior investigator (AKD) if necessary.

The remaining characteristics will then be mapped to the nonadoption, abandonment, scale-up, spread, and sustainability (NASSS) framework [51], a tool outlining the interacting complexity of factors at the policy, organizational, and practice level that may influence the successful implementation of digital health technology [52]. The NASSS will help group the characteristics into broader themes and help identify factors affecting successful implementation that they do not cover.

The included characteristics will then be presented to the SAG, along with those excluded and the NASSS domains not covered by the shortlist. SAG members will be asked to identify any characteristics incorrectly excluded and approve a final shortlist of characteristics for subsequent research phases through discussion or vote.

Phase 2: Drafting the TPP

Scoping Interviews

A TPP typically includes a table of characteristics and their specifications. Characteristics might include "target population" with "people with diabetes aged 12 years or older" as its associated specification. The drafting of specifications for each of the characteristics shortlisted in phase 1 will be informed by semistructured interviews with participants from each key stakeholder group previously identified. The final output of phase 2 will be a full draft TPP for entry into a modified Delphi consensus study in phase 3.

Sampling

Purposive sampling will initially be used with the aim of interviewing at least 1 individual from all the stakeholder groups relevant to the use case previously identified, with the exception of ML-ARIAS developers. As the interviews progress, theoretical sampling will be used to better explore areas of disagreement or characteristics that have not been addressed in previous interviews. Snowball sampling will also be used, with participants invited to suggest potential interviewees. An approximate target of 20 participants has been set; however, the scale of recruitment will be refined by the SMG as the interviews progress.

Recruitment

People with diabetes will be recruited through diabetes charities and offered compensation for their time in accordance with NIHR guidelines [42,43]. Clinical and methodological experts, as well as industry representatives with previous knowledge or experience of AI in DES or TPPs, will be identified through their publications in the field. Representatives of relevant regulatory and policy bodies will be recruited by contacting their organizations (NSC, MHRA, and NICE). It is anticipated that members of the SAG will facilitate the recruitment of key stakeholders in their respective stakeholder groups.

Data Collection

Ahead of the interviews, participants will be sent information in plain English on E-DES, AI, and TPPs.

The interviews will be conducted over video teleconferencing software (Zoom; Zoom Video Communications, Inc). Interview participants will initially be asked to provide demographic data, including stakeholder groups, location, age, sex, gender, and ethnicity. A preprepared topic guide informed by the shortlist of characteristics produced in phase 1 will be developed and used to encourage a free-flowing conversation between interviewer and interviewee focused on the latter's opinions, priorities, and concerns regarding the adoption of ML-ARIAS in E-DES. The topic guide will be iterated as the interviews progress to ensure all implementation considerations are covered and adapted to different stakeholder groups to facilitate meaningful participation.

All the interviews will be conducted by 2 clinicians (TM and JH) with previous training and experience in qualitative interviewing. They will present themselves as researchers during the interviews so as not to introduce bias to the data collected [53]; however, as their status may become apparent during the interview and can be discovered on the internet, they will use reflective journaling to identify and mitigate against any effects this may have on data collection [54]. Both interviewers will take field notes during and after the interviews to provide context for the data analysis.

Data Analysis

All the interviews will be digitally recorded and transcribed verbatim. Data analysis will begin after the first interview and proceed in parallel with the remainder. One researcher (TM) will code the interview transcripts using qualitative analysis software (NVivo, Lumivero). The coded data will then be mapped to the shortlist of characteristics produced from phase 1, using this as a framework to aid analysis [55].

The data collected will be reviewed throughout the collection period by the SMG to identify and manage biases in sampling, data collection, analysis, and interpretation. The data will be used to iterate the topic guide, recruitment, and sampling strategies to allow the exploration of problematic issues, divergent views between or within stakeholder groups, and implementation considerations not previously explored.

On completion of the data analysis, the SMG will draft characteristics' specifications based on the analyzed data. An initial draft TPP will be presented to the SAG for review and approval before entry into phase 3.

Phase 3: Finalizing the TPP

Internet-Based Delphi Consensus Rounds

The draft TPP will be entered into an internet-based Delphi study using purpose-made software (Qualtrics XM; Qualtrics). The contents and form of the Delphi survey will be coproduced by the SMG and SAG with the close involvement of both groups' patient representatives. It will also be piloted to ensure it is broadly comprehensible and accessible.

At the start of each Delphi round, participants will be presented with information in plain English on E-DES, AI, and TPPs. In subsequent rounds after round 1, participants will also be provided with a report of the previous round (see Data Analysis section below). Each round will remain open for a minimum of 2-4 weeks, and it is expected that at least 2 rounds will be conducted. Extensions to rounds' time frames and further rounds may be considered in consultation with the SAG.

Sampling

In line with similar studies successfully conducted in other contexts [56-58], we aim to recruit more than 100 respondents overall, with at least 10 from each broader stakeholder group previously outlined, including ML-ARIAS developers. Completed returns will be monitored by the stakeholder group, and further measures taken targeted at individual groups to boost recruitment if necessary. These may include targeted email or newsletter reminders.

Recruitment

People with diabetes will be recruited by asking diabetes charities to disseminate a link to the Delphi survey among their members. Similarly, the British Association of Retinal Screeners will be asked to disseminate a link among their members to recruit DES professionals. The SMG and SAG will be asked to disseminate a survey link to their wider networks to recruit regulators, clinicians, and academics. ARIAS developers with technologies previously identified by the UK NSC's Rapid Review will be invited to participate, as will those receiving funding from the NHS AI Health and Care Award.

Data Collection

Participants will be asked which stakeholder groups they belong to, their geographic location, age, sex, gender, and ethnicity. In each round, participants will be asked to score each characteristic and specification on a Likert scale ranging from 1 to 5, with 1 being "definitely exclude" and 5 being "definitely include." Recognizing that some stakeholder groups may not have the expertise to confidently score characteristic and specification pairs in some areas, participants will be given the option to omit pairs or identify other stakeholder groups they would be comfortable making this decision on their behalf. Free-text boxes will be provided to comment on characteristic and specification pairs or suggest edits. Another box at the end of the survey will provide an opportunity for participants to suggest entirely new characteristic and specification pairs.

Data Analysis

After each round, the responses will be aggregated and analyzed. A report will be produced summarizing response rates and characteristic and specification pairs scores descriptively, with scores broken down by subgroup. Free-text responses will be imported into qualitative analysis software and coded.

Consensus will be defined as >70% of respondents scoring a characteristic and specification pair 4-5 and <15% 1 in any stakeholder group. Characteristic and specification pairs exceeding this threshold will exit the survey process and proceed to the consensus meeting for discussion. Those not meeting this threshold will be revised by the SMG, taking into account their scores in previous rounds by different stakeholder groups and their coded free-text responses. The revised characteristic and specification pairs will then enter subsequent rounds, along with any new items suggested by participants in the previous round.

Consensus Meeting

The Delphi results will be reviewed, and the final TPP contents will be agreed upon at an in-person consensus meeting.

Before the consensus meeting, feedback will be sought from members of the UG. This feedback, along with the Delphi round results broken down by stakeholder group, will be sent to consensus meeting participants ahead of the meeting.

The consensus meeting itself will be led by an experienced facilitator. At the meeting, participants will be presented with each characteristic and specification pair in turn, and an opportunity will be provided for discussion and edits. The Delphi round results broken down by stakeholder group as well as the UG's feedback on the characteristic and specification

pairs will be made available to aid discussion. Meeting participants will be asked to vote on the inclusion of each characteristic and specification pair, with a supermajority of >70% among voting participants needed for inclusion in the final TPP. An abstention will be permitted.

Recruitment

Participants in the Delphi study will be asked whether they wish to be considered for participation. Meeting attendees will be agreed upon with the SAG and invited to the meeting by email.

Sampling

Purposive sampling will be used to ensure there are at least 2 members from all the key stakeholder groups previously identified, with the exception of ML-ARIAS developers, to avoid conflicts of interest. Travel expenses will be offered to all attendees.

Results

This project has received funding from the NIHR Birmingham Biomedical Research Centre since February 2022 and an NIHR incubator grant for regulatory science awarded to the University Hospitals Birmingham NHS Foundation Trust in June 2023.

Both the SMG and SAG have been assembled and have convened their first meetings. Phase 1 began in April 2023; database searches were performed in May 2023 and the phase was completed in November 2023. Phase 2 began in November 2023 and is expected to be completed in March 2024. As of March 2024, 21 interviews have been performed. Phase 3 is expected to begin in April 2024 and be completed in July 2024. The final TPP and its methods will be submitted to a peer-reviewed journal for publication and reported using the Consolidated Criteria for Reporting Qualitative Research (COREQ) criteria [59].

Discussion

Benefits of Establishing a TPP for an ML-ARIAS for Use in E-DES

ML-ARIAS offer an innovative approach for E-DES to meet rising demand and improve clinical, economic, or service outcomes. However, there is a risk that any or all of these could be negatively impacted by the introduction of an ML-ARIAS due to failures to design, evaluate, or deploy such tools appropriately. For example, placing an ML-ARIAS designed to be highly sensitive but poorly specific as a primary grader may necessitate additional decision arbitration in the screening service, or risk increasing unnecessary referrals to hospital eye services. Either eventuality may significantly reduce (or even negate) any cost benefits, or negatively impact the experience of people with diabetes or E-DES professionals. Alternatively, an ML-ARIAS's economic value could be significantly reduced by any requirement to update existing IT infrastructure, making it economically unviable.

While it is impossible to forecast all such potential pitfalls, some are predictable and could be avoided by outlining the NHS' requirements with regard to an ML-ARIAS within a TPP. This can then be used to guide product development and evaluation. Depending on who is involved in TPP development, these documents can also reflect the priorities of all stakeholder groups, including those often neglected in traditional procurement processes, such as patients and delivery staff.

The knowledge of what should go into a TPP for an ML-ARIAS likely already exists, albeit spread over members of different stakeholder groups and sometimes not formally recorded. Where desired characteristics are not clearly understood, for example, when trade-offs exist between competing priorities, our proposed consensus methodology provides a means to better establish requirements or areas where future research is needed.

Given that product requirements can be hard to identify, it is unsurprising that innovation frequently aligns poorly with the actual needs of health care professionals, health services, and their users. Creating a TPP to gather this knowledge in a concise format can accelerate the development of products that meet these stakeholders' needs at a cost much less than that of late-stage product failures or unsuccessful deployments. As well as improving developers' efficiency in product development or testing, other stakeholders stand to gain from TPPs' development. Knowing the essential characteristics of a tool, commissioners can make more assured commissioning decisions, drawing on the collective knowledge of all stakeholders contributing to the TPP. In an ML-ARIAS context, people with diabetes will also have a unique opportunity to influence product design and implementation strategies, increasing the likelihood that tools are acceptable to them and good DES uptake is maintained.

Comparison to Previous Work

To our knowledge, this project represents the first public use of TPPs for an AI health care technology. Our final TPP and the learning accrued through its development will provide a strong basis for the development of TPPs for other disease areas. As no best practice currently exists on TPP development [45], we will use a 3-phase multistakeholder-modified Delphi-consensus method similar to that used to develop reporting guidelines [56,60], core outcome sets [57,61] and previous TPPs [35,40,62]. This method aims to foster values such as inclusivity, patient empowerment, and consensus, and we intend to transfer these values into best practices in a new field.

Limitations

This project has a number of potential risks that we have sought to mitigate, most notably a failure to recruit and retain participants in the Delphi process, the omission of critical characteristics, and a failure to adequately represent and balance the needs of stakeholder groups.

With regard to securing good recruitment and retention for the Delphi process, we have secured the strong engagement of all relevant stakeholder groups with representatives of each on the SAG. Their involvement in the design of the Delphi survey aims to ensure it is broadly acceptable and achievable by all, as well as mitigate against a significant "drop-off" between Delphi rounds, a common issue that can introduce bias. To further mitigate this, we will also monitor returns collectively and at a

stakeholder group level during each round, allowing interventions such as reminders, further engagement activities, or the extension of round durations, if necessary.

The risk of omitting an essential characteristic in our TPP is increased as this will be the first developed for an AI diagnostic test, and characteristics cannot simply be copied from those previously published in the field. Additionally, some characteristics may only be identified and prioritized by single stakeholder groups. It is therefore important that the TPP development process provide sufficient opportunity for these novel or underappreciated characteristics to be identified. To do this, our reviews will specifically target resources in the field of digital and AI health care to establish which characteristics to report, and our method will provide opportunities for members of all stakeholder groups to put forward additional requirements at multiple stages.

There is also the risk that our methods may generate characteristics that put undue emphasis on the priorities of 1 stakeholder group over another. One may hypothesize that a developer might wish to set TPP requirements at a low, easily achievable level that would be unacceptable to patients and health service providers on the grounds of safety or quality. Conversely, patients and health professionals may have an unrealistic idea of what is possible and argue for TPP requirements to be set near or at perfection (eg, "must not miss any cases"). Our TPP development process seeks to both surface and balance competing priorities to produce a common, achievable target where possible, including being open regarding which stakeholder groups hold different views, potential conflicts of interest, and the actual consequences of decisions and compromises. To ensure that the requirements of the TPP remain achievable, ML-ARIAS developers will be invited to participate in the internet-based Delphi rounds as well as the UG, feedback from which will be presented at the meeting where the final TPP will be agreed. Bidirectional thresholds will also be used in the Delphi phase, such that characteristic and specification pairs must have a minimum level of support as well as a maximum level of dissent allowed to progress, increasing the likelihood that these are achievable as well as acceptable to all.

Conclusions

In developing a TPP for an ML-ARIAS, we will for the first time bring patients, health care professionals, commissioners, methodologists, clinical AI experts, and developers together to provide a target for AI developers to work toward. It is our aim that this will increase the likelihood of the development of ML-ARIAS that are fit-for-purpose for the NHS, improve screening outcomes and of benefit all stakeholders. In addition, we hope that this first public use of TPPs in health care AI and our open sharing of our methods will enable others to develop TPPs for a range of unmet needs, providing clarity to developers and accelerating innovation toward products that will be welcomed by patients and providers alike.

Acknowledgments

All authors were involved in the conception and design of the work. TM, XL, AKD, JD, JH, ST-P, GM, and BS drafted the manuscript. All authors reviewed the manuscript and approved the final version. TM is a doctoral fellow funded by the University Hospitals Birmingham NHS Foundation Trust.

Data Availability

Data sharing is not applicable to this article, as no data sets were generated or analyzed during this study.

Conflicts of Interest

CM acts as the national professional advisor for patient safety at the Care Quality Commission. RGW is a member of the UK National Screening Committee and a nonexecutive director of Moorfields Eye Hospital. FG is employed by NICE and the Department of Health and Social Care in England.

Abstract

Background: This is a research proposal for a case study to explore how a national organization works in partnership with people with lived experience in national mental health improvement programs. Quality improvement is considered a key solution to addressing challenges within health care, and in Scotland, there are significant efforts to use quality improvement as a means of improving health and social care delivery. In 2016, Healthcare Improvement Scotland (HIS) established the improvement hub, whose purpose is to lead national improvement programs that use a range of approaches to support teams and services. Working in partnership with people with lived experience is recognized as a key component of such improvement work. There is, however, little understanding of how this is manifested in practice in national organizations. To address gaps in evidence and strengthen a consistent approach, a greater understanding is required to improve partnership working.

Objective: The aim of this study is to better understand how a national organization works in partnership with people who have lived experience with improvement programs in mental health services, exploring people's experiences of partnership working in a national organization. An exploratory case study approach will be used to address the research questions in relation to the Personality Disorder (PD) Improvement Programme: (1) How is partnership working described in the PD Improvement Programme? (2) How is partnership working manifested in practice in the PD Improvement Programme? and (3) What factors influence partnership working in the PD Improvement Programme?

Methods: An exploratory case study approach will be used in relation to the PD Improvement Programme, led by HIS. This research will explore how partnership working with people with lived experience is described and manifested in practice, outlining factors influencing partnership working. Data will be gathered from various qualitative sources, and analysis will deepen an understanding of partnership working.

Results: This study is part of a clinical doctorate program at the University of Stirling and is unfunded. Data collection was completed in October 2023; analysis is expected to be completed and results will be published in January 2025.

Conclusions: This study will produce new knowledge on ways of working with people with lived experience and will have practical implications for all improvement-focused interventions. Although the main focus of the study is on national improvement programs, it is anticipated that this study will contribute to the understanding of how all national public service organizations work in partnership with people with lived experience of mental health care.

Introduction

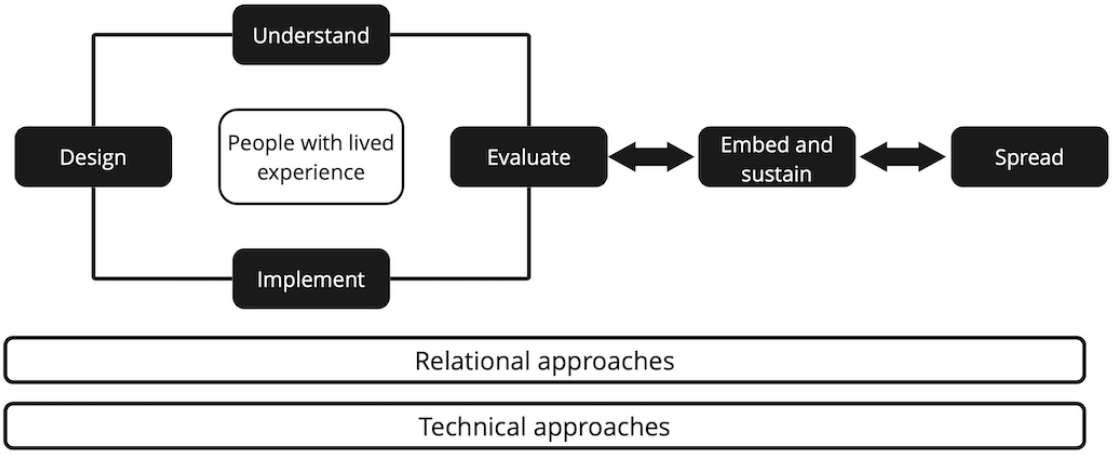
Overview

The need to improve quality in mental health (MH) care is widely recognized, in response to both long-standing problems and more contemporary pressures [1,2]. For several years, quality improvement (QI) has been considered a key solution to many health care challenges, supporting the design and delivery of services. Over the last decade, there has been a significant effort to use QI within health care settings, including the introduction of national organizations to lead improvement programs.

There are several national organizations in Scotland with an improvement focus, including the Centre for Sustainable Delivery, the Health and Social Care Alliance Scotland, the Improvement Service, and Healthcare Improvement Scotland (HIS). In 2016, HIS established the improvement hub (ihub), whose purpose is to enable health and care systems to apply improvement methodologies to the design and implementation of changes that deliver sustainable improvements in the health and well-being outcomes of people in Scotland [3]. The ihub within HIS is uniquely placed with a focus on improvement support for those delivering health and social care across Scotland, including MH services.

Work within the ihub is delivered through improvement programs that use a range of theories and techniques to support teams and services through an improvement journey. National improvement programs have an important role to play in health care. However, there are challenges within centrally led programs that require sensitive understanding and management [4]. The development of improvement programs recognizes growing evidence that the impact of QI in health care is mixed and of poor quality [5], and there is a need to reconceptualize improvement efforts in response to the evidence base [6]. In order to address some concerns within the literature, the ihub has outlined a broad approach to improvement that forms the basis of their improvement programs. The core components of improvement programs within the ihub are described in the framework for planned improvement (Figure 1 [3]), which outlines the stages of improvement work. In the Framework for Planned Improvement, the initial focus is on understanding the system and designing, implementing, and evaluating changes, with people with lived experience at the center of this work. People with lived experience include people who have lived or living experience, their families, caregivers, and supporters. Improvement programs then aim to embed and sustain successful change within practice and spread the learning to other areas. Underpinning the framework is the recognition of the importance of the relational aspect of change and the use of technical QI approaches, including the model for improvement.

Figure 1. Components of improvement programmes, adapted from Healthcare Improvement Scotland's Framework for Planned Improvement.



A key principle to improvement is working in partnership with others in the system, including other agencies, people with lived experience, and frontline staff. In Scotland, a seminal paper by Christie [7] recommended that there should be a stronger partnership working with people and communities in the design and delivery of services they use, including those involved in health care improvement. There is a growing evidence base supporting the need to work with people with lived experience in health care improvement. People with lived experience have a key role to play in understanding problems and identifying solutions to ensure change delivers outcomes that make a difference to patients [8]. Working with people with lived experience in improvement initiatives can strengthen and enrich the organizational agenda for improvement in health care [9] and should be seen as a core component of all improvement programs. Within MH services, people with lived experience should be able to participate in the development of policies to improve MH systems [10] and should therefore be involved in health care improvement initiatives. Working with people with lived experience should be based on authentic, interdependent partnership work [6], which will improve the quality and value of services.

Despite the recognition that working with people with lived experience is central to improvement-focused work, there are a number of challenges and a lack of critical examination of partnership working within the health care improvement literature [11]. There is a lack of understanding of the phenomenon of partnership working, including the mechanisms of partnership working, organizational features supporting partnership working (eg, leadership), and the impact and outcomes achieved from working with people with lived experience [11,12]. There is also little understanding in the

literature of how working with people with lived experience is manifested in practice in national organizations [13].

This research will explore how a national organization works in partnership with people with lived experience in a MH improvement program. This research will focus on one improvement program—the Personality Disorder (PD) Improvement Programme within HIS' ihub. The PD Improvement Programme is a commissioned piece of work funded by the Scottish Government to understand the current service provision in Scotland for people with a diagnosis of PD and identify the key opportunities for improvement. This research will use a case study approach to explore how partnership working is planned, conceptualized, and manifested in practice within the PD Improvement Programme.

Objectives

The aim of this study is to better understand how a national organization works in partnership with people who have lived experience with improvement programs in MH services, exploring people's experiences of partnership working in a national organization. An exploratory case study approach will be used to address the research questions in relation to the PD Improvement Programme:

1. How is partnership working described in the PD Improvement Programme?
2. How is partnership working manifested in practice in the PD Improvement Programme?
3. What factors influence partnership working in the PD Improvement Programme?

This research will consist of 2 phases. The first phase will address the first 2 research questions through document analysis and observations of meetings within the early stages of the PD Improvement Programme. Semistructured interviews will be carried out in the second phase of this research to explore participants' experiences of partnership working, addressing the third research question.

Benefits of This Research

It is anticipated that the findings of this research will contribute to an understanding of partnership working in national organizations and will be used to identify a framework for partnership working so that partnership working can be improved across the organization and other national organizations.

Methods

Overview

In order to address the research aim, it is appropriate to use case study methodology. A case study approach is appropriate when the focus of the study is on how and why questions; the behavior of participants will not be changed; the context is relevant to the phenomenon studied; and when there are unclear boundaries between phenomenon and context [14]. Partnership working sits within the wider context, and case study methodology is well placed to understand relationships between context and intervention [15], with partnership working conceptualized as the intervention in this research. A case study approach will enable a holistic exploration of the complex social processes and mechanisms underpinning partnership working within QI [16]. Data will be collected from a wide range of qualitative sources, including document data, participant observations, and semistructured interviews.

Case Study Design

The DESCARTE model [17] will be used in this research to inform the design, conduct, and reporting of the case study. There are 3 stages to this model: the situation of the research and the researcher, determining the components of the case study design, and data analysis.

Situation of the Research and the Researcher

In designing case study research, it has been recommended that the researcher state explicitly their informing philosophical approach, situation of "Self" within the research, and any ethical considerations to outline the position of research and the researcher [17].

The lead researcher is currently working as part of the improvement team within HIS and therefore will be considered an insider researcher. Although this position may support access to naturalistic data and respondents, there is a risk that there may be conflict between the researcher and participants who have professional relationships, and a risk that respondents may change their behavior or responses due to this relationship [18]. This will increase the risk of bias within the research, and strategies should be used throughout the different stages of the research process to reduce these risks [19]. For this study, strategies will include planning the interview process, using research diaries, reflection, and ongoing monitoring with the supervisory team. The lead researcher will also work closely with a public partner at key stages of this research. Public partners are volunteers who HIS trains and supports to provide a public perspective to their work, and a public partner with lived experience of mental illness will be involved at several stages of this research.

Components of the Case Study

Although case study research can have a level of creativity and flexibility—where the researcher may choose epistemologies and theories suited to their preferences and the nature of the inquiry, clear descriptions of paradigms, theories, and methods should be provided to demonstrate rigor [20]. These will be described to outline the main components of the case study.

Binding the Case

First, it is important to identify what the case will be and set clear parameters or boundaries to ensure the study has a clear and reasonable scope—a process referred to as binding [21]. The parameters of this study will be determined by definition and context; for this research, the case will consist of the PD Improvement Programme within HIS. Early involvement of people with lived experience in the conceptual stages of improvement work has been highlighted to ensure meaningful involvement with influence and impact [22]. The PD Improvement Programme is the first commissioned work for HIS to improve the understanding of the context of service provision for people with a diagnosis of PD across Scotland.

The program will include working with people with lived experience and frontline staff working in clinical roles. The commission is from the Scottish Government and will run between June 2021 and March 2023. This case study will follow the PD Improvement Programme during the current stage of the program: creating the conditions and understanding the system. This stage will involve establishing the program and working practices for working in partnership during the PD Improvement Programme. The parameter for this case is to explore working in partnership with people with lived experience and will not include exploration of wider partnerships working in this program.

Type of Case Study

Exploratory case studies can be used to explore situations in which the intervention being researched does not have a clear, single set of outcomes [21]. Given the diversity within QI and the complexity of partnership work, an exploratory approach is considered appropriate.

Design

In phase 1 of this case study, data will be collected from organizational documents, followed by nonparticipant observations of key program meetings. This data will help explore how partnership working is described, defined, and manifested in practice. This will be followed in phase 2 by semistructured interviews with key participants to explore their experiences of partnership working in the program.

Phase 1: Document Data

In the first phase of data collection, analysis of organizational documents will be used to provide an understanding of plans, infrastructure, and frameworks used to support partnerships working with people with lived experience. It is anticipated that documents may include commission agreements, planning papers, minutes of key meetings, presentations or diagrams describing the program infrastructure, and partnerships working in the program. Further documents relevant to the study may emerge and will be included as appropriate. Access to these documents will be through the program lead within HIS.

As there is no agreed definition of partnership working, documents will be analyzed for any description of partnership, which may include terms such as involvement, participation, engagement, and empowerment. The content of documents will be analyzed, including the document, author, date, description of partnership working, and any actions taken or recommendations. Meetings with the public partner will be agreed upon to discuss the data analysis and the identification of themes at each stage of the data analysis.

Themes developed from the document review will be included in the structure of observations and used to develop the interview proforma in the following phases of the research.

Phase 1: Nonparticipant Observations

Following document analysis, nonparticipant observations of PD Improvement Programme meetings will be used to gather data on how partnership working with people with lived experience in the program is manifested in practice. Meetings observed will be chosen based on a purposive sample, and there will be between 3 and 6 observations completed. The portfolio lead will be asked to provide a list of all meetings taking place in the early stages of the program, which is likely to be within the first 6-9 months of the program. A sample of meetings most likely to demonstrate partnership working in practice [23] will be selected to be observed, such as planning meetings and advisory group meetings. The meetings will be chosen by the researcher to address any potential bias and ensure the appropriate independence of the research.

A framework for partnership working will be used to guide observations (Textbox 1 [24]). This model describes 4 key dimensions of partnership: process, actors (identity and position), decisions, and power relationships. Although the use of this framework provides some structure to the observations, a form of semistructured observation will be adopted to allow for some naturalistic observations [23] and include themes identified in the document analysis.

Nonparticipant observation will allow observation of the environment, language, nonverbal data, and interaction in partnership. General context will be noted for each observation, including location, time, duration, meeting roles, and purpose of the event or meeting.

There is a possibility that the presence of a researcher will increase the risk bias by changing the behavior of participants, and strategies will be used to reduce this risk. Strategies will include giving a clear explanation of the plan for observation and being aware of the position of the researcher to be as unobtrusive as possible [25]. Observations will be primarily descriptive and will provide the basis for the interpretation of data obtained by semistructured interviews in the final stage of data collection. Meetings will be held with the public partner to discuss themes developed at this stage of data collection and to agree on the format of semistructured interviews in phase 2.

Textbox 1. Framework for partnership working observation guide used in an exploratory case study, adapted from Carpentier.

Dimension of partnership working and observation guide

- Process
  - How is partnership working planned for and what preparations are in place to support partnership working?
  - How many events or meetings involve people with lived experience?
  - Who is involved in setting the agenda and context for meetings?
- Actors: identity and position
  - Who attends meetings?
  - What are people's positions within the organization or program?
- Decisions
  - How are decisions in the program made?
  - How are people with lived experience involved in decision-making in the program?
- Power relationships
  - Who contributes to the event or meeting?
  - What is the response to people with lived experience's contribution?
  - What efforts are made to support contributions from people with lived experience?

Phase 2: Semistructured Interviews

The final stage of data gathering will be semistructured interviews with participants from the PD Improvement Programme, including people across disciplines and people with lived experience. Interviews will be used to gain an understanding of participants' experiences and perceptions of partnership working with people with lived experience. A schedule for interviews will be prepared based on themes developed from the document review and observations. The interview proforma will be developed with people with lived experience working as a public partner in HIS to ensure questions are relevant and likely to receive meaningful responses [22]. All interviews will follow the schedule developed as an aide memoire; however, it is important to allow flexibility to adapt to each participant's response to allow exploration of emerging and reported experiences [26]. Interviews will be held at a location agreed upon the researcher and participant and may be face-to-face, remote through Teams (Microsoft Corporation), or by telephone. All interviews will be recorded and transcribed.

The population within this case will include a purposive sample of staff and people with lived experience who are involved in and contribute to the work of the PD Improvement Programme. It is anticipated that this will be between 6 and 8 interviews. Participants will include clinical and improvement staff working directly on the PD Improvement Programme operating at different levels of the organization and people with lived experience working with the PD Improvement Programme. This should ensure diversity within the perspectives gained from the interviews.

Recruitment Strategy and Informed Consent

Participants will be recruited through the PD Improvement Programme and will include a purposive sample of people involved in the program based on their role. All people involved in the program will be offered the opportunity to participate in this study and will be asked to sign a consent form and return it to the researcher at the start of each stage of the research.

There will be a process of ongoing consent for each phase of this research. In phase 1, each participant in the meetings observed will be asked to consent to the observation and recording during selected meetings and consent to being contacted for an interview at the second phase of research if appropriate. This will ensure each participant has a full understanding of the research, their role within it, the benefits and risks, and their right to withdraw from the research. Each participant's consent will be documented in a written form they will be invited to sign before the meeting. Consent will be reviewed at the start of the meeting as a process of ongoing informed consent. If there are participants in the meeting who do not consent, their contribution to the meeting will be omitted during transcription. For meetings held online, participants who do not consent will be offered the chance to turn their camera off during the meeting and use the chat box for contributions if required. This may affect the understanding of the wider context of discussions, and therefore, efforts will be made to observe meetings with full consent.

In phase 2, people will be asked to consent to participate in semistructured interviews. Consent will be documented for each participant; they will be asked to sign a written consent form, and consent will be confirmed verbally at the start of each interview. Once consent is documented, the researcher will select a purposive sample of people who will participate in interviews based on their role in the program. All people who have given consent will be contacted to discuss the next steps, and interviews will be arranged with participants to ensure they take place at a suitable time and setting.

Data Analysis

Data analysis will organize, find patterns, and elicit themes in the data to help deepen an understanding of partnership working within the national PD Improvement Programme. There are various mechanisms for quality assurance within this research, including the use of a reflexive field diary, discussions with supervisors, and member checking where participants can check transcriptions following observations and interviews. During analysis, there will also be regular meetings with a public partner working in HIS to review and discuss themes to check emerging findings and the researcher's interpretation, as a form of participant validation to improve scientific rigor. A framework for data analysis is outlined in Table 1 [27].

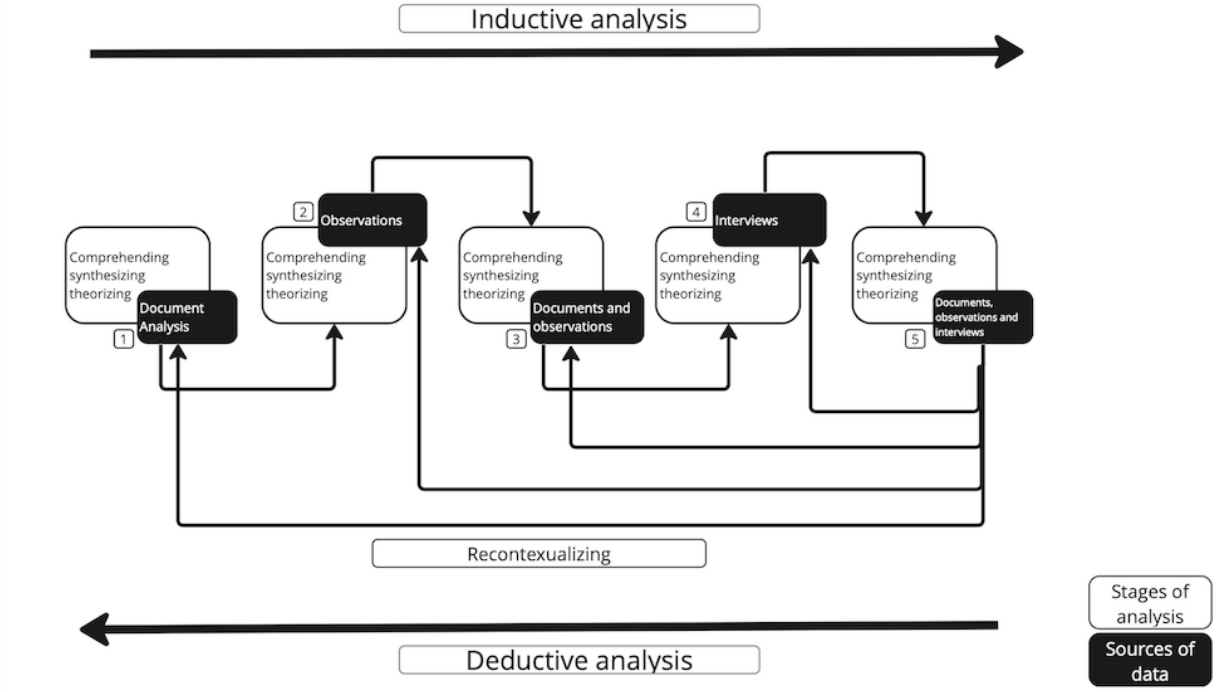
In order to develop convergent evidence, the structure outlined in Figure 2 will be applied to data analysis.

Effective organization of data will be important to this case study to enable the tracking of data sources, notes, documents, narratives, and other data [14]. NVivo (version 12; QSR International) will be used to support the management of data and to assist within and across case study analysis, appropriate to case study research [27]. Data collection and analysis will occur concurrently, as is practiced in qualitative studies [14].

Table 1. Thematic data analysis plan for an exploratory case study adapted from Houghton et al.

Stage of data analysis	Analysis strategy	Application for this research
Comprehending	Broad coding	This stage will analyze data to generate and develop codes. In this stage, enough data will be gathered to write a detailed, coherent, and rich description of partnership working.
Synthesizing	Pattern coding memoing	This stage will review codes identified at the broad coding stage and identify patterns within the data. Memos will provide summaries of key information for each theme, which will be used in further development of propositions of the data.
Theorizing	Distilling and ordering and testing executive summary statements	Relationships between categories of data will be examined, building a more integrated understanding of partnership working from all perspectives and data sources.
Recontextualizing	Developing propositions	Concepts identified will be synthesized to consider how the understanding of partnership working may be applied in different settings.

Figure 2. Data analysis plan for thematic analysis in an exploratory case study.



Patient Involvement

The objective of this research is to deepen an understanding of how national improvement programs work in partnership with people with lived experience. This focus was developed through a review of current literature and organizational objectives [28] and has been highlighted by people with lived experience who have worked with HIS in other national MH improvement programs [29].

Patient involvement has been central to the development and design of this research, and a public partner has been involved in the design and will be involved in the analysis of this research. In phase 1, this included involvement in the review and analysis of themes as a form of participant validation to improve scientific rigor [30]. The public partner advised on the burden of intervention for people with lived experience in this study and has been involved in the design of phase 2, including the

design of interviews, the development of the distress response policy, and advising on participant recruitment. The public partner will continue to be involved during the data analysis of phase 2, reviewing and discussing themes developed at this phase, and will be invited to advise on plans for dissemination of the study results to participants and linked communities.

Ethical Considerations

Ethical approval has been granted from HIS' research oversight group, the University of Stirling Research Ethics Committee, and the Integrated Research Application System through the Queen Square Research Ethics Committee (for phase 1; 318323) and the Black Country Research Ethics Committee (for phase 2; 309926). This study is part of a clinical doctorate program at the University of Stirling and is unfunded.

Results

Data collection was completed in October 2023; analysis is expected to be completed and results published in January 2025.

Discussion

This study will produce new knowledge on ways of working with people with lived experience and will have practical implications for all improvement focused interventions. Though the main focus of the study is on national improvement programs, it is anticipated that this study will contribute to the understanding of how all national public service organizations work in partnership with people with lived experience of MH care. The anticipated time for completion and write-up is 24 months. Information will be shared with key stakeholders on the progress of this research, including HIS and the University of Stirling, and opportunities for presentation of this research will be sought. These may include QI conferences and communities—including the Q Community (The Health Foundation), MH organization events, and NHS Scotland events. The findings will be completed with a thesis submitted to the University of Stirling and will be reported in an appropriate journal, such as *BMJ Open Quality* or the *Journal for Healthcare Quality*.

Acknowledgments

The authors thank Healthcare Improvement Scotland's Mental Health Improvement Portfolio Team. This research has received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

Data Availability

The data sets generated during and/or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

CR is a student in the clinical doctorate program at the University of Stirling. CH is the lead supervisor and researcher. AS is the supervisor for this research. Both supervisors contributed to the design of the research protocol, advising on analysis, and developing the manuscript for this research. GJ is the public partner advising on the design, analysis, and dissemination of this research.

Conflicts of Interest

None declared.

Abstract

Background: The last 2 decades have been a time of exponential growth and maturation for digital health, while the global burden of respiratory disease continues to grow worldwide. Leveraging digital health interventions (DHIs) to manage and mitigate respiratory disease and its adverse health effects presents itself as an obvious path forward.

Objective: We aimed to understand the current digital landscape and enabling environment around respiratory health to reduce costs, avoid duplication, and understand the comprehensiveness of DHIs.

Methods: This study will follow a scoping review methodology as outlined by Arksey and O'Malley, the Joanna Briggs Institute, and the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) checklist. MEDLINE, Embase, CINAHL, PsycINFO, Cochrane Library, Web of Science, PakiMedNet, and MyMedR databases will be searched along with key websites, repositories, and gray literature databases. The terms "respiratory health," "digital health," "South Asia," and "Southeast Asia," as well as related terms will be searched. The results will be screened for duplicates and then against the inclusion and exclusion criteria. For the studies included, data will be extracted, collated, and analyzed.

Results: The scoping review was started in July 2023 and will be finalized by February 2024. Results will be presented following the World Health Organization's classification of DHIs to categorize interventions in a standardized format and the mobile health evidence reporting and assessment checklist to report on the effectiveness of interventions. Further exposition of the evidence extracted will be presented through narrative synthesis.

Conclusions: As DHIs continue to proliferate, the need to understand the current landscape becomes more pertinent. In this scoping review, we will seek to more clearly understand what digital health tools and technologies are being used in the current landscape of digital health in South and Southeast Asia for respiratory health and to what extent they are addressing the respiratory health needs of the region. The results will inform recommendations on digital health tools for respiratory health in South and Southeast Asia will help funders and implementers of DHIs leverage existing technologies and accelerate innovations that address documented gaps in the studied countries.

KEYWORDS

digital health; respiratory health; Asia; scoping review; landscape mapping; digital health intervention; digital health environment; mobile health; mHealth

Introduction

Digital health and care refer to the use of information communication technologies, commonly known as digital health interventions (DHIs), by health and care professionals, patients, carers, or health managers to manage illnesses and wellness [1-4]. The last 2 decades have been a time of exponential growth and maturation for digital health [4] due to the promises of improved health for all and personal health empowerment [5]. Concurrently, the global burden of respiratory disease continues to grow worldwide, with infectious and noncommunicable respiratory diseases being among the top 10 medical conditions (out of 369 diseases and injuries measured) in terms of years of life lost due to premature death and years lived with a disability (measured by disability-adjusted life years) [6,7]. This increased burden of respiratory disease is more acutely felt in Asia, where mortality rates are higher and public awareness and government engagement are lower than in other regions of the world [8,9]. Leveraging DHIs to manage and mitigate respiratory disease and its adverse health effects presents itself as an obvious path forward. However, the first step to harnessing the power of digital health must be understanding the current digital landscape and enabling the environment to reduce costs, avoid duplication, and increase the efficiency, accessibility, and sustainability of such interventions [10-13].

The National Institute for Health Research (NIHR)–funded Global Health Research Unit on Respiratory Health (RESPIRE) is a collaboration between several Asian organizations and universities in Bangladesh, Bhutan, India, Malaysia, Pakistan, Indonesia, and Sri Lanka and the University of Edinburgh in Scotland, United Kingdom [9,14,15]. RESPIRE aims to achieve the following:

> *develop into a world-leading Unit that will: (i) map and collate continuing and emerging respiratory challenges; (ii) prioritise existing evidence-based interventions that have the potential to be adapted to reduce mortality and morbidity in low- and middle-income countries (LMICs); (iii) support local adaptation and tailoring of interventions for deployment in low-resource environments and catalyse developmental work in areas of unmet need; (iv) support local implementation efforts and evaluation of programmes of work; and (v) identify the best delivery mechanisms for long-term delivery and scaling-up.*

This is done through 4 different translational platforms, of which 1 platform focuses on Digital Health and Innovation and aims to provide holistic support to partner countries on the design, funding, deployment, and sustainability of new and existing digital health interventions for respiratory health. This scoping review will contribute to advancing the aims and work of Digital Health and Innovations.

Understanding the current landscape of DHIs that target respiratory diseases will (1) uncover existing gaps, (2) highlight potential opportunities, (3) suggest research and program priorities most needed in the field of digital health to address current respiratory health diseases in South and Southeast Asia, and (4) further advance RESPIRE's overall aims. Therefore, we aim to undertake a scoping review to map respiratory disease DHIs in South and Southeast Asia to identify existing technologies, opportunities, and gaps, and to put forward pertinent recommendations from the insights gained.

Methods

Scoping Review Methodology

The scoping review methodology, as outlined by Arksey and O'Malley and the Joanna Briggs Institute (JBI) [16,17], is an appropriate approach for mapping DHIs. Scoping reviews allow flexibility when exploring the diverse and heterogenous field of digital health, are appropriate when using different sources of data (eg, peer-reviewed journals, gray literature, and expert opinions), and permit inclusion and exclusion criteria to be iteratively refined as more evidence is uncovered [16-19]. Additionally, the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) [20] will be followed to ensure adherence to methodological standards.

Identifying the Research Question

This scoping review will seek to answer the following research questions:

1. What digital health tools and technologies are being used in South and Southeast Asia for respiratory health?
2. How are these addressing (or not) the respiratory health needs of the region?
3. What recommendations can be made from the literature?

Identifying Relevant Studies

To identify relevant literature, academic databases will be searched along with key websites, repositories, and gray literature databases that may contain relevant information for our scoping review. Textbox 1 shows the proposed databases.

The search strategy has been initially drafted for MEDLINE in the Ovid platform (Textbox 2) and will be adapted for the remaining databases. The search strategy has been iteratively developed and refined by the authors' input and the librarian at the University of Edinburgh. The terms "respiratory health," "digital health," "South Asia," and "Southeast Asia," as well as all relevant variations of these terms have been included in the search strategy to gather as much pertinent literature and information as possible.

9. 7 or 8
10. 3, 6, and 9

Study Selection

Exclusion and inclusion criteria have been developed according to the domains of population, concept, context, and type of evidence, suggested by the JBI [17,18]. Additionally, an "other variables" category has been created to include year, language, and format criteria (Table 1). The regions of South and Southeast Asia include 19 countries as established by the United Nations Statistics Division [21]. These 2 regions have been chosen because they contain all the RESPIRE2 countries. Multicountry studies containing countries from the selected regions and other regions of the world will be included in the initial screening and only excluded if they do not provide the data of interest separate for each country. Only studies in English and those published in the last 10 years (since 2013) will be included to keep the scope of this review within manageable boundaries.

Table 1. Inclusion and exclusion criteria.

Domain	Inclusion criteria	Exclusion criteria
Population	• Any population	• N/A[a]
Concept	• Technological interventions for respiratory health that fall under any of the categories of the World Health Organization's classification of digital health interventions • Respiratory health includes respiratory infections, noncommunicable respiratory diseases, and preventable risk factors for respiratory conditions, as defined by RESPIRE[b]	• Other nontechnological interventions used for respiratory health • Not a respiratory health focus
Context	• South and Southeast Asia	• The rest of the world
Types of evidence sources	• Any study design	• Books • Abstracts only • Posters • Protocols
Other variables	• Published in English • Studies or data published in the last 10 years (2013-2023) • Full article or data are available digitally	• Published in any other language • Studies or data published before 2013 • Full article or data are not available digitally

[a]N/A: not applicable.

[b]RESPIRE: The National Institute for Health Research–funded Global Health Research Unit on Respiratory Health.

For information found in a scientific study format, Covidence software [22] will be used to eliminate duplicates and carry out screening and extraction. After deduplication, title, abstract, and full-text screening will be done by 2 authors according to the inclusion and exclusion criteria. Discrepancies will be first addressed by consensus between those 2 authors. If there is a lack of consensus, a third reviewer will decide.

For all other types of information or data found from searches, manual screening by 1 reviewer will happen first. Relevant data will be entered into a spreadsheet, and a second reviewer will assess it. Discrepancies will first be addressed between both reviewers, and if there is no consensus, a third reviewer will make the final decision. We will not contact authors directly to further understand whether a study should be included since it would most likely significantly lengthen the timeline for this scoping review.

Scoping reviews use secondary data and do not require ethics approval under RESPIRE rules. However, the authors will adhere to the highest ethical standards when carrying out the review. This protocol establishes a transparent and reproducible study design, which limits the potential for personal bias [23].

Charting the Data

After selection, relevant data will be extracted to a spreadsheet using Covidence. The extraction form will be first piloted in 3-5 studies to assess if it is fit for purpose as recommended by the JBI. Data selected from a nonscientific study format will be entered into the extraction spreadsheet as accurately as possible. However, it is acknowledged that not all fields may contain relevant information, and some fields may need to be modified (eg, data from the Digital Health Atlas will have a "source of information" field instead of an "author" field).

When 2 or more articles refer to the same overall study, those articles will be grouped as one before data extraction.

Collating, Summarizing, and Reporting the Results

After data analysis, the data will be collated and analyzed as follows:

- Quantitative data (ie, the number of studies, type of study, and year) will be presented.
- Qualitative data will be presented following the World Health Organization's classification of digital health interventions [24] to categorize interventions in a standardized format and the mobile health evidence reporting and assessment checklist [25] to report on the comprehensiveness of the interventions.
- Narrative synthesis will be used to answer the research questions and to present further data extracted.

Consultation

Consultation with stakeholders will be ongoing throughout the scoping review process. We will disseminate early findings among partners so that they can provide feedback on findings and that feedback can be incorporated into the discussion.

Results

This scoping review was started in July 2023 and will be finalized by February 2024. Preliminary findings will be shared with stakeholders and a final write-up of the scoping review is projected to be finalized by the end of March 2024. To date, 10,469 studies have been screened. The screening of abstracts is underway.

Discussion

Expected Outcomes

Through this scoping review, we will seek to better understand what digital health tools and technologies are being used in South and Southeast Asia for respiratory health and to what extent they are addressing the respiratory health needs of the region. The results will inform recommendations on digital health tools for respiratory health in South and Southeast Asia and will help funders and implementers of DHIs leverage existing technologies and accelerate innovations that address documented gaps in the studied countries. The results of this review will be limited by the fact that only studies in English and studies published in the last 10 years will be included. This review will enhance the knowledge of digital health tools and technologies in the region, which is paramount before undertaking any new initiative, as it helps prevent redundant work and investment by building on existing systems and lessons learned.

Conclusions

As DHIs, in general and in respiratory health in particular, continue to proliferate, the need to understand the current landscape becomes more pertinent. Through this scoping review, we will systematically map out DHIs, which serves as the required first step in any well-informed and thought-out design and deployment of DHIs.

Acknowledgments

We would like to thank Marshall Dozier, the librarian at the University of Edinburgh, who provided feedback on the protocol's search strategy and overall design.

Generative artificial intelligence was not used at any time during the research and writing of this protocol.

This research was funded by the UK National Institute for Health and Care Research (NIHR)— Global Health Research Unit on Respiratory Health (RESPIRE; NIHR132826)—using UK aid from the UK Government to support global health research. The views expressed in this publication are those of the authors and not necessarily those of the NIHR or the United Kingdom Government.

Data Availability

The data resulting from this scoping review will be made available as supplementary materials at the time of publication.

Authors' Contributions

JE and LE conceptualized the idea. LE drafted the manuscript and search strategy. JE, MF, AA, and ZA provided feedback on the draft.

Conflicts of Interest

AA is a shareholder of a digital health company in Malaysia (UMCH Technology Sdn Bhd).

Abstract

Background: The process of refugee resettlement and integration into new communities is a complex and multifaceted challenge, not only for the refugees themselves but also for the host families involved in homestay housing arrangements. While these homestay arrangements are designed to facilitate smoother transitions and enhance the well-being of refugees, the nuanced dynamics of these interactions and their overall impact on both refugees and their host families remain underexplored. Understanding the experiences of refugees and their host families is vital for effective refugee settlement, integration, and well-being. However, the intricacies of homestay refugee hosting, their interactions with host families, and the impact on their well-being are still unclear and ambiguous.

Objective: The aim of this scoping review is to examine the breadth of literature on the experiences of refugees living in homestay arrangements with their host families. This review seeks to understand how these dynamics influence refugee well-being, including their integration, social connections, and mental health. Additionally, this scoping review aims to synthesize existing literature on homestay hosting dynamics, focusing on the experiences of refugees and their host families, to identify gaps in knowledge and suggest areas for future research.

Methods: This scoping review follows Joanna Briggs Institute methodology and will search databases such as CINAHL, SOCIndex, MEDLINE through EBSCO; APA PsycInfo, Scopus through OVID; and Web of Science Core Collection, ProQuest Dissertations, and Theses, and SciELO Citation Index, focusing on literature from 2011 onward, in English, in relation to refugee groups in different host countries, including all types of literature. Literature will be screened by 2 independent reviewers, with disagreements resolved by consensus or a third reviewer. A custom data extraction tool will be created by the research team.

Results: The results will be organized in tables or diagrams, accompanied by a narrative overview, emphasizing the main synthesized findings related to the dynamics of homestay hosting with host families and refugee well-being. No critical appraisal will be conducted. This scoping review is expected to identify research gaps that will inform the development of homestay refugee hosting models, policies, and practices. It will also offer insights into best practices and policy recommendations to improve homestay hosting programs, ultimately contributing to more effective refugee settlement and integration strategies.

Conclusions: Understanding the intricate dynamics of homestay hosting arrangements is crucial for developing policies and programs that support the well-being of refugees and the families that host them. This scoping review will shed light on the current knowledge landscape, identify research gaps, and suggest ways to enhance the homestay hosting experience for all parties involved. Through this work, we aim to contribute to the development of more inclusive, supportive, and effective approaches to refugee hosting, resettlement, and integration.

KEYWORDS

cohabitation; homestay; hospitality; host family; host-guest relationship; refugee; well-being

Introduction

Overview

The global displacement of refugees amounted to 35.3 million individuals, with a majority comprising female individuals [1]. However, as the number of individuals seeking refuge in host countries grows, the housing needs of such people beckon resolution. One prosperous solution that has arisen from housing needs is refugee hosting [2]. Within the purview of refugee studies, the term "hosting" signifies the established societies or communities that undertake the resettlement of refugees [3]. Hosting communities are often credited with the expectation to foster welcoming and accepting environments for refugee women and their families to settle after escaping conflict [4].

Families seeking support may be placed, by publicly or privately funded organizations, into the homes of host families. Such homes are volunteered by willing families or individuals, many of whom are refugees or immigrants [4]. Hosting communities and their members often play a crucial role in extending hospitality and support to refugee women and their families to facilitate integration [5]. This culture of hospitality is also observed at the individual level notably within urban communities, where there is a rising trend of individuals and families hosting refugees in their private residences [6]. The role of these host families typically involves temporarily sharing their homes and resources with newly arrived refugees, all with the aim of enhancing the settlement process [6]. However, the use of the terms "host" and "hosting" illustrates a host-guest relationship, positioning refugees within the domain of the hosts. This conveys an underlying power imbalance between the hosts and the refugees [4,7]. This dynamic can also cultivate certain expectations imposed on refugees, dictating their behavior according to the host's perceived standards of being worthy of hospitality [7]. For example, in a study by Monforte et al [7], exploring the responsibility of hosting, private hosts expressed emotional connection and mutual affection as a jointly shared responsibility with refugees, placing expectations on refugees to reciprocate. When refugees did not meet their expectations due to language barriers or unwillingness to discuss their past, hosts' perception of the refugee's value altered [7].

The expectation of the refugee to be a "good guest" highlights the conditional nature of private hosting, therefore requiring refugees to prove they are deserving of being hosted [4,5,7]. When refugees do not match the expectations or ideas of hosts, this can create an uncomfortable environment for refugees [5]. Furthermore, hosting arrangements and expectations can limit refugees' control over their surroundings, as they are essentially guests in someone else's domain [4,6,7]. This lack of control over their living situation can potentially hinder their ability to rebuild their lives autonomously, trigger power differences, and add an extra layer of vulnerability [8,9]. This power difference is even more pronounced for refugee women due to the intersection of gender-related disparities [10]. In addition, refugees' lack of host country citizenship further positions them as guests and makes them vulnerable to various abuses of power [11]. Viewing refugees women as mere guests within host homes and communities increases their social and economic vulnerabilities, especially without sufficient system-level policies and safeguards in place to protect their welfare [12].

Dağtaş [13] argues that refugee lived experience is heavily influenced by the host country's political conditions and social welfare policies (for refugees). In addition, current literature has revealed that hosting frameworks have created a racialized discourse of nonbelonging [14]. Furthermore, reviews of the literature on current homestay or family hosting practices and regulations for refugee groups highlight an enormous gap [6]. Although communities and host families play an immense role in refugee settlement, refugee well-being relies heavily on standards being shaped by inclusive and informed social welfare policies and practices [15]. Host families and the communities in which refugees are hosted are pivotal in their successful settlement and success [7,15]. They may provide crucial aid to refugees, including more tangible forms of support, such as housing or financial aid, in addition to more abstract forms of assistance, such as cultural orientation, emotional support, and social comfort [7]. However, as generally unregulated social groups, the success of such support provided to refugees can vary largely based on cultural competency, empathetic disposition and understanding, and the attitudes and perspectives of communities and host families [4,15]. For a meaningful exploration of the hosting practices and dynamics implemented by the host families, it is imperative to understand the discourse these practices bring forth and their implications on refugees' well-being.

A preliminary search of the literature through review registries (Open Science Framework and Joanna Briggs Institute (JBI) Evidence Synthesis) was conducted. No current or in-progress scoping reviews on this topic were identified. Existing reviews do not study the specific relationship between refugees and host families; reviews on the topic of refugee integration, in general, tend to be focused on a particular geography in terms of the host country or on a particular subset of refugees (eg, by gender, host country, or accommodations practices). The aim of this scoping review is to explore the experiences of refugees with their host families and understand the dynamics of homestay hosting on refugee well-being. A scoping review is an appropriate method to gather, organize, and chart the evidence [16] related to refugees living with host families. It aims to pinpoint variances and parallels in homestay hosting approaches and practices, enhancing our comprehension of their effects on refugee well-being. This review is intended to inform future research that could guide evolving practices or models for refugee hosting.

Review Question

What is known from the existing literature about the experiences of refugees with homestay hosting?

Methods

Overview

The proposed scoping review will be conducted in accordance with the JBI methodology for scoping review [16] and the PRISMA-ScR (Preferred Reporting Items for Systematic and Meta-Analyses extension for Scoping Reviews) [16,17]. The

protocol of this review has been registered with the Open Science Framework [18].

Eligibility Criteria

Participants

This review will consider studies involving participants who identify as refugees, displaced persons, or asylum seekers. There will be no restrictions based on age or gender.

Concept

This review will consider literature that pertains to refugee hosting experience, hosting practices, homestay, host-guest relationship, cohabitation, and refugee well-being.

Context

This review will consider literature specific to refugee accommodation, hosting family, and homestay hosting practices in different host countries and different geographical settings.

Types of Sources

This review will consider all types of study designs. Database searches will not be limited to a particular evidence source type. Primary research articles, review articles, editorials, theses, dissertations, reports, publications after 2011, and other gray literature in English will be included. This scoping review will also include theses and conference proceedings. Opinion papers will also be considered for inclusion in this scoping review, depending on the focus and context.

Search Strategy

In collaboration with a research librarian, the search strategy was built using some seed articles supplied to the librarian by the lead researcher as well as an initial search of several databases using basic terms. The search strategy, encompassing all identified keywords and index terms, will be tailored to suit each database and information source included. These searches were built up and used to develop a full search strategy for CINAHL (Multimedia Appendix 1). For other interfaces, the search will be modified as per the accepted Booleans, etc. The final scoping review will include all searches as appendices. The search strategy was also peer-reviewed by a fellow librarian using the PRESS Peer Review Strategy [19]. Studies published in English since 2011 will be included. The reference list of all included sources will be screened for additional studies. The databases to be searched include CINAHL, SOCIndex, MEDLINE, and Academic Search Complete through the EBSCO interface; APA PsycInfo and Scopus through the OVID interface; and Web of Science Core Collection, ProQuest Dissertations and Theses, SciELO Citation Index, and ProQuest through the Web of Science interface. As no source filters will be used, gray literature on these databases, such as conference proceedings and theses, will also be captured.

Study Selection

Following the search, all identified citations will be collated and uploaded into EndNote (version 21; Clarivate) and duplicates will be removed. Following a pilot test, titles and abstracts will then be screened by 2 or more independent reviewers for assessment against the inclusion criteria for the review. Potentially relevant studies will be retrieved in full and their citation details imported into the JBI System for the Unified Management of the Assessment and Review of Information (SUMARI) for the unified management, assessment, and review of information [20]. The full text of selected citations will be assessed in detail against the inclusion criteria by 2 or more independent reviewers. Reasons for the exclusion of papers in full text that do not meet the inclusion criteria will be recorded and reported in an appendix to the full review. Any disagreements that arise between the reviewers at each stage of the selection process will be resolved through discussion or with an additional reviewer. The results of the search and the study inclusion process will be reported in full in the final scoping review and presented in a PRISMA (Preferred Reporting Items for Systematic and Meta-Analyses) flow diagram [16,17].

Data Extraction

Data will be extracted from studies included in the review by 2 independent reviewers using a data extraction tool developed by the reviewers based on content relevant to the review question (Multimedia Appendix 2). The data extracted will include specific details about the participants, concept, context, study methods, and key findings relevant to the review question. The initial data extraction tool will undergo adjustments and updates as needed throughout the data extraction phase from each selected source of evidence. These changes will be thoroughly documented in the scoping review. Any disagreements that arise between the reviewers will be resolved through discussion or with a third reviewer. We will reach out to the authors for further details or clarifications when necessary. Should we encounter missing, unclear, or ambiguous data crucial for our analysis, we will contact the respective authors.

Results

To address this scoping review's objective of identifying, collating, and mapping the evidence about the term homestay hosting in relation to refugee groups with their host families in different host countries, we will undertake a comprehensive and thorough analytical process. This will involve synthesizing information from the selected studies into a cohesive framework. The key outcomes of this process will be systematically documented in a detailed table, which will encapsulate the diverse definitions, interpretations, and implementations of "homestay hosting" encountered in the literature (Multimedia Appendix 3). This will serve as a crucial reference point, offering a consolidated view of how "homestay hosting" is understood and applied by different researchers and practitioners in the field. Beyond merely summarizing these findings, the review will extend its analysis to include the development of diagrams. These visual aids, to be included in Multimedia Appendix 4 are designed to visually represent the relationships and connections between the various elements of refugee homestay hosting.

The diagramming effort aims to clarify how the specific aspects of homestay hosting interact with the broader concept of family hosting and with each other. This visual mapping will not only make the complex interrelations more accessible but also highlight potential areas for further research or intervention.

Complementing the tables and diagrams, a narrative summary will be provided to weave together the review's findings in a coherent format. This narrative will contextualize the evidence within the scope of the review's objectives, offering insights into how the concept of homestay hosting contributes to our understanding of refugee support mechanisms. It will explore the implications of the findings for policy, practice, and future research, particularly emphasizing the nuances of refugee experiences in homestay settings and the roles of host families. Through this multifaceted approach—combining tabular summaries, visual diagrams, and narrative synthesis—the scoping review will offer a comprehensive and nuanced exploration of refugee homestay hosting, thereby enriching the discourse on refugee accommodation and support strategies.

Discussion

Overview

This scoping review will shed light on the intricate relationship between homestay hosting environments and refugee well-being, offering new perspectives on how these arrangements affect refugees' lives. By dissecting the dynamics within homestay settings, our analysis will bring to the forefront the multifaceted ways in which these hosting arrangements influence refugee well-being. Such insights are invaluable for policy makers and practitioners tasked with crafting and executing refugee hosting programs and models, providing them with a deeper understanding of the elements that contribute to successful refugees' integration and support. Our findings will highlight critical areas ripe for further exploration, suggesting that while this review lays the groundwork, it also underscores the necessity for more focused research. Detailed investigations, particularly longitudinal studies, could elucidate the evolving nature of refugee well-being within homestay contexts, offering a clearer picture of long-term outcomes. Similarly, comparative analyses of various hosting models could reveal best practices, guiding the development of more effective and supportive hosting frameworks. While this scoping review opens the door to a better understanding of the complex interplay between homestay hosting and refugee well-being, it also highlights the critical need for ongoing research. Future studies, armed with the foundational knowledge provided by this review, have the potential to further dissect and enhance the nuances of the homestay-refugee relationship. Such research is crucial for refining hosting practices and policies, aiming for a more empathetic and effective approach to supporting refugees worldwide, ultimately contributing to their well-being and successful integration into host communities.

Implications

The implications of our review extend beyond academic discourse, offering actionable insights for policy makers, practitioners, and researchers alike. By advocating for tailored support mechanisms, clear policy guidelines, and further research into the long-term effects of homestay arrangements, this review sets the stage for future studies that can build on our findings. Ultimately, we hope that our work will pave the way for more empathetic, effective, and sustainable refugee support practices worldwide, ensuring that both refugees and their host families can thrive together in their shared communities.

Limitations

This review protocol is not without limitations. One significant constraint is the scope of the literature reviewed, which may not encompass all existing studies on homestay hosting and refugee well-being due to language and publication date restrictions. Additionally, the inherent nature of scoping reviews to broadly map a field of study implies that the depth of analysis on specific topics might be limited and there will be no quality assessment of the selected resources. This limitation points to the necessity for targeted, in-depth studies that can build on the preliminary insights offered here. Furthermore, the diversity of homestay arrangements and refugee experiences across different cultural and geographical contexts may not be fully captured, highlighting the need for context-specific research to fully understand the nuances of homestay hosting and its impact on refugee well-being.

Conclusion

This scoping review will highlight the complex relationship between homestay hosting and refugee well-being, revealing both the potential and challenges of such arrangements. By examining the current state of research, the multifaceted nature of these hosting arrangements and their effects on both refugees and their host families will be illuminated. Our findings can highlight the critical need for policies and practices that are deeply informed by an understanding of these intricate dynamics to support the well-being of refugees and their hosts effectively. Understanding the intricate dynamics of homestay hosting arrangements is crucial for developing policies and programs that support the well-being of refugees and the families that host them. This review will shed light on the current knowledge landscape, identifying research gaps and suggesting ways to enhance the homestay hosting experience for all parties involved. This review's findings will inform the development of more inclusive, supportive, and effective approaches to refugee hosting, resettlement, and integration. To the best of our knowledge, this review represents the inaugural scoping review designed to explore the dynamic of homestay hosting and refugee well-being and the benefits such exploration brings to inform the development of refugee hosting models and practices.

Acknowledgments

We would like to thank all authors who contributed to this protocol. Their expertise, unique insights, and commitment have been crucial in shaping and enriching this work. Each author's distinct knowledge and dedication have significantly enhanced the quality and depth of our discussion. We are grateful for their valuable contributions and the collaborative effort that made this

protocol both informative and comprehensive. We affirm that ChatGPT was used solely for the purpose of language enhancement in the preparation of this protocol. It did not generate content for the study protocol, contribute to ideation, or provide any statements or references used herein. ChatGPT is not listed as an author, and its use was strictly limited to linguistic improvements. We adhered to all applicable artificial intelligence–related policies, regulations, and best practices in the use of this tool, ensuring that its application was in compliance with ethical standards for academic publication.

This review was supported by the Social Sciences and Humanities Research Council's (SSHRC) Insight Development Grant (grant 430-2023-00080). SSHRC had no role in the design, execution, interpretation, or writing of the manuscript.

Data Availability

This review protocol's supporting data are shared in the manuscript appendices, enhancing transparency and understanding. These appendices include the search strategy, data extraction tool or instrument, table of key findings, and term map diagram, offering insights into our methodology, data analysis, findings, and conceptual framework. For further details or clarifications, readers are encouraged to contact the corresponding author.

Declaration

AAH, YMY, K Metersky, and SG are registered nurses and researchers deeply committed to issues of equity and social justice in practice and inquiry and situate themselves as immigrants working to support the health and well-being of refugee groups. The work of this scoping review represents a continuation of a program of research dedicated to supporting meaningful hosting, settlement, and integration of refugee groups as a fundamental aspect of promoting and protecting their health and well-being.

Authors' Contributions

AAH contributed to the conceptualization of the review topic. K Mahsud contributed to developing and running the search strategies. AAH, YMY, K Metersky, and SG contributed to developing the review methods and criteria, providing feedback for the search strategies, and drafting and critically reviewing the manuscript.

Abstract

Background: The number of people in society living with dementia is growing. In Canada, most people who live with dementia live at home, often in a neighborhood setting. Neighborhood environments can be a source of independence, social engagement, and well-being. They can also contain barriers that limit physical activity, social engagement, and well-being. A dementia-friendly neighborhood includes assets that support persons living with dementia and their caregivers in multiple life domains, including those that support walking within the neighborhood environment.

Objective: The objectives for this scoping review are twofold. First, focusing on walkshed analysis, we aim to extend scholarly understandings of methodological practices used in the monitoring and evaluation of dementia-friendly neighborhoods. Second, we aim to provide clear and practical guidance for those working in planning, design, and public health fields to assess the neighborhood context in support of evidence-based action to improve the lives of persons living with dementia.

Methods: The study design follows Arksey and O'Malley's scoping review framework and PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) guidelines. We will conduct a search of peer-reviewed studies in 6 electronic databases to identify the use of Geographic Information System analysis to measure the walkshed of persons living with dementia in a community setting. As age is a primary risk factor associated with dementia, we will also include studies that focus more broadly on community-dwelling older adults aged 65 years and older. Data will be extracted, analyzed, and represented according to 3 domains. This includes study details, walkshed analysis methods, and criteria and indicators used to measure dementia-friendly neighborhoods.

Results: The results of the study and the submission of a manuscript for peer review are expected in June 2024. The results of the review are expected to contribute to an understanding of methods for monitoring and evaluating dementia-friendly neighborhoods. Expected findings will include a detailed breakdown of current parameters and routines used to conduct walkshed analysis. Findings will also convey criteria that can be operationalized in a Geographic Information System as indicators to assess barriers and facilitators to walking in a neighborhood setting.

Conclusions: As far as we are aware, the proposed scoping review will be the first to provide comprehensive methodological or technical guidance for conducting walkshed analysis specific to persons living with dementia. Both the scalability and objective nature of walkshed analysis are likely to be of direct interest to public health practitioners, planners, and allied professionals. Clearly documenting methods used in walkshed analysis can spur increased collaboration across these disciplines to enable an evidence-informed approach to improving neighborhood environments for persons living with dementia.

KEYWORDS

dementia-friendly; neighborhood; persons living with dementia; walkability; walkshed

Introduction

Overview

Walkshed analysis identifies the extent of the community environment surrounding a central location that is accessible at a scale where walking is a competitive mode of mobility [1]. Once a walkshed is delineated in a Geographic Information System (GIS), criteria and indicators can identify barriers and enablers to walking [2]. Walkshed analysis is relevant to planning and public-health partnerships that seek to support persons living with dementia. More than 55 million people are currently living with dementia across the world. The global prevalence of dementia is projected to continue to rise by approximately 10 million new cases per year [3]. In Canada, most people experiencing dementia live at home. As of 2016, around 69% of those aged 80 years or younger were living outside of the long-term care system [4]. As an umbrella term, dementia captures the experience of progressive cognitive decline. It can impact an individual's mood, behavior, and actions, including the performance of key activities of daily living [5]. There are many types of dementia, including Alzheimer dementia, vascular dementia, frontotemporal dementia, lewy body dementia, mixed dementia, and young-onset dementia. Alzheimer disease is the most common cause, contributing to 60% to 70% of cases of dementia [6].

Literature on dementia-friendly communities (and neighborhoods) takes a relational view [7,8]. This view acknowledges that well-being is conditioned by interrelated aspects of a person's social, built, and ecological surroundings [8-10]. Accordingly, scholars identify dementia-friendly environments as the arrangement of supportive assets into a community fabric that promotes meaningful societal engagement for persons living with dementia and their caregivers [11]. This includes the complex social relations that persons living with dementia experience in a community setting, making the physical neighborhood part of a relational and moral context [12,13].

Scholarship on dementia-friendly communities and neighborhoods stems from calls to better support persons who are living with dementia outside of an institutional setting [11]. These calls reflect the fact that scholars have long viewed neighborhoods as a central relational context shaping individual behavior and life quality [14]. As early as the turn of the 20th century, ideas about neighborhood planning in North America drew on sociological concepts such as Charles H Cooley's primary group. The primary group and similar concepts asserted that the neighborhood was the main setting for the social relations that informed one's perspectives and ideals [15].

A long fascination with neighborhood environments helps explain the growing effort to understand how the neighborhood can enable or hinder self-determination for persons living with dementia. This includes aspects of identity development and one's ability to shape life balance [10,12,16]. Remaining close to the home, or aging in place, is also "closely intertwined with (a person's) sense of self and identity" [17]. By contrast, moving away from familiar areas can have negative effects on persons living with dementia [18]. To remain active and engaged within their environments while aging in place, persons living with dementia need special considerations and support in their neighborhoods [17].

The influence of the built environment on a sense of community and one's place therein remains up for debate in an increasingly mobile and digital society [19,20]. At the same time, there is a convincing body of evidence demonstrating that planning and design can impact behavior. The extent to which a neighborhood setting encourages or discourages important social and health behaviors such as walking is a particular focus for planning-health partnerships [21-23]. There is also a growing body of evidence illustrating that walking outdoors boosts quality of life for those living with dementia, contributing to improved mood, quality of sleep, and sense of freedom [17,24,25].

Urban planning scholar Lawrence Frank significantly advanced the conception and measurement of walkability. He describes walkability as the extent to which an environment's social and physical characteristics promote walking as a competitive and desirable form of mobility [26,27]. Recent work has extended the idea of walkability to a more encompassing notion of "active living environments." Active living environments are defined as "the emergent natural, built, and social properties of neighborhoods that promote physical activity and health and allow for equitable access to health-enhancing resources" [28].

Scholars have used a wide variety of methods to study walkability and its relation to walking behavior. These include phenomenological interviews [29], cross-sectional community surveys [30], observational techniques [31], surveys [32,33], photovoice [34,35], and in-situ walking interviews [12]. Scholars have also deployed criteria and indicators that enable monitoring and evaluation of the social, built, and ecological environments that make up a city [36]. In some cases, criteria and indicators are operationalized using a geospatial approach that assesses barriers and facilitators to walking in a small area (eg, 1 km) surrounding a central location such as a residence. This approach is often referred to as walkshed analysis.

In North America, walkability is now well researched within urban settings in the context of the "general population." By comparison, factors that shape walkability for members of equity-deserving groups, particularly persons living with dementia, are comparatively understudied. There is a need to better document (1) what walkability criteria and indicators are relevant to the lived experience of persons living with dementia, (2) how methods are operationalized to examine barriers and facilitators using a walkshed approach, and (3) where barriers and facilitators of walkability for persons living with dementia

may align or conflict with those of other populations. Given these needs, the objectives for this scoping review are twofold:

1. Focusing on walkshed analysis, extend scholarly understandings of methodological practices used in the monitoring and evaluation of dementia-friendly neighborhoods.
2. Provide clear and practical guidance for those working in planning, design, and public health fields to assess the neighborhood context in support of evidence-based action to improve the lives of persons living with dementia.

To achieve the preceding objectives, this scoping review will address the following research question: What dimensions, criteria, and indicators can be recognized within the academic literature for measuring neighborhood walkability for persons living with dementia based on a walkshed methodology?

Existing Reviews

This protocol was informed by an initial review of existing peer-reviewed literature. The purpose of this review was to identify possible knowledge syntheses on the use of walkshed methodology to document barriers and facilitators faced by persons living with dementia. Table 1 summarizes key aspects of 6 related knowledge syntheses. All but 1 of the identified studies were published within the past 5 years [36]. A total of 2 of the studies directly focused on persons living with dementia. Other studies focused on dementia risk factors among older adults (see Table 1).

Table 1. Summary of comparable existing knowledge syntheses as they relate to the proposed scoping review.

Reference	Title	Objective	Population focus	Addresses aspects of walkshed methods	Addresses objective criteria
Akinci et al [21], 2022	How different are objective operationalizations of walkability for older adults compared to the general population? a systematic review	Summarize and compare methods used to operationalize objective walkability for older adults and the general population	Older adults or general population	Yes	Yes
Cerin et al [36], 2017	The neighbourhood physical environment and active travel in older adults: a systematic review and meta-analysis	Identify correlates of neighborhood physical features and active travel in older adults and quantify the strength of associations	Older adults	No	Yes
Sturge et al [37], 2021	Features of the social and built environment that contribute to the well-being of persons with dementia who live at home: a scoping review	Summarize evidence from qualitative studies about how social and built environment features influence well-being for persons living with dementia	Persons living with dementia	No	Yes
Gan et al [25], 2022	Dementia-friendly neighbourhood and the built environment: a scoping review	Synthesize knowledge and support policy direction related to dementia-friendly neighborhood environments and attendant psychosocial outcomes	Persons living with dementia	No	Yes
Peters et al [2], 2020	Measuring the association of objective and perceived neighborhood environment with physical activity in older adults: challenges and implications from a systematic review	Assess the correlates of neighborhood characteristics and physical activity in older adults to provide a body of evidence to support neighborhood environmental interventions	Older adults	Yes	Yes
Chen et al [38], 2022	Neighbourhood-built environment associated with cognition and dementia risk among older adults: a systematic literature review	Assess the state of current knowledge on the links between neighborhood environments and cognitive health in older adults	Older adults at risk of dementia	No	Yes

Gan and colleagues [25] reviewed 29 studies and documented methodologies ranging from applications of virtual reality to measurements of statistical association. No use of walkshed methods was reported. The authors also assessed the psychosocial outcomes of outdoor use (eg, increased social agency, anxiety, and promotion of personhood) and built environment characteristics that facilitate use and participation (eg, land use diversity, presence of landmarks, and irregular street grids).

By contrast, Sturge and colleagues [37] focused solely on qualitative studies exploring how social and built environments contribute to the well-being of persons living with dementia at home. Under a theme examining "connection to society and supportive relationships," the authors review 4 key areas of support. These include contact with friends and family, social networks afforded by formal events and professional services, connections available across a host of neighborhood settings (eg, pubs and cafés), and the mixed reactions persons living with dementia can experience when disclosing their diagnosis. A second theme titled "interaction with natural environments and public space" examines supports (eg, parks and sounds of children playing) and barriers (eg, complex street environments and noise from traffic).

Both Peters and colleagues [2] and Akinci and colleagues [21] review (respectively) aspects of walkshed methodology in the context of older adults or older adults and the general public. Neither focused specifically on persons living with dementia. Peters and colleagues [2] distinguish between subjective and

objective measures and discuss the use of accelerometers, GIS, and field-based audit approaches. They document key aspects related to the use of walkshed methods with older adults. Elements include operational definitions of a neighborhood, walking times or distances used to define a walkshed, and neighborhood attributes associated with walking and other physical activity. Akinci and colleagues [21] similarly report on GIS-based methods for spatial analysis. They report on walkshed buffer types and sizes and 167 different walkability variables across 24 studies of older adults.

The identified 6 studies are each related to the aim of this proposed scoping review. None directly cover the realm we seek to document. In 4 cases, the studies do not review objective walkshed methods. The remaining 2 cases do not focus on persons living with dementia.

Methods

Study Eligibility

The primary objective of this study is to report on research relevant to the use of walkshed methodology. We are specifically interested in walkshed analysis which involves the monitoring and evaluation of barriers and facilitators to walking in a neighborhood setting. Eligible studies will include those that reveal details about how to define a walkshed in a manner that is appropriate to the walking experience of persons living with dementia (eg, walking distance used to define a walkshed). We anticipate that this group of studies may largely involve quantitative, GIS-based case studies. Studies that document criteria and indicators that can be used to identify and track barriers to and facilitators of walking will also be included. We anticipate that the methodologies of these studies will be more diverse, including qualitative, quantitative, mixed methods and review articles.

We will include publications from any date in our initial pool. This may influence the variability of results, such as key definitions. A start date is not included because we anticipate that there will be a limited number of available studies related to walkshed analysis for our focus population. An open-ended start date may also allow us to identify when walkshed analysis emerged in various literatures.

We will not limit eligibility by geographic scope and will include studies from any country or region. Studies from a diverse range of geographic settings will also be eligible. This will include various community environments (eg, urban, suburban, exurban, and rural), but we anticipate that urban and suburban settings will predominate. Due to the composition of the team, eligibility will be limited to studies available in English. Our primary goal is the transfer of knowledge about rigorous methodological techniques within and beyond the academic sphere. As such, only peer-reviewed journal articles will be eligible. For additional details on study inclusion or exclusion, see Textbox 1.

Textbox 1. Summary of the inclusion and exclusion process and the criteria (framed as prompts) used to exclude studies.

Review level

- Level 1: title, abstract, and keyword review
  - Does the study include a focus on geographic areas within a community setting?
  - Does the study include a focus on outdoor spaces?
  - Does the study include a focus on people's use of the community environment by walking or other forms of non-motorized mobility?
- Level 2: full text article review
  - Did the study collect and analyze primary or secondary data following a structured methodological approach?
  - Does the study identify measurable criteria and indicators related to walkability or report on the use of walkshed methods?
  - Does the study specifically focus on environmental use by persons living with dementia or older adults?

Population and Setting

This review will be guided by Arskey and O'Malley's [39] 6-step scoping review process. It will include studies that involve participants recognized to be living with dementia or mild cognitive impairment and who reside in a community setting. Studies that focus on persons living in congregate care-based facilities such as assisted living homes and long-term care homes will be excluded. We expect to find few published studies that explicitly focus on this population in the context of operational aspects of walkshed methodology. As age is the primary risk factor associated with dementia, we will also include studies that focus more broadly on community-dwelling older adults aged 65 years and older [6]. We will track differences in existing evidence between these population groups.

Search Strategy

Our search strategy was developed by a project manager with experience conducting scoping reviews. It involved consultation with a research librarian and the broader research team. The latter consultation involved a workshop that iteratively identified, tested, and respecified search domains and terms. Our search strategy includes a combination of subject headings and title or abstract-focused keyword searching (Textbox 2). These strategies target the intersection of an activity or policy domain (walking), an environmental setting domain (outdoor neighborhood setting), and a population focus domain (persons living with dementia and older adults). We will apply search

strings to 6 electronic databases known to publish high-quality research around our focus domains (PubMed, Medline, CINAHL, APA PsycINFO, Business Source, and Web of Science). Endnote will be used to manage citations, and DistillerSR (DistilerSR Inc) and Excel (Microsoft Corporation) will be used to manage the inclusion, data extraction, and charting stages of this review.

Textbox 2. Domain areas and search terms to be used in search strings for database searches.

Domain areas and search terms

- Activity or policy - walking, walkshed, walkability, walk, wayfinding, way finding, indicator, criteria, dimension, requirement, experience, audit, measure
- Environmental setting - footpath, greenspace, green space, population density, rural population, neighbourhood characteristics, city planning, communit*, neighbo*rhood*, built environment, urban design*, urban planning, town planning, city planning, building densit*, social densit*, population densit*
- Population focus - dementia, alzheimer*, aged

Article Selection Process

After removing duplicate sources from our initial study pool using DistillerSR, we will use DistillerSR to complete screening at 2 levels. At level 1, we will assess the title, abstract, and keywords of each potential source. This assessment will include 2 independent reviewers using the level 1 inclusion criteria in Textbox 1. Studies will be excluded if both reviewers definitively identify relevant content and answer no to any of the criteria prompts. Studies will be moved to level 2 screening if a prompt cannot be answered definitively. To promote consistency at level 2 article screening, 2 reviewers will assess the full text of all remaining sources. Studies will only be included if reviewers can definitively answer yes to all inclusion prompts. We will address discrepancies at each level at a team meeting that involves a reassessment of the source and a consensus decision made by the team.

Data Charting and Representation

Data charting and representation will follow 2 interrelated steps outlined by Arksey and O'Malley [39]. Common practices in scoping review methodology and existing knowledge syntheses documented above informed the creation of the data charting schema listed below. Using this schema, we will develop a data matrix in Excel. This matrix will organize data and allow for the analysis of key items of information. Following guidance from Levac and colleagues [40], we will review and iteratively update the initial schema shown in Table 2 as the final study pool is examined. A total of 2 reviewers will extract data for a subset of papers (n=5). They will compare and update the schema as they reflect on processes and outcomes. Final data extraction will be completed by a single reviewer.

Table 2. Initial data charting schema for creation of data charting matrix.

Study details	Walkshed methods	Criteria and indicators
Title	Definition of walkability	Measurement domains reported
Lead author	GIS[a] operationalization of walkshed	Measurement criteria reported
Year of publication	Distance or time parameter	Criteria used with persons living with dementia
Journal name	Data sources and types	Criteria used with older adults
Journal discipline (if applicable)	GIS routines (if reported)	Measurement indicators reported
Country of lead author's institution	Population focus	GIS based indicators
Study method	N/A[b]	Data sources for indicator calculation
N/A	N/A	Method for indicator measurement or representation

[a]GIS: Geographic Information System.

[b]N/A: not applicable.

Beyond tracking the breadth (eg, diversity of methods) and location (eg, countries of origin) of literature, descriptive numerical summaries will examine 2 key topics. First, we will document the tools, data, and parameters used to define a walkshed. The review will make a contribution to the existing literature by documenting implementation approaches specific to the context of persons living with dementia. We will also compare these approaches to those used in studies of an older adult population. Second, we will chart criteria and indicators used to measure aspects of dementia-friendly neighborhood and community environments. By documenting indicators that scholars have operationalized using GIS-based analyses, we will make a key contribution to the transfer of the methodology.

The final scoping review will use descriptive results (eg, diversity of methods) represented using a combination of summary tables and figures (eg, Sankey diagrams). Limited textual information will support these visual elements. We will represent comparative results related to criteria and indicators as a larger data matrix. This matrix will visualize how

researchers have operationalized indicators in GIS for the 2 populations of interest. A longer textual description will contextualize these results. Finally, using thematic analysis, we will convey synthesized themes that capture nuance lacking in the descriptive and comparative results [41-43]. We expect to highlight considerations for the use of walkshed methodology not yet documented in recent studies focused on older adults [2,21]. We also expect to identify where criteria used to assess walkability for persons living with dementia and older adults converge and diverge. The risk of bias will not be assessed. This is consistent with the broad nature of our review question and the norms identified in the development of the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) [44,45].

Results

The results of the study and the submission of a manuscript for peer review are expected in June 2024.

Discussion

Overview

Scholars from the fields of planning, public health, urban design, gerontology, and architecture have produced a wealth of evidence and guidance related to walkability. Branching out from the "general population," studies increasingly focus on targeted population groups. These foci better recognize the social, cultural, and demographic barriers and enablers to walking that shape one's experience of the neighborhood. The proposed scoping review will synthesize the growing evidence base with specific reference to persons living with dementia. By including relevant studies focused on an older adult population, the review will also identify where current best practice for monitoring and evaluation diverges and converges for these populations. Expected findings include a detailed breakdown of current parameters and routines used to conduct walkshed analysis. Findings will also convey criteria that can be operationalized in GIS as indicators to assess barriers and facilitators to walking in a neighborhood setting.

Studies already identified here have documented monitoring and evaluation methods relevant to walkability for persons living with dementia. Methods include interviews, community survey techniques, and field audits of the neighborhood environment. Our planned focus on GIS-based walkshed analysis will further document a highly scalable monitoring and evaluation tool and technique.

Limitations

The final scoping review will be subject to limitations, despite following accepted methodological practice [39,40]. First, as a scoping review, there will not be a quality assessment of studies, which presents a risk of bias. Second, only English studies will be included, which will overemphasize evidence and practice from western countries. Third, we expect that the use of walkshed analysis for persons living with dementia will be an offshoot of techniques and literature focused on older adults. There may therefore be limited literature specific to persons living with dementia. To mitigate the risk of making assumptions about the transfer of methodological guidance from one population to another, we will explicitly track and compare findings across groups.

Conclusions

As far as we are aware, the proposed scoping review will be the first to provide comprehensive methodological or technical guidance for conducting walkshed analysis specific to persons living with dementia. There are 3 target audiences for this scoping review. These include applied academic researchers in the field of public health, applied academic researchers in the fields of urban planning and design, and evidence-based practitioners across these fields. Scholars identify neighborhood environments as an upstream source of barriers and enablers that shape walking behavior and associated health and well-being cobenefits [12,17,25]. Understanding the individual and population health impacts of neighborhood environments requires the expertise of health researchers and practitioners. Understanding how neighborhood environments came to be and how to reshape them through land-use and built-form interventions requires the expertise of planners and designers. By clearly documenting methods used in walkshed analysis, our goal is to spur increased collaboration across these disciplines to enable an evidence-informed approach to improving neighborhood environments for persons living with dementia.

Acknowledgments

The authors would like to thank the DemSCAPE team for their efforts.

Data Availability

The data generated and analyzed during this study will include content extracted from published, peer-reviewed journal articles. Full details about parameters, data sets, and Geographic Information System routines used in walkshed analysis, as well as a full list of associated indicators, will be reported in the scoping review publication. Additional data generated and analyzed during the study will be available from the corresponding author upon reasonable request.

Conflicts of Interest

None declared.

Abstract

Background: The global shortage and maldistribution of health care workers, especially medical doctors, pose a significant threat to achieving the United Nations' sustainable development goal 3 of ensuring well-being and healthy lives for all. Low- and middle-income countries (LMICs) are disproportionately affected by this crisis, with a high rate of brain drain from rural to urban areas, as well as to high-income countries. Various retention strategies have been implemented in different settings and organizations. However, their effectiveness remains underexplored, particularly in LMICs.

Objective: We aim to review the available retention strategies for medical doctors in LMICs and to determine the effectiveness of the various strategies. This review aims to compile relevant research findings on this issue to generate a thorough summary of all the retention strategies practiced in LMICs and, more importantly, to provide the current state of evidence of the effectiveness of these strategies in retaining medical doctors in countries with limited resources and high disease burden.

Methods: The structured framework given by Arksey and O'Malley will serve as the basis for conducting this scoping review. A comprehensive search strategy will be conducted across 4 electronic databases (PubMed, EBSCOHost, Scopus, and ScienceDirect). A systematic approach following the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines will be executed to search, screen, review, and extract data from studies that meet predefined inclusion criteria. Data encompassing bibliographical information, study location, retention strategies, influencing factors, and outcomes (effectiveness) will be obtained from the selected studies using standardized data extraction. Endnote and Microsoft Excel will be used for reference management and removal of duplicate studies. A narrative synthesis will be performed after categorizing and analyzing all the extracted data to identify recurrent themes.

Results: This ongoing review will generate a comprehensive compilation of retention strategies implemented in LMICs to prevent brain drain among medical doctors. Data extraction is currently in progress, and completion is expected by early 2024. Themes regarding the types of strategies, influencing factors, and outcomes will be synthesized. The findings will highlight effective retention strategies, gaps, and challenges in implementation for the benefits of future research. By identifying common barriers and facilitators, this review will provide insights into enhancing the policies and initiatives for doctor retention in LMICs.

Conclusions: This scoping review explores the retention strategies practiced in LMICs and attempts to identify effective strategies from existing research. By evaluating the barriers and challenges that influence the effectiveness of these strategies, policymakers and health care leaders can strive to obtain balanced and optimal health human resources in their respective organizations and countries.

KEYWORDS

health care workforce; retention strategies; medical doctors; low-income and middle-income countries; scoping review

Introduction

Overview

Optimal functioning of the health care system relies heavily on the quantity and quality of health care workers (HCWs). The ability to enhance health service coverage and ensure that everyone in the population has access to the highest possible level of health relies on the availability, accessibility, acceptability, and quality of the health care workforce [1]. However, in recent years, a critical global challenge has emerged: a crisis characterized by a shortage and maldistribution of HCWs including doctors, nurses, and other professionals. This crisis poses a significant threat to achieving the United Nations Sustainable Development Goal 3 (promoting well-being and ensuring healthy lives for people of all ages) [2]. Nowhere is the impact of this challenge more acute than in low- and middle-income countries (LMICs), where limited financial and human resources compound the challenge of providing essential health care services. LMICs represent various nations in a diverse economic spectrum, encompassing low-income, lower-middle-income, and upper-middle-income countries. On the basis of the World Bank classification [3], low-income economies are defined as those with a gross national income (GNI) per capita of ≤US $1135 in 2022; lower middle-income economies are those with a GNI per capita between US $1136 and US $4465; upper middle-income economies are those with a GNI per capita between US $4466 and US $13,845. In contrast, high-income economies are those with a GNI per capita of ≥US $13,846. Remarkably, this classification encompasses 137 countries, constituting 63% of all nations worldwide [4].

The World Health Organization projected that by 2030, countries, predominantly LMICs, will face a substantial deficit of approximately 18 million health workers [5]. This significant shortage will greatly hamper the capacity to deliver vital health care services to those populations in most significant need. Simultaneously, countries with varied levels of socioeconomic development encounter different challenges in health human resource planning related to employment, deployment, and retention of their workforce [6]. Medical doctors are vital to the health care system because of their expertise, care, and impact. They play a crucial role in ensuring optimal health care delivery within health care institutions [7]. However, many parts of the world are grappling with a shortage of doctors, which stems from various factors such as emigration, imbalanced distribution between rural and urban areas, and shifts in population demographics [5]. There is a global shortage of approximately 2.8 million doctors [5], with LMICs bearing the brunt of this burden [8]. This scarcity is further exacerbated by the phenomenon of brain drain, with doctors from LMICs emigrating to high-income countries (HICs) due to better job offers and career progress. In some HICs, foreign-trained physicians sometimes amount to one-fifth of the total number of doctors in the workforce [9]. The movement of doctors from lower-to higher-income settings has resulted in substantial economic consequences, not solely due to the transfer of human capital, but more importantly, indirect impacts, such as increased morbidity and mortality associated with the loss of doctors [10].

Apart from brain drain to other countries, there is also a high rate of doctors' resignations from the public health care system to join the more lucrative private sector, especially in countries with dual health care financing systems. Job dissatisfaction, including unsatisfactory work environment (lack of facilities, inflexible working hours, poor career progression, lack of professional autonomy, and ineffective management style) and unfavorable service conditions (poor salaries and funding, duplication of activities), are closely associated with high mobility, especially from the public to private sectors [11-13]. The phenomenon of HCWs resigning poses a significant obstacle to the advancement of the health care system in any given country, making it a topic of widespread concern [14]. The increasing number of resignations among HCWs, particularly in the Asia Pacific region, has been reported as the greatest threat to the development and sustainability of a resilient health care system in a recent study [15]. Despite efforts to increase supply and retain them, the workforce is still struggling to meet public health demands, as demonstrated in Spain and Brazil [16]. The same issue was also reported in India, where the vacancy rates were nearly 21% and 42% for medical officers and specialists at health centers, respectively [17].

Addressing the global health workforce crisis requires comprehensive strategies at both national and international levels. Retaining HCWs is a challenge in almost every country, be it HICs such as Canada, Australia, and Scotland or LMICs in Africa and Asia, especially in rural and remote areas [18,19]. Retention encompasses the duration between the initial engagement with a service and the eventual separation or departure from that service. It serves as a metric to gauge the length of time an individual stays within the service [20]. Retention strategies in the context of doctors encompass a range of interventions designed to attract and keep doctors in particular settings, such as remote or rural areas, with a specific focus on LMICs [21-23]. These strategies are aimed at mitigating doctor shortages and ensuring equitable health care access for underserved populations. Policy makers and health care managers must comprehend the factors that influence doctor retention and formulate targeted measures to address these factors [24,25]. Effective retention strategies contribute to the

stability and continuity of health care delivery, especially in regions with limited accessibility [21,23].

The significance of retention strategies lies in their capacity to yield various benefits, including cost savings, employee engagement, productivity, knowledge retention, competitive advantage, and organizational stability [26]. Addressing doctor shortages requires tailoring retention strategies to the unique challenges and requirements of health care professionals in each country. This is particularly critical in LMICs, where health care systems often contend with fragility, staffing shortages, limited resources, and a higher disease burden [27-29]. Furthermore, these countries grapple with brain drain challenges, issues of health care accessibility, weakened political will, and unstable governmental systems [30-33].

There are many known impediments to the retention of doctors, the most common being unfavorable working conditions, limited opportunities for career advancement, nonappealing financial incentive structures, unsupportive community environments, and the restriction of financial resources [34,35]. Other barriers include inadequate living standards, excessive workloads, insufficient equipment, lack of opportunities for skill enhancement and private practice, and unfair promotion practices [36]. In addition, stress, burnout, and insufficient work-life balance also play a role in doctors' decision to leave [37]. Strategies aimed at addressing these barriers have been proposed and implemented at various levels and organizations, such as providing career development plans, ensuring minimum financial incentives, establishing avenues for private practice, enhancing work conditions, providing opportunities for skill improvement, and implementing transparent and equitable promotion systems.

Objective of Conducting the Scoping Review

Numerous publications have discussed the factors influencing the retention of doctors in LMICs [38-41], providing suggestions for various strategies and initiatives. However, there is limited research evaluating and summarizing the effectiveness of these strategies, particularly in LMICs. Therefore, the objective of this scoping review is to identify and delineate the available retention strategies for medical doctors in LMICs and to determine the effectiveness of these strategies.

To determine if prior research has addressed the same subject, we performed an initial exploratory literature review. Our search revealed the absence of existing or ongoing systematic reviews and scoping reviews related to our specific topic. McClain et al [42] primarily explored retention strategies and barriers concerning nurses, while Noya et al [43] concentrated on the rural and remote medical workforce, and Verma et al [22] focused on primary care doctors in general.

Conversely, our review aims to synthesize research evidence to generate an all-encompassing perspective on the effectiveness of retention strategies for doctors in LMICs. This synthesis will identify gaps in existing literature, pinpointing areas that require additional investigation within the context of doctor retention in resource-constrained countries with high disease burden. Our inclusive methodology considers a broad spectrum of studies and settings and delivers a comprehensive evaluation of these strategies.

Methods

Ethical Considerations

As the methodology for this scoping review solely entails reviewing and collecting data from existing literature without involving human participants, ethical clearance was waived by the Medical Research and Review Committee Malaysia.

Protocol Design

Overview

For this scoping review, we will use the methodological framework introduced by Arksey and O'Malley [44], who structured the review process into 5 stages. In addition, we enhanced the quality and rigor of our review based on the guidelines from the Joanna Briggs Institute Manual [45]. We will also incorporate the recommendations provided by Levac et al [46] to ensure consistency in assessing the studies during this scoping review. Transparent reporting will be ensured by using the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines [47]. We describe the protocol for this scoping review in five stages:

1. Formulating research questions
2. Identifying relevant studies
3. Selecting eligible studies
4. Charting the data
5. Collating, summarizing, and reporting the results

Stage 1: Formulating Research Questions

Following the recommendations given by Levac et al [46], we set our objective to explore strategies or interventions available for retaining doctors within health care institutions in LMICs and to identify effective measures to prevent doctor attrition. Therefore, we formulated two specific research questions for this review:

1. What are the retention strategies currently being implemented for doctors in LMICs?
2. Which strategies have been identified and evaluated as effective in retaining doctors in LMICs?

Stage 2: Identifying Relevant Studies

A meticulous search strategy plays a vital role in ensuring the inclusion of pertinent studies in scoping reviews. The research team has developed a comprehensive search strategy that encompasses various keywords and their synonyms related to the topic of interest. We selected search terms based on the research questions, including terms such as "retention," "retain," "maintain," "doctor," "physician," and "general practitioner." These terms has been used both individually and in combination following the iterative process inherent in the scoping review methodology.

The final search string, adhering to Boolean logic, takes the following form: *(retention OR retain OR intention to leave OR intention to stay OR motivation to stay OR willingness to work) AND (doctor OR physician OR specialist OR general practitioner OR medical practitioner) AND (low- and middle-income countries OR LMIC)*. This meticulously designed search string aimed to gather all pertinent materials aligned with the objectives of this scoping review.

Various types of documents were screened during this stage, including journal articles, documents, or regulatory reviews, sourced from each of the 4 databases: PubMed, EBSCOHost, Scopus, and ScienceDirect. These databases were selected for their relevance to health and human resource services. During the screening process, if the available information in the title and abstract is insufficient to make an informed decision, the articles will be included for full-text screening. Adhering to the standard approach for conducting scoping reviews, we will not conduct quality appraisal of the included studies. An example of a preliminary MEDLINE (PubMed) search strategy is presented in Textbox 1.

Textbox 1. Example of MEDLINE (PubMed) search strategy.

Uzbekistan[Title/Abstract] OR Vanuatu[Title/Abstract] OR Venezuela[Title/Abstract] OR Vietnam[Title/Abstract] OR West Bank OR Yemen[Title/Abstract] OR Zambia[Title/Abstract] OR Zimbabwe[Title/Abstract])

Stage 3: Selecting Eligible Studies

The review process begins with the team convening to discuss decisions related to study inclusion and exclusion based on the principles of transparency, reproducibility, and rigor. This practice further advances a systematic and unbiased approach throughout the review process. The inclusion and exclusion criteria are presented in Textbox 2. We chose to focus primarily on studies published in English language due to their global prevalence, ensuring a comprehensive analysis, increased accessibility, and reduced language-related biases due to limited translation resources. Furthermore, the focus on studies published in English language streamlines the accessibility and application of research findings, making them readily available and applicable to a broader audience.

To maintain the scientific rigor of this review, we made a deliberate choice to exclude gray literature from our review, such as dissertations, essays, consensus, reports, theses, and government documents. However, while gray literature may provide valuable insights that supplement traditional academic

literature [48], it presents challenges in terms of systematic search and quality verification [49].

Following the PRISMA-ScR guidelines [47], the first step begins with identifying articles from various databases. Duplicates and irrelevant studies will then be removed. Abstracts or full texts will be evaluated based on predetermined inclusion and exclusion criteria to determine eligible studies. This screening process involves careful examination of both the retrieved search results and their reference lists. To ensure the most relevant search results, we will refine the literature search throughout the review process. At least 2 investigators will independently assess the eligibility of publications by reviewing their titles and abstracts. Publications deemed relevant to this scoping review are obtained in full text and reviewed against the same inclusion criteria.

In cases of disagreement during publication selection, both reviewers will revisit the full-text articles to reach a consensus. If consensus cannot be reached, an impartial third reviewer will be consulted to resolve the disagreement. Consistent meetings and discussions at different stages of the article review process are essential to maintain alignment, address challenges, refine search strategies, ensure consistency, and foster a collaborative and efficient approach. The scoping review will record and report reasons for excluding sources of evidence in the full text that do not meet the inclusion criteria. The reporting of the review will incorporate a PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram (Figure 1), which visually presents the screening and selection process [50].

Textbox 2. Inclusion and exclusion criteria of the study selection process.

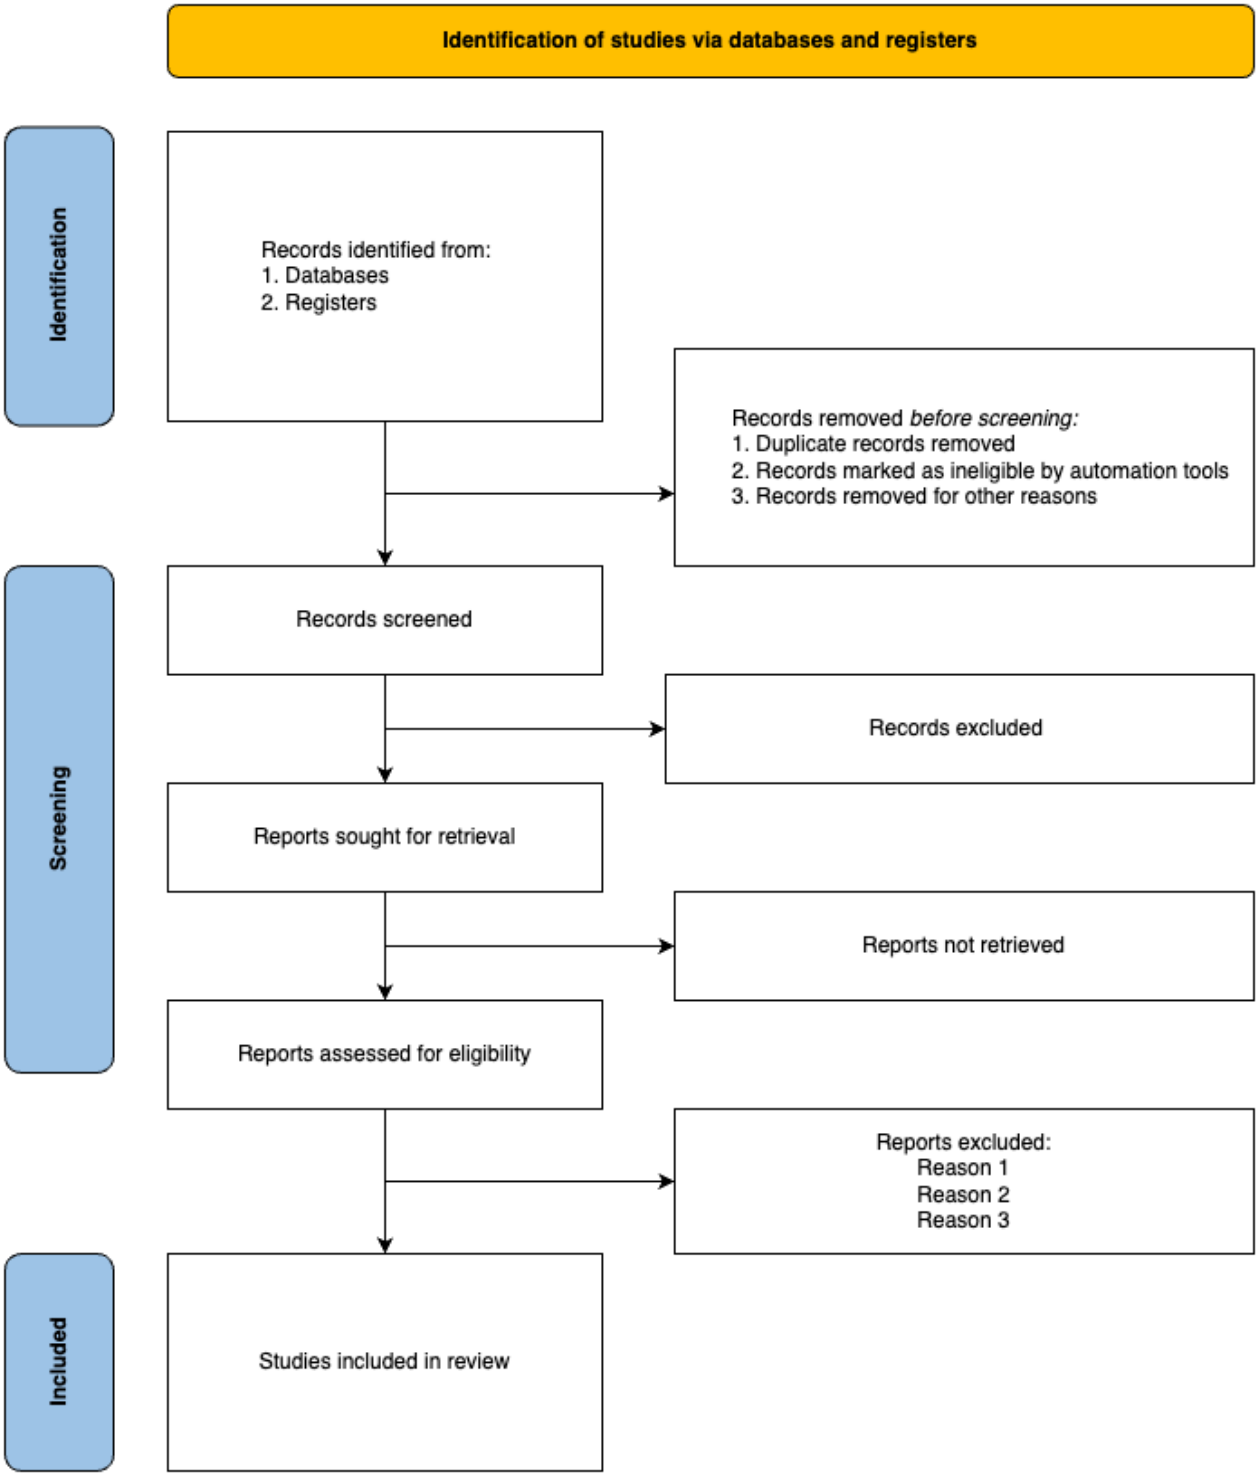
Inclusion criteria

- Publication year: January 2013 to February 2023
- Language in publication: English
- Research location: low- and middle-income countries (LMICs)
- Target population: medical doctors
- Types of documents: journal articles, documents, or regulatory reviews with proper references

Exclusion criteria

- Publication year: before January 2013 and after February 2023
- Language in publication: other languages
- Research location: other than LMICs
- Target population: other health care professionals
- Types of documents: dissertations, essays, consensus, government documents, reports, and theses that do not have any proper references

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram for the scoping review process.



Stage 4: Charting the Data

The data extracted from the full-text articles will be organized into a data extraction table using Microsoft Excel (Microsoft Corporation). The data table will be structured to accommodate the characteristics of the data. The aim of charting the data is to create a descriptive summary of the results to address the objectives of the scoping review and to answer the research questions. This process facilitates the categorization of information before proceeding with further tabulation. For reference, Textbox 3 presents the categories corresponding to each characteristic in the data extraction table. In an iterative process, investigators will continually gather data and keep the data extraction table up-to-date. If significant data are found in records initially not designated for extraction, the data extraction form will be revised, and these additional data will be retrieved from the records already reviewed.

Textbox 3. Preliminary data extraction table.

Basic characteristics and description

- Bibliographical data
  - First author and year of publication of the article
- Article title
  - A succinct description of the content of the article
- Country
  - Name of the low- and middle-income countries
- Aims or purpose of the study
  - Expresses the intention or aspiration of the research
- Type of study
  - Study design or methodology
  - Which type of study was conducted?
- Study population
  - Physician—specialty or department
  - Number of people involved
  - Inclusion and exclusion criteria of the study
  - Demographic characteristics
  - Other characteristics
- Study location
  - Location characteristics (urban, rural, or remote or hospital or district, state, or area)
  - Institution (name)
- Factors influencing retention
  - Financial or career and professional or working conditions, personal, cultural, or living conditions factors
- Retention strategy
  - Strategy type or focus (education and regulatory or ii. monetary compensation or iii. management, and environment and social support)
  - Strategy name
  - Strategy characteristics, content, and description
  - Strategy implementation (levels, duration, and date)
- Outcomes measure
  - Description of the result (effective or successful to retain)
  - How were the turnover and results assessed?
- Barriers and challenges
  - Barriers and challenges in implementing the strategies
- Study limitations
  - Weaknesses within the research design that may influence the outcomes and conclusions of the research

Stage 5: Collating, Summarizing, and Reporting the Results

The primary goal of the scoping review is to present the narrative findings of existing literature through an analytical framework or thematic construction, without the requirement to assess the quality or significance of each study. We will use a traditional integrative review approach to compile all the identified materials. Our objective is to identify recurring themes across research and synthesize data from the selected studies. Using these themes as guidelines, we will create a literature map and present it in the form of a table, summarizing the publications and their respective characteristics.

The results of the scoping review will be organized into tables that categorize the characteristics of each publication. Accompanying these results will be narrative summaries that describe how each result relates to our research questions, including any unexpected or particularly notable findings. We will also address any gaps observed in the literature, research needs, and implications for practice. Subsequently, the outcomes of this review will be shared with relevant stakeholders, and their expertise and perspectives will be incorporated.

Results

This review will provide a comprehensive mapping of existing research and literature pertaining to the retention of medical doctors in LMICs to enhance the understanding of the complex dynamics of doctor retention. It will also assess the current knowledge and pinpoint any gaps in the literature, focusing on factors influencing doctor retention and effective retention strategies such as financial incentives, working conditions, career advancement opportunities, and personal motivations.

Furthermore, this review can offer insights into best practices and approaches for retaining doctors in LMICs to guide policy makers and health care administrators who struggle with retention challenges. They can customize the best policy recommendations based on specific needs and obstacles in local settings to improve doctor retention rates in their respective organizations and governments.

The review was initiated in May 2023, and the research protocol was finalized in July 2023. We registered the review with the Malaysian National Medical Research Register (NMRR ID-23-01994-OGW). The search, which was concluded in August 2023, yielded 9141 articles. The PRISMA flow diagram will be used to illustrate the flow of the literature search in this review [50]. The results will be presented using charts and tables, supplemented by a narrative description. Any existing literature gaps will be identified, and the significance of our findings will be emphasized in the subsequent discussion section. The review is expected to be concluded in January 2024, with the outcomes published in a journal for wider dissemination.

Discussion

Overview

Adequate investment in health care capacity is imperative to move toward the United Nations' sustainable development goals, specifically goal 3 (ensuring good health and well-being) and goal 10 (reducing inequalities), and to achieve various global development objectives, with a robust health care workforce being the top priority. Therefore, establishing a comprehensive plan that encompasses effective retention strategies to complement medical education reforms is vital to cultivating a health care environment that is equitable and resilient at both regional and global levels. Our focus on retention strategies for medical doctors is driven by their unique challenges and critical roles in health care. Doctors hold central positions in health care delivery, not only providing medical expertise but also taking a leadership role in influencing critical patient care decision-making, and their turnover can have significant negative impacts on patient care and quality of health care services [51]. Furthermore, doctors are the most affected by the brain drain crisis, especially in LMICs, leading to a significant financial burden and experience loss. Therefore, prioritizing doctor retention is vital for mitigating brain drain, reducing productivity and financial loss, and sustaining effective health care service delivery.

The shortage of doctors in LMICs represents a pressing concern that demands immediate attention and concerted efforts on a global scale, in view of its significant impact on public health. This predicament has a direct adverse effect on the health and welfare of populations residing in LMICs, as doctor shortages can impede access to crucial medical services, ultimately resulting in preventable illnesses and higher mortality rates. Moreover, cross-border brain drain exacerbates existing health care inequalities both within and between countries. Persistent disparities in the accessibility of health care services, if they continue to exist, will disproportionately affect rural and underserved areas with limited resources, thereby perpetuating social and economic inequalities and impeding advancements toward achieving universal health care coverage.

Expected Outcomes

This scoping review will present a comprehensive overview of retention strategies that have been proposed, practiced, and evaluated in LMICs as a response to overcome the challenges faced in retaining medical doctors and preventing brain drain. These strategies may encompass a wide array of approaches, including financial incentives, opportunities for professional development, initiatives to promote work-life balance, and support for career advancement. Moreover, the focus on LMICs may shed light on distinct regional or country-specific challenges and variations in customized strategies. It may also highlight the varied effectiveness of different strategies, depending on the contextual factors at play. It is unlikely to be a one-size-fits-all solution, as certain strategies may exhibit promising outcomes in bolstering medical doctor retention, while others may demonstrate limited impact depending on the local settings.

In short, this review will present common barriers and facilitators that significantly influence the successful implementation of retention strategies for doctors in LMICs. By exploring the challenges encountered during strategy implementation, we also aim to offer a more comprehensive and nuanced understanding of the factors influencing the effectiveness of doctor retention strategies in LMICs. This, in turn, can contribute to improving the retention of medical doctors in LMICs, aligning with the Sustainable Development Goal 3 goal of promoting well-being and ensuring healthy lives for everyone. Comprehension of these elements has the potential to aid policy makers and health care administrators in developing more relevant interventions and prioritizing effective strategies.

Since it is likely that different contexts play a critical role in the outcomes of various retention strategies, we will also attempt to address this connection in our review. Certain strategies, if proven successful, can also be modified and embedded within a broader health care ecosystem to benefit a wider group of health care professionals. Common factors contributing to brain drain among HCWs include financial rewards, career development, hospital infrastructure, political issues, and family issues [52]. While we focus on the dynamics surrounding medical doctors and the customized retention approach for them in this review, as the challenges faced by doctors may be unique and differ significantly from those of other groups, the comparison and extrapolation of various retention strategies for different health care professionals is a worthy topic for future research or review.

Review Limitations

This review has several limitations that deserve further discussion. First, the language restriction used in the search strategy may have unintentionally excluded relevant studies published in languages other than English. This is a significant concern because many LMICs have diverse linguistic landscapes with numerous languages. The decision to focus primarily on English was necessitated by practical considerations, such as the broader availability and accessibility of English-language research. Furthermore, we believe that the exclusion of non–English-language studies would minimize language-related biases in the review process, given the limited access to translation resources in our setting.

Another limitation of this review is the exclusion of gray literature. This decision is influenced by the difficulties associated with accessing gray literature, which encompasses issues of limited availability, inconsistent indexing, variable accessibility, and challenges in assessing the quality and reliability of information. By excluding gray literature, there is a risk of missing important findings and diverse perspectives not found in peer-reviewed academic sources. Nevertheless, although gray literature can offer valuable insights as a complement to conventional academic literature [48], it introduces difficulties in systematic retrieval and quality assessment [49], thus making it difficult to maintain the scientific rigor of this review.

In addition, this review is likely to include studies with different levels of methodological rigor and quality, and this could potentially affect the overall reliability of its conclusions and may introduce heterogeneity into our analysis. Moreover, this review aims to provide a comprehensive overview of existing literature regarding effective retention strategies for doctors in LMICs; thus, the analysis results are likely to be less in depth compared with systematic reviews that follow a more rigorous and narrowly focused methodology. Nonetheless, this broad approach is valuable for summarizing the diversity of strategies and findings in the field of doctor retention in LMICs, allowing for a holistic understanding of the subject.

Conclusions

This scoping review is fundamental in providing a better understanding of the practical implications of various retention strategies for doctors in LMICs and in drawing valuable lessons from effective strategies in existing literature. Furthermore, by highlighting emerging trends and identifying implementation challenges within LMICs, this review will pave the way for more precisely targeted policies and interventions to strengthen doctor retention in the most needed regions. It also offers valuable guidance to policy makers and health care administrators by showcasing best practices with positive outcomes, thereby refining their approach to addressing attrition and brain drain.

Acknowledgments

The authors would like to thank the Director General of Health, Malaysia for the permission to publish this paper.

Abstract

Background: Clinician-patient communication is an integral component in providing quality medical care. However, research on clinician-patient communication has shown overall patient discontent with provider communication skills. While virtual reality (VR) is readily used for procedural-based learning in medical education, its potential for teaching patient-facing communication skills remains unexplored. This scoping review aims to evaluate the effectiveness and feasibility of VR applications used for patient-facing communication skills development in medical education.

Objective: The primary objective is to synthesize and evaluate the effectiveness of available VR tools and applications used for patient-facing communication skills development in medical education. The secondary objectives are to (1) assess the feasibility of adapting VR applications to develop patient-facing communication skills in medical education and (2) provide an overview of the challenges associated with adapting VR applications to develop patient-facing communication skills in medical education.

Methods: A total of 4 electronic databases (ERIC, Embase, PubMed, and MEDLINE) were searched for primary peer-reviewed articles published through April 11, 2023. Articles evaluating the implementation of non-, semi-, and fully immersive VR training for patient- or caregiver-facing communication skills training provided to graduate, medical, or other allied health care professions students were included. Studies that assessed augmented reality, mixed reality, artificial intelligence, or VR for non–communication-based training were excluded. Study selection will include a title, abstract, and full-text screening by 4 authors. Data from eligible studies will be extracted and entered into a database and presented in tabular format. Findings will be reported according to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines for scoping reviews.

Results: As of April 11, 2023, the search strategy has been confirmed and the search has been completed. We are currently at the title and abstract screening stage. Once complete, the articles will undergo full-text screening according to eligibility criteria as described in the methods.

Conclusions: The findings of this review will inform the development of a graduate-level clinical skills research course within the Institute of Medical Science graduate department at the University of Toronto. It is also expected that these findings will be of interest to other health care–specific faculties inside and beyond our institution. Further, our scoping review will summarize the limited field of literature on VR use in medical communications training and identify areas for future inquiry.

Introduction

Effective communication skills are crucial for health care professionals to establish trust and build rapport with their patients, facilitate shared decision-making, and deliver high-quality care. Poor communication between clinicians and patients has been associated with decreased health care quality, increased human and economic cost of care, disenrollment from health care plans, poor adherence to recommended treatments, and propensity to sue for medical malpractice [1-4]. Accordingly, American medical colleges [5] and Canadian medical schools [6] have stated that clinician-patient communication is an integral component of quality medical care and highlighted the need for formal training programs at the undergraduate, postgraduate, and continuing education levels. However, research on clinician-patient communication has shown overall patient discontent even when clinicians indicate their own communication to be good or excellent [7]. Although there has been increasing emphasis placed on communication skills training in most health care curricula, significant challenges remain in their implementation and evaluation. These training approaches are often limited in time, resources, personnel, contextualization, unclear frameworks, and teaching strategies [8]. Incorporating educational tools that promote and develop patient-focused communication skills is imperative for the delivery of comprehensive care by health care professionals.

Virtual reality (VR) has emerged as a promising tool that addresses the challenges associated with limited access to health care institutions, personnel, contextualization, and feedback to evaluate frameworks and teaching outcomes. VR is defined as an educational tool that uses computer technology to generate a 3D image or environment with which a user can interact in a seemingly real or physical manner [9]. Presently, VR has been mainly used for training in procedural skills, typically for surgical training, but has been expanding to other applications as well [10]. There are currently 3 main categories of VR: nonimmersive, semi-immersive, and fully immersive. Nonimmersive VR is typically a screen-based display that is connected to handheld mechanical or haptic units [11]. Nonimmersive VR is commonly used to develop technical psychomotor skills, such as those needed in endoscopic surgery [12]. In semi-immersive VR, users use a VR headset and dedicated controllers to interact with a 3D VR, usually spanning 180° [13]. The addition of body sensors provides a fully immersive experience in which a user is placed entirely in a virtual environment, and their awareness of the real world is disconnected [9]. Semi- and fully immersive VR is particularly useful for teaching appropriate responses to stressful scenarios such as mass casualties, emergency surgical procedures, and cardiopulmonary resuscitation [14,15].

VR offers a simulated environment for diverse applications that enable learners to practice various skills with patients and caregivers in a safe and controlled setting without relying on health care facilities or personnel [10]. For example, Izard et al [16] demonstrated the effective use of VR in teaching surgical trainees detailed practical knowledge about surgical procedures. Another study by Birrenbach et al [17] leveraged VR during the COVID-19 pandemic to explore the short- and long-term effectiveness of VR simulation versus traditional learning methods for training health care professionals in hand disinfection, nasopharyngeal swab-taking, and donning or doffing of personal protective equipment [17]. VR technology can also provide learners with immediate feedback on their communication skills, tangible learning outcomes for educators, and allow for the repeated practice of challenging scenarios that may not be possible in real-life clinical settings [11,12]. Zackoff et al [14] used VR to train medical students in managing respiratory distress. The participants reported the VR environment as equal or superior to the perceived effectiveness of other training modalities such as standardized patients and high-fidelity mannequins. The learners also perceived VR as equally effective to standardized patients for communication training [14].

While less researched compared to technical medical skills, the rapid progression of technology has expanded the possibilities of using VR as a training tool targeting communication skills. Immersive first-person VR was found to be successful in teaching effective health dialogues and communication skills. For example, clinicians and postgraduate medical residents who used VR were more confident in and more capable of communicating difficult medical information to patients [18]. Furthermore, undergraduate research students who were trained with VR were better prepared for real-world patient interactions that involved obtaining consent [19]. Overall, VR was able to improve the dialogue performance of students with little to no previous communication training, with students posttraining being able to respond to patient questions in a more accurate and timely manner [19]. In another study, VR allowed participants to replay their experiences to help them recognize and analyze their interactions and emotions to help inform their future communications with patients [20]. Altogether, VR delivers immersion and realism, reflecting real-world scenarios that increase empathetic communication with patients [21-23]. Despite the strong evidence presented in these studies, there is still a lack of consensus on the most effective VR tools and applications for patient-facing communication skills development in medical or health care professional education (referred to as “medical education” hereafter).

Effective communication skills are crucial for health care professionals to deliver high-quality care and establish positive patient-clinician relationships, ultimately improving patient outcomes. The use of VR technology for communication skills training in medical education has the potential to provide learners with a safe and controlled environment to practice challenging scenarios and receive immediate feedback on their

communication skills. The majority of VR participants agreed that the technology was reflective of real life, strongly suggesting VR as a capable educational tool [21,23]. VR was also a highly rated learning experience and preferred over standard didactic lectures [24,25]. However, the applications of VR for communication skills development in health care professionals remain limited. This scoping review aims to synthesize and evaluate the available evidence on the effectiveness of VR tools and applications for patient-facing communication skills development in medical education and inform educators and health care professionals on the potential benefits and limitations of this technology.

Methods

Approach

To inform our objectives, we will conduct a scoping review following the methodology described by Arksey and O'Malley [26] and Levac and colleagues [27]. As our research aims to describe the application of an emerging tool (VR) in medical education and we intend on applying the findings of the scoping review to the development of a new clinical research skills course, a scoping review is an appropriate approach. While similar in rigor to systematic reviews, a scoping review allows for a preliminary assessment of the size of existing evidence to inform future directions for research priorities by identifying knowledge gaps, usually in an area of ongoing research and knowledge synthesis [28,29].

The scoping review approach encompasses the following six stages: (1) identifying the research question; (2) identifying relevant studies; (3) selecting studies; (4) charting the data; (5) collating, summarizing, and reporting the results; and (6) engaging in knowledge translation and stakeholder discussions. We will adhere to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) [30].

Stage 1: Identifying the Research Question

The objective of this scoping review is to outline and assess the available VR tools and applications used for patient-facing communication skills development within the context of medical education. To meet this objective, we have developed the following research questions:

1. How is VR implemented in a medical education setting to develop patient-facing communication skills?
2. Is VR an effective tool to develop patient-facing communication skills in a medical education context?
3. Is adapting VR tools to develop patient-facing communication skills in medical education feasible?
4. What are the challenges associated with adapting VR tools and applications to develop patient-facing communication skills in medical education?

Stage 2: Identifying Relevant Studies

To inform our study selection, we developed an operational definition of VR, communication, and medical education students.

Operational Definition of VR

We defined VR as a computer-based tool that generates a 3D image or environment that allows the participant to look about and navigate within a seemingly real or physical world [21,31,32]. Key attributes of VR in our definition included the use of (1) 3D imaging, (2) the ability to actively interact with the virtual environment, and (3) visual and auditory feedback that allows the user to feel immersed in the virtual environment [33]. In order to capture the full breadth of VR, our operational definition included nonimmersive (eg, screen-based VR simulators), semi-immersive (ie, immersive VR without physical movement), and fully immersive VR (usually using head-mounted displays and hand-held equipment) [31].

Operational Definition of Communication

We define communication as effectively engaging in conversation and exchanging information with patients, caregivers, or decision-makers regarding a medical condition in simple, clear, and plain language. Within the context of trainees in a medical education setting, effective communication skills include, but are not limited to (1) obtaining informed consent to perform a procedure; (2) engaging in difficult conversations (eg, breaking bad news); (3) collecting personal, sensitive, and confidential patient information in an ethical manner; (4) listening attentively to patient or caregiver concerns to assess the patient's health and condition; (5) maintaining professional relationships with patients and caregivers; and (6) validating and addressing patient or caregiver emotions and concerns [34,35].

Operational Definition of Medical Education Students

For our scoping review, we identified medical education students as any student in a medical or health care profession field. These students included but were not limited to, graduate, medical, nursing, physical therapy, physiotherapy, occupational therapy, or other allied health care professions students that are required to interact directly with patient populations in the delivery of their care and would thus benefit in communications training in their work. All students and trainees that may be included in the circle of care, either directly or indirectly, that communicated with patients were included in our definition of medical education students.

Search Strategy

In collaboration with a health sciences research librarian at the University of Toronto, a member of our team (MS) developed the search strategy to locate published and unpublished studies on PubMed, ERIC, Embase, and MEDLINE databases on April 11, 2023. The search was limited to data that were published from January 2000 to April 2023.

The search strategy explores specific search terms within subject headings, titles, abstracts, and keywords (Textbox 1). The search strategy, including all identified keywords and index terms, was adapted for each database to account for appropriate MeSH (Medical Subject Headings) terms. Textbox 1 shows the search strategy used for each database, with concepts combined with Boolean operators AND and OR. Further potentially relevant studies will be identified by conducting a search of the

references of included articles and relevant systematic reviews and meta-analyses.

Textbox 1. The search strategy used to obtain studies.

1. computer simulation/ or augmented reality/ or virtual reality/
2. computer-assisted instruction/ or simulation training/ or high fidelity simulation training/ or patient simulation/
3. ((virtual or mixed or augment*) adj3 (realit* or simulation*)).tw,kf.
4. (simulation* adj3 (train or trained or training* or patient* or instruction*)).tw,kf.
5. ((computer* or computational) adj3 (model* or simulation* or assisted instruction)).tw,kf.
6. 1 or 2 or 3 or 4 or 5
7. (class* or postsecondary or educat* or instruct*).tw,kf.
8. 6 and 7
9. ((clinic* or patient or medic* or communicat*) adj2 (skill* or interact* or instruct*)).tw,kf.
10. 8 and 9

Stage 3: Study Selection

Overview

The study selection phase will include the following two screening phases: (1) title and abstract screening and (2) full-text screening. First, 4 authors (NK, KGL, TM, and MS) will screen the titles and abstracts of all eligible studies identified through searching the electronic databases for relevance according to the inclusion and exclusion criteria outlined in Textbox 2. Each title and abstract will be screened by 2 of 4 authors (NK, KGL, TM, and MS), and in order for an article to move past the first screening phase, it must be accepted for inclusion by 2 authors. Disagreements will be resolved through a discussion among at least 3 of the following 4 authors: NK, KGL, TM, and MS. Second, these 4 authors (NK, KGL, TM, and MS) will download and review the full text of all articles passing the first screening phase. Similar to the first screening phase, each article will be reviewed by 2 of 4 authors (NK, KGL, TM, and MS), and in order for an article to move past this screening phase, it must also be accepted for inclusion by 2 authors. Disagreements will be resolved through a discussion among all authors. Screening and study selection will be conducted using the Covidence reference management system.

Textbox 2. Study inclusion and exclusion criteria used during screening.

Inclusion criteria

- Published in a peer-reviewed journal in the English language.
- Participants are graduate medical, nursing, physical therapy, physiotherapy, occupational therapy, or other allied health care professions students receiving patient-facing communication skills training.
- Study evaluates the implementation of nonimmersive, semi-immersive, or fully immersive virtual reality training for patient- or caregiver-facing communication skills training.
- Study reports (quantitatively or qualitatively) the learning outcomes of students, the teaching outcomes of educators, or educators' and learners' perspectives on virtual reality content and delivery.
- Published after 2000.

Exclusion criteria

- Commentaries, editorial notes, systematic reviews, meta-analyses, opinion articles, protocols, dissertations, or book chapters.
- Studies using any form of virtual reality for non–communication-based clinical skills (eg, surgical planning and therapeutic or treatment applications).
- Studies using augmented reality, mixed reality, artificial intelligence, or robotics.
- Studies using manikins for simulation training.

Inclusion Criteria

Only articles published in the English language will be considered for this scoping review. Only articles that are peer-reviewed will be considered in order to ensure that the quality of the articles reviewed is of the highest standard. Articles published only after the year 2000 will be included, as the use of technology in education only became more widespread in the early 2000s. Although most of the literature on VR in medical education was published after 2010, there are relevant articles that were published between 2000 and 2009, as 3 of the 9 studies included in the systematic review by Rourke [36] were published between 2000 and 2009. Similarly, 2 other systematic reviews [37,38] included studies published between

2000 and 2009. We adhered to the PICO framework to define the populations, interventions, comparisons, outcomes, and study designs eligible for our review. Studies were included if they met the following criteria: studies including undergraduate, graduate, medical students, medical residents, and any health care professional (ie, population); studies assessing either asynchronous or synchronous VR training methodologies specifically designed for the cultivation of clinical skills in medical education (ie, intervention); studies may or may not comprise of a control group of learners who do not receive VR training (ie, comparison); and studies that assess either the learning outcomes, feasibility, efficacy, and impact of the VR technology in relation to clinical skills teaching methodologies (ie, outcomes).

Exclusion Criteria

We aim to further develop a clinical research skills graduate-level course focused on patient-facing communication skills. Therefore, we excluded articles that outline the utility of VR for non–communication-based clinical skills, such as studies using VR to teach surgical procedures, other field-specific medical interventions, combining and administering pharmacotherapy, pain management, and other noncommunication skills or practices. We additionally excluded commentaries, editorials, other reviews and meta-analyses, opinion articles, protocols, dissertations, conference abstracts, and book chapters. Studies in a language other than English were excluded, in addition to studies using non-VR tools to teach clinical communication skills, such as manikins, CD-ROMs, or roleplaying actors. As our aim is to inform the development of a graduate-level clinical research skills course using VR, we restricted our search to only capture VR applications and excluded other forms of experiences, including augmented reality (AR) and mixed reality (MR). While VR allows the user to be fully immersed in the virtual environment, AR and MR supplement and integrate VR with the user's reality [39,40]. As our course intends to use technology to simulate patient-facing scenarios to teach medical communications skills to students, AR and MR were not considered due to the low fidelity of these technologies. Textbox 2 presents a comprehensive overview of our review's inclusion and exclusion criteria.

Stage 4: Charting the Data

Data from studies meeting the inclusion criteria will be extracted and entered into a database created by the study team. Proposed data fields for extraction include: bibliographic information (ie, author, year of publication, and study's PubMed ID), location of publication, reported time frame, type of study, participant population (ie, student field of study, student year of study, and affiliated institution), description of the VR tool (eg, nonimmersive, semi-immersive, and fully immersive), technology used to deliver the VR (eg, computer screen and head-mounted device), reported student experience (eg, satisfaction and ease of use), developer and instructor experience (eg, lessons learned), reported barriers and facilitators to the use of VR (if available), and communication-related outcomes. This developed database will be revised upon piloting the data extraction of 25 articles to ensure that the data relevant to the aforementioned aims are satisfied.

Stage 5: Collating, Summarizing, and Reporting Results

The aim of our scoping review is to synthesize the evidence describing the effectiveness and impact of and lessons learned in the feasibility and implementation of VR applications and tools used for patient-facing communication skills. Accordingly, we will use a narrative-qualitative approach to synthesis. Descriptive data about the included studies (ie, location of study, type of study, and participant population) will be reported. Collated data pertaining to effectiveness, impact, lessons learned, and facilitators and barriers to implementation and use of VR will be organized into key themes, then presented through narratives and tables. The results of the search will be included in the final scoping review and presented as a PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram. Data will be charted using a structured form and narratively summarized. Additionally, we will identify and report gaps in the available literature. Lastly, the review's findings will be considered within a broader context of research, practice, and educational design implications.

Stage 6: Stakeholder Discussions

The findings from this scoping review will help modify the clinical research skills graduate course that is being developed by the authors for the Institute of Medical Science (IMS) graduate program. The findings will be shared with the IMS Curriculum Committee, and the recommendations from this committee will be reviewed to further develop the course, which will undergo the governance process at the University of Toronto. The IMS would like to offer this course to students from different clinical departments in the future, and having this review include participants who are graduate medical, nursing, physical therapy, physiotherapy, occupational therapy, or other allied health care professions students will help inform course development.

Ethical Considerations

No protocol was registered, and research ethics approval was not sought as all data are publicly available.

Results

As of April 11, 2023, the search strategy has been confirmed, and the search has been completed. After removing duplicates, our search identified 4141 studies eligible for title and abstract screening. Of these studies, 89 were included for full-text screening. Currently, 4 authors (NK, TM, KGL, and MS) are completing the full-text screening. We anticipate that full-text screening will be completed by February 2024. Following this stage, the results of the review will be tabulated, visualized, and summarized descriptively. The target date for manuscript submission is June 2024.

Discussion

Principal Results

VR is emerging as a promising educational tool in medical education that can address the challenges associated with limited resources, cost, and the provision of immediate feedback. This scoping review aims to synthesize and assess the effectiveness of available VR tools and applications to teach patient-facing communication skills in medical education. In addition, this review will assess the feasibility of implementing VR applications and provide an overview of the challenges and lessons learned in VR application implementation and use in medical education.

Implications and Conclusions

Immediately, the findings of this review will inform the development of a graduate-level VR-based clinical skills research course within the IMS at the University of Toronto, but it is expected that these findings will be of interest to other health care–specific departments within and beyond our institution and will guide future research questions. For example, VR use in medical education has largely focused on technical skills in, for example, anatomy or surgery to date [41,42], with limited literature on VR use in medical communications or professional skills training [10]. Nevertheless, of the scarce literature available on communications and professional skills training in medical education, VR has been shown to foster the development of various competencies, including interprofessional collaboration [43,44], empathy and compassion [45,46], and confidence [47]. Moreover, given the significance of communication as a crucial skill in various medical education specialties, our scoping review holds relevance for educational settings across all medical specialties wherein clinicians and researchers engage with patients and caregivers. Therefore, our scoping review will contribute to this growing field by summarizing the limited field of literature on VR use in medical communications training, informing educators and health care professionals of the potential benefits and limitations of this technology, and identifying areas for future inquiry.

Limitations

Our proposed protocol has potential methodological limitations and limitations related to the current use of VR in medical education. We restricted our search to only include VR applications and excluded AR or MR applications; therefore, our review is not equipped to draw any conclusions regarding AR or MR use in medical communication skills training. Moreover, we only included studies reported in the English language, and therefore we may potentially not entirely capture findings reported in other languages. Additionally, we recognize the current technological and accessibility limitations in the utility of VR within medical education. For example, implementing VR applications requires costly resources, including specialized hardware of high quality and the expertise of trained personnel, which could present technological barriers and create disparities in accessing the technology among academic institutions [48]. From a pedagogical perspective, previous authors have outlined limitations, including decreased face-to-face communication, the need for robust and adequate evaluation procedures that assess real-life skills, and the importance of more research establishing VR as an effective education for clinical and communication skills [49]. However, a comprehensive overview of the limitations of VR is beyond the scope of this protocol and has been the focus of other reviews [48,49].

Conflicts of Interest

None declared.

Abstract

Background: Interactive narrative–based digital health interventions hold promise for effectively addressing the complex determinants of vaccine hesitancy and promoting effective communication across a wide range of settings and vaccine types. Synthesizing evidence related to the implementation and evaluation of these interventions could offer valuable perspectives for shaping future strategies in vaccine communication. Prior systematic and scoping reviews have examined narrative-based vaccine communication interventions but not the inclusion of interactivity in such interventions.

Objective: The overall objective of the scoping review is to summarize the evidence on the use of interactive narrative–based digital health interventions for vaccine communication. Specific research questions focus on describing the use of interactive narrative–based digital health interventions (RQ1), describing evaluations of the impact of interactive narrative–based digital health interventions on promoting vaccine uptake (RQ2), and factors associated with their implementation (RQ3).

Methods: A detailed search string will be used to search the following databases for records that are relevant to the review questions: PubMed, Embase, Scopus, Web of Science, CINAHL, and PsycINFO. Two reviewers will independently screen the titles and abstracts of identified records against the predefined eligibility criteria. Subsequently, eligible records will undergo comprehensive full-text screening by 2 independent reviewers to assess their relevance to review questions. A data charting tool will be developed and used to extract relevant information from the included articles. The extracted information will be analyzed following the review questions and presented as a narrative summary. Tabular or graphical representations will be used to display review findings, as relevant.

Results: Public health informationists were consulted to develop the detailed search strategy. The final search string comprised terms related to narrative communication, digital health, and vaccines. The search string was customized to each proposed publication database and implemented on April 18, 2023. A total of 4474 unique records were identified using the search strategy and imported into the Covidence (Veritas Health Innovation Ltd) review management software for title and abstract screening. Title and abstract screening of identified records are ongoing as of December 29, 2023.

Conclusions: To our knowledge, this will be the first scoping review to investigate the features of interactive narrative–based digital health interventions and their role in vaccine communication. The goal of this study is to provide a comprehensive overview of the current research landscape and identify prevailing gaps in knowledge. The findings will provide insights for future research and development of novel applications of interactive narrative–based digital health vaccine communication interventions.

KEYWORDS

narrative; storytelling; digital health; social media; interactive; vaccine; vaccination; vaccine hesitancy; vaccine communication

Introduction

Background

Vaccinations prevent more than 20 infectious diseases and avert 4-5 million deaths across the lifespan globally each year [1]. Yet, global progress on vaccinations has stalled in the last decade because of factors associated with vaccine complacency, convenience, or confidence [2]. These factors can result in vaccine hesitancy, a state of decisional ambivalence that manifests as a "delay in acceptance or refusal of vaccination despite availability of vaccination services" [2]. Vaccine hesitancy is blamed for backslides in vaccination coverage in high-income countries (eg, in Europe and the Americas), where issues with vaccine availability are less of a factor in suboptimal vaccine uptake [3]. Even in non–high-income settings, vaccine hesitancy may be present because of vaccination service interruptions and barriers to vaccine access [4]. The World Health Organization Strategic Advisory Group of Experts on Immunization noted that "vaccine hesitancy is complex and context-specific, varying with time, population, geographical location, and vaccine type" [2]. Passive or sloganized approaches frequently used by vaccination programs are insufficient to address the complexity and variability of the factors underlying vaccine hesitancy [5]. In a systematic review, Jarrett et al [6] found that dialogue-based communication strategies such as those leveraging mass media, social mobilization, and community influencers were effective in addressing vaccine hesitancy, whereas passive strategies such as those using posters and websites had a lower impact. One way to incorporate dialogue-based content may be through the use of narratives. The growth in the use of narratives for vaccine communication in recent years presents an opportunity to further study and innovate on its use to support vaccination uptake.

Narratives are ubiquitous in human society and have been used for persuasive health communication for decades [7,8]. Narrative-based communication strategies may be effective for understanding and addressing the complex determinants of vaccine hesitancy and enabling dialogue-based vaccine communication across varied settings and types of vaccines. The proliferation of digital technologies such as mobile phones has led to rapid and widespread sharing of health-related narratives via digital media (eg, social media platforms). These digital modalities of information communication may permit new ways for individuals to interact with narratives. For instance, interactive narrative–based digital health interventions, such as choose-your-own-adventure games, may offer individuals the chance to make decisions for their characters, influencing the unfolding of divergent paths and outcomes of their journeys [9]. Such interventions show a promising approach to storytelling by fostering self-efficacy that could be leveraged for vaccination promotion [10].

While prior systematic and scoping reviews have examined narrative-based communication for health [11,12], or specifically vaccines [13], the interactivity of narrative-based digital health interventions was not the focus. A synthesis of ways in which interactive narrative–based digital health interventions have been used for vaccine communication can facilitate the development and adaptation of novel applications to support vaccination. The goal of this scoping review is to summarize the evidence on the use of interactive narrative–based digital health interventions for vaccine communication.

Concepts Included in This Review

Overview

The 4 key concepts included in this review are narrative communication, digital health, interactivity, and vaccine communication.

Narrative Communication

For the purposes of this review, we follow Hinyard and Kreuter [7] definition of narratives as: "any cohesive and coherent story with an identifiable beginning, middle, and end that provides information about scene, characters, and conflict; raises unanswered questions or unresolved conflict; and provides resolution."

Narratives may be presented in different ways (eg, entertainment education, case histories, and testimonials) or delivered through different modalities (eg, social media, comics, and plays) [7,8]. The content of narratives may include "official stories that are constructed to tell an innocuous version of events or the position of a group, invented stories that are made up or fictional, firsthand experiential stories, secondhand stories (ie, retelling of someone else's story), and culturally common stories that are generalized and pervasive in a cultural context" [7,14]. For this review, we are interested in describing all elements of narratives used in vaccine communication, including the use of characters, settings, plots, points of view, features, and themes.

Digital Health

Digital health is defined as "the use of information and communications technology in support of health and health-related fields" [15]. The phrase digital health encompasses computer-based (electronic health or "eHealth") and mobile phone–based approaches for communicating health information and delivering health services. It also includes newer information and communication technology domains such as artificial intelligence [15]. Individuals may leverage digital technologies to cultivate social connections and access medical advice, including information on vaccines [10,16]. For this review, we are interested in describing all elements of digital health interventions that deliver narratives on vaccines, including the types of devices, modalities, and specific digital strategies as defined in the World Health Organization classification of digital health interventions [17].

Interactivity

For the purpose of this review, we define the term "interactive" as the active engagement of individuals with the narrative via digital health, aiming to raise awareness, empower behavior

change, and ultimately lead to improved vaccination outcomes. Interactivity in narrative-based digital health interventions may allow individuals to make sense of stories related to vaccines and vaccination. Interactivity may take various forms depending on the specific narrative, digital medium, or platform being used. For instance, interactive narratives may transcend the boundaries of passive information consumption, empowering individuals to actively shape the narrative's trajectory through decision-making processes (eg, games for health) [9], or individuals may respond to actions and outcomes of the narrative's characters (eg, via likes or comments on posts), or feature in the narratives themselves (eg, as avatars). For this review, we are interested in describing ways in which interaction with narratives has been incorporated via digital health in vaccination communication interventions.

Vaccine Communication

For this review, we describe vaccine communication very broadly as any communication related to vaccines. The purpose of the communication could vary (eg, for mass communication to promote new vaccines, provider-patient communication, to reduce misinformation, counter vaccine hesitancy, or train health workers). Communication about vaccines can involve a wide range of mechanisms including improving knowledge or awareness, shaping attitudes and beliefs, and so forth. We are interested in describing different vaccine communication use cases where interactive narrative–based digital health interventions have been used. We will include all vaccine types and populations targeted for communication. The communication process will be examined for 5 key components: sender, channel, message, receiver, and feedback [18].

Description of the Intervention

We are interested in any digital health interventions that incorporate narratives and interactivity for vaccine communication. We are interested in all types of narrative communication including games for health, entertainment education, storytelling, testimonials, and case histories. The entities delivering the narratives (ie, the messengers) may be formally trained (eg, doctors, public health experts, and researchers), laypersons (eg, community health workers, and peers), organizations, or health systems. The recipients may be persons receiving information on vaccinations or persons providing vaccination services.

The narrative vaccination communication process can take place entirely through a digital medium or via hybrid approaches that have at least 1 digital health component. For instance, in a hybrid approach, a provider may use a digital health aid to communicate vaccination narratives (eg, a narrative vaccination video on a tablet device) but follow up with a discussion (ie, interaction) about the video.

Research Objectives

This scoping review aims to answer the following specific research questions (RQs):

RQ1: How have interactive narrative–based digital health interventions been used for vaccine communication?

RQ2: How have interactive narrative–based digital health interventions been evaluated for promoting vaccine uptake?

RQ3: What implementation factors are associated with the use of interactive narrative–based digital health interventions for vaccine communication?

Methods

Overview

The methods of this scoping review are reported in accordance with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) checklist (Multimedia Appendix 1) [19].

Inclusion Criteria

Due to the hierarchical nature of the research questions, all included articles need to fulfill the inclusion criteria for RQ1. Within this subset of research articles, a subset of articles will also satisfy the inclusion criteria for RQ2 and RQ3.

RQ1: How have interactive narrative–based digital health interventions been used for vaccine communication?

- Studies encompassing any form of vaccine communication irrespective of vaccine type. We will consider studies incorporating vaccine communication alongside other interventions (eg, nutrition)
- Studies using narrative communication where the target audience can engage with the narrative
- Studies where the narrative is delivered via digital health devices (eg, via mobile phones and tablets) and modalities (eg, SMS text messages, applications, and games for health), including hybrid approaches where at least 1 component is delivered digitally
- Studies published as original research articles, presenting empirical findings obtained from data collection efforts.

RQ2: How have interactive narrative–based digital health interventions been evaluated for promoting vaccine uptake?

- Studies that meet the criteria for RQ1
- Studies that have been evaluated for vaccine uptake (eg, whether individuals received a vaccination or not after exposure to the narrative intervention) or vaccination intention.

RQ3: What implementation factors are associated with the use of narrative-based digital health interventions for vaccine communication?

- Studies meeting the criteria for RQ1
- Studies reporting implementation factors (ie, barriers and facilitators) related to the implementation of interactive narrative–based digital health interventions for vaccine communication
- Studies reporting implementation outcomes (eg, feasibility, acceptability, adoption, cost, reach, usability, and sustainability) derived from the evaluation of interactive narrative–based digital health interventions for vaccine communication.

Exclusion Criteria

We will exclude (1) publications classified as gray literature, protocols, trial registries, editorials, opinion pieces, and systematic and scoping reviews (ie, not an original research article); (2) original research articles for which full text are not available; (3) studies published in languages other than English for which certified translations in English are not available from the original source; (4) for RQ2, studies solely reporting intermediate outcomes related to vaccination knowledge, attitudes, or beliefs without data on vaccination intention or uptake; and (5) for RQ3 specifically, studies lacking empirical data on implementation factors or outcomes.

Search Strategy and Data Extraction

Two public health informationists (ER and HR) were consulted to develop the search strategy. A detailed search string was formulated in PubMed (Textbox 1) using a combination of MeSH (Medical Subject Headings) terms and relevant keywords to cover the domains of narratives, digital health, and vaccine communication.

The following other databases were searched using customized versions of the search string presented in Textbox 1: PubMed, Embase, Scopus, Web of Science, CINAHL, and PsycINFO. Studies that were published since 2010 will be included in the review due to the proliferation of digital storytelling as a tool for health care delivery around that time [20]. The research articles will be limited to English only. Screening and data extraction will be conducted using Covidence review management software as follows:

- Titles and abstracts will be independently reviewed by 2 researchers and records will be sorted as included or excluded for the next stage of review based on consensus voting. Full-text screening of included abstracts and titles will be completed by 2 reviewers, and a similar consensus voting approach will be followed. A third independent researcher will be consulted if the reviewers do not reach a consensus, and the majority vote will apply.
- We will develop and implement a data extraction template in Covidence based on the inclusion criteria, research objective, and RQs. Characteristics of the studies (eg, date, author, research question, and study findings) will be documented using the template by 2 researchers for each included study.

During the data extraction process (Textbox 2), we will focus on gathering the following information from included studies.

Textbox 1. Search string used for identifying relevant records in PubMed.

((“Narration”[Mesh] or Communication[Mesh]) or (narrat*[tw] or storytell*[tw] or story-tell*[tw] or “story telling”[tw] or storyline*[tw] or story[tw] or stories[tw] or conversation*[tw] or testimoni*[tw])) AND ((“Social Media”[Mesh] or “Mobile Applications”[Mesh] or “Smartphone”[Mesh] or “Telemedicine”[Mesh] or “Artificial Intelligence”[Mesh] or “Digital Technology”[Mesh] or “Computers”[Mesh]) or (digital[tw] or app[tw] or apps[tw] or “social media”[tw] or twitter[tw] or facebook[tw] or tiktok[tw] or instagram[tw] or Weibo[tw] or youtube[tw] or telegram[tw] or Whatsapp[tw] or Tumblr[tw] or Pinterest[tw] or snapchat[tw] or wechat[tw] or reddit[tw] or myspace[tw] or computer*[tw] or smartphone*[tw] or chat[tw] or blog*[tw] or game[tw] or gaming[tw] or games[tw] or gamification[tw] or weblog*[tw] or online[tw] or web-based[tw] or electronic[tw] or ehealth[tw] or e-health[tw] or “electronic health”[tw] or mhealth[tw] or m-health[tw] or “mobile health”[tw] or “artificial intelligence”[tw] or ai[tw] or “machine learning”[tw] or “deep learning”[tw] or chatbot[tw] or “chat bot”[tw] or chatgpt[tw])) AND ((“Vaccines”[Mesh] or “Vaccination”[Mesh]) or (vaccin*[tw] or immuniz*[tw] or immunis*[tw] or anti-vax*[tw] or antivax*[tw] or “anti vax”[tw] or anti-vaccin*[tw])) AND (English[Filter]

Textbox 2. Proposed elements of data extraction by review question.

Study information: In a table of included studies, we will summarize study dates, publication information, study setting, participants, study designs, and objectives.

RQ1: We will summarize different elements involved in narrative communication across a range of contexts. Our analysis will include how individuals engage with interactive digital health interventions or modalities, examining the various modes of interaction and their impact on the overall narrative experience. The outcome of the narratives, examining factors such as their congruence with individuals’ personal values, their memorability, perceived realism, and other relevant elements will be described. Theories and frameworks used in the included studies such as Schank and Berman categorization of narratives (official, invented, first-hand experiential, second-hand, and culturally common), or other pertinent theoretical frameworks will be analyzed [14]. Furthermore, we will provide insights into the available evidence by vaccine type, whether the emphasis is solely on vaccination, and whether the vaccines are integrated with other health interventions.

RQ2: All elements described for RQ1, and evidence of impact on the uptake of vaccines, specifically examining whether individuals were vaccinated or not after being exposed to interactive narrative-based digital health interventions for vaccine communication. We will also review studies that have evaluated vaccination intention, which relates to individuals’ expressed willingness or plans to get vaccinated.

RQ3: We will include all elements described in RQ1, along with the implementation outcomes related to the use of narrative-based digital health interventions for vaccine communication. These implementation outcomes include outcomes such as acceptability, adoption, cost, reach, usability, sustainability, and others. Additionally, we aim to identify studies that report on the barriers and facilitators associated with implementing interactive narrative-based digital health interventions for vaccine communication. By examining these factors, we seek to gain a comprehensive understanding of the feasibility and implementation of utilizing such interventions for vaccine communication efforts.

Data Analysis

Review findings will be communicated through a PRISMA (Preferred Reporting Items for Systematic Reviews) flowchart, tables, figures containing descriptive statistics, and narrative summaries corresponding to our research questions. Research findings will be published in a peer-reviewed academic journal and presented in scientific conference presentations in the forthcoming months.

Ethical Considerations

Since the review used published journal articles exclusively, an ethical board review board was not necessary to conduct this review.

Results

The detailed search string was implemented in the proposed databases searching for publications from inception until April 18, 2023. The search results (n=6836 records) were imported into EndNote Software (version 20; Clarivate) for the removal of duplicate records, and deduplicated records (n=4676) were uploaded to Covidence review management software for eligibility screening. Title and abstract screening is ongoing as of December 29, 2023. We anticipate the scoping review findings to be published in 2024.

Discussion

Principal Findings

Prior systematic and scoping reviews in the realm of vaccine communication have evaluated various interventions such as behavioral nudges [13] and dialogue-based communication interventions [21]. However, none of these reviews have specifically evaluated the effects of interactive narrative–based digital health interventions for vaccine communication. This scoping review aims to identify and synthesize relevant studies that describe interactive narrative–based digital health interventions tailored specifically for vaccine communication. Our primary goal is to synthesize empirical evidence on the ways these interventions are used, implemented, and evaluated and highlight gaps to inform future research and implementation.

Implications for Research and Practice

The study findings may help researchers and public health practitioners understand how interactive narrative–based digital health interventions have been used to promote vaccinations and add context or perspective that may be missing from traditional messaging campaigns [2,5]. The findings from the scoping review may guide the future development of interactive narrative–based digital health interventions for vaccine communication and identify interventions for further evidence synthesis. Additionally, the review may highlight implementation outcomes linked to these interventions or successful components within them. Through a comprehensive synthesis of existing literature, the review may reveal effective strategies, challenges, and gaps in previously developed interventions. Furthermore, the review has the potential to stimulate new research questions or hypotheses aimed at addressing these gaps, thereby contributing to the dynamic landscape of vaccine communication.

Narratives are often exploited in the spread of vaccine misinformation. While the proliferation of digital devices such as mobile phones and tablets has enabled widespread reach of information through communication channels such as social media, they have also helped the spread of misinformation, thereby affecting the public's confidence around vaccination [22]. Hence, review findings may also inform the use of interactive digital health interventions to combat vaccine misinformation.

Strengths and Limitations

The strength of our study lies in its inclusive research approach, encompassing all populations, vaccine types, narratives, and digital health interventions, potentially capturing a diverse array of use cases for interactive narrative–based digital health interventions. However, several potential limitations exist with our approach. First, our reliance on peer-reviewed journal articles might lead us to overlook relevant interventions described in the gray literature. Second, our search strategy does not include the term "interaction," which necessitates researchers' interpretation of interactivity during title and abstract screening. Finally, this being a scoping review, we do not plan to appraise the studies for risk of bias, and our conclusions may have limitations as we are not accounting for potential biases in the included studies.

Conclusions

In this scoping review, we will summarize the use of interactive narrative–based digital health interventions for vaccine communication. To our knowledge, this study will be the first to investigate the interactive features of these interventions and their impact on vaccine communication. Our study aims to illuminate the prevailing gaps in knowledge and provide an overview of the present research landscape. Furthermore, review findings may provide insights for public health practitioners and researchers, laying the groundwork for future studies and applications using interactive narratives for vaccine communication. Review findings may also be of relevance to vaccine communication researchers and global vaccination programs, enabling them to consider novel applications of interactive narrative–based digital health interventions in future initiatives for vaccine communication.

Acknowledgments

The authors extend their gratitude to Hannah Rogers, MLS (Public Health Informationist, Woodruff Health Sciences Center Library, Emory University) for her invaluable assistance in crafting the search strategy and identifying relevant databases relevant to the review objective.

Conflicts of Interest

None declared.

Abstract

Background: Cardiopulmonary dysfunction is a complex process with a broad range of etiologies. Investigations performed either at rest or those that only assess the function of a single organ (heart or lungs) are often insufficient. A simultaneous cardiopulmonary exercise test with stress echocardiography is a new approach to assessing cardiopulmonary dysfunction as it provides anatomical and functional imaging simultaneously while under increasing stress. To date, the application of cardiopulmonary exercise test-stress echocardiography (CPET-SE) has been broad and without structure, and its effect on patient outcomes is unclear.

Objective: The objective of this scoping review is to explore and analyze the evidence regarding the role of simultaneous CPET-SE in investigating cardiopulmonary dysfunction in outpatients. It will include any published study in which adult (older than or equal to 18 years of age) patients have completed a CPET-SE for the investigation of cardiopulmonary dysfunction.

Methods: This review will follow the Arksey and O'Malley framework, supported by the Joanna Briggs Institute methodology for scoping reviews. It will use the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist. Data sources will include MEDLINE, Scopus, Embase, and Cochrane (including reviews, trials, and protocols) electronic databases, with no date range defined. The search will be limited to the English language with no restrictions regarding pathology. Secondary references of the included sources will also be assessed by a hand search for suitability. A 2-person title-abstract screen and data charting process will be used. Independent experts will be used for consultation including an academic librarian and clinicians. The Covidence software will be used for article screening.

Results: This scoping review will provide a unified and detailed description of the applications of CPET-SE in investigating cardiopulmonary dysfunction. This will provide a platform for future research harnessing this investigatory method. The results will be presented in both tabular and graphical formats to ensure clarity. The results of this scoping review will be submitted to a relevant peer-reviewed academic journal for publication.

Conclusions: The CPET-SE is a powerful tool for investigating cardiopulmonary dysfunction but remains in its infancy with a patchwork approach to indications, data reporting, and interpretation. This scoping review will unify the literature and provide a platform for future researchers and the development of a comprehensive application guideline.

KEYWORDS

cardiopulmonary; echocardiography; exercise; cardiopulmonary exercise test

Introduction

Cardiopulmonary dysfunction is the loss of the normal bidirectional functional relationship that exists between the heart and the lungs [1,2]. It can range in severity from subclinical (and only manifesting under stress) to fatal, with a timeline that can be acute, chronic, or acute on chronic. Cardiopulmonary dysfunction can be the consequence of single-organ (heart or lung) disease, systemic disease (eg, sepsis) [3,4], or iatrogenic (eg, medications or mechanical ventilation) [5,6].

The investigation of cardiopulmonary dysfunction requires an assessment of the complex heart-lung relationship. The 2 primary interfaces where these organs interact are the right heart-pulmonary circulation relationship (often referred to as "coupling") and the alveolus-pulmonary capillary relationship [7]. Coupling denotes the relationship between the pulsatile pump of the right ventricle and its opposing arterial vascular load (ie, pulmonary arterial circulation) [8]. As one component of this relationship changes (eg, the increase in arterial stiffness seen in aging due to loss of vessel elasticity) [9], the other responds (eg, with ventricular remodeling) to maintain normal coupling, giving optimal cardiac mechanics and cardiopulmonary efficiency at rest [10].

The alveolus-pulmonary capillary relationship has pressure as its currency. In the healthy upright lung, the majority of ventilation and perfusion occurs at the lung base, where both the pulmonary arterial and pulmonary venous pressures exceed the alveolar gas pressure (West zone 3) [11]. This facilitates constant blood flow past the alveolus giving uninterrupted gas exchange—in normal physiological conditions the alveolar pressure does not affect blood flow through the pulmonary circulation [11,12]. Lung hyperinflation can cause compression of the alveolar vessels leading to raised pulmonary vascular pressures, an increase in pulmonary blood transit time, myocardial hypoperfusion, and biventricular systolic dysfunction [13-16]. If there is concurrent right heart dysfunction, there may also be reduced pulmonary vascular blood flow, further worsening this process [15]. Patients with airway disease have a predilection for progressive (dynamic) hyperinflation during exercise, a condition characterized by increasing end-expiratory lung volume. This increase in volume within the fixed thoracic cage leads to an increase in the intra-alveolar pressure, with higher degrees of dynamic hyperinflation related to a poorer cardiac output during the activity [17].

In the outpatient setting, the investigation of cardiopulmonary dysfunction often involves a series of single-organ assessment tools such as computed tomography imaging of the lung, complex lung function testing, and transthoracic echocardiography. These single-organ, static investigations provide little insight into cardiopulmonary performance when under physiological (eg, exercise) or pathological (eg, sepsis) stress [18,19]. Current commonly used functional testing modalities such as stress echocardiography can provide additional information and have a role in the investigation of specific conditions in patients with the appropriate pretest probability—for example, assessing for coronary artery disease in patients with anginal symptoms [5]. However, this test is not capable of assessing the intricacies of cardiopulmonary dysfunction. A cardiopulmonary exercise test (CPET) provides integrative information about cardiac, respiratory, and metabolic responses to exercise and is considered the gold standard in the integrative assessment of cardiorespiratory function [20]. Peak oxygen consumption (VO2peak) measured by CPET is the key measure of cardiopulmonary fitness [21], has a stronger relationship with all-cause mortality than many common chronic diseases [22], and can be improved with low-burden lifestyle interventions [23]. Despite this, CPET also has limitations, most notably that it provides no anatomical information about cardiac function under an increasing workload. As a result, conditions with significant prognostic implications including exercise-induced pulmonary hypertension [24] or exercise-induced diastolic function [25] may go unnoticed.

Recently the combination of cardiopulmonary exercise test-stress echocardiography (CPET-SE) has been used to explore cardiopulmonary dysfunction. Studies have explored the role of CPET-SE in exploring conditions such as dyspnea [26], heart failure [27,28], contractile reserve [29], and left atrial dysfunction [30]. While the application is broad, the indications for this test combination remain undefined, and there is no consensus regarding the optimal protocol for the exercise and imaging components. Similarly, any additional prognostic benefits over traditional testing are undefined.

Given the complexity involved in investigating cardiopulmonary dysfunction, the breadth of applications for CPET-SE, and the lack of standardization for the test, we propose a scoping review to assess the literature surrounding the use of CPET-SE in investigating cardiopulmonary dysfunction in the outpatient setting. This will include an exploration of its impact on shaping the diagnostic and management processes of cardiopulmonary dysfunction. This scoping review will provide shape to the literature regarding this combined testing modality and provide an evidence base for future research.

A preliminary search of MEDLINE, the Cochrane Database of Systematic Reviews, and Joanna Briggs Institute (JBI) Evidence Synthesis was conducted and no current or underway systematic reviews or scoping reviews on the topic were identified.

Methods

Overview

This scoping review will be conducted in accordance with the JBI methodology for scoping reviews [31], based on earlier work from Arksey and O'Malley [32]. It will follow the process of (1) identifying the research question; (2) identifying the

relevant studies; (3) defining criteria for study inclusion; (4) data charting; (5) collation, summarizing, and reporting of results; and (6) peer feedback [29]. The PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) [33] checklist will be followed.

Identification of the Research Question

The primary question of this scoping review is "What is the role of simultaneous cardiopulmonary exercise testing and echocardiography in investigating adult outpatients with symptoms of cardiopulmonary dysfunction?" Associated subquestions for this review are "What are the primary pathologies in which simultaneous cardiopulmonary exercise testing and echocardiography has been used?" and "Is there any evidence that CPET-SE provides additional diagnostic benefit over traditional testing?"

Identification of the Relevant Studies

Overview

The Population, Concept, Context (PCC) framework was used to scaffold the main components of the research question.

Population, Concept, and Context

Population and concept have been combined in this scoping review as they are interlinked, that is, it is inclusive of all patients undergoing this particular combined investigatory modality.

All studies involving patients aged 18 years or older with either known cardiopulmonary disease or symptoms suggestive of cardiopulmonary dysfunction who underwent a simultaneous transthoracic echocardiogram and CPET will be included. There will be no limitations regarding specific disease states or symptom burden.

To best capture the potential breadth of the literature, all studies involving simultaneous echocardiography and cardiopulmonary exercise testing will be included. The minimum data set required for the CPET is continuous gas exchange data, continuous cardiac monitoring, and either a stationary bike or treadmill ergometer. This is in line with accepted clinical practice [34].

The outcomes of interest are the range of contexts in which the combined investigation technique has been applied and the overall assessment of its use in providing clinically relevant information.

Sources

This scoping review will consider the following study designs: randomized and nonrandomized controlled trials, observational studies (retrospective and prospective), and descriptive studies including case series and reports. Systematic reviews that meet the inclusion criteria will also be included.

A hand search of all studies included in the final review will be performed to identify additional literature that may not have been uncovered in the initial database search. Published abstracts and conference proceedings will be considered if they meet the inclusion criteria. Consideration will also be given to grey literature (including expert opinion pieces) if they contain sufficient detail to meet the inclusion criteria. Such data will be identified through discussion with an existing local and international network of experts in the field.

Study or Source of Evidence Selection

All identified citations will be collated via the online software Covidence [35]. EndNote (version 20.3; Clarivate Analytics) will be used as the reference management software. The title and abstract screening will be performed by 2 independent reviewers to determine relevance and suitability using the inclusion criteria.

Studies identified as relevant will undergo full-text assessment by 2 independent reviewers. Appropriate studies will undergo data extraction. Studies deemed inappropriate will have the rationale for such recorded and reported in the scoping review.

Disagreements at either title-abstract or full-text screening will be resolved through the use of a third independent reviewer. The results of the search and the study inclusion process will be reported in full in the final scoping review and presented in a PRISMA-ScR flow diagram [33].

Study Inclusion Criteria

The search strategy will be constructed with assistance from an experienced academic librarian. An initial limited search of MEDLINE and Scopus was performed to identify relevant keywords from titles and abstracts. These index terms were used to develop the complete search strategy for MEDLINE, Scopus, Embase, and the Cochrane Library (including reviews, protocols, and trials; see Multimedia Appendix 1). The search strategy, including all identified keywords and index terms, will be adapted for each included database and information source. The search strategy deliberately does not reference inpatient or outpatient to ensure that the search results have an appropriate breadth. Only studies published in English will be included. No date restrictions are in place, that is, the databases will be searched from inception to the search date.

Data Charting

Data extraction will be performed by 2 independent reviewers using a customized data extraction tool based on the JBI template [31] (see Multimedia Appendix 2 for the draft data extraction tool). This tool will be piloted using the first 10% of the included full-text studies. After this period the tool will be reevaluated and modified as appropriate to ensure collection of all relevant data. If necessary, this modified (final) data extraction tool will be used for all included full-text studies including the cohort used in the pilot.

Any disagreements with the data charting process will be resolved through discussion, or where necessary, by a third independent reviewer. Where there is missing data, the authors of the original manuscripts will be contacted for additional data or clarification. A critical appraisal of the articles included in the full-text analysis will not be performed.

Result in Collation, Summary, and Reporting

The PRISMA-ScR [33] checklist will be used to guide collation and reporting. The extracted data will be presented predominately in tabular format, in line with the data extraction tool and the review questions of this scoping review (Multimedia

Appendix 3). It is expected that some data (specifically diagnostic categories and symptom burden) will also be presented diagrammatically to aid clarity. A narrative summary will accompany the tabulated results and will describe how the results relate to the objective and research questions of this scoping review.

Validation, Consultation, and Feedback

Local experts on echocardiography, cardiopulmonary disease, and exercise testing not involved in the authorship of this protocol will be consulted at specific points in this process, including during stages 3 and 5. An academic librarian will be used during stage 2 to ensure the search is thorough and relevant.

Ethical Considerations

Ethics approval has not been sought for this review as data are being collected from published literature.

Results

This scoping review is expected to yield results by late 2023 or early 2024. These results will be presented within the local hospital network by the authorship group to inform current clinical practice and provide an evidence base for future studies using this combined modality. The results of this scoping review will also be presented in article format and submitted for publication in a relevant peer-reviewed journal.

Discussion

Principal Findings

We seek to explore the application and outcomes of a combination of CPET-SE in clinical practice. To the best of our knowledge, this is the first exploratory review on this subject and will be a comprehensive description of the literature.

Advanced functional testing (including CPET) provides data that are more representative of an individual's ability to tolerate a stressor (eg, surgery) or it can induce the symptom (eg, exercise intolerance) of a patient while simultaneously capturing a comprehensive data set for thorough investigation. Combining this with real-time imaging such as echocardiography adds another layer of information [26,27]. Individually there are international guidelines for these tests [20,36,37], but how to best combine them is not clear.

There are significant potential advantages with the CPET-SE; however, the literature appears heterogeneous across testing or acquisition protocols and inconsistent in reporting results making interpretation challenging for clinicians. This scoping review can serve as part of the groundwork required for future guidelines regarding simultaneous CPET-SE.

Strengths of this protocol include the use of a structured, multi-database literature search with few constraints; the use of an established scoping review framework; and the use of independent expert consultation throughout the process.

Limitations

There are 2 primary limitations to this scoping review. The first is the risk of missing relevant studies in the search steps. Multiple databases relevant to medical literature are being included, and the search terms include both whole words and conventional acronyms for CPET, there is a risk that there are additional acronyms or abbreviations used internationally that are unknown to the authors of the scoping review and therefore the literature may be missed. Limiting search results to articles published in English is the second limitation.

Conclusions

The role of exercise testing in clinical practice is expanding, and with this expansion comes novel testing regimens such as CPET-SE. By providing a summary of the application of combined CPET and echocardiography in current practice we will have the base from which a unified, comprehensive, and standardized testing approach can be proposed including indications, testing procedures, and reporting protocols. This will benefit clinicians (by providing an evidence base on which they can structure their testing), researchers (by giving a degree of data homogeneity and allowing more rigorous statistical analysis), and ultimately patients.

Acknowledgments

The authors acknowledge the University of Sydney library staff (Tess Aitken) for their assistance in search planning and preparation. The authors acknowledge the Nepean and Blue Mountains Local Health District, and Nepean Hospital for their support of the project.

Abstract

Background: Digital health twins (DHTs) have been evolving with their diverse applications in medicine, specifically in older care settings, with the increasing demands of older adults. DHTs have already contributed to improving the quality of dementia and trauma care, cardiac treatment, and health care services for older individuals. Despite its many benefits, the optimum implementation of DHTs has faced several challenges associated with ethical issues, quality of care, management and leadership, and design considerations in older care settings. Since the need for such care is continuously rising and there is evident potential for DHTs to meet those needs, this review aims to map key concepts to address the gaps in the research knowledge to improve DHT implementation.

Objective: The review aims to compile and synthesize the best available evidence regarding the problems encountered by older adults and care providers associated with the application of DHTs. The synthesis will collate the evidence of the issues associated with quality of care, the ethical implications of DHTs, and the strategies undertaken to overcome those challenges in older care settings.

Methods: The review will follow the Joanna Briggs Institute (JBI) methodology. The published studies will be searched through CINAHL, MEDLINE, JBI, and Web of Science, and the unpublished studies through Mednar, Trove, OCLC WorldCat, and Dissertations and Theses. Studies published in English from 2002 will be considered. This review will include studies of older individuals (aged 65 years or older) undergoing care delivery associated with DHTs and their respective care providers. The concept will include the application of the technology, and the context will involve studies based on the older care setting. A broad scope of evidence, including quantitative, qualitative, text and opinion studies, will be considered. A total of 2 independent reviewers will screen the titles and abstracts and then review the full text. Data will be extracted from the included studies using a data extraction tool developed for this study.

Results: The results will be presented in a PRISMA-ScR (Preferred Reporting Items for Systematic Review and Meta-Analysis extension for Scoping Reviews) flow diagram. A draft charting table will be developed as a data extraction tool. The results will be presented as a “map” of the data in a logical, diagrammatic, or tabular form in a descriptive format.

Conclusions: The evidence synthesis is expected to uncover the shreds of evidence required to address the ethical and care quality-related challenges associated with applying DHTs. A synthesis of various strategies used to overcome identified challenges will provide more prospects for adopting them elsewhere and create a resource allocation model for older individuals.

Introduction

Overview

Digital health twins (DHTs), defined as digital representations (digital twins) of patients (physical twins), are an emerging technology aimed at meeting some of the above challenges. DHTs are generated from multimodal patient data, population data, and real-time updates on patient and environmental variables [1]. The field of a digital twin, particularly in health care, has been evolving by using machine learning data aggregated from various patients through modeling the conditions and attributes of a particular patient [2].

The application of digital twins in health and medicine is diverse; for example, DHTs have been used in intensive care units for critical care [3], treatment of patients with trauma [4], and cardiac treatment [5]. Precision health or personalized care for primary prevention with DHTs for older adults has emerged to address the need to mitigate these significant resources and reinforcements. This can allow for collecting data that enables more individually tailored interventions, both to promote and prevent, diagnose, and treat—interventions with greater precision [6].

Moreover, digital twins have widely been used in older care settings, for example, care homes [7] or for older individuals in different settings, such as hospitals [8]. The evidence suggests that the application of DHTs in dementia is broad, such as detecting the signs of dementia [8], assessing the risks associated with Alzheimer disease–related dementia [9], and supporting better dementia care [10]. DHTs have also been found to improve health care services for older individuals by providing real-time supervision and accurate crisis warning [11] and to improve the efficiency and accessibility of medical services for older individuals [12].

With the increase in life expectancy, older adults are growing in the United Kingdom and around the world and are expected to live longer with multiple disabilities and diseases [13]. Around 19% of the population in the United Kingdom is aged 65 years or older, many of whom require health and social care services to enable them to live longer and have a better quality of life [14]. This number is expected to grow by a further 77% (from 1.4 million to 2.4 million) for older adults by 2040 [15]. While this demographic shift makes older adults the major users of health and care resources [16], it places an unprecedented strain on the workforce of the social care sector [17].

Health and social care for older adults is a complex sociotechnical system that undergoes continuous change [18]. Over the last 3 decades, quality of care has progressively been on the agenda because the care delivery can itself harm patients [19,20], either by providing less than optimal care [21] or by things going wrong with its delivery [22,23]. Whenever a new technology or technological innovation is introduced to improve the quality of care, such as efficiency and effectiveness, new and often unforeseen issues emerge that require attention and awareness [18,21,24]. Thus, new challenges arise continuously, which need resetting priorities for other dimensions of quality of care [18], such as patient safety [25] and health equity [26]. This new technology, that is, the implementation of DHT, is no exception, which can even cause technical [27], ethical [26,27], legal [27,28], and societal challenges [27].

The challenges associated with management and leadership include a lack of discussions, cooperation, negotiations, and agreement among various health and social care providers while new routines are being adopted [6,29]. Design considerations concerning big data-related problems involve data visualization, data availability and accessibility, data integration and interoperability into clinical workflow [10], and privacy and security across the entire system [6,10]. Issues involving the quality of care in terms of DHT implementation are safety, equity, and appropriateness [10,26,28]. Some of the ethical challenges regarding the application of DHTs include autonomy, informed consent, the right to privacy, and surveillance health care [26].

The UK Government's Plan for Tech and Digital Economy desires an expansion of the United Kingdom's existing expertise in deep foundational technologies, including digital twins and artificial intelligence [30]. This has been supported by the Government's Plan for Digital Health and Social Care to expedite technology adoption [31], while the UK Research and Innovation (UKRI) inaugurated a funding scheme to establish a multidisciplinary research community in digital twinning [32]. The UKRI's initiative focuses on addressing aspects of ethics, human interaction, environmental sustainability and security, and resilience [32], while NHS (National Health Service) England emphasizes the digital transformation of adult social care—the need for personalized care [33].

In order to shape this review, we will focus on older individuals and consider the following dimensions for the quality of care: safety, equity, effectiveness, and accessibility. Conducting a scoping review for the care of older adults is the most ideal and reliable approach to illuminate the current issues associated with DHTs. There is a need for mapping the key concepts to address questions beyond those associated with the experience and effectiveness of this intervention due to DHT's evolving applications in older care settings [34]. Our proposed review is in line with the vision of the NHS and the UKRI to understand the challenges faced by health and social care professionals, older adults, and their relatives concerning DHT used in personalized care for older adults. Therefore, the review results can readily be accepted, with more prospects of being adopted elsewhere and meeting today's societal challenges—creating a model for gathering individualized data, disease prevention, monitoring, and resource allocation for older adults.

A preliminary search of Campbell systematic reviews, the Cochrane Database of Systematic Reviews, PROSPERO

(International Prospective Register of Systematic Reviews), and Joanna Briggs Institute (JBI) Evidence Synthesis was conducted; however, no current or underway systematic reviews or scoping reviews on the topic were identified.

Aim and Review Questions

The primary purpose of this scoping review is to compile and synthesize the best available evidence regarding the challenges of DHT encountered in older care settings. This review is believed to uncover the shreds of evidence that will require diligent attention to address the ethical challenges and the challenges concerning the quality of care associated with the application of DHT. Moreover, this study will identify the strategies that have been used to overcome those challenges in older care settings. Therefore, there is a need for new knowledge through evidence synthesis using existing knowledge to be put to good use.

Specifically, the review questions are as follows:

1. What problems are faced by older individuals (their family and relatives) and health and social care providers associated with the application of DHTs in older care settings?
2. What are the documented issues related to the quality of care for older adults, such as safety, equity, effectiveness, and accessibility, concerning DHTs?
3. What are the ethical challenges concerning the application of DHTs in older care settings?
4. What strategies have been evaluated and implemented in older care settings that address the challenges associated with DHTs?

Methods

The proposed scoping review will be conducted in accordance with the JBI methodology for scoping reviews [35].

Search Strategy

Databases will be searched for both published and unpublished studies. The approach to searching for studies for a scoping review will follow the standard 3-step method (Table 1). The first step will be an initial limited search of a selection of relevant databases, followed by an analysis of text words in the title and abstract and the index terms used to describe the article. The search for published studies will include a 2-way search strategy. One is to search the journal and reference databases, such as CINAHL, MEDLINE, JBI, and Web of Science. Another is to search article-based (journal) databases, such as the ACM digital library, IEEE Xplore, and BMJ Journals. The search for unpublished studies will include Mednar, Trove, OCLC WorldCat, and Dissertations and Theses. A second search using all identified keywords and index terms will then be undertaken across all included databases. Additional search strategies, that is, citation search—specific researcher or article (eg, gold-standard article), and chain search—review reference list of the systematically selected articles will be included to complement the search for published and unpublished papers. Studies, such as reviews (systematic, scoping, and umbrella) and letters to editors, will be excluded. Any studies that lack ethical concerns will also be excluded. Studies published in English will be considered. Studies published from 2002 (when the concept of “digital twin” was first coined by Dr Michael in 2002) [36] onward will be considered for inclusion in this review.

Eligibility Criteria

Overview

This scoping review will include the following PCC mnemonics—population, concept, and context. These mnemonics will be used as a guide (not a policy); therefore, the inclusion criteria of this systematic review will include a detailed description of types of participants, concepts, and context, as well as search strategies, data extraction, charting, analysis, and presenting the results. The eligibility criteria are listed in Textbox 1.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Review articles
- Conference paper
- Gray literature
- Early access
- English
- Studies involving older individuals associated with a digital health twin (DHT), regardless of gender, age, ethnicity, socioeconomic status, disorders, or disability.
- Studies that include paid or unpaid carers, whether they are family members or friends.
- Studies that include care providers involved in older care settings and DHTs, whether they are licensed or unlicensed.
- Studies that evaluate and discuss the process and application of DHTs involving caregivers, older individuals, or family, friends, or relatives.
- Studies from 2002 through 2023.
- Studies that specifically evaluate and discuss the process and application of DHTs in settings such as geriatric wards of primary health care, hospitals or clinics, nursing homes, care homes, and home care facilities for older individuals.

Exclusion criteria

- Meeting abstracts
- Editorial materials
- Book chapters
- All other languages
- Studies that do not involve older individuals or care providers associated with DHTs in older care settings.
- Studies that do not focus on the application of DHTs or are not directly related to older care settings.
- Studies from 2001 and earlier.
- Studies not in the context of older care settings.
- Studies where DHTs are not used.

Participants

This review will include studies of older individuals (aged 65 years or older) undergoing care delivery associated with DHTs, irrespective of gender and diversity, including age, ethnicity, socioeconomic status, disorders, and disability. Studies that focus on caregivers (family and friends—paid or unpaid) and care providers (licensed or unlicensed) involved in the care of older adults in relation to DHTs will also be included.

Concept

In this scoping review, the key concept is the process and application of DHTs. Studies that evaluate the application of DHTs involving older care providers, older individuals, family, friends, or relatives will be considered.

Context

The systematic review will consider studies that are based in the older care settings associated with DHTs, such as geriatric wards of primary health care, hospitals or clinics, old-age homes, nursing homes, care homes, and home care facilities for older individuals.

Types of Sources

This scoping review will consider both experimental and quasi-experimental study designs, including randomized controlled trials, nonrandomized controlled trials, before and after studies, and interrupted time-series studies. In addition, analytical observational studies, including prospective and retrospective cohort studies, case-control studies, and analytical cross-sectional studies, will be considered for inclusion. This review will also consider descriptive observational study designs, including case series, individual case reports, and descriptive cross-sectional studies, for inclusion.

Qualitative studies that focus on qualitative data, including but not limited to designs such as phenomenology, grounded theory, ethnography, qualitative description, and action research, will also be considered.

Text and opinion papers regarding the benefits and challenges of DHT and strategies to overcome the challenges posed by DHTs will also be considered as a scoping review that includes a broad scope of evidence.

Study or Source of Evidence Selection

Following the search, all identified citations will be collated and uploaded into EndNote (version 20; Clarivate Analytics),

and duplicates will be removed. Following a pilot test, titles and abstracts will then be screened by 2 or more independent reviewers for assessment against the inclusion criteria for the review. Potentially relevant sources will be retrieved in full, and their citation details will be imported into the JBI System for the Unified Management, Assessment and Review of Information [37]. The full text of selected citations will be assessed in detail against the inclusion criteria by 2 or more independent reviewers. Reasons for the exclusion of sources of evidence in full text that do not meet the inclusion criteria will be recorded and reported in the scoping review. Any disagreements that arise between the reviewers at each stage of the selection process will be resolved through discussion or with an additional reviewer or reviewers. The results of the search and the study inclusion process will be reported in full in the final scoping review and presented in a PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) flow diagram [38].

Data Extraction

Data will be extracted from papers included in the scoping review by 2 or more independent reviewers using a data extraction tool developed by the reviewers. The data extracted will include specific details about the participants, concept, context, study methods, and key findings relevant to the review questions.

A draft charting table will be developed as a data extraction tool. The charting table will be modified and revised as necessary during the process of extracting data from each included evidence source. Modifications will be detailed in the scoping review. Any disagreements that arise between the reviewers will be resolved through discussion or with an additional reviewer or reviewers. If appropriate, authors of papers will be contacted to request missing or additional data, where required.

Results

The results will be presented as a “map” of the data extracted from the included papers in a logical, diagrammatic, or tabular (as necessary) form and in a descriptive format that aligns with the objective and scope of the review. Some critical information that the charting table will include is (but is not limited to): year of publication, country of origin for the study, aims, study population and sample size, methodology or methods, type of intervention or comparator, duration of the intervention, and type of outcomes and how they were measured (if applicable). A clear explanation for each category will be provided, accompanied by a narrative summary describing how the results relate to the review objective and questions.

This scoping review protocol was first developed by the principal author as part of a postdoctoral fellowship at Linnaeus University in February 2022. Later, the protocol was refined and continued as part of research development at the University of Bradford by the lead author, who has been undertaking a full search since July 2023. We expect the analysis to be completed by January 2024 and the final scoping review manuscript to be submitted by April 2024.

Discussion

Overview

The world’s population is getting older—aging brings with it complicated and multiple challenges such as poorer mobility, balance, sight or hearing, dementia, diabetes, and an increased risk of injuries [39]. With the trend of increasing older adults, it is estimated that almost 1 in 6 adults must work in care by 2038 to meet the demand for older adults in home care alone. This is a hard target to meet, given the current shortfalls in the workforce available in social care sectors, which became more apparent during the COVID-19 pandemic [17]. Not to mention the lack of incentive in many countries to take such jobs. Since technology is seen as a means to address the shortage of care workers by health and social care policy makers [13], we believe that DHTs have the capability of addressing the demand for the care of older adults and compensating for the shortage of care workers.

A recent rapid literature review of studies of DHT for managing health care systems identified 17 studies, concluding that DHT can contribute to safety management, information management, health management and well-being promotion, and health care operational control [40]. With appropriate implementation, DHT helps treat patients as virtualized standalone assets [41], improve patient treatment and diagnostics [6], and improve the quality of life overall [42].

The current concept of DHT is diverse as it is still a new and emerging domain, particularly in older care settings [7-10,34], with the aim of improving the quality of care by increasing efficiency [43]. New definitions, concepts, and dimensions in regard to DHT may be identified in this review that may have the potential to help in furthering the design, development, implementation, and evaluation process of DHT. We believe that the evidence synthesis will help us design a larger implementation project, that is, assembling unique and existing technologies to create a new digital twin platform for older care settings.

Since DHTs are expensive and sometimes may not be readily available to older adults to a large extent [44], this study will assess the different circumstances and needs of older adults. This study will ensure appropriate resources and solutions are allocated to needy individuals, covering aspects of equity, and closing the gap in health inequality. The benefits of DHT will help us understand informed decision-making in older care settings.

Limitations

The findings of the review need to be treated with caution since our search is restricted in terms of language and publication period. To overcome these limitations, a comprehensive strategy, that is, a standard 3-step method, will be followed, such as the inclusion of gray literature, which may provide additional insights into the review findings. There may also be a possibility pertaining to the findings in terms of the limited number of included studies, which may further add a layer of bias to the

selected studies. The evidence-based practice center methods guide proposed by the Agency for Healthcare Research and Quality will be followed to minimize the risk of bias in individual studies [45].

To ensure the systematic scoping review generates generalizable findings, discussions with older adults, their relatives, and the relevant public will be held to support the interpretation of the findings and dissemination of the review.

Conclusions

No current or ongoing systematic reviews or scoping reviews on the topic were identified. This review will uncover the shreds of evidence requiring diligent attention to address the ethical challenges and the challenges concerning the quality of care associated with the application of DHT. Additionally, this study will identify the strategies that have been used to overcome those identified challenges in older care settings, providing more prospects for adopting them elsewhere and creating a model of resource allocation for older individuals.

Acknowledgments

The authors would like to thank Evalill Nilsson and the librarians from Linnaeus University and the University of Bradford for their guidance and assistance in this research. This study is being undertaken without external funding. A publishing grant has been received from Linnaeus University as part of the University Library's research support.

Data Availability

All data generated during this study will be included in the original review article (and its supplementary information files).

Conflicts of Interest

None declared.

Abstract

Background: Chronic pain is a highly prevalent condition and one of the most common reasons why people seek health care. As a result, chronic pain has a significant personal and economic burden. The COVID-19 pandemic has aggravated the situation for patients with chronic pain through increased risk factors (eg, anxiety or depression) as well as decreased access to health care. Digital health solutions to support people with chronic pain are becoming increasingly popular. Most of the research has focused on patient-facing digital health solutions, although it is clear that the involvement of health and care professionals is crucial in chronic pain care. Certainly, digital health solutions intended for the use of health and care professionals in the care of patients with chronic pain (ie, professional facing) exist, for example, for clinical decision support; however, no review has investigated the studies reporting these interventions.

Objective: The overall aim of this scoping review is to identify the available professional-facing digital health solutions for the purpose of chronic pain management. The objectives of this review are to investigate the components, target populations, and user settings of the available professional-facing digital solutions; health and care professionals' perspectives on using digital health solutions (if reported); the methods in which the digital health solutions are developed; and the outcomes of using professional-facing digital health solutions.

Methods: Databases including MEDLINE, Embase, CINAHL, PsycInfo, and Inspec will be searched for studies reporting professional-facing digital health solutions for chronic pain care, using a comprehensive search strategy developed for each of the specific databases. A total of 2 independent reviewers will screen the titles and abstracts for review inclusion and then conduct full-text screening. Any conflicts in study inclusion will be resolved by a third reviewer at each stage of the screening process. Following data extraction and quality assessment, a qualitative content analysis of the results will be conducted. This review will identify the available professional-facing digital health solutions for chronic pain management. The results of this review are likely to be heterogeneous in terms of content (ie, the digital solutions will serve a variety of purposes, settings, target populations, etc) and methods (ie, experimental and nonexperimental designs).

Results: The review is expected to finish in March 2024 and published in the summer of 2024.

Conclusions: This protocol outlines the need for a scoping review to identify professional-facing digital health solutions for the management of chronic pain. Results from this review will contribute to the growing field of research into the utility of digital health for chronic pain management.

KEYWORDS

burden; chronic pain; clinician; digital health solution; digital health; digital solutions; eHealth; healthcare professional; mHealth; pain management; patient-facing; risk factor

Introduction

Overview

Chronic pain is a highly prevalent condition, estimated to be affecting 20% to 30% of people worldwide [1,2]. Pain is defined by the International Association for the Study of Pain as an "unpleasant sensory and emotional experience associated with actual or potential tissue damage" [2]. Although there is some debate on the length of time an individual must experience pain for it to transition from "acute" to "chronic," the *International Classification of Diseases, 11th Revision* defines chronic pain as pain lasting ≥3 months [3]. Chronic pain can also be further categorized into primary (no evident cause); secondary (as a result of an underlying condition); or in some cases, both [4,5].

Various approaches to chronic pain treatment exist, including pharmacological interventions (ie, analgesic medication from paracetamol to opioids) and nonpharmacological interventions (eg, physical therapy and psychological therapy such as cognitive behavioral therapy) [6]. The treatment of chronic pain can be extremely complex; mismanagement can lead to significant issues, for example, opioid dependency [7]. Working toward providing appropriate and effective treatment for patients with chronic pain is crucial to reducing the issues surrounding the mismanagement of chronic pain.

Pain is one of the most common reasons why people seek health care [1]. Due to the prevalence of the condition and its consequent impact on health care, chronic pain has a significant economic burden [1,8] with the estimated costs to the economy reaching billions in the United Kingdom [9,10] and other countries within Europe [11]. Furthermore, during the COVID-19 pandemic, health care resources were diverted from chronic pain management toward more emergency, COVID-19–related conditions [12]. The pandemic has exacerbated the challenges that patients with chronic pain may face; for example, social isolation and lockdown have led to reduced access to health care as well as increased anxiety or depression and reduced mobility, all of which are factors that may aggravate chronic pain symptoms [13-15]. Certainly, the pandemic has led to a reconsideration of traditional health care methods and has highlighted the importance of being flexible with novel methods of health care delivery [13,16]. There is a clear need for new innovations in chronic pain management [17] as a result of its economic burden, which has been further aggravated by the issues presented by the pandemic.

Digital health solutions may provide a unique opportunity to mitigate these challenges to chronic pain management cost-effectively [8,12]. There has been a recent rise in the number of digital solutions available for chronic pain management [14], such as applications for patient self-management [18] and digitally delivered physical therapy [19]. There is variation in the nomenclature of "digital health," with definitions continuing to evolve [20]. Although there is no universally accepted definition for "digital health," digital health refers to all digital, electronic, and computer technologies to improve health [21]; it is used synonymously with "eHealth" in much of the literature [21]. Indeed, terms such as "digital health," "eHealth," "mobile health (mHealth)," and "telemedicine or telehealth" have been used interchangeably [21]. The components of digital health are broad and may include mobile apps (mHealth), web applications, wearable technology, artificial intelligence, analytics, and telemedicine [20]. Digital solutions within health care provide many benefits, specifically to chronic pain management; they offer access to remote care and reduce the impact in some areas of health care service provision, for example, staff shortages and lack of resources [22]. It may also help in reducing waiting lists for care [23]. Now more than ever, this is important due to the challenges that health care systems face.

Previous reviews have focused on digital solutions for chronic pain [24-26] and for specific chronic pain conditions such as osteoarthritis and lower back pain [22,27]. Such reviews have focused particularly on the effect of digital solutions on patient outcomes, with many of the included interventions being patient-facing for the purpose of self-management. The results of these reviews show that digital solutions have a positive impact on patients with chronic pain, on outcomes such as pain intensity, quality of life, coping skills, and adherence to exercise [22,24-27].

There has been an emphasis on health and care professional involvement and contact as an important facilitator in the adoption of digital health solutions, as collaboration with key stakeholders and end-user groups is essential for the development of sustainable and usable systems [28]. Despite this, many digital solutions are developed and implemented without the involvement of health and care professionals [27]. Much of the literature also highlights the importance of multidisciplinary professional involvement in general chronic pain care [2,29,30]. Primary care clinicians are particularly essential in the process of chronic pain management [5,30]. Chronic pain management must go beyond self-management alone (through purely patient-facing solutions) and also involve multidisciplinary health and care professionals [2,5,29,30].

Previous studies on the perspectives of health and care professionals have also highlighted the potential of digital solutions as a useful tool for health and care professionals, that is, for education, patient-follow ups, etc [23]. Digital solutions targeting education for professionals may be particularly useful for chronic pain management, as negative attitudes and a lack of clinician knowledge are significant barriers to chronic pain care [31]. National guidelines state that it is essential for health and care professionals to have the best possible resources and support to manage patients with chronic pain [5], which could be facilitated by digital health solutions. Indeed, there are existing professional-facing digital solutions for the management of chronic pain, such as clinical decision support tools [32]. It is clear that there is a utility to digital health solutions for health

and care professionals (ie, to provide education and other resources that adhere to guidelines for care) and that such applications exist; however, to our knowledge, no previous reviews have investigated the available professional-facing digital solutions for chronic pain.

Thus, the objective of this scoping review is to investigate the professional-facing digital solutions available for the management of chronic pain conditions.

Review Question

This scoping review aims to answer the question: What research-based digital health solutions, specifically designed for the use of health and care professionals, are available for the management of chronic pain?

Therefore, the objectives of this scoping review are to investigate the following:

1. The components of existing professional-facing digital solutions for the management of chronic pain: (1) what are the user features, (2) what data do they collect, (3) are they integrated into larger systems or stand-alone (eg, within a system involving a patient-facing application), (4) security or privacy considerations, (5) target populations, and (6) settings (eg, pharmacy, hospital, or multisite adoption)
2. The frameworks and methods with which the digital solutions were designed and developed.
3. The outcomes measured and the effectiveness of the digital solutions, that is, implementation success and clinical effectiveness
4. Health and care professionals' perceptions of the usability and usefulness of digital solutions in the management of chronic pain (if reported)

Methods

The proposed scoping review will be conducted in accordance with the Joanna Briggs Institute methodology for scoping reviews [33] and will be reported according to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) [34].

Eligibility Criteria

The population, concept, and context (PCC) will be used to guide the assessment of studies for review inclusion.

Inclusion Criteria

Population

Studies will be included if the reported digital health solutions' intended user demographic is health and care professionals directly involved in the care of patients (aged 18 years or older) with chronic pain. "Health and care professional" will refer to any professional who provides a health and care service, including, but not limited to, nurses, pharmacists, general practitioners, physiotherapists, other therapists, psychologists, and social care professionals. There will be no restrictions on the type of health and care profession of the participants.

Concept

The concept of interest for this review is digital health solutions (including, but not limited to, eHealth, mHealth, telehealth, web-based interventions, etc) intended to assist health and care professionals in the diagnosis and management of chronic pain. Any chronic pain-specific digital health solutions that are specifically designed for the end user to be health and care professionals will be considered in this review; therefore, the included solutions are likely to be heterogeneous in aim, user features, and functionality. This may include those intended for clinical decision support, education, remote patient monitoring, etc. Solutions may include mobile apps, web-based applications, or any other tools provided digitally.

Digital health solutions for the management of all types of chronic pain conditions will be considered, including chronic primary pain (eg, fibromyalgia, complex regional pain syndrome, and chronic primary headache), chronic secondary pain (eg, osteoarthritis and chronic pain secondary to cancer), or both [4,5]. Digital health solutions must be chronic pain specific, that is, for the management of a diagnosed chronic pain condition, with pain defined as "chronic" and lasting 3 or more months.

Context

There will be no restrictions on the context of this review. Contexts may include research and clinical settings, that is, any environment in which health and care professionals may be involved in the management of patients with chronic pain. Settings will likely include primary, secondary, and tertiary care settings (eg, pharmacies, general practitioners, and hospitals) and community settings (eg, residential facilities and the patient's home).

Exclusion Criteria

Studies reporting digital health solutions intended for use by patients only (eg, for self-management purposes) without a professional-facing component will be excluded. Studies will also be excluded if the digital health solution is not specifically intended for the management of a chronic pain condition (eg, studies reporting communication between health care professionals and patients through telephone or videoconferencing [Zoom, Zoom Video Communications; Microsoft Teams, Microsoft Corporation; etc] only, without specific digital chronic pain support, or studies reporting management of chronic pain using a digital health solution designed for general health care, that is, electronic health records). Digital health solutions will not be considered if they support the care of acute or nonchronic pain, for example, nonspecific low back pain. Studies reporting digital health solutions for nonadult patients (<18 years old) with chronic pain will also be excluded. Other exclusion criteria include gray literature and studies not written in the English language.

Types of Sources

This scoping review will consider all types of study designs. This may include experimental studies on the effectiveness of professional-facing digital solutions for the management of chronic pain (eg, randomized controlled trials, before and after sequential design, etc) or nonexperimental studies on the

development of digital solutions (eg, qualitative studies involving interviews). If only the abstract is available for a relevant study, the author will be contacted for further study information.

Search Strategy

A comprehensive search strategy will be developed using subject headings specific to databases MEDLINE, Embase, CINAHL, PsycInfo, and Inspec (Multimedia Appendix 1). The search strategy will comprise three categories relevant to the PCC inclusion criteria: terms relating to (1) chronic pain (concept of interest), (2) digital health (concept of interest), and (3) health and care professionals (population). There will be no terms in the search strategy limiting the context, as there will be no restrictions on setting. Search terms used for chronic pain will be developed using terms used in the National Institute for Health and Care Excellence guidelines for the management of chronic pain [4]. Keywords and index terms from previous relevant literature will be used to form search terms for all categories within the search strategy. The search strategies will be reviewed by an academic librarian to gain assistance on database-specific guidelines and to ensure the searches capture as many papers fitting the eligibility criteria as possible. Backward-citation searches will also be conducted by reviewing the references of the included studies for relevant articles. Researchers and experts in the field will be contacted to inquire about studies that fit the inclusion criteria.

Study or Source of Evidence Selection

Following the search and after removing duplicates, titles and abstracts will be screened by 2 independent reviewers against the inclusion criteria, with any disagreements resolved through discussion with a third independent reviewer. Full texts of potential studies fitting the inclusion criteria will then be reviewed again, in detail, by 2 independent reviewers. Reasons for exclusion will be recorded at the full-text reviewing stage and reported in the scoping review. Any disagreements that may arise at this stage will be resolved through discussion with a third independent reviewer. Screening and full-text review will be conducted on Covidence (Veritas Health Innovation Ltd).

Data Extraction

Data will be extracted from the studies fitting the inclusion criteria by 2 independent reviewers using a data extraction tool developed for the purpose of this review (Multimedia Appendix 2). The data extraction tool will be developed from the Template for Intervention Description and Replication checklist [35], which focuses on the digital solution components, that is, the rationale of the intervention, user features, procedures, etc. Additional information specific to the review aims will also be collected, for example, participant demographic information and perspectives of health and care professional users (if reported). Data extraction will first be piloted by the 2 reviewers by extracting the data from 10% of the studies fitting the inclusion criteria together through discussion.

As the included studies are likely to be diverse in design (due to no restrictions being imposed on the type of source), quality assessment will be conducted using Quality Assessment for Diverse Studies [36]. Although it is not essential to conduct a quality assessment in a scoping review [33], ascertaining the overall quality of the studies included in this review will be beneficial, as the literature suggests research in digital health for chronic pain is of low quality [37].

Data Analysis and Presentation

This scoping review will aim to conduct a qualitative content analysis of the results, that is, code the features of the digital health solutions used by the included studies into overall categories using NVivo (Lumivero, QSR International). If the results of the review are too heterogeneous for this, a narrative synthesis of the features of the digital health tools will be conducted. No analyses will be conducted to ascertain the overall effectiveness of professional-facing digital health solutions (as this is out of the scope of a scoping review). However, we will report the effectiveness of the individual digital health solutions as reported by each of the included studies in a narrative summary.

Expected Results

This scoping review will identify the available professional-facing digital health solutions for the management of chronic pain, their components, user settings, and target populations; professionals' perspectives on the use of digital health solutions; the methods in which the professional-facing digital health solutions are developed (ie, co-design framework used); and the outcomes of professional-facing digital health solutions. It is expected that the included studies will report on a variety of professional-facing digital health solutions. This may include systems for clinical decision support, symptom management, patient follow up, and educational tools. The outcomes of individual professional-facing digital solutions are also expected to be varied; they will likely have differing measures of effectiveness.

The types of studies fitting the inclusion criteria will most likely be heterogeneous in their methodology, as no restrictions have been imposed on design. Some included studies may report the early stages of developing the professional-facing digital solution (eg, nonexperimental studies such as those using interviews, surveys, and focus groups), while others may report on the effectiveness of the professional-facing digital solution (eg, experimental studies like randomized controlled trials). It is difficult to predict the quality assessment of these studies, at this stage.

The qualitative content analysis of the results will help to answer the review questions, that is, what are the user features, what data do they collect, are they integrated into larger systems or stand-alone, and what are their target population and user settings? If the included studies report on health and care professionals' perspectives, for example, through interviews or surveys, qualitative analysis will also provide information on the health and care professionals' perspectives on using professional-facing digital solutions.

Results

The scoping review is expected to be finished by March 2024 and the first search will be implemented in July 2023. The

results of the scoping review are expected to be published by the summer of 2024.

Discussion

Overview

To the best of our knowledge, this will be the first scoping review of professional-facing digital health solutions for the management of chronic pain. As we move further into a more digital age, there is a growing need for research into digital health and chronic pain care. This has been further emphasized by the challenges to care presented by the pandemic.

This scoping review will provide a foundation for further research into digital health solutions to make chronic pain care more efficient and innovative, from a health and care professional perspective. Results from this review will contribute to knowledge on the available professional-facing digital health solutions (including their components, user settings, target populations, development, and the perspectives of professionals on the use of such systems), as well as the gaps in the research on digital health solutions targeted toward health and care professionals (for example, areas of care that are not covered). As this is a scoping review, no conclusions can be drawn on the overall effectiveness of the professional-facing digital solutions, only the outcomes of the individual digital solutions as reported by the included studies.

We intend to conduct a qualitative content analysis to synthesize the results of this review. However, it is difficult to ascertain the method by which the included studies will report their findings (most likely extremely heterogeneous, given the broad inclusion criteria). Therefore, it may only be possible to conduct a narrative synthesis of the features of the professional-facing digital health solutions for chronic pain management. Either method of synthesizing the results of this review will produce valuable information on practices in chronic pain care and contribute knowledge to the field of digital health research.

Patient-Facing Versus Professional-Facing Digital Health Solutions for Chronic Pain Management

Although previous reviews have not focused on digital health solutions intended for use by health and care professionals, the literature supports the effectiveness of digital health solutions for the management of chronic pain. Recent systematic reviews suggest that mHealth interventions for chronic pain have a positive effect on patient outcomes (eg, pain intensity, quality of life, and functional ability) [25,26]. However, the literature also suggests that the quality of studies on digital health solutions for chronic pain is subpar, with Moreno-Ligero and colleagues [25] reporting “medium” quality for the majority of their included studies. This further highlights the need for a quality assessment to be conducted in this scoping review, to ascertain the quality of the studies on professional-facing digital solutions for chronic pain management.

Similarly, previous studies reporting on health and care professionals’ perspectives have focused on patient-facing digital health solutions for chronic pain management, that is, self-management interventions. Varsi and colleagues [23] emphasized the need for a comprehensive treatment approach to chronic pain care of which digital health solutions could provide if factors such as health care provider involvement, timely support, and follow up are also considered. Professional-facing digital health solutions may be one of the ways in which the latter factors could be incorporated into a more comprehensive system for managing chronic pain. Additionally, health and care professional involvement is required, not only in the use of digital health solutions but also in their development; many studies reporting digital health solutions for chronic pain management were designed without stakeholder involvement [23] and developed without using co-design methods or any form of user evaluation. This is also particularly essential for professional-facing digital health solutions and will be addressed in this review.

Strengths and Limitations

A significant strength of this scoping review is the systematic method of conducting the searches. A specialized academic librarian will aid in the development of comprehensive and individualized search strategies (Multimedia Appendix 1). Search terms will be formulated using specific subject headings for each database (eg, Medical Subject Headings for MEDLINE) as well as keywords taken from previous similar reviews. Search terms to describe chronic pain will be developed from terms used in the National Institute for Health and Care Excellence guidelines for the management of chronic pain [4]. A total of 2 blinded reviewers will independently complete all steps of the reviewing process, and a third reviewer will resolve any disagreements. Due to this systematic process, this review is likely to include most of the relevant studies that fit the inclusion criteria. Furthermore, this scoping review will follow the Joanna Briggs Institute scoping review manual as well as the PRISMA-ScR checklist.

The findings of this review will be limited to those published in the English language; therefore, there is a possibility that some professional-facing digital health solutions developed and reported in non-English–speaking countries will be missed by this review. It is important to consider that, as guidelines for chronic pain care and digital health differ between countries, jurisdiction of development and implementation may be a significant factor in the type of digital health solutions reported in this review. Furthermore, as some digital health solutions are developed commercially and do not have an academic foundation, the search of academic databases (without a market review, eg, app store search) may not have captured all professional-facing digital health solutions for chronic pain management. However, the quality of digital health solutions is largely dependent on their scientific foundation, which is facilitated by academic development, and nonevidence-based professional digital health solutions are not likely to be useful or realistically implemented in clinical chronic pain care settings. In order to find all available digital health solutions, it would be useful to communicate with health and care professionals currently involved in chronic pain care. Future studies may benefit from conducting interviews with health and care professionals to ascertain what digital health solutions are currently implemented in clinical settings and the benefits or

drawbacks of such systems in the care of patients with chronic pain.

Conclusion

This protocol outlines the need for a scoping review to identify professional-facing digital health solutions for the management of chronic pain. The results of this review will highlight the available digital health solutions available for health and care professionals to use specifically for chronic pain care and provide information regarding the system's components, user settings, specific target populations, and development. This scoping review will be systematically conducted to ensure most of the relevant literature is included; however, some professional-facing digital health solutions may be missed if they are developed commercially (without academic publication) or not reported in the English language. Findings from this review will contribute to the ever-growing field of digital health research and provide further information on how digital health can improve chronic pain care.

Acknowledgments

Special thanks to Dr David Stirling for funding the PhD project that this scoping review forms a part of, as well as to the academic support librarian, Elaine Blair, who helped in developing the search strategies.

Data Availability

Data sharing is not applicable to this article as it is a protocol and no data sets have been generated or analyzed yet.

Abstract

Background: Complex and expanding data sets in clinical oncology applications require flexible and interactive visualization of patient data to provide the maximum amount of information to physicians and other medical practitioners. Interdisciplinary tumor conferences in particular profit from customized tools to integrate, link, and visualize relevant data from all professions involved.

Objective: The scoping review proposed in this protocol aims to identify and present currently available data visualization tools for tumor boards and related areas. The objective of the review will be to provide not only an overview of digital tools currently used in tumor board settings, but also the data included, the respective visualization solutions, and their integration into hospital processes.

Methods: The planned scoping review process is based on the Arksey and O'Malley scoping study framework. The following electronic databases will be searched for articles published in English: PubMed, Web of Knowledge, and SCOPUS. Eligible articles will first undergo a deduplication step, followed by the screening of titles and abstracts. Second, a full-text screening will be used to reach the final decision about article selection. At least 2 reviewers will independently screen titles, abstracts, and full-text reports. Conflicting inclusion decisions will be resolved by a third reviewer. The remaining literature will be analyzed using a data extraction template proposed in this protocol. The template includes a variety of meta information as well as specific questions aiming to answer the research question: "What are the key features of data visualization solutions used in molecular and organ tumor boards, and how are these elements integrated and used within the clinical setting?" The findings will be compiled, charted, and presented as specified in the scoping study framework. Data for included tools may be supplemented with additional manual literature searches. The entire review process will be documented in alignment with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) flowchart.

Results: The results of this scoping review will be reported per the expanded PRISMA-ScR guidelines. A preliminary search using PubMed, Web of Knowledge, and Scopus resulted in 1320 articles after deduplication that will be included in the further review process. We expect the results to be published during the second quarter of 2024.

Conclusions: Visualization is a key process in leveraging a data set's potentially available information and enabling its use in an interdisciplinary setting. The scoping review described in this protocol aims to present the status quo of visualization solutions for tumor board and clinical oncology applications and their integration into hospital processes.

Introduction

Multidisciplinary team interventions, and especially tumor boards (or multidisciplinary cancer conferences [MCCs]) have been shown to significantly improve the quality of cancer care [1-3]. Complex, multimodal, and ever-growing data sets in multidisciplinary settings present special challenges when it comes to data visualization [4]. These data sets can include anything from demographic information and laboratory results to tumor imaging, pharmacotherapeutic timelines, and genomics data, providing limitless opportunities for aggregation and joint visualization. The need for digital support and customized visualization solutions becomes especially apparent when discussing the time constraints often found in clinical oncology settings. Available time frames for treatment decisions might range between 10 and 20 minutes per patient [5], highlighting the importance of aggregated and annotated data to enable participating health care professionals to include all relevant information in the decision-making process. However, even without taking limited time into account, the growing complexity of patient data makes it difficult to fully understand a patient's health status without the support of visualization, even more so when multiple points of data on the patient journey are available [6,7]. While tools for the visualization of multimodal data in the described settings exist [8-10], there is no current overview of actively used and established visualization tools and their key differences, especially on an international level.

The rise of molecular tumor boards (MTBs) has been an additional driving factor in the development of digital support applications for interdisciplinary settings and the incorporation of multimodal data. Combining ordinary clinical information with the complexity of genomics data required special tooling to enable oncologists to make fully informed treatment decisions and limit the time necessary for the MTBs' preparation [11,12]. Virtual MTBs and rising numbers of outpatient referrals lead to a heterogeneous pool of tumor board participants and increase the need for intuitive visualization. Complex patient journeys have to be presented in a condensed and clear manner, sometimes crossing language barriers, without prior knowledge of the patient or their history [12,13]. This led to the emergence of software solutions such as cBioPortal (Memorial Sloan Kettering Cancer Center) [14-16], The Cancer Core Europe Molecular Tumor Board Portal [17], and AMBAR [18], offering complex visualization of genomic variants found in cancer samples.

Additionally, knowledge bases such as OncoKB [19] or CIViC [20] have been created, providing access to annotations with aggregated and structured information on available targeted therapies. The usage of these established tools not only supports the preparation and execution of MTBs but also increases the consistency of therapy recommendations between molecular tumor conferences, even for patients with rare cancers and mutation patterns [21]. Research indicates that differing processes and tools may lead to inconsistent therapy recommendations [22].

To enable the visualization of data for the preparation and execution of MCCs, patient and supplementary data must be made available to the tools used. This is challenging as the availability of interfaces or APIs for the import of data sets can vary greatly and is often only possible through the use of proprietary data formats, which may require the development of extract, transform, and load processes to automate data import and export [23]. Additionally, data privacy regulations and ethical concerns may limit the usage of external services. Several German initiatives and consortiums (eg, Medical Informatic Initiative [24], Bavarian Center for Cancer Research [25], and German Network for Personalized Medicine [26]) are working on standardized data sets and processes related to the cancer patient journey in German hospitals. This includes software extensions for established tools such as cBioPortal, for example, covering the documentation and visualization of therapy decisions in MTBs [27,28].

In summary, there is an increasing need for additional visualization in the context of tumor board settings to leverage the full potential of growing data sets for patient care and therapy decisions. Integrating these software solutions into clinical processes is a challenging task, requiring data from a variety of sources to be readily available to facilitate their use in the preparation and execution of tumor boards. With this in mind, the objective of the proposed scoping review is to identify available software support for MCCs described in scientific literature, gather key aspects of applied visualization strategies as well as their integration into existing processes, and present them in a comprehensive overview.

Methods

Design

For conducting this scoping review study, we will use the scoping study framework of Arksey and O'Malley [29] as a methodological blueprint for this review.

Arksey and O'Malley describe a five-stage model for scoping study design: (1) identification of the research questions; (2) identification of relevant studies; (3) study selection; (4) data extraction and charting; and (5) collating, summarizing, and reporting the results. Any subsequent deviations of the final report from the scoping review protocol will be highlighted and explained in the scoping review report.

Stage 1: Identification of the Research Questions

While there has been a continuous development of digital support tools for clinical oncology settings over the last few years, currently no structured overview of the visualization tools and techniques used in these applications exists. The core research question driving the scoping review was proposed based on these circumstances, and further developed through multiple iterations of discussion in the research team:

> *Research question: What are the key features of data visualization solutions used in molecular and organ tumor boards, and how are these elements integrated and used within the clinical setting?*

Starting from this overarching research question, specific questions we wanted to answer while extracting data from relevant literature were developed. These were used at a later step to design the data extraction template. They were the following: (1) What data visualization solution is being used? (2) What kind of data are being visualized? (3) How do they visualize the available data? (4) How are these elements integrated and used within the clinical setting? (5) How accessible are the solutions? (6) Are the solutions already being used in hospitals? (7) Have the proposed or implemented solutions been evaluated?

Stage 2: Identification of Relevant Studies

Core Concepts and Keywords

To find relevant studies and gain an insight into the search domain an initial manual literature search was executed. In total, 19 key papers were identified and used to extract concepts for the development of a search strategy. All in all, we were able to identify 3 core concepts that relevant literature would have to encompass. First, tumor boards or similar settings as the target domain. Second, software or some other form of digitalized support. Lastly, the described mode of support delivered by the software, for example, visualization, usage as a decision support system, or personalized medicine.

In the following process, these concepts were used to define keywords for the development of individual search strategies for the chosen databases (Textbox 1). The initial manual literature search showed that relevant literature can be found in a variety of different contexts. Supporting applications for tumor boards may be described in publications covering the development of those tools, their integration into hospital processes, evaluations of their efficacy, or even as a sidenote in the medical literature. As such some of the keywords may seem out of scope at first glance but lead to the inclusion of additional relevant results. MTBs present one of the driving institutions for the development of multimodal and interactive visualization solutions for clinical oncology settings and as such provide a variety of keywords to the search strategy.

Textbox 1. Concepts and corresponding keywords.

Target domain

- Tumor board, tumor conference, molecular tumor board, mutation database, and cancer genomics.

Software

- Virtual, digital, software, tool, platform, and portal.

Mode of support

- Visualization, interactive, preparation, usability, clinical decision support system, personalized medicine, and precision medicine.

Query Construction

Using the defined concepts and corresponding keywords, search strategies for the different databases were built. The general strategy for this process was connecting concepts through "AND" operators, while keywords were connected by "OR" operators. The search was limited to title and abstract where possible since this proved to consistently recall key literature and articles of interest while greatly reducing the amount of out-of-scope search results. The queries were adapted to the specific database needs, for example, the usage of Medical Subject Heading Terms for PubMed. The resulting queries were tested on their recall of key literature and accuracy. They underwent an iterative optimization process based on their performance and in a last step were validated by a librarian. The proposed queries can be found in Multimedia Appendix 1. All future deviations will be documented and discussed in the final publication.

Stage 3: Study Selection

Inclusion and Exclusion Criteria

Only articles published in English during the last 10 years will be included. Since our initial search showed a very broad range of target literature types, we decided not to use further inclusion or exclusion criteria to include all potentially relevant articles.

Selection Process

All literature found by applying the search strategies to PubMed [30], Web of Knowledge [31], and SCOPUS [32] will be exported into a compatible format and uploaded to Rayyan (Rayyan) [33], which will be used for the 2-step study selection process. In the first step, title-abstract screening will be

performed to quickly exclude out-of-scope literature, reducing the workload for the full-text screening stage. Each paper will be screened by at least 2 reviewers. An additional reviewer will solve conflicting inclusion decisions. During the second screening phase, full-text screening will be performed to exclude results that will not assist in answering the research question described in Stage 1. To increase consistency, criteria for the inclusion and exclusion of literature during the screening process will be supplied to all participating researchers and discussed in a meeting before the start of the screening. The study selection process will be documented using Rayyan. The results of this process will be compiled into a PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) [34] flowchart.

Stage 4: Data Extraction and Charting

All selected literature will be searched for metadata and information relevant to answering the proposed research question. For a standardized approach between reviewing parties, a data extraction template (Table 1) was developed, encompassing all required metadata, as well as specifics regarding each aspect of the overarching research question. The data extraction template was designed in a close fashion to templates from similar review projects [35,36] as their authors were consulted during the development process of this protocol. Potential modifications to the template will be documented, properly highlighted, and discussed in the final publication.

Table 1. The data extraction tool template.

Data and item	Description
Metadata	
Title[a]	Title
Citation details[a]	Author (first), journal, and DOI
Year of publication[a]	Year of publication
Publication type[a]	Type of publication
Institute[a]	Corresponding institute
Funding source	Funding source of the publication
Objective[a]	Publication objective
Methods[a]	Short description of the methodology used
Summary result[a]	Short description of the results
Conclusion	Short description of the conclusion
Keywords	Keywords
Citations	List of articles citing this paper
Results related to the research question	
What data visualization solutions are being used?	Name and description of the applications or tools that are being used
What kind of data are being visualized?	List and description of the data that is being visualized. Name and a short description of the corresponding standardized or harmonized data set if applicable
How do they visualize the available data?	List and description of the modes of visualization applied, including interactive features such as filtering or customization
How are these elements integrated and used within the clinical setting?	Description of the integration into the clinical setting if available, covering the process integration as well as software interfaces and capabilities for the documentation of tumor boards, if available
How accessible are the solutions?	Accessibility of the software, for example, open source or commercial product, and licensing information
Are the solutions already being used in hospitals?	List of hospitals that are already using the software
Has there been a methodical evaluation of the proposed or implemented solution?	Description of the evaluation methodology and the corresponding results, if available

[a]Mandatory field.

Stage 5: Collating, Summarizing, and Reporting the Results

After data extraction and charting, the results will be analyzed in a 2-step process per Arksey and O'Malley's framework [29]. First, the findings will be analyzed numerically, comparing the extent, nature, and distribution of the literature found. Following that we will prepare a thematic overview on visualization solutions for tumor boards and clinical oncology. The visualized data per tool, as well as the respective visualization strategies

used and remaining elements of the data extraction template, will be charted and appropriate graphics will be created. The findings will be presented following the PRISMA-ScR reporting guidelines [34].

Ethical Considerations

Since our review will not involve human participants, this study does not require ethics approval.

Results

The scoping review started with a tentative search beginning in September 2023 leading to 2057 results with a suspected 1227 duplicates. In the next step titles and abstracts will be iteratively screened by reviewers to decide on the paper's inclusion in the further review process (see stage 3). This will be based on the criteria described in the Methods section. Included articles will be analyzed by applying the appended data extraction tool (see stage 4). This step is expected to be finished by December 2023. Lastly, the results will be summarized and compiled (see stage 5) up until the beginning of 2024. We expect them to be published during the second quarter of 2024.

Discussion

We designed a scoping review, aiming to present the current state of software support for clinical oncology settings, focusing on visualization solutions used in MCCs and their integration into hospital processes. The initial search, executed using the methods and queries described in this protocol, was able to show that a significant amount of potentially relevant literature can be found in the selected electronic databases. By asserting that manually identified key papers are included in the results, we are confident that the results produced by the search queries include the target domains.

However, a potential limitation of the completeness of the scoping review might be its focus on scientific literature. While tumor boards are often actively part of research projects and publicize their findings including used software solutions, commercial visualization tools and supporting software are being used as well. These might present new and interesting approaches but would not be necessarily found during a literature search. However, limited access to these applications would make their analysis difficult, and closed-source solutions often present limited possibilities for extensions and follow-up work. Additionally, available literature on supporting software might focus on features apart from visualization and offer limited insight into the questions posed. We aim to mitigate this by supplementing the findings through additional manual searches for included software.

We expect the scoping review's findings to show the current state of data visualization in clinical oncology settings. By comparing these results with the data most commonly available in the context of tumor boards and upcoming data sets we aim to anticipate visualization needs and provide starting points for more focused requirement analysis. Lastly, we hope to inform the future development of flexible visualization solutions for expanding oncology data sets.

Acknowledgments

This work was funded by the German Federal Ministry for Education and Research through the PM4Onco project (01ZZ2322S, 01ZZ2322N, and 01ZZ2322R), and by the Bavarian Cancer Research Center (BZKF). This work was performed in (partial) fulfillment of the requirements for obtaining the degree "Dr. rer. biol. hum." at the Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU).

Conflicts of Interest

None declared.

Abstract

Background: Decompressive craniectomy (DC) is a widely used procedure to alleviate high intracranial pressure. Multidisciplinary teams have designed and implemented external medical prototypes to improve patient life quality and avoid complications following DC in patients awaiting cranioplasty (CP), including 3D printing and plaster prototypes when available.

Objective: This scoping review aims to understand the extent and type of evidence about innovative external prototypes for patients who undergo DC while awaiting CP.

Methods: This scoping review will use the Joanna Briggs Institute methodology for scoping reviews. This scoping review will include noninvasive medical devices for adult patients who undergo DC while waiting for CP. The search strategy will be implemented in MEDLINE, Embase, Web of Science, Scielo, Scopus, and the World Health Organization (WHO) Global Health Index Medicus. Patent documents were also allocated in Espacenet, Google Patents, and the World Intellectual Property Organization (WIPO) database.

Results: This scoping review is not subject to ethical approval as there will be no involvement of patients. The dissemination plan includes publishing the review findings in a peer-reviewed journal and presenting results at conferences that engage the most pertinent stakeholders in innovation and neurosurgery.

Conclusions: This scoping review will serve as a baseline to provide evidence for multidisciplinary teams currently designing these noninvasive innovations to reduce the risk of associated complications after DC, hoping that more cost-effective models can be implemented, especially in low- and middle-income countries.

Introduction

Traumatic brain injuries (TBIs) remain a significant global health challenge affecting more than 69 million people annually [1]. The incidence of TBIs in low- and middle-income countries is disproportionate, 3 times greater than in high-income countries [1]. Severe forms of TBI (5.58 million people each year or 73 cases per 100,000 people) and other critical pathologies such as strokes and brain tumors often require a life-saving neurosurgical procedure called decompressive craniectomy (DC) [1]. DC is an essential surgical procedure that alleviates intracranial pressure, which consists of removing a section of the skull to avoid inward brain constriction due to brain parenchyma and cranial rigidity [2]. However, this intervention leaves patients vulnerable and at risk of neurological impairment, further traumas, and self-esteem difficulties while waiting for cranioplasty (CP) [3].

The overall complication rate after DC has been reported to be as high as 50% [3]. These complications include (1) the syndrome of the trephined, in which the atmospheric pressure compresses the brain parenchyma and the neurological status of the patient deteriorates after the removal of a skull bone flap, in 13% of patients who undergo DC; (2) hemorrhage, in 58%; (3) external herniation, in 25%; (4) wound complications (such as ulceration or necrosis) or surgical site infection, in up to 9%; (5) cerebral spinal fluid leakage, in 6.3%; and (6) increased risk of severe injuries from falling, among others [4-6].

A critical challenge post-DC patients face is the need for protective measures for the craniectomy site. A study described that at least 88.9% of patients have reported needing a device to prevent contact with the craniectomy site [7]. In response to this challenge, external protective devices have emerged as a potential solution to replicate the protective effects of CP and minimize postoperative complications.

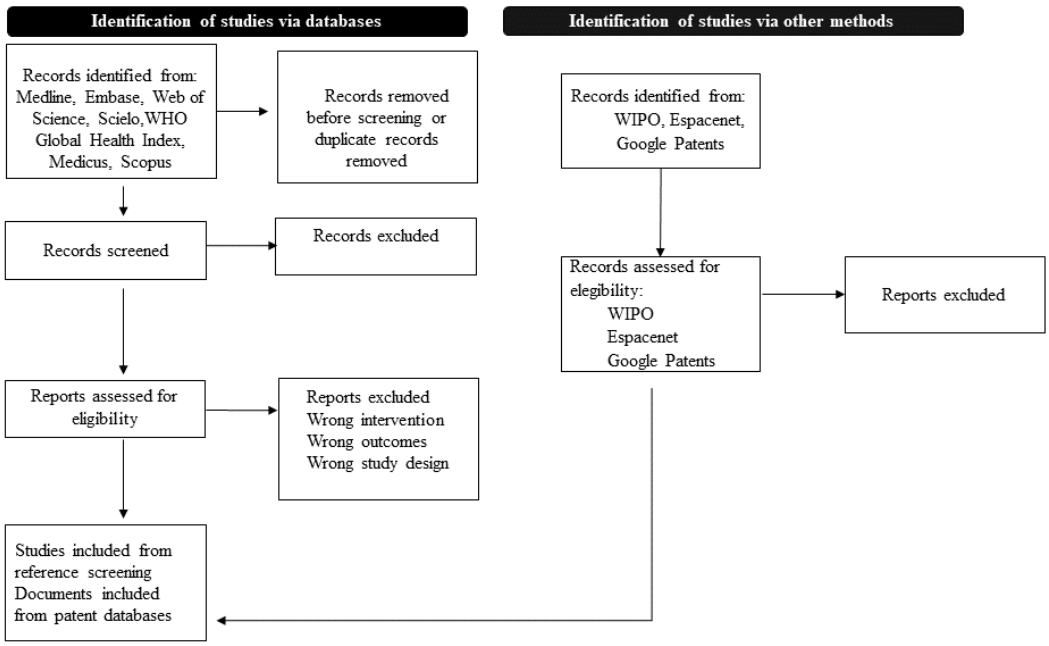
Nowadays, technological innovation in medicine drives care improvements, surgical techniques, and preventative medicine. This is especially true in neurosurgery, as shown by neurostimulation in functional neurosurgery, microneurosurgery, and the merging of computed tomography and magnetic resonance imaging intraoperatively, always possible because of the multidisciplinary teams [7,8]. The global medical device industry is highly competitive, with many countries contributing to its development and growth worldwide. Interdisciplinary teams have designed and implemented external medical prototypes in response to the need to improve patient's quality of life and avoid complications following DC in patients awaiting CP, including 3D printing and plaster prototypes, when available. Therefore, the objective of this scoping review is to develop a better understanding of available innovations in technology for patients with DC who are awaiting CP worldwide.

Methods

Overview

The proposed scoping review will use and follow the Joanna Briggs Institute methodology for scoping reviews [9]. The proposed methodology is presented in Figure 1.

Figure 1. Summary of the search strategy process. WHO: World Health Organization; WIPO: World Intellectual Property Organization.



Review Question

What is the current landscape of external medical devices replicating the effects of CP worldwide?

Eligibility Criteria

Participants

This scoping review will include prototypes for adult patients who undergo DC while waiting for CP.

Concept

External medical devices that replicate the effects of CP.

Context

This scoping review will not exclude documents based on geographic areas as it is intended to identify and locate where they have been designed and implemented.

Types of Sources

This scoping review will consider experimental and quasi-experimental study designs, including randomized controlled trials, non-randomized controlled trials, before and after studies, and interrupted time-series studies. Consideration will be given to the inclusion of analytical observational studies, which may include prospective and retrospective cohort studies, case-control, or analytical cross-sectional studies. This review will consider descriptive observational study designs, including case series, individual case reports, and descriptive cross-sectional studies for inclusion. Qualitative studies that focus on qualitative data will also be included, but are not limited to, designs such as phenomenology, grounded theory, ethnography, qualitative description, and action research.

In addition, systematic reviews that meet the inclusion criteria will also be considered, depending on the research question. Text and opinion papers will also be considered for inclusion in this scoping review. Worldwide patents will be allocated in the central databases Espacenet, Google Patents, and World Intellectual Property Organization (WIPO).

Search Strategy

The search strategy will be carried out by an experienced librarian (IK) to locate both published and unpublished documents. An initial limited search of MEDLINE was undertaken to identify studies on the topic. The text words in the titles and abstracts of relevant studies and the index terms used to describe the studies were used to develop a complete search strategy for PubMed, Scopus, Web of Science, Scielo (see Multimedia Appendix 1), and the World Health Organization (WHO) international database. Patents will also be allocated in Espacenet, Google Patents, and WIPO. The search strategy, including all identified keywords and index terms, will be adapted for each included database and information source. The reference list of all included sources of evidence will be screened for additional studies. Studies published in any language will be included, and translation services will be used if necessary. No time limit has been established.

Study or Source of Evidence Selection

All identified citations will be collated and uploaded to EndNoteX9 (Clarivate Analytics) after the search. The citations will then be imported into Covidence software (Veritas Health Innovation) for screening. A total of 2 independent researchers will examine titles and abstracts for inclusion. The full text of selected studies will be retrieved and assessed. Full-text studies that do not meet the inclusion criteria will be excluded, and the reasons for exclusion will be provided in the final scoping review. Any disagreements between the researchers during either title and abstract screening or full-text screening will be resolved through discussion or with a third reviewer. All included studies will undergo a process of data extraction using a standardized data extraction tool. The final study will report the search results in complete and present using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews (PRISMA-ScR) checklist.

Data Extraction

Data will be extracted from papers and patent documents included in the scoping review by 2 or more independent reviewers using a data extraction tool developed by the reviewers. The data extracted will include specific details about the participants, concept, context, study methods, and critical findings relevant to the review questions.

A draft extraction is provided in Multimedia Appendix 2. It will be modified as necessary while extracting data from each included evidence source. Modifications will be detailed in the scoping review. Any reviewer disagreements will be resolved through discussion or with additional reviewers. If appropriate, authors of studies could be contacted to request missing or other data, where required.

Data Analysis and Presentation

The extracted data will be presented in tabular form and as a narrative summary that aligns with the aim of this scoping review. The table will report (1) the distribution of medical devices by countries of origin or study design, (2) functional claims or features, (3) implementation strategies, (4) patient outcomes, (5) costs, and (6) strengths and weaknesses. This table may be further refined at the review stage. Graphical representations may be used, including bar charts, line charts, pie charts, and diagrams. A narrative summary will accompany the tabulated or charted results and describe how the results relate to the review's objectives.

Ethical Considerations

No ethics approval will be required, as this review is based on already published data and does not involve interaction with human participants.

Results

The research for this systematic review commenced in February 2023, and we expect to publish the findings in 2024. The plan for dissemination, however, is to publish the review results in a peer-reviewed journal and present findings at high-level conferences that engage the most pertinent stakeholders involved in innovation and neurosurgery.

Discussion

Cumulatively, 6838 studies were identified from the database searches and 1652 from patent searches, after which 64 scientific papers and 4 patent documents were left for full-text review. Of these, 9 documents met the inclusion criteria and will be used in the final synthesis. Three categories of study design were identified: case reports (n=6), cohort studies (n=1), and exploratory clinical trials (n=1). One of the documents was not a scientific report and was categorized as a patent document. The complete data analysis and discussion will be published in an indexed journal once it is finished in an indexed journal upon completion.

This protocol has been rigorously developed and explicitly designed to illustrate and summarize the evidence regarding innovative external devices for patients with DC awaiting CP worldwide. This scoping review will serve as a baseline to provide evidence for multidisciplinary teams currently designing these noninvasive innovations to reduce the risk of associated complications after DC, hoping that more cost-effective models can be implemented, especially in middle-income and low-income countries. The principal limitation of this and any scoping review is the quality of the included studies leaving the included literature with a higher risk of bias.

Although most of these devices were developed in middle- and high-income countries, they serve as a starting point for implementation and future development in lower-income countries where no current solutions exist.

Acknowledgments

Abstract

Background: Healthy aging is a pressing public health priority. Focusing on what people do every day may be a meaningful approach to lifestyle change, suggesting a need for occupation therapy interventions to promote healthy aging. A preliminary database search was conducted, and no current or underway systematic or scoping reviews on the topic were identified. Developing an overview of studies of occupational therapy interventions to promote healthy aging is a necessary first step to understanding the existing knowledge and increasing the impact of future interventions. This scoping review will build on previously conducted reviews.

Objective: This scoping review will identify the following: (1) what occupational therapy interventions exist for promoting healthy aging in community-dwelling adults? and (2) what are the intervention characteristics, their evaluated outcome, and the impact observed?

Methods: This protocol was reviewed by 2 occupational therapists as part of a patient and public involvement consultation. The review will consider all studies and publications of occupational therapy focused on promoting healthy aging in community-dwelling adults who are aged 18 years and older. Databases to be searched are AMED, CINAHL, Cochrane Library, Embase, JBI EBP database, MEDLINE, OAlster, PsycINFO, PsycArticles, ProQuest Dissertations & Theses, ProQuest nursing and allied health source, PubMed, and Science Direct. Studies published in any language will be included. Titles and abstracts will be screened against the inclusion criteria using Covidence (Veritas Health Innovation). Potentially relevant studies will be retrieved in full and assessed against the inclusion criteria. No date limiters will be used. Study selection will be completed by 2 independent reviewers. Data will be extracted using a data extraction tool, including descriptive characteristics of the participants including age, sex, and socioeconomic status. Data will be charted using the TIDieR (Template for Intervention Description and Replication) checklist in alignment with the review objectives. The scoping review will be reported in accordance with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) statement.

Results: The research began in October 2023, and the results are expected to be published in 2024.

Conclusions: This scoping review will produce valuable information about occupation-based interventions to promote healthy aging to support the development of an occupational therapy intervention.

KEYWORDS

healthy aging; interventions; occupational therapy; public health; scoping review; intervention; aging; lifestyle change; aging population; well-being; occupation-based approach; occupational therapists; older people

Introduction

Overview

The proportion of older people in society will double to 22% between 2015 and 2050 [1]. To this end, the United Nations has instituted a *decade of healthy aging 2021-2030* aimed at promoting healthy aging and addressing the challenges associated with an aging population across the life course [2]. This means active aging and healthy lifestyles have become priorities for public health internationally [3]. Healthy aging is "the process of developing and maintaining the functional ability that enables well-being in older age" [4]. It comprises the intrinsic capacity of the individual—their physical and mental capacities, environmental characteristics, and the interactions between them [2]. It is not necessary to be completely free from illness or disability to achieve healthy aging [2]. A meaningful life, such as a life filled with worthwhile activities [5] or being able to remain living in the community, may help promote successful and healthy aging [6]. This suggests an occupation-based approach centered on what people do every day could be a key to unlocking the 5 pillars to aging well, namely, healthy eating, hydration, exercise, social connections, and cognitive health [7]. Occupational therapists provide opportunities for individuals to engage in activities and live how they wish at every stage of life, and this may offer a meaningful approach to healthy aging [8]. It has been suggested that "The occupational therapy profession has an essential role to play in healthy aging that includes enabling participation" [9].

Occupational therapists already work in this field and occupation-based health promotion interventions exist [10]. However, some of the existing reviews are no longer current; for example, Gustafsson et al [11], Arbesman and Mosley [12], and Stav et al [13] have not been updated. A review of older people's lived experience of occupation and well-being, based on 3 studies of moderate quality, suggests there is a relationship between well-being and occupation for older people. This is shaped by 2 factors: "first, variation and independence in undertaking activities; second, having a choice between the occupations and a structure of activities that make up daily life. The two factors are influenced by a balance between having activities alone and with others." [14]. A review of economic evaluations of occupational therapy for people with cognitive or functional decline, or both, found that evidence was scarce, with few comprehensive high-quality economic evaluations having been conducted, but those that have been conducted suggest the interventions are effective and have economic benefits [15].

The literature focuses on older people, rather than other points in the life span, despite the life course approach endorsed by the United Nations' *decade of healthy aging 2021-2030* [2]. Nonetheless, the population of older adults has been variously defined as 60 years old [13], over 65 years of age or older [9], or 80 years of age or older [12]. Interventions have targeted people living in nursing homes [16], Australian residential aged care facilities [17], and community-dwelling older people [10,17,18]. The focus has tended to be on secondary prevention, within the context of disease management, rather than primary prevention with community-dwelling adults [10]. No study was identified that delineated the characteristics of the interventions reviewed, which is a necessary first step to understanding the existing knowledge and supporting the design, evaluation, and impact of future interventions [19]. Intervention development should be explicit about the content of the intervention, its theoretical foundation, and the context in which the intervention is delivered [11]. Therefore, to further understand how occupational therapy can contribute to promoting healthy aging, it is important to understand the interventions available, their characteristics, and the impact observed [20].

A scoping review is a first step toward identifying what occupational therapy interventions exist to promote healthy aging for community-dwelling adults. A preliminary search of Cochrane Library, figshare, JBI Evidence Synthesis MEDLINE, Open Science Framework, PROSPERO, and PubMed was conducted. The search identified 11 recent reviews. While the reviews identified had a bearing on the topic, most were not specifically about the topic. A total of 7 of the 11 reviews were about discrete topics, that is, older adults' occupations in heatwaves [21], joy among older people [22], quality of life [16,23], e-tools for transportation planning [24], occupational therapy in residential aged care [17], and instruments to support occupational therapy practice [9]. A review by Kim et al [18] focused on daily functioning and included occupational therapy, but its focus was on activities of daily living and instrumental activities of daily living rather than the broader concept of healthy aging. A scoping review by Mehrotra et al [20] about healthy aging and occupational therapy in South Asian countries was potentially replicable for a wider population, but the full report is not available and the authors of the protocol have not responded to requests for the full report. The rapid review by Owusu-Addo et al [25] was about implementation approaches rather than interventions. Occupational therapy was included in the review of the theory-based specification of nonpharmacological treatments in aging and dementia by Sikkes et al [26], but it did not cover specific interventions and its focus was dementia—secondary prevention—rather than healthy aging more generally. This means that no existing or contemporary review was identified, but these reviews provide valuable insights into how to conduct a review in this field. For example, keywords for searching should include productive aging [10], aging well, healthy aging, positive aging, and successful aging [20]. Thus, a scoping review will be conducted to provide an overview of occupational therapy in relation to promoting healthy aging and discover gaps in knowledge. This will provide up-to-date evidence about occupational therapy interventions to promote healthy aging and its characteristics [19].

Review Questions

This scoping review will identify the following: (1) what occupational therapy interventions exist for promoting healthy aging in community-dwelling adults? and (2) what are the intervention characteristics, their evaluated outcome, and the impact observed?

Methods

Study Design

The proposed scoping review will be conducted in accordance with the Joanna Briggs Institute (JBI) methodology for scoping reviews [27]. This scoping review protocol is registered on the Open Science Framework [28] and will be reported in accordance with the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) statement [29]. This scoping review protocol will be conducted using the JBI guidelines for scoping reviews to ensure a systematic methodology that can be replicated and reported in line with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) [30].

Eligibility Criteria

Participants

This review will consider studies of occupational therapy focused on promoting healthy aging in adults living in the community—community-dwelling—aged 18 years or older. This may include adults living in their own homes or a care setting. Studies will be excluded if they focus on children.

Concept

The concept being mapped in this scoping review will be occupational therapy interventions to promote healthy aging in the context of the life course approach. The life course approach acknowledges that health and well-being are influenced by social, economic, and environmental factors throughout a person's life, as well as personal characteristics [31]. The terms active aging and healthy aging, although subtlety different, are often used interchangeably, that is, active aging refers to "optimizing opportunities for health, participation and security in order to enhance the quality of life as people age" [32], and healthy aging is defined as "developing and maintaining the functional ability that enables well-being in older age" [4], where functional ability includes people's ability to meet their basic needs to ensure an adequate standard of living, learning, growing and making decisions, being mobile, building and maintaining relationships, and contributing to society [2]. Therefore, this scoping review will consider studies with interventions that focus on active aging or healthy aging as part of health promotion, that is, primary prevention. Studies will be excluded if they address secondary prevention, that is, interventions that focus on the early stages of disease, such as fall prevention for older adults following a fall, or tertiary prevention, that is, interventions during the symptomatic phase of a disease to minimize disability and maximize quality of life, such as foot care for people living with diabetes.

The word "occupation," in the context of occupational therapy, refers to the everyday activities that humans engage in as part of their daily routine to occupy time, providing purpose and meaning to their lives [33,34]. Occupations are the activities people want to do, need to do, or are expected to do [34]. Examples of these meaningful activities can include social interaction with peers, cooking, different forms of exercise, and working [35]. Occupation-based interventions aim to enhance the performance of an individual when undertaking meaningful activities of daily living by increasing their social and community interaction [36]. Occupation-focused interventions encapsulate the rapid improvement of an individual's performance through compensatory methods by implementing adaptive measures to be tailored to their current performance level [37]. Interventions are implemented to increase the performance of the individual in the desired or necessary tasks [38].

Context

This review will consider studies from any setting, in any country. As a global perspective will be considered, it means no limit on language will be made in the search strategy. This will ensure valuable insights are not lost because they were published in a language other than English [39]. As no language limits will be imposed, relevant papers that are not published in the English language will be translated using Google Translate. Jackson et al [40] have revisited the work by Balk et al [41], who recommended that Google Translate can be used with caution because Google has updated its translation engine. Jackson et al [40] concluded that it is a viable, accurate tool for translating non-English language trials for the purpose of conducting systematic reviews, which is why we will use it for our review. We appreciate that a scoping review is more narrative based than a systematic review; therefore, if we have access to a native speaker, the translation will be checked by them. If it is not possible to verify the translation, this will be reported within the review report. The number and sources of non-English language literature will be reported in the review report.

Types of Sources

This scoping review will consider both experimental and quasi-experimental study designs, including randomized controlled trials, nonrandomized controlled trials, before and after studies, and interrupted time-series studies. In addition, analytical observational studies, including prospective and retrospective cohort studies, case-control studies, and analytical cross-sectional studies will be considered for inclusion. This review will also consider descriptive observational study designs, including case studies, individual case reports, and descriptive cross-sectional studies for inclusion. Qualitative studies will also be considered that focus on qualitative data including, but not limited to, designs such as phenomenology, grounded theory, ethnography, qualitative description, action research, and feminist research. In addition, systematic reviews that meet the inclusion criteria will also be considered depending on the research question. Text and opinion papers will also be considered for inclusion in this scoping review.

Review Team

The review is being conducted by a team comprised of an academic (KB) and 3 postgraduate researchers (JCHS, NJL, and ERRM).

Patient and Public Involvement

The scoping review protocol has been reviewed by 2 occupational therapists working in the field of healthy aging or with older people.

Search Strategy

The search strategy will aim to locate both published and unpublished studies. An initial limited search of AMED, CINAHL, Cochrane Library, MEDLINE PsycINFO, and PubMed was undertaken to identify if a review of this topic has previously been conducted. The text words contained in the titles and abstracts of relevant studies, and the index terms used to describe the studies were used to develop a full search strategy for AMED, CINAHL, Cochrane Library, Embase, JBI EBP database, MEDLINE, OAlster, PsycINFO, PsycArticles, ProQuest nursing and allied health source, ProQuest Dissertations & Theses, PubMed, and Science Direct (see Multimedia Appendix 1 for an example search strategy). The search strategy, including all identified keywords and index terms, will be adapted for each included database and information source. The reference list of all included sources of evidence will be screened for additional studies. The searches will be conducted by KB, NJL, JCHS, and ERRM. No date or language limiters will be used.

Study or Source of Evidence Selection

Following the search, all identified citations will be collated and uploaded into Covidence [42] and duplicates will be removed. Following a pilot test, titles and abstracts will then be screened by 2 or more independent reviewers for assessment against the inclusion criteria for the review. Potentially relevant sources will be retrieved in full, and their citation details imported into Covidence [42]. The full text of selected citations will be assessed in detail against the inclusion criteria by 2 or more independent reviewers. Reasons for the exclusion of sources of evidence that do not meet the inclusion criteria during full-text screening will be recorded and reported in the scoping review. Any disagreements that arise between the reviewers at each stage of the selection process will be resolved through discussion or with additional reviewers. The results of the search and the study inclusion process will be reported in full in the final scoping review and presented in a PRISMA-ScR flow diagram [30].

Data Extraction

A draft extraction form is provided (see Multimedia Appendix 2). The draft data extraction tool may be modified and revised as necessary during the process of extracting data from each included evidence source. Modifications will be detailed in the scoping review. Any disagreements that arise between the reviewers will be resolved through discussion or with additional reviewers. If appropriate, authors of papers will be contacted to request missing or additional data, where required.

Ethical Considerations

As this scoping review covers reviewing and extracting data from publicly available materials, this study does not require ethics approval.

Data Analysis

The TIDieR (Template for Intervention Description and Replication) checklist will be used in this review to ensure completeness in the reporting of the characteristics of interventions [43]. The extracted data will be charted in tabular form using the TIDieR checklist. The charted results will be accompanied by a narrative summary and will describe the relationship between the result and the review's objectives and questions. The results will be presented in accordance with the TIDieR format and the main conceptual categories used in the extraction too, as well as gaps in the existing literature. These results will be presented in relation to the question of this scoping review. The narrative will be guided by the Patterns, Advances, Gaps, Evidence for practice and Research recommendations (PAGER) framework [44]—a structured approach to the analysis and reporting of scoping reviews.

Results

The research began in October 2023, and the results are expected to be published in 2024.

Discussion

Findings

This scoping review will produce a map of the current body of research about occupational therapy interventions to promote healthy aging among community-dwelling adults. As far as we know, this is the first scoping review that maps the occupational therapy interventions that exist to promote healthy aging for community-dwelling adults, the intervention characteristics, and their evaluated outcome and impact that is not limited to any country. Similar to any review, there exist limitations when conducting a scoping review. Although a rigorous identification and inclusion strategy has been delineated, there is still a risk that some valuable information, which could have enhanced our comprehension, might be inadvertently excluded. This is particularly prevalent in the case of grey literature, which may not always come up in academic searches. As the aim and nature of a scoping review are to explore the breadth of a topic to see what has been done, but not the depth, the reviewers are not able to evaluate the quality of the studies that are incorporated within the scoping review. Although scoping reviews can be helpful in generating hypotheses and identifying research gaps, they may not offer the same degree of thoroughness or meticulousness as a systematic review that involves a more rigorous and comprehensive methodology for data collection and analysis and, consequently, may offer a higher level of evidence than scoping reviews [45]. A methodological appraisal of the included studies will not be performed. It is important to note that the limitations and results presented in the suggested review may not be all-encompassing or investigated beyond the peer-review stage of the published paper.

Conclusions

The review authors will use the findings of this scoping review to support the development of a manualized occupational therapy intervention [46] to promote healthy aging within the EmpowerAge program being developed at Glasgow Caledonian University.

Acknowledgments

The authors would like to thank Laura Hall and Rowena Harrison for their contribution to the development of this protocol.

Data Availability

Data sharing is not applicable to this study as no data sets were generated or analyzed during protocol development.

Authors' Contributions

The design of the protocol was conducted by KB. The drafting of the study was done by KB, JCHS, NJL, and ERRM. All authors approved the final study.

Conflicts of Interest

None declared.

Abstract

Background: Diabetes mellitus is a chronic disease that is growing worldwide. It is estimated that 15.7 million people aged between 20 and 79 years live with diabetes in Brazil, and the majority of cases are type 2 diabetes (T2D). To successfully manage diabetes, the patient needs to develop self-care activities. However, there is limited understanding of what self-care activities are performed by people with T2D in Brazil.

Objective: This study aims to identify and map studies that evaluate self-care activities in T2D in Brazil.

Methods: This is a scoping review protocol structured according to the methodological guidelines of the Joanna Briggs Institute. Six databases and gray literature were used. The process of searching, identifying, and evaluating the papers was carried out by 2 independent reviewers, guided by the assumptions established by the Joanna Briggs Institute. We sought to answer the following guiding question: How are self-care activities for people with T2D evaluated in Brazil? We included papers and publications in any language, from public and private domains, and with different methodological approaches.

Results: Initial database searches produced a total of 681 results. These papers will be critically analyzed, and relevant information will be extracted. Quantitative and qualitative results of the papers reviewed will be presented to respond to the study's objective. We intend to publish the scoping review in the first half of 2024.

Conclusions: The protocol for this scoping review will evaluate the main self-care activities carried out by adults and older people with T2D in Brazil. The results may help identify knowledge gaps and contribute to future research and diabetes education interventions.

Introduction

Diabetes mellitus (DM) is a significant and growing health problem worldwide. In 2021, the International Diabetes Federation estimated that 8.8% (537 million) of the world's population aged 20 to 79 years had diabetes. If current trends persist, the number of people with diabetes is projected to exceed 783 million by 2045. Brazil ranks sixth in the number of cases, with 15.7 million people diagnosed in the 20-79 years age group, which is projected to increase to 23.2 million cases in 2045 [1].

DM can be classified into 4 main types, based on its etiology: type 1 diabetes (T1D), type 2 diabetes (T2D), gestational DM,

and other types of diabetes. T2D is the most prevalent form, accounting for approximately 90% to 95% of diabetes cases worldwide [2].

The causes of T2D are still poorly understood, but there is a strong link with excess weight, obesity, lack of physical activity, aging, ethnicity, and family history. T2D has an insidious onset and is characterized by insulin resistance, partial deficiency of insulin secretion by pancreatic β cells, and changes in incretin secretion [2,3].

There is evidence that T2D can be prevented or delayed [1]. However, the patient often remains undiagnosed with T2D for several years. T2D occurs when hyperglycemia is the result of insulin resistance that has been established gradually over many years until diagnosis [1,2]. In this case, the person does not present the classic signs of diabetes, such as dehydration or involuntary weight loss, and the diagnosis comes with acute or chronic complications of diabetes [2].

Diabetes complications are categorized as microvascular and macrovascular disorders. Thus, diabetes and its complications can lead to disability and constitute one of the main causes of early mortality in most countries [1,4].

For satisfactory management of diabetes and effective adjustment in lifestyle, it is necessary to develop self-care activities, which include adherence to a healthy diet, regular physical activity, blood glucose monitoring, foot care, medication use, and smoking cessation [5].

Self-care is defined as the ability of individuals, their families, and the community to promote and maintain their health, prevent disease, and manage their illness and disability with or without the support of a health professional [6].

The Association of Diabetes Care & Education Specialists (ADCES) emphasizes that diabetes self-care can be effective through 7 important behaviors (ADCES7 self-care behaviors [7]): (1) ensuring variety and balance between quality, quantity, and food safety (healthy eating)—fresh or minimally processed foods should be prioritized and thus form the basis of the diet, and ultraprocessed foods should be avoided; (2) engaging in physical activity and regular training with aerobic and resistance exercises (being active); (3) blood glucose monitoring, using reagent strips and glucometers or glucose monitoring with interstitial glucose sensors (controlling blood glucose values); (4) understanding and managing the use of medications at the correct times every day, according to medical prescription (taking medication); (5) being prepared to face unexpected complications, such as hyperglycemia or hypoglycemia, resulting from an error in carbohydrate counting, physical activity, use of alcoholic beverages, excess medication, or change in medication schedule (solving problems); (6) practicing behaviors that prevent or minimize chronic complications and adverse outcomes related to diabetes (reducing risks)—examples of these behaviors include making positive lifestyle changes and participating in a diabetes education program, and it is recommended to be up to date with laboratory and complementary tests (glycated hemoglobin, cholesterol levels, assessment of renal function, and fundus examination), clinical assessment, and emotional aspects; and (7) developing personalized strategies to face daily stress and know how to act in special situations such as travel, parties, and intercurrent illnesses (eg, infections and other clinical situations that impact blood glucose, etc). Seeking information and alternatives to adapt to different situations, thus benefiting glycemic control and self-efficacy, favors patients to face the challenges of diabetes (adapting healthily) [7].

There is vast scientific literature on diabetes and many self-care–related studies. However, to the best of our knowledge, no previous attempt to establish an analysis of different self-care activities in T2D focused on Brazilians. Thus, this protocol will guide a scoping review to identify and map studies evaluating self-care activities in T2D in Brazil. Scoping reviews are considered a type of literature review that maps and identifies the nature and extent of relevant evidence in a given field of research. It also seeks to identify gaps in evidence, clarify key concepts, and report on the types of evidence that address and inform practice in a thematic area [8].

This protocol will guide a scoping review to identify and map studies that evaluate self-care activities in T2D in Brazil.

Methods

Scoping Review

To maintain rigor, the scoping review methodology used for this protocol will be that of the *Joanna Briggs Institute (JBI) Reviewer's Manual 2020* [9], which establishes five steps: (1) identification of research question; (2) identification of relevant studies; (3) selection of studies; (4) data analysis; and (5) grouping, synthesis, and presentation of data. The authors also followed the recommendations of the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews), according to the JBI Manual [9].

This study also followed all procedures standard to systematic reviews (search tests during elaboration of the protocol, data collection, data extraction, synthesis, analysis, and discussion of results and conclusions), as recommended by Cochrane (*Cochrane Handbook for Systematic Reviews of Interventions* [10]). A preliminary search of the PROSPERO Cochrane Database of Systematic Reviews and JBI Evidence Synthesis was performed. No existing or ongoing scoping reviews or systematic reviews were identified on this topic.

After completing the scoping review, the results will be submitted for publication in a peer-reviewed scientific journal. The research project for this scoping review protocol was previously registered in the Open Science Framework [11].

Stage 1: Identifying the Research Question

The first step comprises the elaboration of a research question. This review followed the *Population*, *Concept*, and *Context* strategy for a scoping review [9]. The following were defined: people diagnosed with T2D (*Population*); actions or strategies to evaluate self-care, self-management, or self-efficacy of people with T2D (*Concept*); and studies developed in Brazil (*Context*). Thus, the guiding question of this study is as follows: How are self-care activities for people with T2D evaluated in Brazil?

Stage 2: Identifying Relevant Studies

We performed a database search: (1) MEDLINE, (2) Web of Science - Core Collection, (3) Scopus, (4) Embase, (5) LILACS, and (6) SCIELO. In addition, a search was carried out for unpublished and possibly eligible studies in the gray literature, retrieved from 3 sources: the Brazilian Digital Library of Theses and Dissertations, Google Scholar (limited to the first 10 pages, in order of relevance), and the website of the Brazilian Diabetes Society. For the search strategy, terms were extracted from recognized thesauruses in the health area: Health Sciences Descriptors, Medical Subject Headings, and Embase Subject Headings. Thus, it started with the following terms: type 2 DM, self-management, self-efficacy, self-care, and Brazil. In order to broaden the search and better direct the findings, synonymous terms and the Boolean operators OR and AND were used according to the needs of each database (Multimedia Appendix 1).

As eligibility criteria, we included (1) Brazilian studies that were conducted with people diagnosed with T2D, older than 18 years, of both genders, and with or without comorbidities; (2) studies that focus on self-care activities for people with T2D; (3) studies that describe the evaluation process of these activities; and (4) studies that evaluate 2 or more self-care activities. The time frame used was the period from 2011 to 2023. The year 2011 is marked by the elaboration of the Strategic Action Plan for Combating Chronic Noncommunicable Diseases in Brazil 2011-2022 [12] and the Model of Attention to Chronic Conditions [13]. Original studies, dissertations, and theses were considered without language restriction, with quantitative, qualitative, or mixed design. Duplicate studies; studies on T1D, gestational diabetes, or prediabetes; studies that associate T2D with other types of diabetes; research protocols; editorials; reviews; letters; and Brazilian studies carried out in partnership with other countries were excluded.

Stage 3: Study Selection

The identified literature was exported to the Mendeley reference manager (Elsevier), via the web version, to remove duplicates. It was then imported into the Rayyan (Qatar Computing Research Institute) systematic review management software, online version [14], for screening and selection of studies. The studies were selected independently by 2 previously trained researchers from the team, and a third researcher resolved conflicts in the absence of consensus. All identified studies' titles and abstracts were evaluated based on the established inclusion and exclusion criteria. After the assessment of a study's pertinence to the review question, it was selected for reading in full for later data extraction. Its references were analyzed in search of additional studies. This stage was developed based on the recommendations of the international guide PRISMA-ScR, with the presentation of a flowchart on the process of the search and selection of studies, quantitative results of each database, included or excluded studies, and the total number of works selected for evaluation and synthesis [15].

Stage 4: Charting the Data

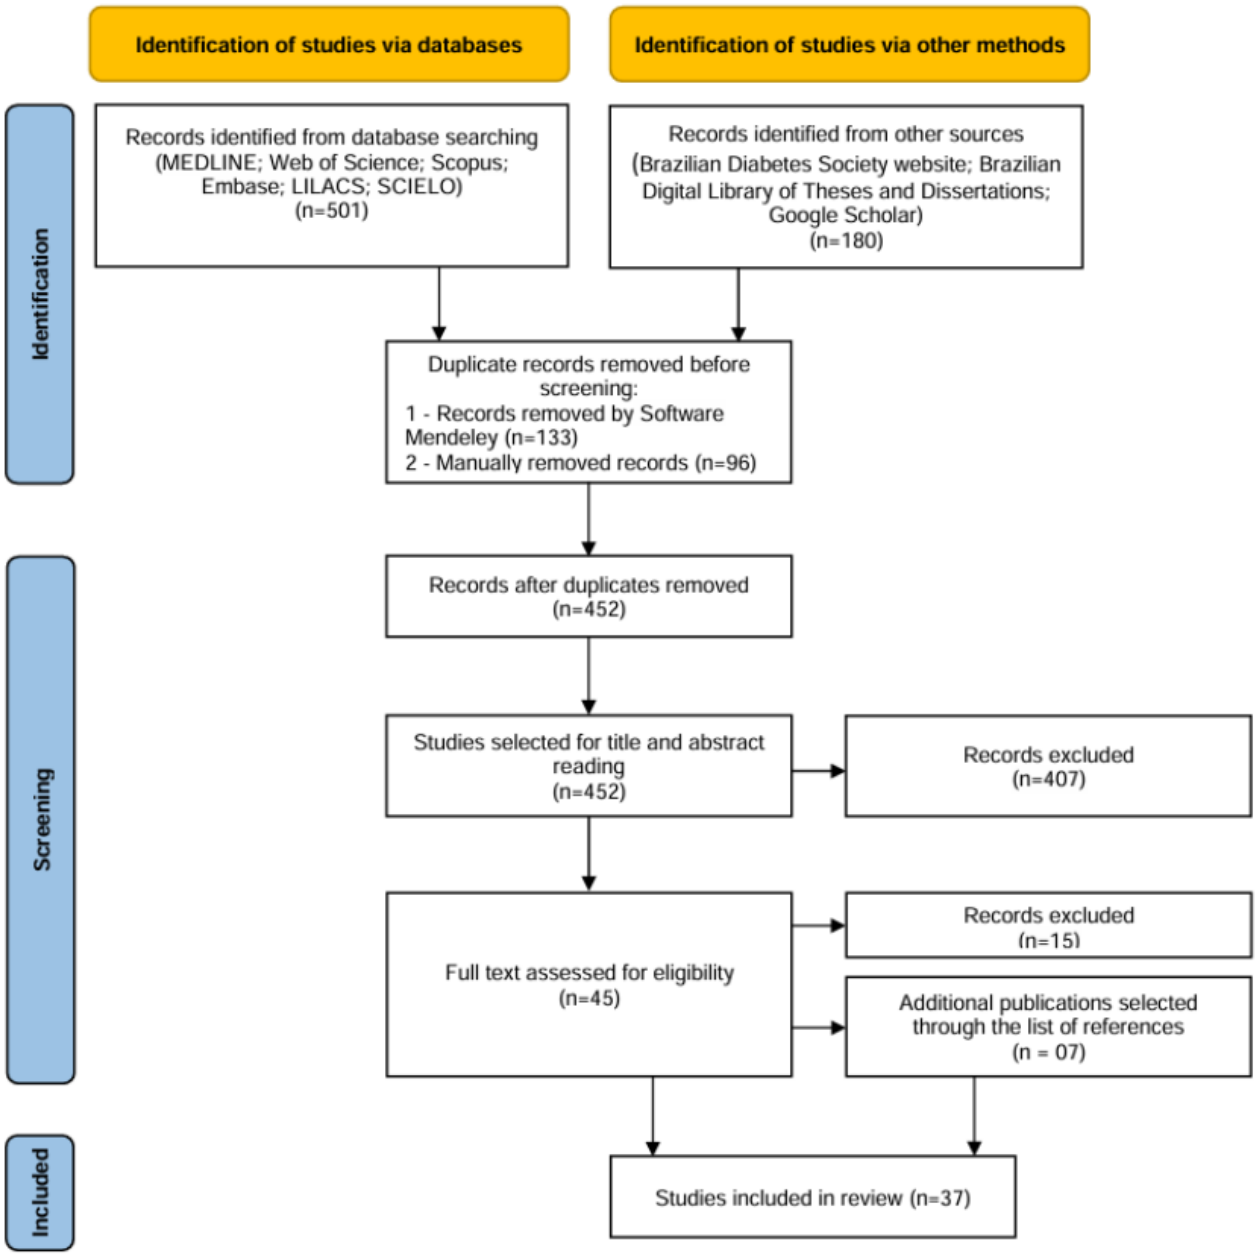
For the data extraction, a standardized data extraction tool was created in a Microsoft Office Excel Online spreadsheet, developed by the reviewers, and tested for this study in a pilot test based on the JBI tool [9] to characterize the studies. The instrument was independently used by 2 researchers to capture information to describe the extent and nature of the studies (authorship, year of publication, study typology, objectives primary results, and authors' recommendations). Information was also collected, such as characteristics of the population, specific self-care activities (general food, specific food, physical activity, blood glucose monitoring, foot care, medication use, and smoking), and identification of diabetes self-care behaviors. If there was any disagreement between the data extracted by the 2 reviewers, it was resolved by dialogue between both reviewers or, if necessary, with a third reviewer. The studies were coded with letters and numbers following a logical sequence. Tables S1-3 in Multimedia Appendix 2 [7,16] are examples of the data extraction tools created for this study.

Stage 5: Collating, Summarizing, and Reporting the Data

Qualitative data will be analyzed using the Bardin content analysis technique [17] and descriptively by 2 authors and validated by the entire research team. As for quantitative data, Table S1 in Multimedia Appendix 2 will verify which self-care activities were carried out in each study and classify each activity as favorable or unfavorable. Table S3 in Multimedia Appendix 2 will verify which of the 7 self-care behaviors are addressed in the studies. The results will be presented in tables, graphs, and images, along with the construction of narratives to clarify the information and discuss it in light of relevant and updated literature. The scoping review will record and report reasons for excluding sources of evidence in the full text that do not meet the inclusion criteria. The review report will incorporate a PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram (Figure 1), visually presenting the screening and selection process.

The assessment of methodological quality and risk of bias is optional [8] and will not be performed in our study.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram for the scoping review process.



Ethical Considerations

This scoping review does not require ethical approval from the institutional review board.

Results

In August 2023, our initial database searches identified 681 papers. Duplicates were removed, and screening of extracted titles and abstracts resulted in 37 papers. A critical evaluation analysis of the collected papers was carried out to extract relevant information. The screening was carried out in September 2023. Similarities and differences contained in various data from the papers are being analyzed and compared between September and November 2023. We estimate the publication of the scoping review will be in the first half of 2024.

Discussion

Principal Findings

Reviews that focus on self-care for adults and older people with T2D have been specific to educational interventions for self-care. To the best of our knowledge, this will be the first scoping review to understand how self-care activities carried out by people with T2D in Brazil are evaluated.

This scoping review will identify gaps in the literature and provide information on future research needs related to self-care assessment and its relationship to the 7 ADCES self-care behaviors [7] of adults and older adults with diabetes.

The method of this scoping review complies with the JBI recommendations [9] and the most recent guidelines for using the PRISMA-ScR tool [15], adapted for the study context. One of the benefits of using PRISMA is that it makes it possible to

guide the writing of the research so that it reflects the investigative activities that will be carried out without losing details, in addition to guaranteeing methodological rigor [18]. Another advantage of a scoping review is the possibility of obtaining an overview of the scientific evidence about a given phenomenon in a structured, systematized, impartial, and transparent way [8].

The results of the scoping review will be discussed thoroughly based on the research question and will be discussed with the evidence reported in the literature on the research topic. We believe that our results will support the development of guidelines, thereby overcoming identified challenges and revealing new opportunities for assessing self-care behaviors in diabetes.

Limitations

This scoping review will follow well-established methods, yet limitations will exist. First, most of the studies included are cross-sectional, which does not allow for long-term conclusions. Second, the noninclusion of texts published in other indexing databases and the choice to select studies only on the first 10 pages of Google Scholar may result in omitting potentially relevant research.

Conclusions

This review will map and compare how the main self-care activities carried out by people with T2D in Brazil are evaluated. Our study will help identify existing knowledge gaps and how research on the topic is conducted. This knowledge will enable researchers and health care professionals to understand self-care activities in T2D better. Consequently, the results of our scoping review may contribute to future research and health education programs focusing on T2D.

Acknowledgments

The authors deeply thank the Universidade Federal dos Vales do Jequitinhonha e Mucuri (UFVJM) for institutional support and Coordenação de Aperfeiçoamento de Pessoal de Nível Superior - Brasil (CAPES) for financial support and scholarship. The authors declare that they did not use generative artificial intelligence to write the manuscript. However, they did use Grammarly [19] in some parts to spell-check the writing.

Data Availability

The data sets analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

The study was designed by MMT, ES, and EAE. MMT and ES contributed to data collection. MMT wrote the manuscript, and ES and EAE contributed to the final draft of the manuscript. All authors approved the final article.

Conflicts of Interest

None declared.

Abstract

Background: Atypical presentations have been increasingly recognized as a significant contributing factor to diagnostic errors in internal medicine. However, research to address associations between atypical presentations and diagnostic errors has not been evaluated due to the lack of widely applicable definitions and criteria for what is considered an atypical presentation.

Objective: The aim of the study is to describe how atypical presentations are defined and measured in studies of diagnostic errors in internal medicine and use this new information to develop new criteria to identify atypical presentations at high risk for diagnostic errors.

Methods: This study will follow an established framework for conducting scoping reviews. Inclusion criteria are developed according to the participants, concept, and context framework. This review will consider studies that fulfill all of the following criteria: include adult patients (participants); explore the association between atypical presentations and diagnostic errors using any definition, criteria, or measurement to identify atypical presentations and diagnostic errors (concept); and focus on internal medicine (context). Regarding the type of sources, this scoping review will consider quantitative, qualitative, and mixed methods study designs; systematic reviews; and opinion papers for inclusion. Case reports, case series, and conference abstracts will be excluded. The data will be extracted through MEDLINE, Web of Science, CINAHL, Embase, Cochrane Library, and Google Scholar searches. No limits will be applied to language, and papers indexed from database inception to December 31, 2023, will be included. Two independent reviewers (YH and RK) will conduct study selection and data extraction. The data extracted will include specific details about the patient characteristics (eg, age, sex, and disease), the definitions and measuring methods for atypical presentations and diagnostic errors, clinical settings (eg, department and outpatient or inpatient), type of evidence source, and the association between atypical presentations and diagnostic errors relevant to the review question. The extracted data will be presented in tabular format with descriptive statistics, allowing us to identify the key components or types of atypical presentations and develop new criteria to identify atypical presentations for future studies of diagnostic errors. Developing the new criteria will follow guidance for a basic qualitative content analysis with an inductive approach.

Results: As of January 2024, a literature search through multiple databases is ongoing. We will complete this study by December 2024.

Conclusions: This scoping review aims to provide rigorous evidence to develop new criteria to identify atypical presentations at high risk for diagnostic errors in internal medicine. Such criteria could facilitate the development of a comprehensive conceptual model to understand the associations between atypical presentations and diagnostic errors in internal medicine.

Introduction

Diagnostic errors, defined as "the failure to (a) establish an accurate and timely explanation of the patient's health problem(s) or (b) communicate that explanation to the patient" [1], is an important concern in improving patient safety and diagnostic excellence. According to a recent report, approximately 0.8 million people may become permanently disabled or die annually due to diagnostic errors in the United States [2]. While diagnostic errors can occur across care settings, internal medicine is one of the highest-risk care settings for diagnostic errors [3,4]. Internal medicine physicians, as well as surgery and emergency medicine physicians, also frequently confront malpractice claims related to diagnostic errors [5,6]. Internal medicine covers a broad spectrum of complaints and diseases, which can contribute to higher diagnostic uncertainty in patients presenting to internal medicine with undiagnosed conditions [3,7]. Therefore, more complex and difficult diagnostic decisions are required in internal medicine, which can result in higher susceptibility to diagnostic errors [3].

Diagnostic errors are usually related to multifactorial causes such as system-related errors; cognitive errors; and patient factors, including challenging disease presentations [8-10]. To date, while many studies have been conducted to address major system-related and cognitive errors using common measurements, patient factors, including challenging disease presentations, have not been investigated as much. However, among challenging disease presentations, atypical presentations have been increasingly recognized for their significant impact on diagnostic errors [11-15]. Atypical presentations are described as "a shortage of prototypical features that are most frequently encountered in patients with the disease, features encountered in advanced presentations of the disease or simply features of the disease commonly listed in medical textbooks" [16], which can make diagnosis more challenging and distract the diagnostic process. Indeed, atypical presentations were reported to be associated with a higher prevalence of diagnostic errors compared to typical presentations [12-14], and a pilot systematic review of case reports of diagnostic errors suggested that higher numbers of contributing factors were detected in the cases with atypical presentations compared to the cases without atypical presentations [15]. Moreover, a previous study showed that the prevalence of diagnostic errors in patients with atypical presentations of stroke was smaller when cared for by health care providers who are familiar with atypical presentations of stroke [17]. Although the results cannot be easily generalized to other conditions, developing strategies to prevent progression from an atypical presentation to diagnostic error seems to be a promising approach to improving patient safety [11,12].

Atypical presentations seem to be especially an important issue for diagnostic errors in internal medicine: first, atypical presentations may be commonly observed (up to approximately 30%) in the internal medicine department [13]; second, internal medicine physicians consider atypical presentations to be the most important contributor to diagnostic errors in their clinical practice [18]; and third, atypical presentations can be an important contributing factor to a higher prevalence of diagnostic errors in internal medicine [10,13]. Therefore, a comprehensive understanding of the association between atypical presentations and diagnostic errors is required. Knowledge gaps in this area persist possibly due to the lack of consensus on the definition and measurement of atypical presentations and because a comprehensive conceptual model to understand how atypical presentations progress to diagnostic errors is still lacking.

A scoping review is more appropriate than a systematic review when the review aims to identify knowledge gaps, scope a body of literature, and clarify concepts. A scoping review is also more appropriate than a narrative review when clarification around a concept or theory is required [19]. From this perspective, a scoping review is more ideally suited to determine the body of literature on atypical presentation and diagnostic errors and identify any gaps in knowledge [20]. Moreover, without a universal definition for atypical presentations, future studies about diagnostic errors may have systematic biases by excluding patients with atypical presentations at high risk for missed diagnostic opportunities [21]. Therefore, this scoping review will also facilitate future studies by developing practical criteria and measurements for atypical presentations.

Throughout this scoping review, the key terms such as diagnostic errors, atypical presentations, and internal medicine are defined as follows:

- Diagnostic errors—defined as the failure to (1) establish an accurate and timely explanation of the patient's health problems or (2) communicate that explanation to the patient [1], which also include delayed, wrong, and missed diagnosis [10].
- Atypical presentations—defined as patient demographics (eg, age, sex, and race); symptoms and signs; test results; or clinical course, including the response to treatment, deviated from the prototypical patterns for the final diagnosis.
- Internal medicine—defined as a medical specialty concerned with the diagnosis and treatment of diseases of the internal organ systems of adults.

To develop a new definition and useful criteria to identify atypical presentations that are at high risk of diagnostic errors,

this scoping review aims to identify and present the available information regarding the definitions and measurements for atypical presentations in the evidence sources about diagnostic errors in internal medicine.

The primary review question is "What definitions and measurements have been used to identify atypical presentations in the studies investigating diagnostic errors in adult patients in internal medicine?" The subquestions are "What specific diseases have been targeted by the studies investigating the association between atypical presentations and diagnostic errors in adult patients in internal medicine?" and "What specific types of atypical presentations have been reported as relevant to diagnostic errors in adult patients in internal medicine?"

Methods

Study Design

The proposed scoping review will be conducted in accordance with the Joanna Briggs Institute methodology for scoping reviews [22,23] and in line with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) [24].

Inclusion Criteria

Participants

This review will consider studies that include adult patients. We will exclude studies that focus on children.

Concept

This review will consider studies that explore the association between atypical presentations and diagnostic errors (using any clear definition or criteria or measurement to identify atypical presentations and diagnostic errors). We will exclude studies that investigate only atypical presentations or diagnostic errors.

Context

This review will consider studies that focus on the setting of internal medicine.

Types of Sources

This scoping review will consider quantitative, qualitative, and mixed methods study designs for inclusion. In addition, systematic reviews and text and opinion papers will be considered for inclusion in the proposed scoping review. Case reports, case series, and conference abstracts will be excluded.

Search Strategy

The search strategy will aim to locate both published and unpublished primary studies, reviews, and text and opinion papers. An initial limited search of MEDLINE (PubMed) and Science Citation Index Expanded (Web of Science) was undertaken to identify papers on the topic. The text words contained in the titles and abstracts of relevant papers, and the index terms used to describe the papers, were used to develop a full search strategy for MEDLINE (PubMed; Multimedia Appendix 1). The search strategy, including all identified keywords and index terms, will be adapted for each included information source. The reference lists of papers included in the review will be screened for additional papers. Papers published in all languages will be included. Papers indexed from database inception to December 31, 2023, will be included. The databases to be searched include MEDLINE (PubMed), Science Citation Index Expanded (Web of Science), CINAHL, Embase, Google Scholar, and Cochrane Library. Sources of unpublished studies and gray literature to be searched include medRxiv.

Study or Source of Evidence Selection

Following the search, all identified records will be collated and uploaded into Covidence (Covidence), and duplicates will be removed. Following a pilot test, titles and abstracts will then be screened by 2 independent reviewers (YH and RK) for assessment against the inclusion criteria for the review. Potentially relevant papers will be retrieved in full, and their citation details imported into Covidence. The full text of selected citations will be assessed in detail against the inclusion criteria by 2 independent reviewers (YH and RK). Reasons for exclusion of full-text papers that do not meet the inclusion criteria will be recorded and reported in the scoping review. Any disagreements that arise between the reviewers at each stage of the selection process will be resolved through discussion or with a third reviewer (MY). Interrater reliability will be monitored and reported. The results of the search will be reported in full in the final scoping review and presented in a PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram [25].

Data Extraction

Data will be extracted from papers included in the scoping review by 2 independent reviewers (YH and RK) using a data extraction tool developed by the reviewers. The data extracted will include specific details about the patient characteristics (eg, age, sex, and disease), the definitions and measuring methods for atypical presentations and diagnostic errors, clinical settings (eg, department and outpatient or inpatient), type of evidence source, and the association between atypical presentations and diagnostic errors relevant to the review question. A draft extraction tool is provided in Table 1. The draft data extraction tool will be modified and revised as necessary during the process of extracting data from each included paper. Modifications will be detailed in the full scoping review. Any disagreements that arise between the reviewers will be resolved through discussion or with a third reviewer (MY). Authors of papers will be contacted to request missing or additional data, where required.

Table 1. Data extraction instrument for the scoping review. The scoping review will include published or unpublished studies indexed in databases until December 2023; the scoping review will include quantitative, qualitative, and mixed methods study designs; systematic reviews; and opinion papers. The target population is adult patients cared for in internal medicine settings without restriction on disease, location, or time frame.

Data Analysis and Presentation

The extracted data will be presented in tabular format with descriptive statistics, and from this, the key components or types of atypical presentations—the purpose of this scoping review—will be identified to develop new criteria to identify atypical presentations for future studies of diagnostic errors. Developing the new criteria will follow the Joanna Briggs Institute guidance for a basic qualitative content analysis approach (following an inductive approach) [26]. In addition, we will classify the sources of evidence into 2 categories: disease-specific or generic studies to identify diseases and settings where the current evidence is lacking. Finally, we will list the specific types of atypical presentations highly associated with diagnostic errors.

Results

As of January 2024, a literature search through multiple databases is ongoing. We will complete this study by December 2024.

Discussion

Expected Findings

This scoping review aims to identify and present the available information regarding the definitions and measurements for atypical presentations to inform a new definition and criteria to identify atypical presentations at high risk of diagnostic errors. To maximize the quality of this scoping review, we will follow the updated scoping review guidelines, use multiple databases, and develop search strategies in consultation with experienced and skilled librarians. In addition, our review group includes expertise in diagnostic error research and has experience in developing new theories and concepts related to the diagnostic process. This scoping review aims to provide a rigorous evidence summary to describe how atypical presentations have been defined and measured in prior literature and use these findings to develop new criteria to identify atypical presentations at high risk for diagnostic errors. Findings will also inform the development of a comprehensive conceptual model to understand the associations between atypical presentations and diagnostic errors in internal medicine.

Comparison With Prior Work

In a systematic review focused on diagnostic errors in primary care, Kostopoulou et al [16] defined atypical presentations as "a shortage of prototypical features that are most frequently encountered in patients with the disease, features encountered in advanced presentations of the disease or simply features of the disease commonly listed in medical textbooks"; however, this definition has not been applied in subsequent research investigating the association between atypical presentations and diagnostic errors due to several limitations. For instance, the difficulty in defining the gold standard classic textbook disease descriptions may be one of the possible reasons that the definition has not been used. Current studies use disease-specific criteria for atypical presentations to detect and measure atypical presentations at high risk of diagnostic errors [12]. However, such an approach also has limitations: understanding of certain

atypical presentation features of a disease evolves over time, and these features might not stand the test of time. An example of this is the loss of taste, which was recognized as an atypical symptom of COVID-19 during the early stages of the pandemic; however, as we learn more about the disease, the loss of taste is no more considered atypical for COVID-19. This scoping review will clarify the gaps and complexity in each disease's diagnostic criteria to diagnose atypical presentations and suggest a more refined approach that accounts for the limitations of prior definitions. The implications of our findings will be significant, indicating the potential for improving diagnostic processes and diagnostic accuracy by applying our new criteria.

Limitations

This scoping review will have several limitations. First, this scoping review will not include studies outside of internal medicine, and findings may not generalize to specialties outside of internal medicine. Furthermore, the evolving nature of diagnostic criteria and practices in internal medicine necessitates ongoing revision and validation of our proposed definitions and criteria. Second, although we will search for unpublished studies and gray literature, we may overlook some, potentially bringing bias to our understanding and conclusions. Third, confirmation bias can distort the findings in this scoping review because each study related to diagnostic errors may have overlooked atypical presentations. However, the upcoming new criteria from this scoping review can be expected to increase sensitivity to detect atypical presentations and reduce confirmation bias in future studies. Fourth, defining "atypical presentation" itself may present challenges, as evidenced by the difficulty in clearly distinguishing between concepts such as atypical presentations, phenotype, and nonspecific symptoms, as well as the challenge in defining the degree of atypicality and the boundary between typical and atypical. However, this is precisely the reason this research needs to be done because these issues need further clarification. Definitions and distinctions of these concepts will become clearer as a result of this exploration.

Conclusions

This scoping review can provide a rigorous evidence summary to describe how atypical presentations have thus far been defined and measured and help develop new criteria to identify atypical presentations at high risk for diagnostic errors in internal medicine. Developing the new criteria is expected to facilitate the development of a comprehensive conceptual model to understand the associations between atypical presentations and diagnostic errors in internal medicine. Additionally, such criteria can reduce the systematic selection biases in future diagnostic error studies that evaluate patients with atypical presentations. Review findings will highlight the need for further research to validate and refine these criteria, aiming to improve diagnostic processes and outcomes for patients with atypical presentations.

Acknowledgments

The authors acknowledge Ms Tomoko Nagaoka and Mr Shunya Suzuki (Reference Service Unit, Dokkyo Medical University Library, Tochigi, Japan) for their insightful suggestions as specialist librarians for creating search strategies. HS is funded in part by the Houston Veterans Administration (VA) Health Services Research and Development (HSR&D) Center for Innovations in Quality, Effectiveness and Safety (CIN13–413), the VA National Center for Patient Safety, and the Agency for Healthcare Research and Quality (R01HS028595 and R18HS029347). Abstract

Background: The rapid expansion of telehealth services, driven by the COVID-19 pandemic, necessitates systematic evaluation to guarantee the quality, effectiveness, and cost-effectiveness of telehealth services and programs in the United States. While numerous evaluation frameworks have emerged, crafted by various stakeholders, their comprehensiveness is limited, and the overall state of telehealth evaluation remains unclear.

Objective: The overarching goal of this scoping review is to create a comprehensive overview of telehealth evaluation, incorporating perspectives from multiple stakeholder categories. Specifically, we aim to (1) map the existing landscape of telehealth evaluation, (2) identify key concepts for evaluation, (3) synthesize existing evaluation frameworks, and (4) identify measurements and assessments considered in the United States.

Methods: We will conduct this scoping review in accordance with the Joanna Briggs Institute (JBI) methodology for scoping reviews and in line with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews). This scoping review will consider documents, including reviews, reports, and white papers, published since January 1, 2019. It will focus on evaluation frameworks and associated measurements of telehealth services and programs in the US health care system, developed by telehealth stakeholders, professional organizations, and authoritative sources, excluding those developed by individual researchers, to collect data that reflect the collective expertise and consensus of experts within the respective professional group.

Results: The data extracted from selected documents will be synthesized using tools such as tables and figures. Visual aids like Venn diagrams will be used to illustrate the relationships between the evaluation frameworks from various sources. A narrative summary will be crafted to further describe how the results align with the review objectives, facilitating a comprehensive overview of the findings. This scoping review is expected to conclude by August 2024.

Conclusions: By addressing critical gaps in telehealth evaluation, this scoping review protocol lays the foundation for a comprehensive and multistakeholder assessment of telehealth services and programs. Its findings will inform policy makers,

health care providers, researchers, and other stakeholders in advancing the quality, effectiveness, and cost-effectiveness of telehealth in the US health care system.

Introduction

Overview

Telehealth has witnessed a remarkable transformation in recent years, propelled by the COVID-19 pandemic, which has greatly accelerated its adoption and expansion. The imperative for social distancing and the need to minimize in-person contact have made telehealth a pivotal tool at the forefront of health care delivery, helping to ensure accessibility and continuity of health care. This transformation has been further facilitated by significant expansions in telehealth service coverage, as well as regulatory requirements for telehealth visits, by the Centers for Medicare and Medicaid Services (CMS) and other payers, enhancing accessibility and affordability for patients across the nation [1-5].

The rapid expansion of telehealth services underscores the necessity for comprehensive guidance and evaluation of telehealth programs to guarantee the quality and effectiveness of health care delivery. The World Health Organization (WHO) has published a series of operational guidelines and evaluation frameworks to facilitate its global strategy on digital health development [6-9].

Recognizing the importance of maintaining service quality in practice, professional groups and telehealth stakeholders across the United States have actively contributed to the development of clinical guidelines. For instance, the American Telemedicine Association (ATA) published practice guidelines to enhance the technical quality and reliability of telemental health services for children and adolescents [10]. The ATA's practice guidelines for ocular telehealth-diabetic retinopathy were updated to their third edition in 2020 to incorporate new evidence and technologies [11]. Furthermore, the American Heart Association (AHA) has advocated using remote patient monitoring technologies to improve cardiovascular disease outcomes [12], highlighting the ever-expanding role of telehealth in quality health care. The American Nurses Association (ANA) updated its core principles on telehealth in 2019 to provide guidance for health care professionals in delivering quality care using health technologies [13]. Similarly, the National Association of Social Workers (NASW) published guidance on legal considerations for telemental health, promoting adherence to state and federal practice guidelines and payer contract agreements among social workers [14].

Concurrently, in response to the rapidly evolving landscape of telehealth services, researchers, professional groups, and organizations have crafted telehealth evaluation frameworks. These frameworks have been designed to guide and facilitate the assessment of specific dimensions of telehealth programs. For example, Zhang et al [15] designed a framework to guide the development and evaluation of sustainable telehealth programs. Curfman et al [16] developed an economic framework focusing on measuring the value of pediatric telehealth. Moreover, a consortium of experts from the Kaiser Permanente (KP) Institute for Health Policy, AcademyHealth, the ATA, and the Physician Insurers Association of America (PIAA) collaborated on a telehealth research and policy framework, facilitating the assessment of health services and the quality of health care [17]. During the COVID-19 pandemic, the National Quality Forum (NQF) updated its telehealth measurement development framework, initially created in 2017, through an environmental scan conducted in 2021 [18-20].

Despite the wealth of telehealth evaluation frameworks available, several critical questions remain unanswered. First, the rapidly evolving state of telehealth programs, along with the emergence of innovative telehealth tools, has underscored the pressing need for a comprehensive grasp of the essential concepts that should be considered in their evaluation. For instance, the growing use of artificial intelligence in clinical assessments and the application of virtual reality among pediatric patients with autism spectrum disorder have garnered broad attention [21,22]. It is imperative to acquire a broader evaluation framework that accommodates these emerging technologies and provides a comprehensive understanding of integrating state-of-the-art technologies on telehealth platforms. As such, a scoping review that systematically identifies what telehealth services and programs are evaluated and how they are assessed is needed.

Additionally, while numerous frameworks have been proposed, many of them have been developed primarily from a narrow perspective or to address a specific need, potentially limiting their broader applicability and the comprehensiveness of the evaluation. For example, the framework developed by Zhang et al [15] focused on the sustainability of single telehealth programs, encompassing domains of program implementation, clinical effectiveness, and economic analysis. In contrast, the framework developed by KP, AcademyHealth, the ATA, and the PIAA considered five domains, including (1) policy context, (2) payment policy, (3) delivery, (4) modality, and (5) outcomes [17]. In the case of the NQF telehealth measurement development framework, it emphasizes assessing the impact of telehealth on health care system readiness and health outcomes in rural areas, spanning across another five domains: (1) access to care and technology; (2) costs, business model, and logistics; (3) experience; (4) effectiveness; and (5) equity [15,18,19]. Given the diverse array of telehealth stakeholders in the United

States, including patients, providers, hospitals, payers, professional associations, federal agencies, policy makers, and legislators, it is necessary to consider the perspectives of multiple stakeholders and comprehensively evaluate telehealth services and programs.

Moreover, the measurements and assessments associated with telehealth evaluation domains and frameworks remain unclear, raising questions about how to effectively gauge the impact and outcomes of telehealth services and programs. While the frameworks developed by the WHO, Zhang et al [15], and NQF outline the measurements to be considered, this clarity is absent in the frameworks developed by KP, AcademyHealth, the ATA, and the PIAA [6-9,17,18].

Objective and Review Question

The broad objective of this scoping review is to answer the question of what is known about telehealth services and program evaluation in the United States. Specifically, this scoping review will be conducted to (1) map the existing landscape of telehealth evaluation, (2) identify key concepts for evaluation, (3) synthesize existing frameworks, and (4) identify measurements and assessments that have been considered.

A preliminary search of PROSPERO, MEDLINE, the Cochrane Database of Systematic Reviews, the Open Science Framework, and JBI Evidence Synthesis was conducted, and no current or in-progress scoping reviews or systematic reviews on the topic were identified.

Methods

Study Design

The scoping review will be conducted in accordance with the Joanna Briggs Institute (JBI) methodology for scoping reviews and in line with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) [23-25].

Protocol and Registration

The protocol for this scoping review is registered on the Open Science Framework (osf.io/aytus) [26]. The scoping review is expected to be completed in 6 months.

Eligibility Criteria

The eligibility for this scoping review is elaborated following the Population, Concept, and Context (PCC) framework.

Participants

This scoping review will consider a range of document types, including reviews, reports, and white papers, specifically related to telehealth evaluation frameworks and associated measurements. The evaluation frameworks to be included will focus on telehealth services and programs used for the provision of health services through well-established modalities, such as store-and-forward telemedicine, remote monitoring, real-time counseling, audio and video conferencing, and videotelephony, as well as emerging innovations integrated with telehealth platforms, such as virtual realities and artificial intelligence [27]. We will exclude manuscripts with data analyses only, case studies, project intervention reports (including scale-up and scale-down studies), and commentaries.

Concept

This review will examine concepts pertaining to the evaluation frameworks of telehealth services and programs. The concepts to be examined will encompass existing evaluation frameworks and associated measurements developed by telehealth stakeholders, professional organizations, and authoritative sources, excluding those developed by individual researchers. This approach will allow us to collect data that reflect the collective expertise and consensus of experts within the respective professional group. The aim is to create a comprehensive overview of telehealth evaluation, incorporating perspectives from multiple stakeholder categories, including but not limited to public and private payers, providers, and policy makers.

Context

This review will consider documents published in English for various health care settings, for example, primary care, specialty care, and rural health care for adult and pediatric patients. Considering the diversity of the contexts of telehealth services and programs across different health care systems and the unique nature of the US health care system, publications reporting on evaluation frameworks developed for regions that do not include the United States will be excluded. Documents published by worldwide health organizations will be included, given their relevance and influence in US health care.

Search Strategy

As many evaluation frameworks are likely to be published on stakeholders' websites, we will source data from peer-reviewed journals and gray literature, such as reports, white papers, policy documents, and guidelines.

The search strategy will aim to locate published reviews, reports, and white papers. An initial PubMed search was undertaken to identify articles on the topic. The text words contained in the titles and abstracts of relevant articles and the index terms used to describe the articles were used to develop a full search strategy for PubMed (Multimedia Appendix 1). The search strategy, including all identified keywords and index terms, will be adapted for each included database and information source. The reference lists of all included studies will be screened for additional titles. The databases to be searched include PubMed (US National Library of Medicine), Health Technology Assessments (International Network of Agencies for Health Technology Assessment), and Web of Science Core Collection (Clarivate Analytics). The websites of telehealth stakeholders, professional organizations, and authoritative sources mentioned in the included articles will be screened for additional documents.

Documents published from January 1, 2019, to the present will be considered for inclusion. While we recognize the relevance of earlier publications, the rapid expansion of telehealth, particularly accelerated by the COVID-19 pandemic, has led to significant changes in telehealth services and programs. During and after the pandemic, not only did the volume of telehealth

services increase, but there was also a diversification in the types of modalities considered under the telehealth umbrella. For example, before the pandemic, audio-only interactions were not widely regarded as telehealth, and various modalities like e-consults and e-visits were not as commonly used as they are now. Therefore, the inclusion of documents published from January 1, 2019 onward will allow us to focus on the most recent and relevant telehealth service and program evaluations.

Source of Evidence Selection

Following the search, all identified records will be collated and uploaded into EndNote (V21; Clarivate Analytics), with duplicates removed. A total of 2 reviewers will independently screen titles and abstracts against the inclusion criteria. Following a pilot test, titles and abstracts will then be screened by 2 independent reviewers for assessment against the inclusion criteria for the review. All screening will be completed through Rayyan, a web-based tool for evidence synthesis projects [28]. The full text of selected citations will be assessed in detail against the inclusion criteria by 2 or more independent reviewers. Reasons for the exclusion of full-text documents that do not meet the inclusion criteria will be recorded and reported in the scoping review. Any disagreements that arise between the reviewers at each stage of the selection process will be resolved through discussion. The results of the search will be reported in full in the final scoping review and presented in a PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram [29].

Data Extraction

Data will be extracted from documents selected for inclusion in the scoping review by 2 independent reviewers using a data extraction tool developed by the reviewers based on the JBI data extraction template for scoping review [24]. The data extracted will include specific details about the PCC methods and key findings relevant to the review question. A draft extraction tool is provided in Multimedia Appendix 2. The draft data extraction tool will be modified and revised as necessary during the process of extracting data from each included document. Modifications will be detailed in the full scoping review. Any disagreements that arise between the reviewers will be resolved through discussion.

Results

Reviewers will synthesize data across selected documents using tools such as tables and figures. Frequency counts of domains and measurements considered in frameworks and guidelines will be presented when applicable to highlight key patterns. Visual aids like Venn diagrams will be used to illustrate the relationships between the evaluation frameworks from various sources. Additionally, a narrative summary will be crafted to further describe how the results align with the review objectives, facilitating a comprehensive overview of the findings. This scoping review is expected to conclude by August 2024.

Discussion

Implications

In light of the rapid expansion of telehealth services, this scoping review seeks to address critical gaps in the current understanding of telehealth evaluation. The urgency of this endeavor is underscored by the need to ensure the quality, effectiveness, and cost-effectiveness of telehealth programs, with their increasing significance to the US health care system.

This scoping review will be the first to synthesize existing evidence of telehealth services and program evaluation in the United States and to facilitate the future development of telehealth in the postpandemic era. It will provide insights into the evaluation of state-of-the-art technology integration into telehealth.

In addition, the synthesized evaluation concepts and frameworks crafted by multiple telehealth stakeholders will guide the development of a multistakeholder evaluation framework that allows the comprehensive assessment of telehealth services and programs. Specifically, a multistakeholder framework will offer an inclusive and adaptable approach to telehealth evaluation, making it relevant and valuable to a wide range of users. By accommodating the diversity of telehealth initiatives, technologies, and objectives that exist within the US health care system, it will provide flexibility for stakeholders to tailor their evaluations for specific needs and objectives. In the evolving landscape of telehealth, where innovations and changes occur regularly, new technologies, practices, and policies would also be considered in the multistakeholder framework. The consideration of measurements and assessments will further illuminate the path toward actionable telehealth evaluation by providing more context and details.

Limitations

While we aim to conduct a comprehensive scoping review, some limitations should be considered. First, to ensure the comprehensiveness and relevance of this study's findings, we only consider frameworks developed for regions that encompass the United States. For instance, frameworks from organizations like the WHO are considered if they pertain to the US context. However, given the unique and complex nature of the US health care system, the results from this scoping review might not be directly applicable to other countries. In addition, given that the scoping review aims to provide a comprehensive overview of telehealth evaluation from a multistakeholder perspective, the scoping review will exclude documents carried out by individual researchers. Therefore, when evaluating local telehealth programs, it is advisable to include specific local considerations in addition to the results of this scoping review.

Conclusions

This scoping review will serve as a critical initial step in advancing the understanding of telehealth evaluation, given the current role of telehealth in the US health care system. Its findings will inform policy makers, health care providers, researchers, and other stakeholders involved in the rapidly evolving field of telehealth. By addressing these fundamental questions, this protocol lays the foundation for the scoping

review for comprehensive telehealth evaluation and future telehealth advancement.

Acknowledgments

This work is supported by the Office for the Advancement of Telehealth, Health Resources and Services Administration, US Department of Health and Human Services, under a cooperative agreement award (2 U66RH31459 - 04 - 00). Abstract

Background: Globally, around 80% percent of adults aged 65 years or older are living with at least 1 chronic disease, and 68% percent have 2 or more chronic diseases. Older adults living with chronic diseases require greater health care services, but these health care services are not always easily accessible. Furthermore, the COVID-19 pandemic has resulted in unprecedented changes in the provision of health care services for older adults. During the COVID-19 pandemic, digital health interventions for chronic disease management were developed out of necessity, but the evidence regarding these and developed interventions is lacking.

Objective: In this scoping review, we aim to identify available digital health interventions such as emails, text messages, voice messages, telephone calls, video calls, mobile apps, and web-based platforms for chronic disease management for older adults in high-income countries.

Methods: We will follow the Arksey and O'Malley framework to conduct the scoping review. Our full search strategy was developed following a preliminary search on MEDLINE. We will include studies where older adults are at least 65 years of age, living with at least 1 chronic disease (eg, cancer, cardiovascular disease, chronic obstructive pulmonary disease, and diabetes), and residing in high-income countries. Digital health interventions will be broadly defined to include emails, text messages, voice messages, telephone calls, video calls, mobile apps, and web-based platforms.

Results: This scoping review is currently ongoing. As of March 2023, our full search strategy has resulted in a total of 9901 records. We completed the screening of titles and abstracts and obtained 442 abstracts for full-text review. We are aiming to complete our full-text review in October 2024, data extraction in November 2024, and data synthesis in December 2024.

Conclusions: This scoping review will generate evidence that will contribute to the further development of digital health interventions for future chronic disease management among older adults in high-income countries. More evidence-based research is needed to better understand the feasibility and limitations associated with the use of digital health interventions for this population. These evidence-based findings can then be disseminated to decision-makers and policy makers in other high-income countries.

KEYWORDS

chronic disease; high-income countries; digital health; interventions; older adults; quality of life

Introduction

Globally, according to the World Health Organization (WHO), 41 million people die from chronic diseases each year [1]. Four chronic diseases, including cancer, cardiovascular diseases, chronic respiratory diseases, and diabetes, are responsible for over 80% of all premature mortality worldwide [1]. Chronic disease outcomes are worse for older adults compared to their younger counterparts [2]. For instance, according to the US Centers for Disease Control and Prevention (CDC), around 85% of older adults in the United States endure at least 1 chronic disease and approximately 60% have at least 2 chronic diseases [3,4]. In Canada, approximately 70% of people aged at least 65 years are living with at least 1 of 10 common chronic diseases [4]. Life expectancy continues to increase, especially in high-income countries [5], and, given that age increases the risk of developing chronic diseases [6], the prevalence of chronic disease is also expected to grow. Thus, it is crucial to identify potential strategies for older adults with chronic diseases in high-income countries. Furthermore, while older adults living with chronic diseases require a greater amount of health care services, these health care services are not always easily accessible for this population [7].

The COVID-19 pandemic has had and continues to have a detrimental impact on the global health systems [8]. During the initial stages of the COVID-19 pandemic, older adults were often unable to access health care services due to public health mandates [9]. In the later stages of the COVID-19 pandemic, access to health care services was still limited due to lengthened waitlists and increased staff shortages [10]. Older adults living with chronic diseases and their caregivers experienced increased levels of stress and worse chronic disease outcomes due to this lack of access [11,12]. It is therefore essential that alternatives to in-person interventions be developed to ensure accessible health care services during public health emergencies such as the COVID-19 pandemic.

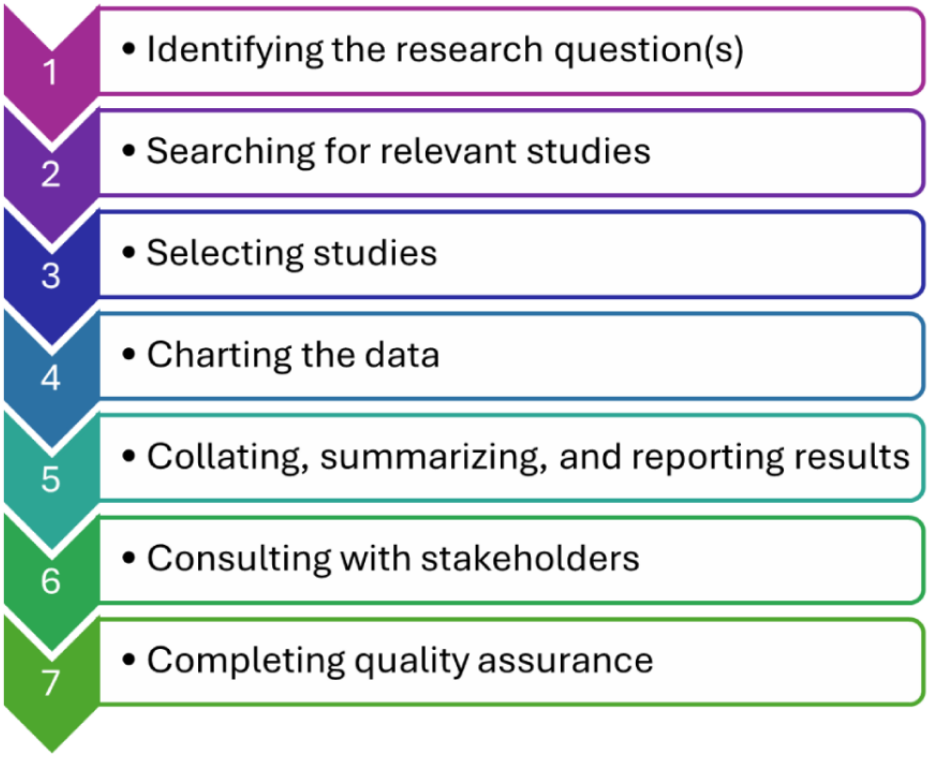
Amid the emergent COVID-19 pandemic, digital health interventions such as telehealth and app-based health care were developed in response to limitations to in-person interventions [13]. There are few evidence-based guidelines on digital health intervention for chronic disease management. Thus, this review is essential to identify available digital health interventions to manage chronic diseases among older adults. So, the primary aim of this scoping review is to identify available digital health interventions for chronic disease management among older adults in high-income countries. The secondary aim of this scoping review will be to identify potential outcomes associated with these digital health interventions such as early diagnosis, increasing health literacy for chronic disease management, or improving quality of life. Findings from this scoping review will further support the development and evaluation of future digital health interventions.

Methods

Overview

The 6 steps of the Arksey and O'Malley [14] framework will be used to conduct a scoping review to investigate digital health interventions to manage chronic disease among older adults in high-income countries. Given the possibility of a high risk of bias when conducting reviews [15], we will include a quality assessment as an additional step in our scoping review as recommended by Levac et al [16]. Thus, the scoping review will be completed in the 7 steps illustrated in Figure 1.

Figure 1. Arksey and O'Malley's methodological framework with the additional step of quality assurance.



Step 1: Identifying the Research Questions

For this scoping review, the research questions that have been identified are as follows: What are the digital health interventions aimed at improving outcomes associated with chronic disease management for older adults? (2) With regards to the identified digital health interventions, what are the associated outcomes (such as early diagnosis, prevention, or treatment for chronic disease or increasing health literacy on chronic disease management) for (1) older adults, (2) their caregivers, and (3) the health system?

Step 2: Searching for Relevant Studies

A preliminary search was conducted in the Cochrane Database of Systematic Reviews, Joanna Briggs Institute (JBI) Evidence Synthesis, Open Science Framework, and International Prospective Register of Systematic Reviews (PROSPERO) to identify other similar scoping reviews. Following this preliminary search, the full search strategy was conducted by an academic librarian. An initial MEDLINE search was undertaken in February 2023 to identify papers on the topic by focusing on the concepts of older adults, caregivers, the health care system, digital interventions, and chronic disease. The text words contained in the titles and abstracts of relevant papers, as well as the index terms used to describe the papers were used to develop a full search strategy for Ovid MEDLINE(R) and In-Process, In-Data-Review and Other Non-Indexed Citations and Daily (1946-2023; Multimedia Appendix 1). Papers published in any language from database inception to the present were included. The search strategy, including all identified text words and index terms, was translated to CINAHL Plus (Ebsco; 1966-2023), JBI EBP Database (Ovid; 2012-2023), PsycINFO (Ovid; 1806-2023), and Web of Science (1966-2023) by the academic librarian that can be accessed upon request. Finally, using similar text words and index terms, sources of grey literature searched included Google Advanced, Grey Literature Report, and ProQuest Dissertations & Theses: Global (1861-2022). The full search strategy was undertaken on April 3, 2023.

Step 3: Selecting Studies

Following a pilot test, titles and abstracts of studies including methodology of randomized controlled trials, nonrandomized controlled trials, pre-post studies, interrupted time-series studies, prospective cohort studies, retrospective cohort studies, case-control studies, and cross-sectional studies will be imported into Covidence (Veritas Health Innovation). The titles and abstract will be screened by 2 independent reviewers for assessment against the inclusion criteria for the scoping review as outlined below for full-text review. The selected papers will be downloaded for full-text review in detail against the inclusion criteria by 2 independent reviewers. Reasons for exclusion of full-text studies that do not meet the inclusion criteria will be recorded and reported in the scoping review. Any disagreements that arise between the reviewers at each stage of the selection process will be resolved through discussion or with a third reviewer.

Inclusion Criteria

Population

The population of interest includes adults who are aged at least 65 years and living with chronic disease. For a study to be included in this review, at least 50% of the sample must be aged at least 65 years or the mean age of the sample needs to be at least 65 years. Chronic diseases considered eligible for this review include cancer, cardiovascular diseases, chronic obstructive pulmonary disease, and diabetes. Finally, studies will be included if they are with populations residing in 1 of the selected countries with a high or very high Human Development Index [17]—Australia, Canada, and the United States.

Interventions

Studies examining digital health interventions for chronic disease management will be included. Digital health interventions will be broadly defined to include emails, text messages, voice messages, telephone calls, video calls, mobile apps, and web-based platforms. Chronic disease management will be defined as the management of at least one of the following chronic diseases: cancer, cardiovascular diseases, chronic obstructive pulmonary disease, and diabetes.

Comparisons

Studies with comparisons to digital health interventions (such as placebo or health service delivery as usual) or without comparison (no comparative intervention), will be considered.

Outcomes

Following the initial screening of papers, we have identified a few potential outcomes such as studies that include outcomes related to physical health (eg, blood pressure and blood sugars) and mental health (eg, anxiety and depression) assessed with validated tools or approaches will be considered for this scoping review. Improvements in health education or health literacy as well as quality of life will also be considered as appropriate. However, we are open to adding other outcomes following full-text review after iterative discussion with research team members.

Exclusion Criteria

The exclusion criteria for this study are (1) studies published in a form other than a peer-reviewed journal paper; (2) studies written in a language other than English; (3) studies with less than 50% of the sample aged at least 65 years or the mean age of the sample less than 65 years; (4) studies focused solely on chronic diseases other than cancer, cardiovascular diseases, chronic obstructive pulmonary disease, and diabetes; (5) studies published in a country other than Australia, Canada, or the United States; and (6) studies examining health interventions that are not digital (eg, in-person counseling) or digital interventions that are not focused on health (eg, general time management skills).

Step 4: Charting the Data

Data will be extracted from studies included in the scoping review by 2 independent reviewers using a data extraction tool developed by the reviewers. Any disagreements that arise between the reviewers will be resolved through discussion or

with a third reviewer. The data extracted will include the following details: authors, year of publication, objectives, type of study, population, intervention, comparisons, and outcomes. Where required, authors of papers will be contacted to request missing or additional data. A draft of our data extraction tool is provided (Multimedia Appendix 2). The draft data extraction tool will be modified and revised as necessary during the process of extracting data from each included paper. Modifications will be detailed in the full scoping review.

Step 5: Collating, Summarizing, and Reporting the Results

The results will be reported in full in the final scoping review and presented in a PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram [18,19]. When summarizing, we will list the type and format of interventions included in eligible studies. We will also organize similar outcomes together to determine the direction of outcomes included in the interventions. We will use descriptive numerical summary analysis for the results. The data will be mapped and presented in tabular format to make it easier to answer our research questions. A narrative summary will accompany the results and will describe how the results relate to the research questions.

Step 6: Consultation With Stakeholders

For this step, we will consult with researchers from high-income countries with expertise in older adults, chronic disease management, and digital interventions to provide any relevant studies aligned with our research questions. We will also consult with a group of patient partners living with chronic disease to validate the study findings.

Step 7: Quality Assessment

We will assess the quality of the studies included in this scoping review using JBI's Critical Appraisal Checklist for Systematic Reviews and Research Syntheses [20]. Prior to critical appraisal, 2 independent reviewers will meet to determine the criteria for indicating a "yes," "no," "unclear," or "not applicable" response in the context of this scoping review for each of the 11 items. For items that are deemed "unclear," authors of the reviews will be contacted to request missing or additional data for clarification. Each study will be ranked according to findings from the critical appraisal as low quality (ie, "yes" for 0%-33% of critical appraisal items with a "yes" or "no"), medium quality (ie, "yes" for 34%-66% of critical appraisal items with a "yes" or "no"), and high quality (ie, "yes" for 67%-100% of critical appraisal items with a "yes" or "no"). The results of critical appraisal will be reported in a critical appraisal table.

Results

Screening of titles and abstracts has been completed. The full-text review is expected to be complete by the end of October 2024, followed by data extraction in November 2024, and data synthesis in December 2024. We will disseminate the findings of the scoping review at the national and international scientific conference proceedings and by publishing the paper in a peer-reviewed journal.

Discussion

Principal Findings

With our rapidly aging population, digital health interventions may play a crucial role, especially for the management of chronic diseases among older adults. To our knowledge, our research will be one of the first that will highlight the available digital health interventions for the management of chronic disease which leads to major issues such as disability and interruption in the activities of daily living among older adults [7]. This scoping review will provide a comprehensive synthesis of existing digital interventions that will contribute to designing a feasible intervention model that can be customized by communities that need to manage chronic disease and improve the quality of life among older adults.

Though we will conduct a comprehensive scoping review, there may be some limitations that we will not be able to address. In this scoping review, we will only include peer-reviewed journal papers, so we may miss and exclude some of the evidence-based unpublished data from our findings. Another important limitation is that papers written in a language other than English will be excluded from our scoping review. Thus, additional research focusing on the available unpublished data findings and non-English papers would be helpful for generating evidence to gather available digital health interventions for chronic disease management.

The findings of the scoping review will assist researchers in the further establishment of digital health interventions for chronic disease management among older adults. More evidence-based research is crucial to understanding the potential barriers and enablers of digital health for older adults and, especially, older adults with chronic diseases.

Conclusions

Digital health interventions have become a prevalent form of health care services since the COVID-19 pandemic, but more evidence-based research is needed to assess the outcomes associated with digital health interventions. Findings from this scoping review will provide an overview of empirical evidence regarding digital health interventions and provide a stepping stone for the development and evaluation of future digital health interventions for older adults living with chronic disease.

Acknowledgments

This scoping review was supported by a grant awarded to NLG from the Saskatchewan Health Research Foundation (6127) along with President's Publication Fund and Arts Publication Fund awards from the University of Regina. MNA was supported by scholarships from the University of Regina's Faculty of Arts and Faculty of Graduate Studies & Research.

Authors' Contributions

All authors contributed to the paper writing, revision, and identifying the search strategy. NLG and MNA conceptualized the study. CB formulated and modified the search strategy.

Conflicts of Interest

None declared.

Abstract

Background: Several types of health care professionals are responsible for the care of patients with cancer throughout their engagement with the health care system. One such type is the radiotherapist. The radiotherapist not only administers treatment but is also directly involved with the patient during treatment. Despite this direct contact with the patient, the narrative tends to focus more on technical tasks than the actual patient. This task-focused interaction is often due to the highly sophisticated equipment and complex radiotherapy treatment processes involved. This often results in not meeting the psychosocial needs of the patient, and patients have acknowledged noncompliance and delayed treatment as a result.

Objective: The scoping review aims to explore, chart, and map the available literature on holistic person-centered care in radiotherapy and to identify and present key concepts, definitions, methodologies, knowledge gaps, and evidence related to holistic person-centered care in radiotherapy.

Methods: This protocol was developed using previously described methodological frameworks for scoping studies. The review will include both peer-reviewed and gray literature regarding holistic, person-centered care in radiotherapy. A comprehensive search strategy has been developed for MEDLINE (Ovid), which will be translated into the other included databases: Scopus, CINAHL (EBSCO), MEDLINE (PubMed), Embase (Elsevier), Cochrane Library, and the Directory of Open Access Journals. Gray literature searching will include Google (Google Books and Google Scholar), ProQuest, the WorldWideScience website, the OpenGrey website, and various university dissertation and thesis repositories. The title and abstract screening, full-text review, and relevant data extraction will be performed independently by all 3 reviewers using the Covidence (Veritas Health Innovation) software, which will also be used to guide the resolution of conflicts. Sources selected will be imported into ATLAS.ti (ATLAS.ti Scientific Software Development GmbH) for analysis, which will consist of content analysis, narrative analysis, and descriptive synthesis. Results will be presented using narrative, diagrammatic, and tabular formats.

Results: The review is expected to identify research gaps that will inform current and future holistic, person-centered care in radiotherapy. The review commenced in November 2023, and the formal literature search was completed by the end of February 2024. Final results are expected to be published in a peer-reviewed journal by 2025.

Conclusions: The findings of this review are expected to provide a wide variety of strategies aimed at providing holistic, person-centered care in radiotherapy, as well as to identify some gaps in the literature. These findings will be used to inform future studies aimed at designing, developing, evaluating, and implementing strategies toward improved holistic, person-centered care in radiotherapy.

Introduction

Radiotherapy, also referred to as radiation therapy, is a treatment modality that uses high-energy radiation or radioactive substances to destroy cancer cells or prevent their growth [1]. The clinical usefulness of ionizing radiation was discovered after the discovery of X-rays and has since developed into a medical specialty. Ionizing radiation damages the genetic material of cancer cells, blocking the cells' ability to proliferate, thus destroying the cancer cells [2]. Radiotherapy has become a highly cost-effective, leading modality in cancer treatment, as it can be used as a primary form of treatment or in combination with other modalities for curative or palliative purposes within cancer treatment [3]. Radiotherapy has an approximate 40% cure rate when used as a single modality of treatment compared to only 11% achieved by chemotherapy when used as a single modality of treatment [4]. Chemoradiotherapy use has experienced substantial growth and is now established as the standard treatment for various types of tumors, such as cervical, non–small cell lung cancer, and bladder cancer, as elaborated in this discussion. It provides considerable advantages in patient survival and local disease control while not significantly increasing long-term toxicities [5]. Radiotherapy is considered a conservative form of treatment with reduced adverse effects, unlike other treatments such as surgery, which can have mutilating and other long-term adverse effects, thus maintaining a good quality of life [6].

Evidence-based practice shows that more than 50% of patients with cancer will undergo a course of radiotherapy as part of their treatment, and despite this, patients appear to lack knowledge of the importance of radiotherapy treatment and its effects [7,8]. Negative perceptions toward receiving radiotherapy treatment have been expressed, as some patients with cancer consider it to be a form of poison, while others fear the effects of radiation as they believe it would cause another cancer, thus delaying seeking care [6,9]. Despite the vast improvement in radiotherapy technology, in addition to dealing with treatment-related toxicities [10], many patients also experience emotional challenges such as fear, anger, depression, stress, and anxiety [7,11]. Almost a third of patients with cancer acknowledge not having their psychosocial needs taken care of during treatment, resulting in a decrease in compliance, delayed treatment, and a decrease in quality of life, thus negatively impacting tumor control [7,12,13]. These perceptions, therefore, present an urgent need for a person-centered care approach to enhance the experience and well-being of the patient with cancer [14]. A person-centered care approach considers the needs and preferences of patients and thus allows patients to be actively involved in any treatment and decision-making [15]. Although patients with cancer come across many health professionals along their journey, radiotherapists have a key role in the experience of the patient with cancer as they find themselves in direct contact with the patient throughout the course of their radiotherapy treatment [12,16].

Radiotherapists are experts in the technical and clinical planning and delivery of radiotherapy treatment. They are equally responsible for providing care and support, monitoring and managing treatment-related toxicities, and coordinating supportive care, which can be last up to 6 weeks [8]. This places the radiotherapist in a unique position to engage with patients concerning their diagnosis and treatment [16,17]. However, despite the radiotherapist's direct contact with the patient, the narrative tends to focus more on technical tasks and other barriers, often at the cost of important psychosocial needs not being met [18]. Radiotherapists' disregard for patient care has also been influenced by the stressful nature of the workplace environment and the time pressures they face [17]. Nonetheless, the consequences of providing support in the form of empathy, compassion, and reassurance must be understood by radiotherapists, as it can result in alleviating their patients' anxiety and fear before the treatment [19]. Empathy is of particular importance in cancer delivery, as patients acknowledge having greater satisfaction and self-awareness when treated with empathy [20,21]. The length of time that a patient with cancer spends interacting with a radiotherapist has been shown to have a considerable impact on their overall experience [17]. Radiotherapists' daily direct contact with patients with cancer, therefore, not only enables them to prioritize their unique needs and values but also allows them to be involved in their care, creating a person-centered approach to treatment.

Radiotherapists can facilitate person-centered care by ensuring patients have their undivided attention [22]. This process can be initiated by building a rapport with each patient, communicating effectively, answering their questions, discussing their preferences, listening actively, addressing their physical and emotional needs, providing them with dignity, and collaborating with other health care professionals to ensure the patient's needs are met. Patients stated that they felt more included and positive about their radiotherapy treatment when these aspects were addressed [8,17,22]. Person-centered care is also considered to be synonymous with "wholism," or, as some may prefer, "holism." Holistic care considers the body, mind, soul, and spirit as interrelated and acknowledges the whole experience [23]. Holistic, person-centered care is, therefore, becoming increasingly important in cancer treatment, including radiotherapy [24]. Holistic care in radiotherapy allows for a personalized approach to patient care, which includes addressing the physical, emotional, social, and spiritual needs of the patient, empowering the patient, and promoting healing and well-being, thus improving the overall quality of life of the patient.

There is a paucity of literature related to holistic, person-centered care in radiotherapy. A search of the Open Science Framework, the Cochrane Database of Systematic Reviews, and Johanna Briggs Institute (JBI) Evidence Synthesis was conducted, and no published or in progress scoping or

systematic reviews were identified relating to holistic person-centered care in radiotherapy.

The proposed scoping review will explore, map, and summarize the nature, range, and extent of published literature available that relates to holistic person-centered care in radiotherapy. Identified sources will be described in terms of population, purpose, and setting, as well as theoretical underpinnings, outcome measures, and key findings. The proposed scoping review will assist in identifying common practices, knowledge gaps in the literature, and potential areas for future research and development.

Methods

Protocol Design

The proposed scoping review was developed using the methodological framework for scoping reviews developed by Arksey and O'Malley [25] and incorporates the updated frameworks suggested by Levac et al [26] and Peters et al [27], as well as the updated JBI methodology for scoping reviews [28]. The "population, concept, and context" (PCC) framework will guide the review, which will follow the following stages: (1) identification of the review question or questions and (2) identification of relevant studies. This will assist with the development of specific inclusion criteria to facilitate a comprehensive search of the literature. A comprehensive search for relevant studies will then be conducted, followed by the screening of those studies. The PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) will guide the reporting process [29].

Step 1: Identification of the Review Question or Questions

The research questions that will guide this scoping review are as follows: (1) What sources are available that relate to holistic, patient-centered care in radiotherapy? (2) What types of studies have been conducted on holistic, patient-centered care in radiotherapy? (3) In what settings have these studies been conducted? (4) What health care professionals and patients have been included in the studies? (5) What has the key approach been to the studies? (6) What theories have underpinned the studies? and (7) Were there any identified measures or outcomes from the studies?

Step 2: Identification of Relevant Studies

A comprehensive search strategy has been developed by the 3 members of the research team and an experienced librarian and information specialist. An exploratory search in MEDLINE (PubMed) and CINAHL (EBSCO) was performed to identify relevant articles on the topic (Multimedia Appendix 1). Once the scoping review commences, identified keywords in the titles and abstracts of articles related to the review question will be used to complement the search strategy, thus allowing for a more comprehensive search. The search strategy will also be adapted as required by scrutinizing the reference lists of articles that meet the inclusion criteria to find additional papers. Literature published in English and studies that can be translated will be considered. The search will commence in August 2023 and will not have a date limit to ensure that all studies that meet the inclusion criteria are considered. Once the search for each database has been completed, the results will be imported into Covidence (Veritas Health Innovation) for storage, organization, removal of duplicates, screening, and mapping of the data [30].

Step 3: Selection of Studies for Inclusion

The preliminary inclusion criteria will be defined using the PCC format. Details for each aspect of this format are described in the following sections.

Population

The population for this scoping review will be radiotherapists and patients involved in radiotherapy. Given that the scoping review aims to explore holistic person-centered care in radiotherapy, there will be no limitations placed relating to cancer or radiotherapy type, duration of treatment, or final outcome, nor will there be age, geographical, or time-based limitations placed on sources.

Concept

This review will consider studies that focus on person-centered care within radiotherapy to identify key concepts, definitions, methodologies used, existing models of care, and knowledge gaps in the literature. Any studies that included an intervention to improve person-centered care in radiotherapy and sources of evidence that informed practice will also be included.

Context

The scoping review will consider literature that is relevant to the radiotherapy context. The review will include the experiences of patients receiving radiotherapy treatment and evidence on the role of radiotherapists in providing any form of care or support to patients with cancer during radiotherapy treatment. in both private and public settings.

Types of Sources

In view of the fact that patient-centered care has been and is still a key issue in health care, the scoping review will aim to explore and integrate qualitative, quantitative, and mixed methods research data concerning person-centered care. Literature will be sourced from databases that will include Scopus, CINAHL (EBSCO), PubMed, the Education Resources Information Centre, the Cochrane Library, Sabinet, and the Directory of Open Access Journals. Any systematic reviews that meet the inclusion criteria will also be taken into account. Secondary sources that will be used in the search include Google (Google Books and Scholar), ProQuest, the WorldWideScience website, the OpenGrey website, and various university dissertations and thesis repositories.

Study Selection

Studies identified in the initial database search will be collated and then transferred into Covidence, which allows for duplicates to be removed and for appropriate studies to be sorted and selected based on the inclusion criteria [30]. The first stage, which involves the screening of titles and abstracts, will be performed independently by all 3 members of the research team, who will vote in Covidence to determine primary inclusion. Any disagreements will be resolved through discussion among

the team members, and in the event of an impasse, the decision will be by majority vote. The second stage of article selection will involve the downloading of identified sources from the first stage and then a screening of these articles in Covidence. Full-text sources that do not meet the inclusion criteria will be recorded, and reasons for exclusion will be reported in the scoping review. Any disagreements between the research team members at any stage of the selection process will be resolved through discussion. The PRISMA-ScR checklist and flow diagram will be used to report and present in full the results of the search and study inclusion selection in the final scoping review [28,29].

Step 4: Charting and Extraction of the Data

The extraction tool will be developed by the research team (Multimedia Appendices 2 and 3) in accordance with the JBI methodology for scoping reviews [29] and will be piloted in Excel (Microsoft Corporation) for relevance and ease of use. With the aid of an extraction tool, data will be independently extracted from the selected studies by the 3 members of the research team. Covidence has the advantage that changes can be made to the data extraction form at any time, even while extraction is in progress [30]. The data extracted will include study-specific details regarding article title, authors, geographic area, journal or other source, year of publication, aim or purpose, study population and sample size, context, methodology, intervention, outcomes, and key findings related to the scoping review questions. Data must be compared, and a consensus must be reached before the data can be exported. After completing the literature search and collecting all related evidence regarding person-centered care in radiotherapy, the next step will be to chart the data. This step involves synthesizing and interpreting the data, which allows key issues and themes to be highlighted. Sources will be imported into ATLAS.ti (ATLAS.ti Scientific Software Development GmbH), and thematic analysis will be used to identify themes that will then be summarized and discussed in relation to the study aims and objectives [31]. The identified codes and themes will be used to map the different aspects of person-centered care in radiotherapy as well as any evidence gaps. Should any missing data be noted in the data extraction table, it will be noted as “missing.” The data will be collated from ATLAS.ti and presented in a narrative summary and table format.

Step 5: Collation, Synthesis, and Reporting of the Results

The results will allow the researchers to better understand the delivery of holistic, person-centered care in radiotherapy. In addition, the role of the radiotherapist will be analyzed, as will what is required of them to enhance this phenomenon. The results may also raise awareness of important issues in the radiotherapy profession that should be included in the education of future radiotherapists. The results will be reported in accordance with the PRISMA-ScR reporting guidelines.

Results

The scoping review commenced in November 2023, and the formal literature search was completed by the end of February 2024. We are currently in the process of screening articles. A preliminary search of the literature was conducted using the Scopus database in November 2023, revealing 37,345 results using the initial search terms. We intend to publish the manuscript in an appropriate, peer-reviewed, and open-access health care journal to describe our findings and conclusions to the academic audience in 2025.

Discussion

Overview

There are several aspects related to patient-centered care within radiotherapy where gaps exist, but these are not well described. This scoping review intends to provide an overview of the current knowledge related to patient-centered care in radiotherapy, the effects that patient-centered care in radiotherapy has on both patients and radiotherapists, and to highlight existing gaps in the literature. The use of gray literature may also supplement the search to find pertinent information that cannot be found in the databases. Finally, this strategy will provide an important lens for understanding the value of delivering holistic, person-centered care in radiotherapy. The scoping review method complies with the JBI recommendations [28] and will use the most recent reporting guidelines [29] to ensure that a comprehensive process that can be tracked is used.

The findings will assist radiotherapists and radiotherapy departments, as well as educational institutions, in identifying elements that are vital for the delivery of holistic, person-centered care in radiotherapy. The study may also determine the need for additional curriculum content or additional courses for radiotherapists to fulfill their role as holistic care providers.

Limitations

The scoping review has some limitations. First, the search terms are variable due to the differing terminology used to describe radiotherapy and patients with cancer. Also, the research team will only consider sources available in English, meaning that sources not written in English will be missed, limiting generalizability. The quality of the studies included will not be evaluated for quality or methodological rigor; however, this is acceptable within the context of a scoping review and the aims of this review.

Conclusion

The scoping review will assist in providing information that will be indispensable in the development of a conceptual framework to guide holistic, person-centered care in radiotherapy. The results will be disseminated at a national radiotherapy conference, including publishing a paper in a radiotherapy journal. This scoping review strategy hopes to address a gap in the literature and create awareness for radiotherapists about the importance of delivering holistic, person-centered care.

Acknowledgments

The researchers would like to express their gratitude to their library consultant, Ms Dorcas Rathaba, at the University of Johannesburg, for her assistance in developing the search strategy for this protocol.

The review will contribute to the completion of a doctoral degree from the Faculty of Health Sciences, University of Johannesburg, for the author FB.

Authors' Contributions

All authors contributed to the manuscript. AWM led the development of the methods and search strings. FB and KH contributed to the contextualization of the protocol and reviewed the Methods section. AWM is the primary supervisor, and KH is the co-supervisor of FB.

Conflicts of Interest

None declared.

Abstract

Background: Artificial intelligence (AI) has emerged as a transformative force across the health sector and has garnered significant attention within sexual and reproductive health and rights (SRHR) due to polarizing views on its opportunities to advance care and the heightened risks and implications it brings to people's well-being and bodily autonomy. As the fields of AI and SRHR evolve, clarity is needed to bridge our understanding of how AI is being used within this historically politicized health area and raise visibility on the critical issues that can facilitate its responsible and meaningful use.

Objective: This paper presents the protocol for a scoping review to synthesize empirical studies that focus on the intersection of AI and SRHR. The review aims to identify the characteristics of AI systems and tools applied within SRHR, regarding health domains, intended purpose, target users, AI data life cycle, and evidence on benefits and harms.

Methods: The scoping review follows the standard methodology developed by Arksey and O'Malley. We will search the following electronic databases: MEDLINE (PubMed), Scopus, Web of Science, and CINAHL. Inclusion criteria comprise the use of AI systems and tools in sexual and reproductive health and clear methodology describing either quantitative or qualitative approaches, including program descriptions. Studies will be excluded if they focus entirely on digital interventions that do not explicitly use AI systems and tools, are about robotics or nonhuman subjects, or are commentaries. We will not exclude articles based on geographic location, language, or publication date. The study will present the uses of AI across sexual and reproductive health domains, the intended purpose of the AI system and tools, and maturity within the AI life cycle. Outcome measures will be reported on the effect, accuracy, acceptability, resource use, and feasibility of studies that have deployed and evaluated AI systems and tools. Ethical and legal considerations, as well as findings from qualitative studies, will be synthesized through a narrative thematic analysis. We will use the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) format for the publication of the findings.

Results: The database searches resulted in 12,793 records when the searches were conducted in October 2023. Screening is underway, and the analysis is expected to be completed by July 2024.

Conclusions: The findings will provide key insights on usage patterns and evidence on the use of AI in SRHR, as well as convey key ethical, safety, and legal considerations. The outcomes of this scoping review are contributing to a technical brief developed by the World Health Organization and will guide future research and practice in this highly charged area of work.

Introduction

Artificial intelligence (AI) refers to the development of algorithms, processes, machines, and computer programs capable of performing automated tasks, without the programming of each step explicitly by a human [1,2]. Advances in computing processing combined with the amassing of data through digital tools, particularly with increases in the penetration of mobile devices, have propelled the field of AI within health [3-6]. AI includes approaches such as machine learning, in which statistical and mathematical modeling techniques are used to define and analyze data. This can also be applied through natural language processing to analyze text-based data and signal processing for audio, images, and videos [6,7]. The use of AI varies across health fields, with radiology and pathology being the dominant areas where machine learning has been leveraged to optimize the processing of large volumes of medical imaging data [6,7]. Recent advancements in AI, particularly generative AI and large language models, have expanded the ability to address a diverse set of health needs.

The field of sexual and reproductive health encompasses health domains, such as family planning and fertility care, maternal health, sexually transmitted infections (STIs), safe abortion care, sexual health and well-being, and gender-based violence [8,9]. It is underpinned by broader principles of bodily autonomy, human rights, women's empowerment, and gender equality, encapsulated as sexual and reproductive health and rights (SRHR) [10]. Considering the perceived sensitivity and often politicization of these health topics beyond the influence of technology, the use of AI in SRHR is an emerging area with both great potential and justifiable concerns. Individuals' desires for anonymity in seeking sexual and reproductive health services positions AI systems and tools, such as conversational agents, as critical conduits for expanding access to information and care [11-13]. Furthermore, shortfalls in human resources and the need for targeted health interventions, such as in the areas of maternal health care and management of STIs, serve as key issues that have the potential to be addressed through the predictive capabilities offered by AI [14]. In addition, the use of AI to power "software as a medical device" [15] presents an opportunity to leapfrog access to diagnostic devices, such as ultrasounds [16] and blood pressure equipment [17]. This has also been seen with the emergence of contraceptive and fertility software applications [18,19], which are increasingly securing regulatory approvals from national authorities [20,21].

The convergence of AI in SRHR also presents heightened risks and implications. This is especially evident as the use of underlying health data raises concerns about infringements on women's health and bodily autonomy, as well as the potential misuse of this technology for surveillance of populations in vulnerable situations. Furthermore, existing challenges in digital health implementation [22], including biases, limited inclusivity, and gender disparities, could be exacerbated with the introduction of AI [6,23-25]. As such, the intersection of AI and SRHR raises nuanced implications and warrants close examination of the current landscape to highlight the evidence base and document the ethical, regulatory, and human rights considerations. This scoping review will build on the general literature of AI in health and focus specifically on how AI is being used within SRHR, including evidence on effect and related considerations to inform a comprehensive understanding of the state of the field.

Methods

Overview

We will conduct a scoping review using the established methodological framework of Arksey and O'Malley [26] that includes (1) identifying the research question; (2) identifying relevant studies; (3) study selection; (4) charting the data; and (5) collating, summarizing, and reporting the results. Considering this is an emerging area of research, we will also include a stakeholder consultation to inform the discussion. We will follow the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) format for the publication of the findings [27].

Stage 1: Identifying Research Questions

This scoping review aims to explore the range of ways in which AI is being applied in SRHR and synthesize the key considerations to ensure its effective, safe, and ethical use. The research questions for this review include the following:

- Patterns and characteristics of use: How are AI systems and tools being applied to SRHR, in terms of health domains, intended purpose (eg, screening, counseling, forecasting), target users, and AI data life cycle?
- Evidence on harms and benefits: What are the effect, acceptability, feasibility, resource use, and implications on gender, equity, and rights of AI systems and tools used in SRHR?
- Ethical, legal, and safety implications: What are the ethical, legal, and safety considerations specific to the use of AI systems and tools in SRHR?

Stage 2: Identifying Relevant Studies

To identify relevant studies for inclusion, we will search the following electronic databases: MEDLINE (PubMed), Scopus, Web of Science, and CINAHL. In addition, we will use citation searching from relevant articles to identify sources that may not have been retrieved in our original search.

The search strategy will be a combination of constructs related to AI and SRHR. An overview of search terms is presented in Multimedia Appendix 1. We will leverage search strategies and Medical Subject Headings (MeSH) terms used in other scoping reviews focused on AI in health care [28-32]. Considering this is an emerging topic, we will not set a start date for the search.

Stage 3: Study Selection

We will conduct a 2-step abstract and title screening following the eligibility criteria in Textbox 1. We will use Covidence, a standard web-based screening and extraction tool, to manage the screening process.

We will not exclude manuscripts based on geographic location, language, or publication date. Commentaries, opinions, and editorials that do not have an underlying empirical basis will be excluded to adjust for potential subjectivity and bias. In addition to using Covidence, we will search the citations of included studies to identify relevant articles that may have been overlooked in our initial search.

All references will be collated into a single reference manager (EndNote), where duplicate entries will be removed. Articles will be screened independently by 2 coauthors. Identified discrepancies will be resolved through discussion, and, if needed, escalated to a coauthor for arbitration.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Studies reporting on artificial intelligence (AI) applications to aspects of sexual and reproductive health and rights
- Clearly described methodology; we will include quantitative studies, qualitative studies, and program evaluations and descriptions

Exclusion criteria

- Focus exclusively on digital interventions (eg, traditional text messaging or targeted client communication) that do not explicitly use AI systems and tools
- Focus on health care robotics or nonhuman studies
- Commentaries, opinion pieces, and editorials

Stage 4: Charting the Data

We will develop a data extraction sheet to standardize the retrieval of information in alignment with the research questions (Table 1). The data extraction form will be developed by adapting common themes from other scoping reviews on AI [31,33], as well as reviewing requirements from digital health reporting checklists [34,35], information on the intervention, including how AI was applied to SRHR, the specific SRHR domains of interest, population, geographic coverage, implementation challenges, outcomes, and ethical and legal considerations.

Table 1. Categories for data extraction.

Category	Illustrative information to be extracted	Relevant research questions
Article information	• Article title • Author(s) • Year • Country • Setting or context (facility, community, home or self, research) • Aim or objectives • Study design or methodology	• Patterns of use
SRHR[a] health domain	• To be selected from a predefined list of common SRHR areas and expanded on accordingly • Examples include family planning or contraception counseling and provision, fertility care, safe abortion, sexually transmitted infections, antenatal care, post-natal care, etc	• Patterns of use
Targeted population	• Will be selected from a predefined list and expanded accordingly. Examples include health workers, health system managers, individuals or health service users	• Patterns of use
Intended purpose of AI[b]	The intended purposes for using AI: • Health information, education, and promotion • Screening and diagnostics • Clinical care and management • Personal health monitoring • Forecasting health trends • Health systems management • Research and drug development	• Patterns of use
AI life cycle	Stages of AI development and evaluation [36]: • Data creation • Data acquisition • Model development • Model evaluation • Model deployment	• Patterns of use
Algorithm development and models	• Predictive or generative models • Documentation of algorithm development and training process • Presence of regulatory approval	• Patterns of use
Outcomes and findings	• Outcomes based on the Evidence to Decision framework [37], which includes effect, accuracy, acceptability, feasibility, equity, resource considerations, gender, equity, and rights • Key themes and findings • Implementation challenges • Lessons learned • Unintended consequences, risks, and implications • Approaches used to mitigate unintended consequences	• Evidence on harms and benefits
Implications	• Legal implications • Ethical implications	• Ethical and legal implications

[a]SRHR: sexual and reproductive health and rights.

[b]AI: artificial intelligence.

Stage 5: Collating, Summarizing, and Reporting the Results

We will collate and summarize information from the data extraction sheets. The results will present the general patterns of use of AI in SRHR, including the specific health domains for which AI is being applied, the intended purpose of the AI system and tools, and maturity within the AI life cycle. We will use established frameworks, including the continuum of care and SRHR conceptual model for categorizing health domains [8,9] and the AI life cycle to map the maturity of AI systems and tools in use [36].

To assess evidence on harms and benefits, studies will first be tagged based on their AI life cycle [36] to distinguish between interventions that are in the early stages of model development and validation versus those that have been implemented and evaluated. We will extract outcomes on the subset of studies identified as being in the model deployment and evaluation phases of the AI life cycle [36]. The type of outcome data to be extracted will be guided by the domains of the Evidence to

Decision framework, including accuracy, effect, acceptability, feasibility, resource use, and gender equity and rights [37]. Where possible, we will pool findings across similar outcome measures and present a summary of findings on outcomes related to accuracy and effect. We will conduct a thematic analysis on ethical, legal, and safety considerations, as well as on findings from qualitative studies.

Results

The database searches described above resulted in 12,793 records when the searches were conducted in October 2023. Screening is underway, and the analysis is expected to be completed by July 2024.

Discussion

Building on the broader literature on AI and health, findings from this review will provide fundamental insights into the usage patterns, implications, and evidence related to AI in SRHR, as well as highlight key considerations and risks. A key strength of this review is the composition of a multidisciplinary authorship team to ensure both the technological and SRHR perspectives are appropriately reflected. Moreover, this scoping review serves as a foundational resource to inform a technical brief developed by the World Health Organization [38] and to guide future research and practice. One limitation of this review is its focus on empirical studies, in which insights from the gray literature and AI consumer products may be overlooked if they are not reflected in the peer-reviewed literature. However, due to the high number of records in the search, we believe this scoping review can reliably provide a comprehensive overview of usage patterns and key implications.

The intersection of AI and SRHR has been fraught with concerns, particularly related to infringements on women's reproductive health choices and the exacerbation of gender biases and inequity [39]. Meanwhile, technological advances hold great promise for overcoming longstanding challenges in access to and provision of SRHR services. This systematic analysis of AI in SRHR seeks to facilitate clarity and nuanced discussion in this highly charged field and direct efforts toward responsibly and meaningfully harnessing of AI to address SRHR needs and the broader goals of universal health coverage.

Acknowledgments

We acknowledge Rebecca Carlson and Kavita Kothari for serving as the information specialists in developing and conducting the search strategy. We thank Ana Pilar Betran and Agata Ferretti for their guidance in discussing the eligibility criteria. We are grateful to the participants from the World Health Organization technical consultation on artificial intelligence and sexual and reproductive health and rights for their insights and expertise in refining the taxonomies underpinning the extraction of studies. This work is funded by the UNDP/UNFPA/UNICEF/WHO/World Bank Special Programme of Research, Development and Research Training in Human Reproduction, a cosponsored program executed by the World Health Organization.

Data Availability

Access to the Covidence database can be made available after the publication of findings by emailing srhhrp@who.int and through a mutually signed agreement.

Authors' Contributions

TT developed the protocol and manuscript with input from YZ, DS, SA, SP, and LS. All authors have made substantial intellectual contributions in developing the manuscript and have reviewed and approved it for submission and publication.

Conflicts of Interest

None declared.

Abstract

Background: The generation of research evidence and knowledge in primary health care (PHC) is crucial for informing the development and implementation of interventions and innovations and driving health policy, health service improvements, and potential societal changes. PHC research has broad effects on patients, practices, services, population health, community, and policy formulation. The in-depth exploration of the definition and measures of research impact within PHC is essential for broadening our understanding of research impact in the discipline and how it compares to other health services research.

Objective: The objectives of the study are (1) to understand the conceptualizations and measures of research impact within the realm of PHC and (2) to identify methodological frameworks for evaluation and research impact and the benefits and challenges of using these approaches. The forthcoming review seeks to guide future research endeavors and enhance methodologies used in assessing research impact within PHC.

Methods: The protocol outlines the rapid review and environmental scan approach that will be used to explore research impact in PHC and will be guided by established frameworks such as the Canadian Academy of Health Sciences Impact Framework and the Canadian Health Services and Policy Research Alliance. The rapid review follows scoping review guidelines (PRISMA-ScR; Preferred Reporting Items for Systematic Review and Meta-Analysis Extension for Scoping Reviews). The environmental scan will be done by consulting with professional organizations, academic institutions, information science, and PHC experts. The search strategy will involve multiple databases, citation and forward citation searching, and manual searches of gray literature databases, think tank websites, and relevant catalogs. We will include gray and scientific literature focusing explicitly on research impact in PHC from high-income countries using the World Bank classification. Publications published in English from 1978 will be considered. The collected papers will undergo a 2-stage independent review process based on predetermined inclusion criteria. The research team will extract data from selected studies based on the research questions and the CRISP (Consensus

Reporting Items for Studies in Primary Care) protocol statement. The team will discuss the extracted data, enabling the identification and categorization of key themes regarding research impact conceptualization and measurement in PHC. The narrative synthesis will evolve iteratively based on the identified literature.

Results: The results of this study are expected at the end of 2024.

Conclusions: The forthcoming review will explore the conceptualization and measurement of research impact in PHC. The synthesis will offer crucial insights that will guide subsequent research, emphasizing the need for a standardized approach that incorporates diverse perspectives to comprehensively gauge the true impact of PHC research. Furthermore, trends and gaps in current methodologies will set the stage for future studies aimed at enhancing our understanding and measurement of research impact in PHC.

Introduction

High-performing primary health care (PHC) is recognized as the cornerstone of robust health care systems [1,2]. High-income countries often possess robust health care systems with well-established PHC organizations and research institutions, making them pivotal in shaping global health policies and practices [3,4]. High-quality research identifying what is needed to strengthen the performance of PHC organizations and their integration with each other and the broader health system is essential to inform the sustainable development of health care [5]. A PHC orientation to health service research strives to understand the influence of health's socioeconomic, physical, biological, and cultural determinants within the relevant broader political, sociohistorical, and economic contexts. PHC services can improve health and health services delivery, which could result in improved individual, community, and population health outcomes.

The need for PHC research to determine the efficacy of treatment and test theories and develop new models of care has been documented [6]. PHC encompasses primary care, disease prevention, health promotion, population health, and community development within a holistic framework to provide essential community-focused health care [7,8]. We operationalize "PHC research" to refer to studies that investigate a broad range of topics related to preventive care, health promotion, diagnosis, treatment, ongoing management of common illnesses and chronic conditions, and the social determinants of health within the context of PHC settings [9].

There are several conceptual frameworks and approaches that have been developed for research impact assessment [10]. In Canada, the Canadian Academy of Health Sciences (CAHS) Impact Framework has been adapted to examine the impact of investments in health research. The CAHS Impact Framework uses 5 impact categories: advancing knowledge, capacity building, informing decision-making, health impacts, and socioeconomic impacts and provides a menu of nearly 70 indicators that map onto these domains [11]. In 2018, the Canadian Health Services and Policy Research Alliance (CHSaPRA) was developed by the Canadian health research community based on CAHS to guide the assessment of the impact of research on decision-making [12].

Despite the development of these frameworks, little is known about how research impact is conceptualized in PHC [13]. Globally, PHC research is a small proportion of research output [14]. While existing reviews address research impact within the health care and health service research context [15,16], these reviews are not tailored to consider the unique functions of PHC. As noted by the Council of Academic Family Medicine, PHC research is unique since it involves the delivery of care to patients across the care life cycle, which includes disease prevention, health promotion, and chronic care management [17-20]. It also provides evidence that is unique for the organization and delivery of care, evaluation of innovations, translation of research into practice, and participatory action and community-based approaches [17]. Due to the broader effects of research on patients, practices, services, population health, community, and policy formulation, a dedicated review in PHC is essential to broaden our understanding of research impact, including nuances of how it may or may not be different than other health services research. To establish directions to evolve definitions of research productivity in the context of PHC, funders, academic institutions, researchers, and the public need a better understanding of "research impact" in PHC.

Several scoping reviews, such as those conducted by Murphy et al [21] on measurement in rural PHC, Noorihekmat et al [22] on performance measurement frameworks in public health and primary care systems, and Akl et al [23] on faculty productivity in academic medical centers, have explored aspects of research productivity and measurement within health care. However, to the best of our knowledge, there is no existing review that has offered a focused exploration of the specific conceptualizations and measures of research impact within the context of PHC. Such a review would offer a unique and detailed analysis that aims to elucidate the nuances and intricacies of research productivity, thereby contributing a distinct perspective to the existing literature.

This review protocol aims to fill a gap in knowledge by examining the scientific literature on research impact in the context of PHC. Drawing from established frameworks like the

CAHS Impact Framework [24] and CHSaPRA [25], we will aim to (1) elucidate the various conceptualizations of research impact within the context of PHC and (2) identify measures of research impact used in the PHC literature by PHC researchers. The study will contribute to understanding and identifying trends in how the impact is understood and measured, highlighting existing gaps or areas needing further investigation within this domain. The findings of the study will be leveraged to inform a future study that will explore the perspectives of patients, citizens, community groups representing equity-deserving groups, PHC leaders, researchers, and policy makers on the definition and measurement of research impact in PHC.

Methods

Study Design

A rapid scoping review [26] and environmental scan [27] will be conducted. A rapid scoping review methodology is suitable for this investigation, as it allows for a comprehensive but expedited exploration of the existing literature surrounding research impact within PHC. Given the breadth of the topic and the need to capture a wide array of literature quickly, the rapid scoping review methodology aligns with the urgency to understand conceptualizations and measurements of research impact in PHC [26]. This approach permits the incorporation of diverse study designs, including gray literature and various publication types, facilitating a thorough investigation of research impact concepts within a condensed timeframe [26]. However, the rapid review will be informed by existing guidelines for scoping reviews [28] and the Arksey and O'Malley [29] methodological steps (stages 1 to 5 described below), aiming for standardized execution and reporting and enhancing the credibility of the findings. Scoping reviews aim to map fundamental concepts in a research area, define key terms, and delineate conceptual limits, making it suitable for our purposes [29,30]. The CRISP (Consensus Reporting Items for Studies in Primary Care) statement proposed by Sturgiss et al [31] will be used for the comprehensive extraction and reporting in PHC research to enable the analysis of practices and policies across a diverse range of countries and territories.

Similar to a rapid review, an environmental scan is often used by institutions to collect information [27]. An environmental scan is a systematic approach to gathering and analyzing information from various sources beyond traditional academic literature, including publicly available data, unpublished reports, and consultations with experts [32]. It aims to comprehensively identify relevant information, trends, and developments within a specific field or context [32]. Researchers can also use an environmental scan to identify current and potential research needs and trends to enhance decision-making [27]. While there are various methodologies and sources for collecting and analyzing information for an environmental scan [32], our environmental scan will be conducted by identifying professional organizations, academic institutions, and experts in the fields of information science and PHC to begin our search.

We will adhere the reporting of our review to the PRISMA-ScR (Preferred Reporting Items for Systematic Review and Meta-Analysis Extension for Scoping Reviews) reporting guidelines [33], as there are currently no existing guidelines for rapid reviews. The study will be conducted in 2024 with results anticipated by the end of the year. The research team is comprised of PHC researchers (clinicians, PhD trained) or leaders in the field.

Stage 1: Identifying the Research Questions

We intend to address the following research questions: (1) How is research impact conceptualized in PHC? (2) How is research impact measured in PHC? (3) What methodological or conceptual frameworks are used to evaluate PHC research impact? What are the benefits and challenges of assessing PHC research impact?

Stage 2: Identifying Relevant Studies

We will work with an information specialist to develop a search strategy for the following academic databases: PsycINFO, MEDLINE, Embase, and CINAHL Plus. These databases were intentionally selected for their inclusion of PHC literature and thus are likely to capture relevant scholarly material. The strategy will initially be applied in MEDLINE before being adapted for other databases. We will also search for literature in Google Scholar to "the wide range of resources including papers from academic journals, conference papers, theses, and dissertations" [34]. The peer-reviewed search strategy will also be used in Google Scholar. A citation search of the reference lists of selected papers will be conducted to ensure that a wider scope of papers is included. Forward citation searching will also be done for literature that cites eligible studies included in the review [35]. Scopus, Web of Science, and Google Scholar will be used for forward citation tracking to ensure a comprehensive search.

To ensure a comprehensive review of relevant sources and databases, relevant gray literature databases, catalogs, and search engines (eg, Google, OpenGrey, and TripPro) will be hand searched across high-income countries. White papers will also be explored through health care–focused think-tank websites. We will also contact librarians in the field of PHC and information specialists through several mailing lists (including Canadian Medical Libraries and expert searching through the College of Family Physicians of Canada) to ask for further studies or gray literature. We define gray literature as "that which is produced on all levels of government, academics, business and industry in print and electronic formats, but which is not controlled by commercial publishers" [36].

An environmental scan of institutes and initiatives that follow their strategic funding to understand research impacts, such as the Canadian Institute for Health Research's Community-Based Primary Health Care reports and the SPOR Evidence Alliance [37] will also be conducted. We also aim to examine metrics used by funding agencies within jurisdictions. We will contact each one individually for any published or unpublished evaluations of these PHC activities and ask for any other organizations or experts, who may help us to find as many materials as possible.

The search strategies for the databases were devised in collaboration with the 2 information specialists (Multimedia Appendix 1). Before the literature search and screening process,

reviewers will receive training from the principal investigator (MA) to ensure a foundational grasp of the field's background and the review's objectives.

Stage 3: Study Selection

Two research assistants (one of whom is KMK) will perform all searches in the databases, citation searching, as well as the environmental scan. Findings from all databases will be amalgamated and imported into Covidence (Veritas Health Innovation) for streamlined documentation and management of studies throughout the review process [38]. Additionally, any duplicate publications will be eliminated.

For the gray literature and environmental scan, the research assistants will independently conduct searches across the sources. The research assistants will document the sources and databases accessed for gray literature, specifying the search terms, strategies, and any limitations applied. Any date range, filters, and criteria used to identify relevant gray literature sources will be noted. The research assistants will document the results obtained, including the number of documents retrieved, and provide a clear account of any exclusions made along with justifications. During frequent team meetings, the research team will discuss how duplicates were managed. This documentation should ensure transparency and reproducibility, allowing others to follow and validate the search methodology [39,40]. Gray literature will be organized and managed in a structured Microsoft Excel (Microsoft Corp) spreadsheet. Microsoft Excel will also be used to organize details of the environmental scan, such as the institute or initiative names, contact information, links to relevant reports or evaluations, dates of contact, and any additional notes or follow-up actions required.

We will include gray and scientific literature of any study design that (1) have an explicit focus on the research impact, (2) explicitly focus on PHC research, and (3) are published from a high-income country (defined as per the World Bank classification [41], ie, Andorra, Antigua and Barbuda, Aruba, Australia, Austria, Bahamas, Bahrain, Barbados, Belgium, Bermuda, British Virgin Islands, Brunei Darussalam, Canada, Cayman Islands, Channel Islands, Chile, Croatia, Curaçao, Cyprus, Czech Republic, Denmark, Estonia, Faroe Islands, Finland, France, French Polynesia, Germany, Gibraltar, Greece, Greenland, Guam, Hong Kong SAR China, Hungary, Iceland, Ireland, Isle of Man, Israel, Italy, Japan, Republic of Korea, Kuwait, Latvia, Liechtenstein, Lithuania, Luxembourg, Macao SAR China, Malta, Monaco, Nauru, Netherlands, New Caledonia, New Zealand, Northern Mariana Islands, Norway, Oman, Palau, Poland, Portugal, Puerto Rico, Qatar, San Marino, Saudi Arabia, Seychelles, Singapore, Sint Maarten (Dutch part), Slovakia, Slovenia, Spain, St Kitts and Nevis, St Martin (French part), Sweden, Switzerland, Taiwan China, Trinidad and Tobago, Turks and Caicos Islands, the United Kingdom, United Arab Emirates, Uruguay, the United States, and Virgin Islands (United States).

We define an "explicit focus on the research impact" as studies or papers where the primary or significant emphasis is placed on evaluating, measuring, or discussing the effects, outcomes, influence, or implications of research activities or interventions in the field of PHC or by PHC providers. This includes studies using both formal methodological frameworks, such as the CAHS Impact Framework, and ad hoc approaches using single or limited metrics. This could involve investigations into the tangible outcomes or effects of research endeavors such as changes in health care practices, policy implications, patient outcomes, health system improvements, or societal impacts resulting from PHC research initiatives [42]. Additionally, studies proposing frameworks for evaluating PHC research impact, regardless of whether they are empirically trialed or piloted, are considered, recognizing the value of theoretical advancements in this domain. However, studies predominantly focused on assessing the impact of health care interventions themselves, rather than the research process or outcomes, are excluded to ensure a manageable scope and relevance to the review objectives.

Limiting inclusion to studies published from high-income countries aligns with the rapid nature of this review while ensuring a focus on PHC research that reflects contexts, systems, and health care settings that share similar socioeconomic and health care infrastructure characteristics.

Only literature from 1978 (signing of the Alma-Ata Declaration [43]) to the present day and published in English will be considered. Research conducted within this timeframe ensures relevance to contemporary PHC practices and current understanding but also allows for the inclusion of recent advancements, methodologies, and perspectives in the field. Setting a specific timeframe and language criteria can help manage the volume of literature to be reviewed, which is key in a rapid review [26,44].

The results from all databases will be imported into EndNote (Clarivate Analytics), and all duplicates will be removed [45]. The unique papers will then be added to Covidence software to help facilitate screening, study selection, and extraction [38]. After generating a list of papers from our search strategy, we will engage in a 2-stage screening process with at least 1 independent reviewer at each stage. In the first stage, 2 trained, independent reviewers will screen papers for suitability based on their titles and abstracts in duplicate. We will report on the calculation of interrater reliability using Cohen κ coefficient [46] to assess the consistency of screening decisions between reviewers and ensure the reliability of the study selection process. A third reviewer will review 25% of the excluded papers to ensure no papers were inadvertently excluded. If there is ambiguity on whether specific papers fit the scope of this protocol, the principal investigator (MA) will be consulted. In the second stage, single reviewer (KMK) will conduct full-text reviews of the potentially eligible studies using the inclusion criteria aforementioned [47]. Again, a third reviewer will review 25% of the excluded papers to ensure no papers were inadvertently excluded. Throughout the process, disagreements between reviewers regarding the inclusion or exclusion of papers will be resolved via discussion with the principal investigator (MA), who will advise the reviewers of the outcome (ie, include or exclude). Given the iterative nature of scoping reviews, the inclusion and exclusion criteria will be refined (eg, added specificity), if needed, after increased familiarity with the data.

The comprehensive outcomes of both the searches (ie, databases and gray literature, including the environmental scan) and the study inclusion procedure will be thoroughly detailed in the final report of the review. These will be articulated using a PRISMA-ScR flow diagram, ensuring a clear and structured presentation of the search process and the selection of studies for the review [33].

Stage 4: Charting the Data

The research team will develop initial charting variables based on the research questions and the CRISP statement [48]. The preliminary variables that will be extracted from the studies will include (1) authors, (2) year, (3) country where the study was conducted or country of first author's affiliation, (4) journal, (5) methodology of paper (including whether a framework or ad hoc approach is used for measuring impact), (6) definition or conceptualization of impact (including how the impact is measured), (7) notice of research team's primary care experience and collaboration, (8) description of the study participants and populations in the context of primary care, (9) description of the primary care team, (10) description of the conditions under study in the context of primary care outcome measures (primary and secondary), (11) units of analysis, (12) findings, and (13) recommendations or discussion (eg, gaps, challenges or barriers, recommendations, and evidence-based or best practices).

Two team members will independently chart the first 5 papers that meet our inclusion criteria and refine the definitions for the variables or charting categories if necessary. The research team will discuss the extracted data. If consensus is reached, 1 researcher (KMK) will extract data from the remaining papers. If consensus is not reached, the 2 individuals will continue to extract 1 paper in duplicate until consensus is reached. All discrepancies between reviewers will be addressed through discussion and by involving additional individuals. The charted data will be organized and presented in a Microsoft Excel spreadsheet.

Stage 5: Collating, Summarizing, and Reporting the Results

To achieve our aims, we will adopt 3 distinct strategies for reporting and presentation. Initially, the research team will use a PRISMA-ScR checklist to ensure systematic reporting of our methods and screening processes [33]. Additionally, the charted data will be reviewed, synthesized, and analyzed through a numerical summary analysis that will include an overview of study characteristics and help to identify predominant conceptualizations and measurement frameworks used for research impact in PHC [29]. A directed content analysis will be carried out on the extracted data [49]. This method entails identifying specific concepts, definitions, methodological approaches, recommendations, benefits, and challenges associated with research impact in PHC. A coding framework will be developed based on established theories and frameworks relevant to PHC research impact, ensuring that the analysis remains focused and aligned with the study objectives. Each piece of extracted data will be systematically coded according to predefined categories, allowing for consistent and structured analysis. Through the directed content analysis, key themes extracted from the selected papers will be categorized, summarized, and presented using a narrative synthesis [47] that describes how research impact is conceptualized and measured in PHC. This analysis will also encompass definitions of research impacts, methodological techniques to measure research impact, and recommendations for improving PHC research impact and identify benefits or challenges of measurements of research impact in the context of PHC.

Finally, the synthesis will address strengths, study limitations, existing knowledge gaps, and potential avenues for future research pertinent to research impact in the realm of PHC. This is aligned with the goals of scoping reviews, which aims to comprehensively outline the scope and characteristics of existing literature [29]. However, as consistent with the scoping review methodology, we anticipate that the narrative synthesis will be an iterative process and dependent on the literature found [47].

Results

The results of this study are expected in December 2024. The dissemination of findings from this rapid scoping review on the conceptualization and measurement of research impact in PHC will ensure that the insights generated are shared with relevant stakeholders and contribute to informed decision-making and further research efforts.

The findings of this scoping review will be disseminated through various channels to reach a wide audience. A paper detailing the methodology, findings, and implications of the rapid review and environmental scan will be submitted to a relevant peer-reviewed journal in the field of PHC, family medicine, health services research, or impact assessment (eg, *Journal of Primary Care & Community Health*, *BMC Family Practice*, *Health Services Research*, *Journal of Health Services Research & Policy*, and *The Annals of Family Medicine*). A concise and accessible policy brief summarizing the key findings and their implications for policy makers, stakeholders, and PHC leaders will be developed and distributed through appropriate channels (eg, College of Family Physicians of Canada, Canadian Institute for Health Information, Canadian Foundation for Healthcare Improvement, Canadian Institutes of Health Research, Canadian Primary Care Sentinel Surveillance Network, and Canadian Primary Care Research Network). The research team will present the findings at relevant academic conferences, seminars, and workshops attended by researchers, practitioners, and policy makers in the fields of PHC and health services research (eg, North American Primary Care Research Group, Canadian Association of Health Services and Policy Research, Society for Academic Primary Care, and International Conference on Primary Health Care). Collaboration with existing networks and initiatives in PHC research and impact assessment will be sought to integrate the findings into ongoing discussions and efforts. The dissemination materials will be tailored to the needs and interests of different stakeholders. For example, academic publications will provide detailed methodology and findings for researchers, while policy briefs will focus on practical implications for decision makers. We will also create 1-page infographics for patient and public communities (eg, National Association of Community Health Centers). Presentations and

webinars will be customized to engage different audiences effectively.

Discussion

Preliminary Findings

The preliminary findings from this study have yet to be compiled and analyzed as the review is ongoing. The forthcoming rapid review and environmental scan on research impact in PHC will help to elucidate conceptualizations and measurement methodologies of impact, shaping the understanding of research impact within this domain. By rigorously and systematically reviewing a breadth of literature sources, this study aspires to unravel the diverse perspectives and approaches used to gauge the impact of research activities in PHC. This review will be able to discern trends, illuminate potential gaps, and outline areas necessitating further exploration or refinement in the assessment of research impact. Such delineations are envisioned to inform future research, policy considerations, and practice innovations in medicine and academia, ultimately contributing to the continuous enhancement of PHC services and policies in PHC settings.

Limitations

The methodology and methods outlined for the scoping review and environmental scan present several potential limitations. First, the selection process might carry biases due to restrictions such as language and publication date, possibly excluding valuable insights from diverse settings or languages. We acknowledge that relying solely on the World Bank's classification system for high-income countries may oversimplify the diversity of socioeconomic and health care infrastructure characteristics among nations and may not consider the varied health care contexts, systems, and priorities among high-income countries that could in turn influence research impact.

Additionally, researcher biases might influence study interpretation or selection, potentially affecting the review's credibility. Second, while the rapid review approach aids efficiency, it may compromise a comprehensive understanding of nuanced concepts related to research impact in PHC. Third, accessing relevant unpublished materials in gray literature might pose challenges, potentially affecting the credibility or reliability of findings.

Conclusions

This protocol outlines a rapid scoping review and environmental scan for exploring research impact in PHC, which will provide critical insights for advancing PHC systems. Recognizing PHC's pivotal role in health care, this study underscores the need for comprehensive research to bolster PHC organizations' performance and integration within broader health systems. Drawing from established frameworks such as CAHS and CHSaPRA, the forthcoming review will examine how research impact is conceptualized and measured in PHC, addressing an existing gap in knowledge. Emphasizing the scarcity of recent reviews specifically focused on this domain, this upcoming study pioneers a comprehensive analysis, shedding light on the nuances of research impact. By delineating varied conceptualizations of research impact and measures used in PHC, this review charts a pathway for future research, potentially refining measurement methodologies and informing decision-making for stakeholders in the PHC landscape.

While findings are pending, the study aspires to inform future research endeavors, policy formulations, and practice enhancements in the realm of PHC, which has a pivotal role within health care systems both provincially and federally, for example, Indigenous people living on reserve and people living in prisons.

Data Availability

The data sets generated and analyzed during this study will be made available from the corresponding author on reasonable request.

Abstract

Background: Seasonal malaria chemoprevention (SMC) is recommended by the World Health Organization for the sub-Sahel region in sub-Saharan Africa for preventing malaria in children 3 months old to younger than 5 years. Since 2016, the Malian National Malaria Control Program has deployed SMC countrywide during its high malaria transmission season at a rate of 4 monthly cycles annually. The standard SMC regimen includes sulfadoxine-pyrimethamine (SP) plus amodiaquine (AQ). Resistance against SP is suspected to be rising across West Africa; therefore, assessing the effectiveness of an alternative antimalarial drug for SMC is needed to provide a second-line regimen when it is ultimately needed. It is not well understood whether SMC effectively prevents malaria in children aged 5 years or older.

Objective: The primary goal of the study is to compare 2 SMC regimens (SP-AQ and dihydroartemisinin-piperaquine [DHA-PQ]) in preventing uncomplicated *Plasmodium falciparum* malaria in children 3 months to 9 years old. Secondly, we will assess the possible use of DHA-PQ as an alternative SMC drug in areas where resistance to SP or AQ may increase following intensive use.

Methods: The study design is a 3-arm cluster-randomized design comparing the SP-AQ and DHA-PQ arms in 2 age groups (younger than 5 years and 5-9 years) and a control group for children aged 5-9 years. Standard SMC (SP-AQ) for children younger than 5 years was provided to the control arm, while SMC with SP-AQ was delivered to children aged 3 months to 9 years (arm 2), and SMC with DHA-PQ will be implemented in study arm 3 for children up to 9 years of age. The study was performed in Mali's Koulikoro District, a rural area in southwest Mali with historically high malaria transmission rates. The study's primary outcome is *P falciparum* incidence for 2 SMC regimens in children up to 9 years of age. Should DHA-PQ provide an acceptable alternative to SP-AQ, a plausible second-line prevention option would be available in the event of SP resistance or drug supply shortages. A significant byproduct of this effort included bolstering district health information systems for rapid identification of severe malaria cases.

Results: The study began on July 1, 2019. Through November 2022, a total of 4556 children 3 months old to younger than 5 years were enrolled. Data collection ended in spring 2023, and the findings are expected to be published later in early 2024.

Conclusions: Routine evaluation of antimalarial drugs is needed to establish appropriate SMC age targets. The study goals here may impact public health policy and provide alternative therapies in the event of drug shortages or resistance.

Introduction

Malaria is endemic to south and central Mali, where over 90% of its approximately 17.6 million population is at risk for infection [1]. The disease primarily burdens rural areas that maintain suitable larval habitats and lack access to adequate health care [1]. Malaria transmission is highly seasonal in Mali (length of the transmission periods varies from 3 to 6 months), with a peak of malaria cases at the end of the rainy season (October through November), though it may be affected by irrigation schemes [2,3]. Deaths due to malaria registered at health centers totaled 1050 in 2017, with 669 (63.7%) occurring among children younger than 5 years. However, these results are likely substantially underreported. For instance, in 2015, health facilities in Mali reported over 2.3 million confirmed malaria cases and 1544 malaria deaths, but actual estimates were 7.5 million and 21,000, respectively [1].

Since 2007, support from the US Presidential Malaria Initiative program and other sponsors resulted in a 50% reduction in Mali's malaria burden. These efforts have been carried out through increased preventive and treatment measures such as long-lasting insecticide-treated mosquito nets (LLINs), indoor residual spraying, artemisinin-based combination therapies (ACTs), and intermittent preventive treatment of pregnant women (IPTp); and more recently, seasonal malaria chemoprevention (SMC). The most widely implemented malaria control interventions are the joint use of LLINs and rapid treatment of malaria cases with ACTs, IPTp, and SMC. Indoor residual spraying was previously implemented on a small scale in several Malian districts but is currently implemented in only a single district in central Mali.

Despite the broad deployment of these interventions, malaria prevalence and incidence rates remain high in Mali according to the routine Malaria Indicators Surveys [4]. Since 2010, the International Centers of Excellence in Malaria Research (ICEMR), in collaboration with Mali's National Malaria Control Program (NMCP), has identified significant constraints to malaria control implementation strategies in Mali, including the upward shift of the prevalence of infection and incidence of disease in children younger than 5 years to children aged 5-9 and 10-14 years [5,6]. These findings are particularly significant as the World Health Organization (WHO) guidelines recommend SMC only for children 3 months old to younger than 5 years. Therefore, the Mali NMCP and its partners have expressed SMC effectiveness and intervention strategies as key research priorities.

While the sulfadoxin and pyrimethamine regimen (SP) remains effective in West Africa, resistance to this regimen has been observed in East African regions where *Plasmodium falciparum* is highly prevalent. SMC is not currently recommended for countries in southern and eastern Africa due to widespread resistance, although there are some locations where transmission patterns suggest potential suitability [7,8]. In western parts of Africa, higher frequencies of the triple dihydrofolate reductase mutants and the quadruple mutant (triple dihydrofolate reductase plus dihydropteroate synthetase 437) associated with significant resistance to SP have been observed in children receiving SMC in both Mali and Senegal [9,10]. Recent studies have also reported SP resistance in several parts of Mali [11,12]. The wide-scale deployment of SMC in sub-Saharan African countries required increased focus on *P falciparum* resistance as well as ongoing assessments of new alternative drug combinations for SMC as this strategy has proven to be effective in reducing the impact on severe malaria and mortality in children 3 months old to younger than 5 years [13]. A recent study in Burkina Faso suggests that higher dosages and extended dosing of dihydroartemisinin-piperaquine (DHA-PQ) to 4 monthly doses (and cover the entire high malaria transmission period) could reduce malaria incidence up to 58% during the peak transmission season [14,15]. DHA-PQ has demonstrated excellent efficacy for chemoprevention and benefits from the long half-life of piperaquine and offers a protective efficacy of 98% against malaria in Thai adults when administered monthly [7]. In Senegalese children, similar monthly malaria incidence was observed among children receiving monthly DHA-PQ vs SP+amodiaquine (AQ) as SMC regimen [8].

A study in Uganda reported a 58% greater protective efficacy for DHA-PQ over SP-AQ based on monthly administration among children younger than 5 years [9]. This study aims to determine whether SMC effectively prevents malaria in children aged 5-9 years. The evidence-based approaches used will guide policy in Mali and other countries in West Africa using SMC.

Methods

Ethical Considerations

The study was approved by the University of Sciences, Techniques and Technologies Ethics Board under the following reference (N°2019/04/CE/FMPOS). The trial will report the

efficacy of 2 SMC subtypes (SP-AQ and DHA-PQ) for preventing *P falciparum* malaria in children aged 5-9 years in Mali. Should the findings show that SMC is efficacious for children in this age group, it may impact policy SMC delivery in Mali.

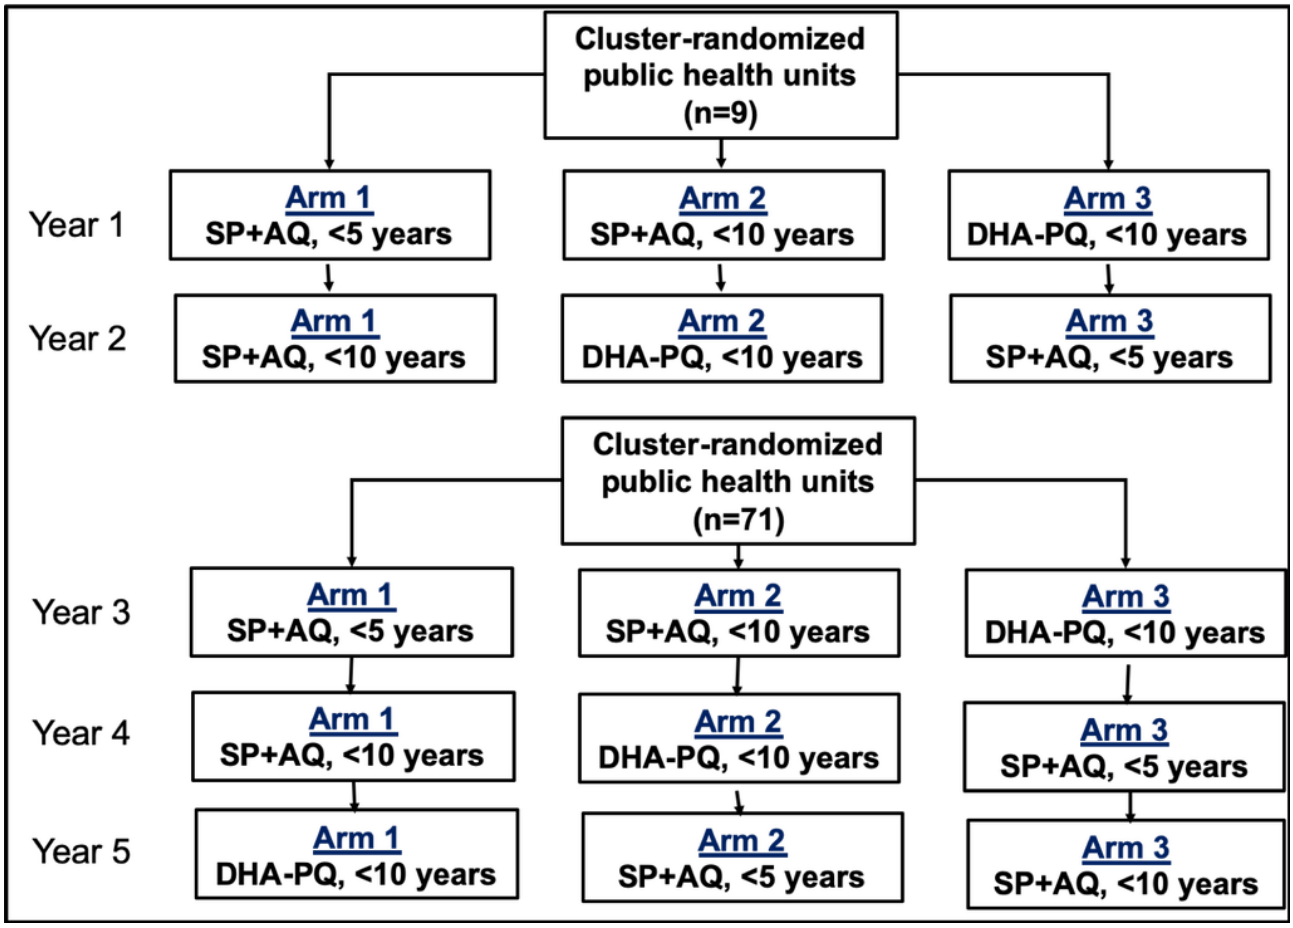
Study Site

Mali's Koulikoro District is situated in its southern region, approximately 50 miles (18 km) north of Bamako and 255 miles (410 km) from the Guinea border [11]. The district maintains 21 health zones and 71 community health posts. The current population in the district is 282,570, with approximately 4% of its population <1 year of age and 18% between 1 and 4 years of age. The total number of villages a community health center covers ranges from 8 to 31. The most populous village is Kolebougou, with 34,712 persons; the least populated is Souban Village, with 5085 persons. Ongoing malaria control activities include case management (rapid diagnostic tests and ACTs), IPTp, SMC, and LLIN use. District health centers maintain clinical and laboratory research capacity and full-time staff and clinicians for malaria screening and patient care. The site was chosen for the proposed research because of its diverse range of malaria control interventions, collaborative research agreements with the University of Sciences, Techniques and Technologies of Bamako, Mali (USTTB), high malaria transmission rates, and rural location.

Study Design and Population

The study was as a 3-arm cluster-randomized design, as illustrated in Figure 1.

Figure 1. Study design of a 3-arm cluster-randomized trial on age targets for season malaria chemoprevention. The study was performed from July 2019 to March 2023. AQ: amodiaquine; DHA: dihydroartemisinin; PQ: piperaquine; SP: sulfadoxine-pyrimethamine.

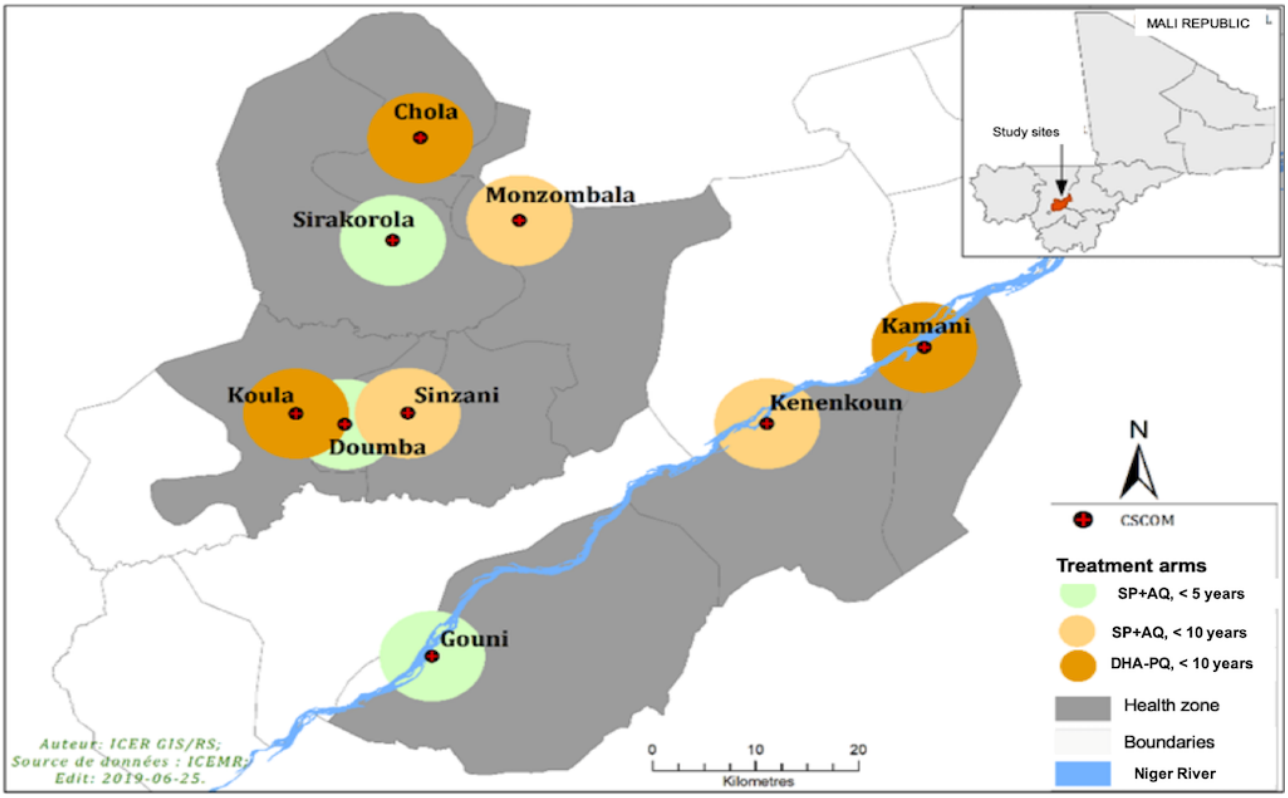


The study population includes children aged 3 months to 9 years in each village. Each study arm includes 3 corresponding public health units (PHUs) that differ with respect to their ecology, proximity to the Niger River, and region in the context of Koulikoro District (northern, central, and southern).

Cluster Selection

A total of 9 villages were randomly selected from Mali's Koulikoro District for participation. The selection strategy focused on 3 aspects: proximity to the Niger River (which lies in the southern part of the region) and the central and northern parts of the sampling region. Within these strata, villages were rank-ordered according to their populations. Random selection was carried out such that villages of high, medium, and low populations were sampled from each of these strata. A total of 3 villages (1 village per stratum with different ranking in terms of population size) were assigned to a single treatment arm (Figure 2).

Figure 2. Map of the 9 study sites in Mali's Koulikoro District. The 9 study sites are near the central part of Mali's Koulikoro District. Study sites were selected as 3 villages near the Niger River, 3 villages in the northern part of Koulikoro District, and 3 villages in the central part of Koulikoro. AQ: amodiaquine; DHA: dihydroartemisinin; PQ: piperaquine; SP: sulfadoxine-pyrimethamine.



The southernmost villages (Gouni, Kenenkoun, Kamani) are situated near the Niger River, while the remaining villages (Doumba, Sinzani, Koula; and Sirakorola, Monzombala, and Chola) lie in the northern and southern parts of the region above the Niger River, respectively.

Randomization

Probability proportional to population size sampling was used for allocating villages to the study arm. Random treatment assignment was balanced according to population size in each stratum (low, medium, and high), resulting in a 3 by 3 Latin square arrangement (Table 1).

Table 1. Study site classification per sampling region within the Koulikoro District, Mali.

Region	Population size		
	Small	Medium	Large
South	Gouni (A)[a]	Kamani (C)	Kenenkoun (B)
Central	Sinzani (B)	Doumba (A)	Koula (C)
North	Chola (C)	Monzombala (B)	Sirakorola (A)

[a]A, B, and C denote the 3 study arms.

Specifically, PHUs were rank-ordered according to their total populations, and the top 3 PHUs (in terms of their populations) were chosen to represent Koulikoro's southern, central, and northern regions. The PHUs were then randomized to treatment according to the Latin square arrangement shown in Table 1.

Eligibility and Enrollment

Participants were eligible to participate if they were residents of the sampled village, aged 3 months to 9 years of age at enrollment, were asymptomatic of current chronic diseases, and did not have a history of allergies to SP, AQ, or DHA-PQ therapies. Informed, written consent is required for all study participants annually. Consent was administered in oral or written formats and included a full description of voluntary participation, the right to withdraw from the study at any time, and the right to refuse to answer any question or participate in any research component.

Study Outcomes

The primary study outcome is the incidence of severe or uncomplicated *P falciparum* malaria. The population denominator for incidence calculations was derived from the house-to-house enumeration with household member listing. Secondary outcomes were abstracted from censuses and enumeration lists for selected villages, including village-level distributions on populations, age, gender, residential status, and LLIN use. Exhaustive selection was carried out in villages for selected PHUs for those children who met the eligibility criteria

and for whom consent of parents or tutors for enrollment was obtained. A baseline malaria infection prevalence survey was carried out before the initial SMC campaign. Follow-up surveys at community health centers were also carried out to assess malaria incidence among study participants. Monthly SMC administration and compliance with treatment assessment were captured via reports by caregivers and measurement of AQ metabolite by enzyme-linked immunosorbent assays. Demographic data, including age, sex, and clinical parameters (including temperature, pulse, and respiration rate), were recorded at a community health center visit. Malaria cases were defined as fever or a history of fever within the past 48 hours associated with either positive malaria rapid diagnostic test or a positive blood smear prepared during that visit.

Hypotheses and Rationale

The primary hypotheses were as follows:

1. Malaria incidence in children was at least 10% higher in the 5- to 9-year age group without SP-AQ than in children in the 5- to 9-year age group with SP-AQ.
2. Malaria incidence in children 3 months old to younger than 5 years receiving DHA-PQ was not statistically different from children in the same age group receiving SP-AQ.

Data Collection and Management

Confirmed malaria case incidence data will be collected from public health facilities through electronic data capture. A REDCap (Research Electronic Data Capture; Vanderbilt University) database and mobile app were used for this study, and data synchronization will be performed daily for quality checking complemented with data queries distributed to the centralized data center at USTTB.

A Priori Sample Size and Statistical Power

The power and sample size assessment is based on the ability to detect a clinically significant difference in malaria incidence proportions between the 3 comparison groups in year 1. The minimum clinically meaningful differences between the comparison groups was set at 10%. The sample sizes were calculated assuming a design effect of 2 with a 2-sided type I error set at 0.05 and power set at 80%. The number of required subjects per study arm for detecting at least 10% differences in malaria incidence proportions was 1552 in year 1. This result was inflated by 233 subjects in year 2 to account for new subjects due to increased child ages, yielding 1785 participants per arm total or 5355 participants overall.

Phase 2 (Years 3-5, 2021-2023)

This phase involved expansion to 71 public health posts in years 3-5 (Figure 3). The district-wide data collection plan will build on the efforts for years 1-2 and focus on (1) cluster-randomized health posts to the 3 treatment arms and (2) semiannual community cross-sectional surveys. More specifically, the 71 health posts over the entire district were divided into 4 regions (Table 2).

Figure 3. Map of the selection approach for 71 public health posts in Mali's Koulikoro District.

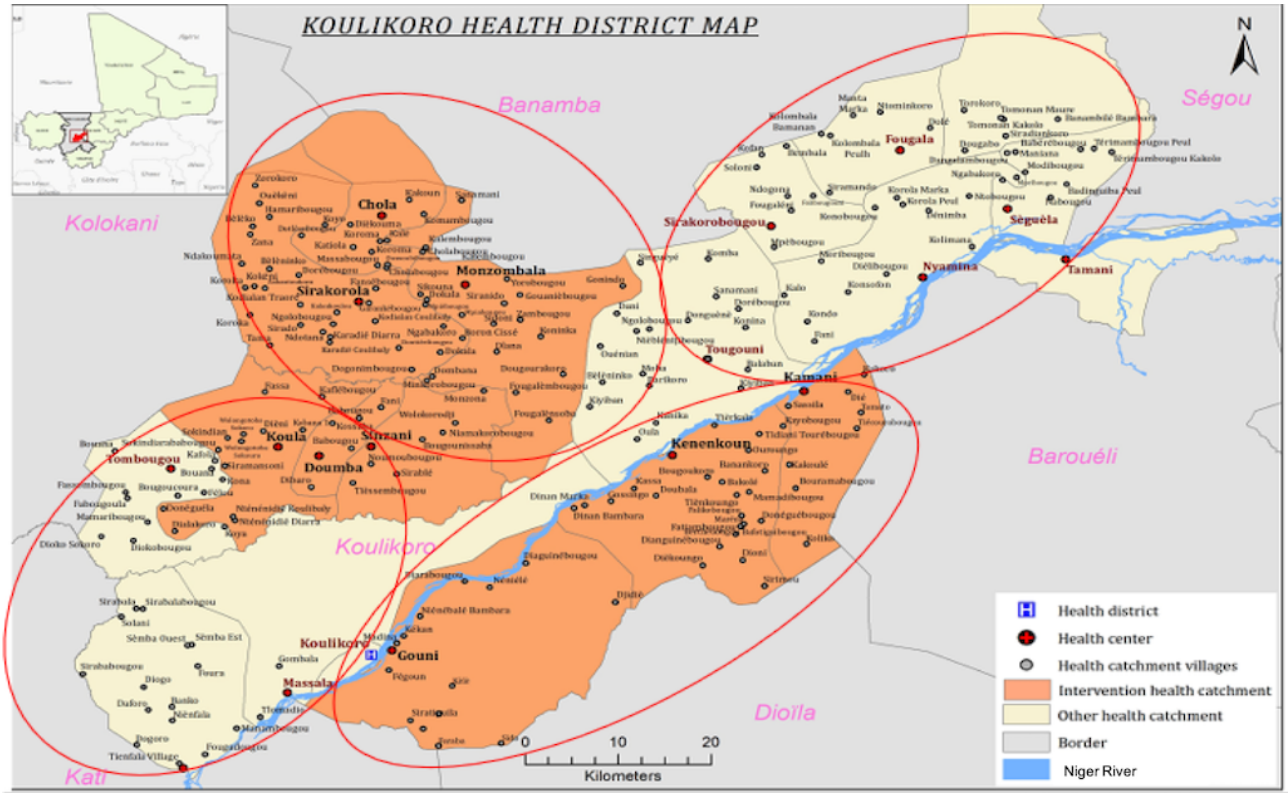


Table 2. Stratum matched by the year of the study.

Stratum (region), years 3-5 sampling approach	Stratum (region), years 1-2 sampling approach
Northeast	Not done
Northwest	North
Southwest	Central
Southeast	South

Within the stratum, health posts will be randomized to 1 of 3 treatment arms (SP-AQ <5 years, SP-AQ <10 years, and DHA-PQ <10 years). Allocation was proportional to population size based on census populations up to 9 years of age while balancing on population sizes across the 3 study arms. For regions maintaining a total number of health posts that were not divisible by 3, 1 or 2 adjacent health posts were considered as a single unit to ensure divisibility (Figure 3).

The health facilities selected in years 1 and 2 were also be selected in years 3-5 and will leverage the process and training already in place in 9 health centers. Patterns over the entire 5-year study period will be analyzed for these 9 villages. Semiannual cross-sectional household surveys will permit assessment of community-level effects over the entire 5-year period.

Results

The study began on July 1, 2019. Through November 2022, a total of 4556 children were enrolled during the pilot phase (2019-2020) in 9 villages across the Koulikoro Health District. In 2022, preliminary findings have been presented at the American Society of Tropical Medicine Conference [16] and published in the *American Journal of Tropical Medicine and Hygiene* [17]. SP-AQ and DHA-PQ were highly effective in reducing *P falciparum* malaria in children 5-9 years in Koulikoro, Mali, at both the pilot and district-wide study phases. Data collection ended in spring 2023, and the findings are expected to be published later in early 2024. Results will be summarized and reported using both intention-to-treat and per-protocol analyses.

Discussion

This study was designed to assess the effectiveness and efficacy of SP-AQ in children aged up to 9 years and of DHA-PQ as an alternative in the event of drug resistance to AQ or SP in West Africa and, more broadly, across Africa. The trial included 2 SMC regimens to provide a viable alternative therapy in the event of drug resistance or shortages in drug supply. The study enrolled over 5000 subjects in 9 villages in Mali's Koulikoro District. The expanded phase of the study covered the entire Koulikoro District. The initial phase of the study covered 9 villages, which may be considered as a pilot for the larger district-wide trial.

This study provides an opportunity to directly measure the effect of the 2 drugs while extending SMC to older children in response to recent reports showing an age shift in malaria incidence and prevalence among older children. The study site here comprised different ecological settings represented countrywide with differential malaria transmission intensities. For instance, each study arm was composed of a village located along the Niger River where longer transmission seasons have historically occurred, a village located in the central part of Koulikoro District where malaria transmission peaks between July and October, and a village in the southern part of Koulikoro District where malaria transmission season has been historically shorter (August to November) than the other 2 locations. Also, all selected villages maintain community health facilities where malaria case management is done routinely. Additionally, a routine assessment of treatment compliance by measuring amodiaquine metabolite in the veinous blood of children after treatment will be performed for the first time to determine SMC compliance across all 4 dosing periods. While the number of villages was initially restricted to 3 per study arm, all 71 PHUs in Koulikoro will be covered across the 3 study arms should the study meet the go/no go criteria for continued funding.

Particular challenges at the outset of the study planning involved garnering support from regional health administrators about using DHA-PQ instead of SMC and extending SMC use to children aged 5-9 years. Since the inception of Mali's NMCP, a key partner in this effort made apparent the study's rationale in terms of its implications on potential drug resistance with health agents, community leaders, and health workers before the SMC campaign was launched in Mali. Determining the appropriate age target for preventive therapies remains challenging for developing countries like Mali. The age captured during the most recent census was used to estimate the number of children failing in the <5 and 5-9-year age groups, which was usually reported by the participants' parents or guardians. However, approximately 2% of subjects were misclassified during the SMC administration due to erroneous reporting during the census. Therefore, more accurate estimations of participant age (which was used to define the comparison groups) were captured for the study here at baseline.

SMC covers the rainy season that coincidentally occurs during school vacations and agricultural activities in rural Mali. Therefore, a child's movement during that period is often a cause for losses to follow-up as children frequently might travel to Mali's capital city of Bamako from July to September, while others will move with their family to the farms (hamlets) until October when school commences.

We believe that this study provides a somewhat novel study design that will aid researchers in assessing age targets in locations where controlled studies are not feasible.

Acknowledgments

We are grateful to the National Institutes of Health for funding this study. We also thank the kind community leaders and residents in Koulikoro District for their guidance, support, and participation. We thank Dr Donald J. Krogstad for his lifelong mission for improving health outcomes in West Africa and whose efforts laid the groundwork for this study. We dedicate the study to those impacted by malaria and hope the study contributes to reducing the burden of malaria in Koulikoro and across Mali. This work was supported by Cooperative Agreements from the National Institutes of Allergy and Infectious Diseases (NIAID) for the West African International Center of Excellence for Malaria Research (ICEMR): U19AI089696 and U19AI129387 (from 2010 to 2017, 2017 to 2024, and 2016 to 2021, respectively). The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Data Availability

Data will be archived on the ClinEpiDB institutional repository [18] to ensure long-term availability, preservation, and access. The data sets generated during this study are available from the corresponding author on reasonable request as well as from the West Africa International Centers of Excellence in Malaria Research (ICEMR) Program Director by e-mail (sdoumbi@icermali.org or sdoumbia@gmail.com)

Conflicts of Interest

None declared.
